FOREWORD

Facilities Criteria (FC) provide functional requirements (i.e., defined by users and operational needs of a particular facility type) for specific DoD Component(s), and are intended for use with unified technical requirements published in DoD Unified Facilities Criteria (UFC). FC are applicable only to the DoD Component(s) indicated in the title, and do not represent unified DoD requirements. Differences in functional requirements between DoD Components may exist due to differences in policies and operational needs.

All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the most stringent of the UFC (replace w/ FC), the SOFA, the HNFA, and the BIA, as applicable.

Because FC are coordinated with unified DoD technical requirements, they form an element of the DoD UFC system applicable to specific facility types. The UFC system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applicable to the Military Departments, Defense Agencies, and the DoD Field Activities. The UFC System also includes technical requirements and functional requirements for specific facility types, both published as UFC documents and FC documents.

FC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and the Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet site listed below.

FC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://dod.wbdg.org/.

Refer to UFC 1-200-01, *General Building Requirements*, for implementation of new issuances on projects.

AUTHORIZED BY:

JOSEPH E. GOTT, P.E.

Chief Engineer

Naval Facilities Engineering Command

FACILITIES CRITERIA (FC)

NEW SUMMARY SHEET

Document: FC 4-171-06N, Navy Operational Support Center

Superseding: None.

Description: This FC provides design criteria for Navy Operational Support Centers in support of the Navy mission. It outlines all of the required functional spaces and optional spaces in the facility, and it provides guidance on key dedicated Navy spaces for Armed Forces Reserve Centers.

Reasons for Document: This FC was developed to provide design requirements for Navy Operational Support Centers to accomplish the following:

- Assist planners to understand the facility requirements to ensure accurate space programs and budgets
- Provide architects, engineers, and construction surveillance personnel with the essential, minimum requirements for the design and construction of Navy Operational Support Centers.
- Assist Navy and Marine Corps Reserve personnel to understand the operational intent of the facility design.

Impact: This FC identifies the basic requirements for Navy Operational Support Centers. This FC will reduce the initial cost of design and reduce costs associated with redesign of facilities that do not meet minimum standards. The design should also streamline facility operations.

Unification Issues: None.

CHAPTER 1 INTRODUCTION

1-1 PURPOSE AND SCOPE

This FC provides requirements for evaluating, planning, programming, and designing Navy Operational Support Centers (NOSC). The information in this FC applies to the design of all new construction projects, to include additions, alterations, and renovation projects in the continental Unites States (CONUS) and outside the continental US (OCONUS). It also applies to the procurement of design-build services for the above noted projects. This FC is not intended as a substitution for thorough review during design by individual Program Managers and Operations Staff.

1-2 APPLICABILITY.

This FC applies to all military service elements and contractors involved in the design, and construction of NOSC.

1-3 USERS OF FACILITY.

Users will include both able-bodied and disabled individuals. Design facility in accordance with ABA accessibility guidelines included in UFC 1-200-01, *General Building Requirements*. The following are the typical facility users:

- Commanding officer,
- Executive officer,
- Senior enlisted personnel,
- Full-time support,
- Reserve unit commanders and reservists
- Recruiter, and
- Civilians

1-4 GENERAL BUILDING REQUIREMENTS

Comply with UFC 1-200-01, *General Building Requirements*. UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this FC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

1-5 PHYSICAL SECURITY

That part of security concerned with physical measures designed to safeguard personnel; to prevent or delay unauthorized access to equipment, installations, material, and documents; and to safeguard them against espionage, sabotage, damage, and theft.

1-5.1 Physical Security System.

A physical security system is comprised of people, equipment, and operational procedures that control access to critical facilities or assets. Electronic Security Systems and security lighting are two of the elements that comprise the equipment component of a physical security system.

1-5.2 Physical Security Requirements.

NOSC may contain assets that must be protected against damage or theft. The requirement to protect assets such as classified materials or arms are defined in SECNAV and OPNAV Instructions.

1-5.2.1 Defining Requirements.

For assets not defined in policy, the requirements are determined by evaluating the value of the assets and the threats to those assets. Defining the requirements of a physical security system and its components involves an interdisciplinary team. The team should consider all interests relating to a project to determine how security fits into the total project design. The specific membership of the team will be based on local considerations, but in general, the following functions should be represented; facility user, antiterrorism officer, operations, security, logistics, architecture, engineering, life safety, and others as required. This team identifies the design criteria, which includes the assets to be protected, policy based requirements, threats to the identified assets (the Design Basis Threat), and the level of protection to be provided to protect the assets. In addition, the team must identify user constraints such as appearance, operational considerations, manpower requirements or limitations, energy conservation and sustainment costs when establishing the physical security system requirements. For information on Security Engineering Planning, refer to UFC 4-020-01, *DoD Security Engineering Facilities Planning Manual*.

When required, integrate physical measures into the site, building, room(s), or area(s) as applicable. Refer to specific design criteria and functional data sheets (FDS) for specific area requirements.

1-6 REFERENCES.

Appendix A contains a list of references used in this document. The publication date of the code or standard is not included in the reference. In general, the latest available issuance of the reference is used.

1-7 GLOSSARY

Appendix C contains acronyms.

CHAPTER 2 TECHNICAL REQUIREMENTS

2-1 SCOPE OF FACILITY

The NOSC size is determined by the number of units, the number of reservists, the number of full-time staff, and other exclusive spaces as determined by a detailed planning analysis, which, in turn, will define the authorized facility spaces and functions reflected on the 1391 project documentation. In general, administrative, medical and support spaces are either fixed sizes or increase in relatively small increments based on unit size. The primary increase in facility size occurs in the unit areas.

2-2 PROGRAM AREAS

The Program Area headings shown in Table 2-1 are described in the following sections. The individual functional program spaces are listed and described in Table 2-1, and addressed in greater detail in Chapters 2 and 4.

2-2.1 Administrative Support.

These areas accommodate the day-to-day functions of the facility and are occupied during normal facility operating hours by full-time staff.

2-2.2 Medical Suite.

These spaces are provided when a medical unit is assigned. The suite of spaces will vary in scope depending on where the NOSC is located and the availability of other nearby medical facilities. If medical spaces are not included because of an agreement to allow use of medical facilities on base, the agreement must be well documented.

2-2.3 Fitness Spaces.

Before fitness spaces are included, determine if they are allowed by CNIC Instruction 1710.1. If allowed, they must conform to this instruction and the DD1391.

2-2.4 Unit Areas.

The unit areas provide the training, administrative, and storage requirements for the specific reserve units assigned to the NOSC. An individual unit can vary in size from around 15 reservists to over 100 reservists. These spaces are typically only used during drill weekends, and each unit drills once a month. Up to two drill weekends per month can be conducted, so these spaces are typically shared by units drilling on different weekends. The space is designed to accommodate the largest weekend drilling population, not the entire unit population.

2-2.5 Drill Hall.

This area provides a room to accommodate large groups, typically more than one unit at a time, for various activities such as testing, muster, training, drill assessment, team

building, basketball, other physical fitness, messing, and ceremonies. It includes storage, support, and toilet spaces, the latter designed to facilitate urinalysis testing.

Table 2-1. NOSC FUNCTIONAL PROGRAM AREAS

Functional Program Area	Description/Service Exceptions
Administrative Support	
ID Check	Area immediately off the main entry vestibule with a transaction counter to the full-time staff area and an entrance to the recruiting office.
Recruiting office	Small suite for recruiting officer(s) to meet with prospective reservists. Includes administrative, meeting/interview, and display spaces. Provide separate room to accommodate a table and chair for knowledge testing adjacent to the recruiting office.
Quarterdeck	The Quarterdeck is near the main entry and serves multiple functions: Central circulation node, formal gathering area for small staff ceremonies, and display area for flags and unit memorabilia.
Full-time staff spaces	The following full-time staff areas work as a suite of spaces.
Commanding Officer office	Private office adjacent to the open office area with an entrance from a separate, dedicated vestibule that serves the CO office and the family services office. Office includes a private toilet and shower.
Executive Officer office	Private office (optional, only for larger commands).
Senior Enlisted office	Private office.
Open office area	Space for workstations, secure personnel files, other files, printers, and general work space.
Service counter/waiting area	The service counter provides access between the waiting area and the open office area. The waiting area is a vestibule between the service counter and the main entry corridor, typically with a glass storefront/door to the corridor.
ID service area (if required)	Sub-space of the open office area and directly adjacent to the service counter. Includes a digital camera and equipment for creating and issuing ID cards.
Navy family services office	Private office with desk and small three- to four-person conference area off the entry vestibule serving the CO office.
Copier/mail nook	Area off a main corridor and with easy access from the full-time staff spaces with copiers and secure individual mail boxes for units and command staff.
Mail distribution	Sub-space of the open office area located directly adjacent to the copier/mail nook and with a mail sorting table.

Table 2-1. NOSC FUNCTIONAL PROGRAM AREAS

Functional Program Area	Description/Service Exceptions
Mail receiving	In a NOSC located off-base, an additional room must be provided that meets antiterrorism requirements per UFC 4-010-01, *DoD Minimum Antiterrorism Standards for Buildings*.
Conference room	VTC-capable conference room adjacent to the CO's office and full-time staff area.
Funeral honors office	Space for staff workstations and coffin storage near/adjacent to Drill Hall
Distance learning center	Classroom configured to accommodate remote instruction with computers, microphones and cameras. Can be two equally sized rooms if desired.
Mess	Warming/staging kitchen for catered events with a direct adjacency to the drill hall, and, if possible, an exterior door.
SIPRNET	Secure private office with SIPRNET capability.
Supply storage	Space to store and fit new uniforms and store administrative supplies. Includes a private dressing room, workstation for the supply personnel, and storage shelving.
Fitness room (when allowed)	Space for several cardio and weight machines. If fitness spaces are included in the enacted DD1391, confirm that they are authorized by CNIC Instruction 1710.1.
Public toilets	Male and female toilets with associated janitor's closet(s) sized per code. Located near the distance learning center, service counter and waiting area, and medical suite, if included.
Shower/locker room	Male and female facilities for use by full-time staff and reservists. Includes toilet facilities.
Break room	Space for vending machines, counter with sink, microwave, refrigerator and a small seating area.
Recycling area	Space for the collection and storage of trash and recyclable materials adjacent to the service entrance with an exterior exit. Locate near Mess.
Telecommunications closet	LAN and telecom space per the paragraph in Chapter 3, "Electrical Design".
NMCI closet	NMCI equipment.
Medical Suite	
Medical office/reception	Includes a reception counter with a small waiting area and staff administrative areas.
Check-in/admitting/vision	Private area off of reception where information such as blood pressure, temperature, etc. can be obtained. Also includes vision testing.
Medical exam room	Private exam space. Typically, at least one exam room is provided in the NOSC even if other medical facilities are available.

Table 2-1. NOSC FUNCTIONAL PROGRAM AREAS

Functional Program Area	Description/Service Exceptions
Dental exam room	Similar to medical exam room but with dentist chair and equipment. Dental cleaning is not performed. Typically not included if other medical facilities are available.
Doctor library and transcription room	Open office area for doctor/dentists with medical resource library.
Dental x-ray	Divided space with controls on one-side of a protective screen and the x-ray machine/chair on the other side. Typically not included if other medical facilities are available.
Audio room	Sized for one to two reservists to undergo hearing tests. Enclosed area includes the sound booth with adjacent control area. Typically not included if other medical facilities are available.
Immunization room	Includes area for storing and administering shots. Typically not included if other medical facilities are available.
Blood draw	Area for drawing, initial processing, and storing blood. It is also directly adjacent to the medical toilet to accommodate processing of urine samples. Typically not included if other medical facilities are available. Electrically monitored refrigerator needed.
Medical toilet	Single-use toilet with a carousel to the blood draw room. Typically not included if other medical facilities are available.
Medical file room	Securable room with secure medical and dental file storage.
Medical supply room	Includes shelving for medical supplies. Typically not included if other medical facilities are available.
Medical equipment storage	Storage for larger items such as CPR dummies, back boards and other deployable medical supplies.
Unit Areas	
Unit classrooms	Classroom(s) sized for between 25 and 100 reservists.
Unit administrative area	Mix of private offices and open office area. Each unit gets two private offices (CO and senior enlisted) and three workstations.
Unit storage	One storage area per unit for miscellaneous unit supplies with access from the unit administrative area.
Drill Hall	
Drill hall	Large room for various activities such as testing, muster, messing, and ceremonies. Includes either a permanent or portable stage. Locate with direct access to the mess and urinalysis area.

Table 2-1. NOSC FUNCTIONAL PROGRAM AREAS

Functional Program Area	Description/Service Exceptions
Storage	Storage behind stage for tables, chairs, and AV equipment.
Urinalysis area	Separate male and female toilets directly off of drill hall. Includes enough space for observation for testing.
Support	Dedicated mechanical room.

2-3 SIZE DETERMINANTS.

2-3.1 Navy Operational Support Centers.

The NOSC space program is determined by a detailed planning analysis to be conducted according to UFC 2-000-05N (P-80), *Facility Planning Criteria for Navy/Marine Corps Shore Installations.* Information regarding the use of the interactive Space Planning Spreadsheet for establishing authorized space allowances in NOSC projects can be found in Appendix B to this document. The paragraph entitled, "Layout and Adjacencies" in Chapter 2, provides additional information for how the spaces are broken down and configured and must be reviewed during the planning and design process.

Support spaces identified on Table 2-1 and elsewhere in this FC may not be specifically identified in the final space program if their space allowance is included in the net-to-gross multiplier. However, they are included here to identify required adjacencies or design elements. Note that the shower/locker room is programmed space, but space for the public and unit toilets will come out of the net-to-gross multiplier.

2-4 LOCATION DETERMINANTS.

Determine the most appropriate and cost-effective location for a NOSC based on the following factors. Ensure the availability and capacity of required utilities and the compatibility of the mass/scale of the facility relative to adjacent structures.

2-4.1 Access.

Locate the NOSC to be easily accessible to the users, including potential recruits and active reservists. If the NOSC is located on an Installation, locate it as near the main Installation entrance as possible. Provide adequate parking as close to the facility as possible within antiterrorism (AT) requirements.

2-4.2 Complementary Facilities.

Locate the NOSC near other potentially complementary functions, such as a fitness facility, large parking areas, medical facilities, and a dining facility. Any adjacent parking

facilities that are intended to be shared must be available on weekends when the NOSC parking demand is highest.

2-4.3 Sustainable Design.

The location of a facility can have a significant impact on achieving sustainable design rating points. Consider issues such as brownfield redevelopment, access to public transportation, building orientation, and reuse of existing paving and hardscape when selecting a site.

2-4.4 Cost.

These facilities must be designed with the objective of achieving the lowest life cycle cost over a 40-year period. To do so, the project's design program must adequately define the scope and performance requirements and match those needs against a budget. Conversely, the budget must adequately support an appropriate and high-quality program and the performance requirements outlined and identified in this FC.

Note that additional Navy mission funds may be required for the computers and data outlets in the Distance Learning Center. This additional funding must be budgeted separately and should include IT installation, servers, and terminal connections. Confirm requirements with Region Resfor N6 for each project. Regardless of whether or not the computers and data connections are funded, the Distance Learning Center will be designed and outfitted with the VTC capabilities as indicated in Chapter 4.

2-5 LAYOUT AND ADJACENCIES.

The appropriate layout and adjacencies of the NOSC and key subareas are illustrated in Figures 2.1 through 2.3. These diagrams do not convey a building shape. Required adjacencies may be accommodated vertically. If a multi-story facility is required, unit areas will work most efficiently on the upper levels.

Figure 2-1. NOSC Adjacencies

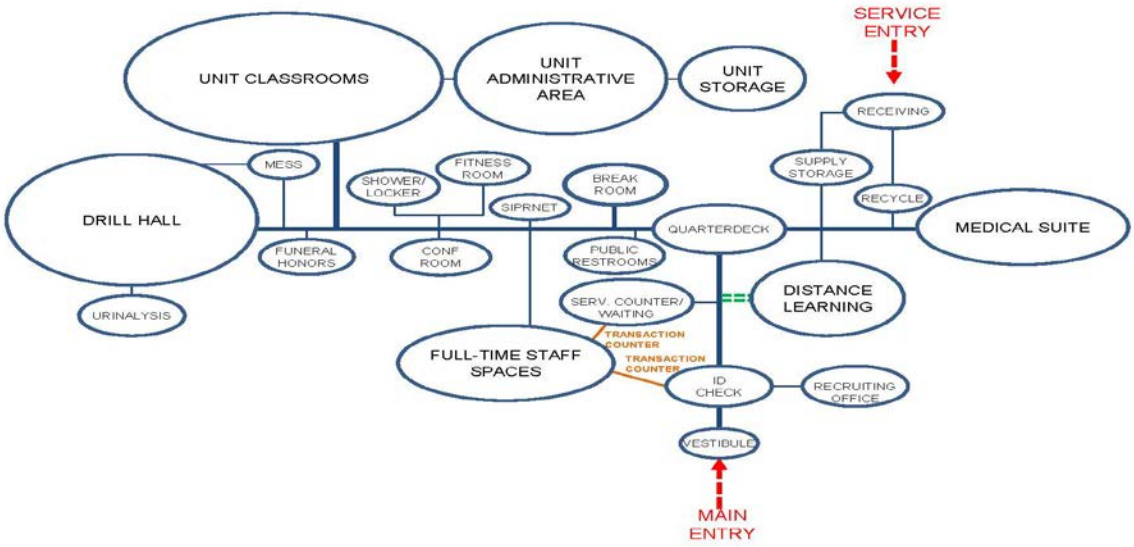

Figure 2-2. Full-Time Staff Spaces Adjacencies

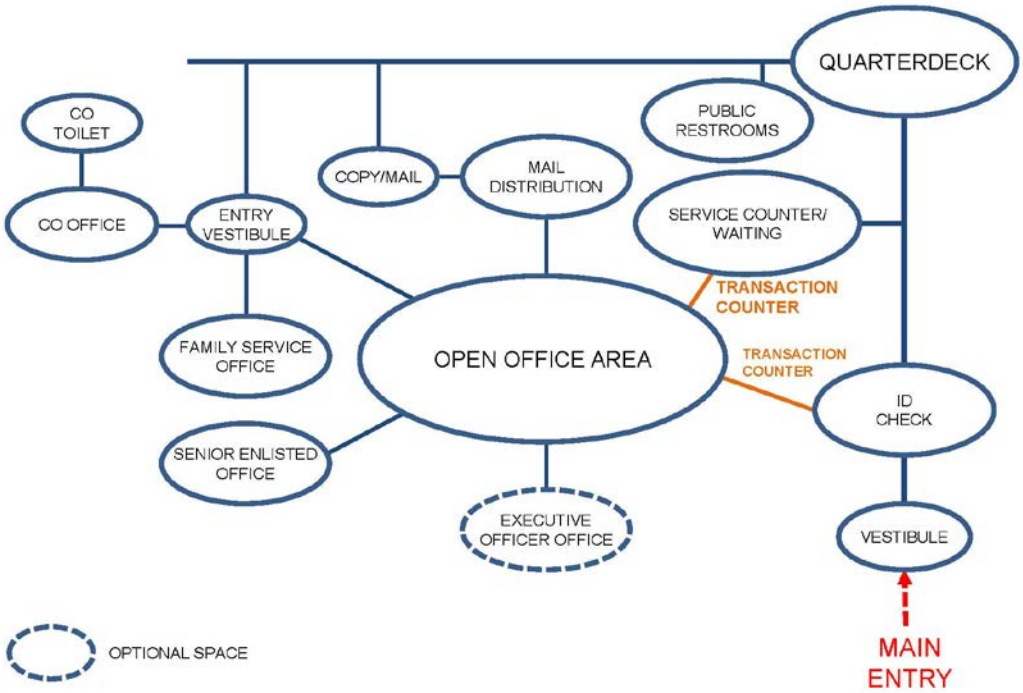

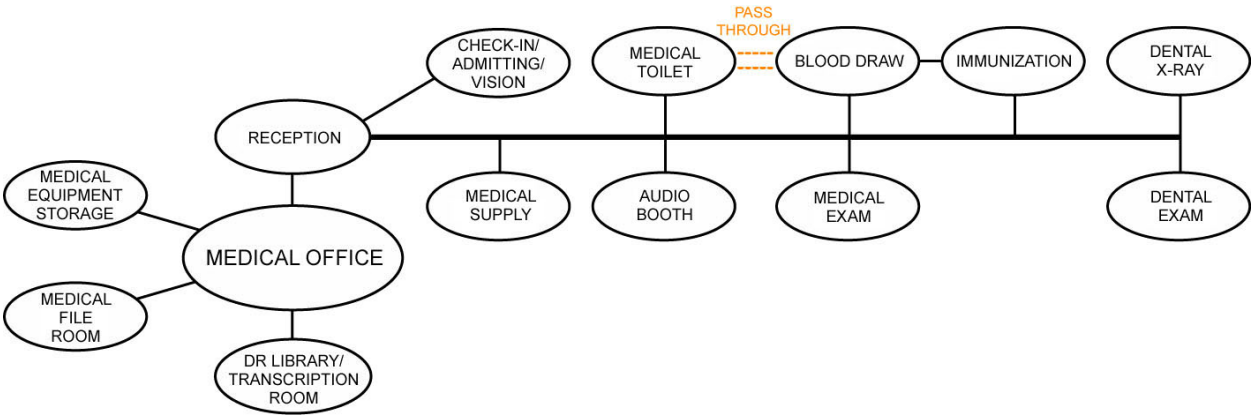

Figure 2-3. Medical Suite Adjacencies

2-5.1 NOSC in an Armed Forces Reserve Center.

When a NOSC is located within an Armed Forces Reserve Center (AFRC), the spaces identified in Table 2-1 must be dedicated Navy spaces, not shared. These spaces have been broken down by those that are required in all AFRCs and those that are optional. Desired adjacencies are also identified. See Table 2-2.

Table 2-2. Dedicated NOSC Spaces In An Armed Forces Reserve Center

NOSC Functional Program Area	Desired Adjacency/Proximity	Required/Optional
ID Check	To main entry and open office area	Only optional if building layout precludes a separate Navy entrance
Recruiting office	To main entry	Required
Quarterdeck	To full-time staff areas and distance learning center	Only optional if building layout precludes a separate Navy entrance
Public restroom	To quarterdeck and break room	Required
CO office	To open office area and quarterdeck (if provided)	Required
Executive Officer office	To CO office and open office area	Based on number of Navy reservists
Senior enlisted office	To CO office and open office area and quarterdeck (if provided)	Required
Navy family service office	To CO office and open office area	Optional based on Navy mission
Open office area (incl. service area, copier/mail nook and mail distribution)	To CO office and quarterdeck (if provided)	Required
Conference room	To CO office and open office area	Required
Funeral honors office	To drill hall	Required
Distance learning center	To quarterdeck (if provided)	Required
Dedicated IT room and SIPRNET	SIPRNET to CO office	Required
Supply storage	None required	Required
Shower/locker room	To full-time staff areas	Space for Navy personnel is required, but dedicated Navy space is optional
Medical Spaces	To other medical spaces	The scope of the medical spaces will depend upon both facility and program factors
Unit administrative areas (incl. private offices and workstations)	To unit classrooms	Required
Unit storage	To unit administrative areas	Required

2-5.2 Unit Classrooms.

Unit classrooms are designed to flexibly accommodate the variable unit sizes as noted in the paragraph in Chapter 2 entitled, “Functional Space Relationships”. Total classroom area is based on the number of reservists in the largest weekend drill population as described in Appendix B, but this area must be configured into rooms as follows:

2-5.2.1 Quantity of Rooms.

Round the weekend drilling population up to the closest multiple of 100 and provide one room for every 100 reservists as follows:

- Provide one room for up to 100 reservists.
- Provide two rooms for 101 to 200 reservists.
- Provide three rooms for 201 to 300 reservists.
- Continue as such to accommodate the largest weekend drill population.

2-5.2.2 Sizing of Rooms.

The final sizing of the individual classrooms must conform to the following criteria: Each room is sized to accommodate multiples of 25 reservists, is never larger than needed to accommodate 100 reservists, and is never smaller than needed to accommodate 25 reservists. If only one room is provided, it must accommodate 100 reservists. Any room larger than for 25 reservists must be partitionable into sections sized for 25. Within these parameters, the Activity must select the room size options that result from these criteria. Note the following examples:

- For up to 100 reservists in a weekend drill population, provide one classroom sized for 100 reservists. This classroom must have three operable walls to create four sections, each to accommodate 25 reservists.
- For 101 to 125 reservists, provide two separate classrooms with a total area sized for 125 reservists. Room sizes could be for 75 (with two operable walls) and 50 (one operable wall) or for 100 (three operable walls) and 25 (no operable walls).
- For 125 to 150 reservists, provide two separate classrooms sized for 75 and 75 or for 100 and 50, with the appropriate operable walls.
- For 150 to 175 reservists, provide two separate classrooms sized at 100 and 75, with the appropriate operable walls.
- For 175 to 200 reservists, provide two separate classrooms, each sized for 100 reservists and each with three operable walls.
- Beyond 200 reservists, a third room is added and the same criteria are applied to the individual room sizing.

2-6 FUNCTIONAL SPACE RELATIONSHIPS.

See the Functional Data Sheets in Chapter 4 for additional information on the space types and their relationships to each other.

2-7 ALTERATIONS TO EXISTING FACILITIES.

2-7.1 Navy Regulatory Authorities.

Authorities are contained in OPNAVINST 11010.20G, *Facilities Projects Manuals* and NAVFACINST 11010.45, *Comprehensive Regional Planning Instruction.* Prior to planning alterations to an existing facility to convert it to a NOSC, the activity should consult the following: Military Construction Navy Reserve (MCNR) Program Manager at Commander, Navy Reserve Force Command N5.

2-7.2 Other Considerations.

If other facilities are being considered for conversion to a NOSC, ensure that the structure can accommodate the required functions, such as the Drill Hall and/or unit areas. Also ensure adequate site space for parking. Whether planning a conversion, alteration, addition, or new construction, all the criteria in this FC must be met by the resulting facility.

This page intentionally left blank.

CHAPTER 3 DESIGN

3-1 GENERAL.

Use UFC 1-200-01, *General Building Requirements* for Applicability of model building codes and referenced government criteria. UFC 1-200-01 identifies through references key unified facility criteria and requirements including accessibility, antiterrorism, security, sustainability, safety, discipline-specific, and building systems. The design requirements in this FC are to be used in addition to UFC 1-200-01 and referenced UFC's and government criteria.

3-1.1 Medical Facility Requirements.

Design and construct the medical portions of the facility to comply with applicable portions of UFC 4-510-01, *Design: Medical Military Facilities,* particularly in the paragraph in Chapter 4 entitled, "Architectural". UFC 4-510-01 is a multidiscipline UFC; therefore, all architectural/engineering disciplines need to be aware of the requirements.

The medical spaces in a NOSC are not classified as clinical spaces, and treatment and ambulatory services are not provided. The NOSC clinic performs non-therapeutic activities related to the health of the personnel served, such as physical examinations, immunizations, medical administration, preventive medicine services, and health promotion activities to support the military mission. The Navy Bureau of Medicine and Surgery (BUMED) approval is not required for medical spaces in a NOSC.

3-2 STRUCTURE.

The NOSC must comply with UFC 3-301-01, *Structural Engineering*.

Provide clear spans for the drill hall, classrooms and Distance Learning Center.

3-3 ARCHITECTURE.

In addition to UFC 3-101-01, *Architecture*, the following requirements are specific to NOSC.

3-3.1 Stories.

Single-story structures are preferred for NOSCs. Site constraints may drive the need for multi-story structures. If a multi-story structure is required, ensure the appropriate adjacencies are maintained. See the paragraph in Chapter 2 entitled, "Layout and Adjacencies", for more information on the required adjacencies.

3-3.2 Exterior Design.

The building design must comply with Command and Installation architectural standards and incorporate the local geographical and cultural environment.

3-3.2.1 Entrance.

The main entrance serves as the architectural focal point of the exterior design for a standalone NOSC. Provide a vestibule at the main entrance. Provide flooring features for cleaning of footware. In climate appropriate areas, the vestibule must incorporate an airlock to act as a buffer from the exterior weather.

Provide a canopy (or a recess) at required egress doors to ensure that doors can open completely without obstruction.

3-3.2.2 Exterior Finishes.

Exterior finishes must be durable and low-maintenance. Coordinate exterior finishes with the interior design standards noted in the paragraph in Chapter 3 entitled, “Interior Design”.

3-3.2.3 Windows/Natural Light.

Provide for the admission of natural light in the design of the facility window systems and in the design of the overall footprint and floor depth. Select furniture systems that maximize the admission of natural light into the facility. The goal should be to achieve the LEED® “Daylight & Views” points.

In designing for natural light admission, coordinate with the paragraph in Chapter 3 entitled, “Electrical Design”.

3-3.3 Interior Design.

In addition to UFC 3-120-10, *Interior Design*, the following requirements are specific to NOSC.

3-3.3.1 Countertop and Casework Design.

Counters, casework, and cabinets must be of high-quality and durable construction. Specify Architectural Woodwork Institute (AWI) Premium or Custom for finishes per *AWI Quality Standards Illustrated, Current Edition.* Casework, cabinet doors, and drawer faces must be veneer panel core. Doors, drawers, and casework faces must be plastic laminate at a minimum. Where no water source is present, countertops must be plastic laminate as a minimum with self-edging. Where a water source is present, countertops must be solid surface/solid composite plastics only. Specify .75-in. (20-mm) minimum thickness for plywood, plywood backing, and solid wood panels.

3-3.3.2 Finishes.

Finishes should take into account the intended uses and be highly durable and require low maintenance. They must meet the requirements listed in NFPA 101, *Life Safety Code* and UFC 3-120-10, *Interior Design.*

3-3.3.2.1 Moist Climate Considerations

In moist climates, do not cover the inside of exterior walls with impervious materials such as mirrors or vinyl wall coverings to help preclude mold development in the wall.

3-3.3.2.2 Finish Criteria

For finish criteria in specific areas, see the Functional Data Sheets in Chapter 4.

3-3.3.2.3 Vinyl Composition Tile

Vinyl composition tile (VCT) is not permitted in a NOSC.

3-3.4 Acoustics.

Provide acoustical design to prevent sound from noisy spaces such as corridors, toilets, elevator machine rooms, and mechanical rooms from having negative impact on the adjacent spaces.

At a minimum, provide the required sound transmission coefficient (STC) ratings identified in Chapter 4 Functional Data Sheets, for individual spaces. Use the "Suggested Design Values" STC ratings in UFC 3-450-01, *Noise and Vibration Control* as the basis for the sound design of partition, door and window assemblies. Utilize gypsum board wall "improvements" to increase the STC of gypsum board "Stud Type" partitions to achieve the project sound requirements. Unless noted otherwise extend the room partitions and seal to the structure above for rooms that have a noise source such as, but not limited to, corridors, toilets, classrooms, training rooms, maintenance rooms, and mechanical rooms. Unless indicated in Chapter 4 STC ratings do not need to be field verified.

3-4 PLUMBING.

Design domestic hot and cold water, sanitary and storm drainage, propane, fuel oil, or natural gas systems to meet the requirements of local Installation standards, and UFC 3-420-01, *Plumbing Systems.*

To calculate fixture counts, use a population split of 70% male and 30% female. While the shower/locker room is programmed space and does not come out of the net-to-gross multiplier, include the shower/locker room fixtures in the overall facility fixture count when performing code calculations.

3-5 HEATING, VENTILATING, AND AIR CONDITIONING (HVAC).

Design the HVAC system to meet the requirements of UFC 3-410-01, *Heating, Ventilating, and Air Conditioning Systems.*

Zone the system to allow for separate operation of the administrative support (including medical) areas, the unit areas, and the drill hall. Only the administrative support areas are occupied during a normal work week.

3-6 FIRE PROTECTION.

Design fire protection and life safety to comply with UFC 3-600-01, *Fire Protection Engineering for Facilities*.

3-7 ELECTRICAL DESIGN.

In addition to UFC 3-501-01, *Electrical Engineering*, comply with the following NOSC-specific requirements:

3-7.1 Lighting.

See Chapter 4, Functional Data Sheets, for light level and control requirements that are exceptions or in addition to the requirements referenced above.

3-7.2 Power.

Provide a minimum of six outlets (one quad and one duplex receptacle) at each workstation throughout the facility.

3-7.3 Electronic Security System (ESS).

ESS is the integrated electronic system that encompasses one or more of the following subsystems; access control system (ACS), intrusion detection system (IDS), and closed circuit television (CCTV) systems for assessment of alarm conditions.

ESS must meet the policy based requirements for assets being protected and designed in accordance with UFC 4-021-02NF, *Security Engineering: Electronic Security Systems*. See Chapter 4, Functional Data Sheets, for locations.

3-7.3.1 Intrusion Detection System (IDS).

Provide an Intrusion Detection System (IDS) unless there is a documented exception. IDS must include:

- Point sensors on perimeter doors and other "accessible" openings.
- Line supervision on transmission lines. If line supervision is unavailable, two independent means of alarm signal transmission is required.
- Reporting to a central monitoring station where alarms will sound and from which a response force can be dispatched. An alarm bell located only at the protected location is not acceptable.

3-7.3.1.1 Motion Detection Sensors.

Must be UL 639 listed.

3-7.3.1.2 Point Sensors.

Must be UL 634 high security switches (HSS) level 1 or 2. HSS Level 2 is preferred. Balanced Magnetic Switches meet HSS Level 2. Level 2 rated switches include only Balanced Magnetic Switches that pass additional performance testing.

3-7.3.1.3 IDS Local Processor or Intrusion Panel.

Provide an IDS local processor or intrusion panel within the protected area. System must be configured to only allow cleared personnel located within the protected area to initiate changes in access modes or alarm conditions.

3-7.3.1.4 Sensor Cabling.

Cabling between all sensors and the IDS local processor or intrusion panel must be dedicated to the system and contained within the protected area. If the wiring cannot be contained within the protected area, provide tamper protection in accordance with UFC 4-021-02NF.

3-7.3.1.5 Backup power.

Provide eight hours of uninterruptible backup power. This may be provided by internal batteries, uninterruptible power supply (UPS), generators, or any combination. Emergency backup power for IDS must not generate the requirement for a UPS or generator. If a generator or UPS is not available for backup, provide backup with internal batteries.

In the event of primary power failure, the IDS must:

- Automatically transfer to the emergency electrical power source without causing alarm activation.
- Initiate an audible or visual indicator at the IDS local processor or intrusion panel to provide an indication of the primary or backup electrical power source in use.
- Initiate an audible or visual indicator at the monitoring station indicating a failure in a power source or a change in power source.

3-7.3.2 Access Control System (ACS).

Provide card reader with keypads at entry to building to ensure only authorized personnel are permitted ingress. The ACS must log and archive all transactions and alert authorities of unauthorized entry attempts. When provided, the ACS may be interfaced with the CCTV system to initiate event activated recording of unauthorized access attempts. Unless otherwise directed, the default ACS identifier credential must be the Common Access Card (CAC).

3-7.3.3 CCTV.

Provide the infrastructure for a CCTV system when the need for a CCTV system has been established.. Currently, there is no policy based requirement for a complete and useable CCTV system. Therefore, the decision to provide a CCTV system must be determined based on the value of the asset being protected, designs basis threat, and the desired capability to record events for evidentiary archiving. The program manager will determine if design and construction funds will be provided. See the paragraph below entitled, “Camera Locations” and Chapter 4, Functional Data Sheets for workstation and camera locations.

3-7.3.3.1 CCTV Workstation

Provide a minimum of one workstation for the CCTV system if provided by local command. Multiple workstations may be required for a large distributed system. Video management software must be compatible with all cameras, encoders, and recording devices.

3-7.3.3.2 Video Recording

System must have the capability to digitally record and store all cameras images for a minimum of seven days.

- Event activated recording and on-demand recording must be 30 frames per second (fps).
- Routine recording must be not less than 5 fps.
- Resolution must be no less than 720 X 480 pixels.

3-7.3.3.3 Camera Locations

In addition to the locations indicated in Chapter 4, a camera outlet should be provided at each emergency exit and the building entrance.

3-7.4 Telecommunication Systems.

See Chapter 4, Functional Data Sheets, for outlet locations.

3-7.5 Television Systems.

See Chapter 4, Functional Data Sheets, for outlet locations.

3-7.6 Intercommunication Systems.

See Chapter 4, Functional Data Sheets, for locations.

3-8 FURNISHINGS.

All windows and other glazed openings to the exterior of the building must be provided with horizontal blinds or solar shading systems and are considered part of the

construction project. Soft window treatments such as draperies are considered collateral equipment and must be included in the FF&E package as required.

Additional furnishing and equipment criteria for specific spaces within a NOSC are provided in Chapter 4.

3-9 SITE WORK.

Comply with UFC 3-201-01, *Civil Engineering.* Organize the site to be compatible with the site planning and style of adjacent existing structures. Locate the building to reflect local climatic conditions. For example, provide protection from prevailing winds and glare and orient operable windows to take advantage of summer breezes. Orient the building, to the maximum extent possible, to take advantage of passive solar heating and day lighting.

3-9.1 Landscaping.

Comply with UFC 3-201-02, *Landscape Architecture.*

3-9.1.1 Plants

The plant selection must be easy to maintain and enhance the visual quality of the facility in all seasons. Indigenous species are preferred. Comply with local Installation landscape standards.

Address sustainable design issues when designing the landscape. Select plants that require little to no additional water beyond normal rainfall. Avoid plants that require an irrigation system or consider a gray water or storm water irrigation system.

3-9.1.2 Site Furnishings and Amenities

Site furnishings and related amenities must address issues of vandal resistance, durability, and handicapped accessibility, and should be coordinated in a manner that reflects the architecture and context in which the facility is situated. While not all-inclusive, the following site components may be considered to complement landscaping when designing outdoor spaces: facility signage, flagpoles, tables and chairs for outdoor dining, benches, trash receptacles, ash urns, bike rakes, bollards, fencing, trash dumpster enclosures, and specialty paving surfaces for accent and focus. Consider the need in the landscaping plan for a large flat area for physical training (PT).

The following are required:

- Provide a facility sign for all NOSC. Match the style of other signs on the base or the Installation Appearance Plan of the base.

- Provide a screen wall around three sides of the trash dumpster pad with an exterior surface that matches the exterior walls of the facility. Provide a gate on the open side for access to the dumpster.

- Provide a flagpole for NOSC that are located off-base.

- Provide hard surfaces with covered roof at the building entry, adjacent to Drill Hall, and adjacent to Mess.

3-9.2 Site Circulation and Parking.

Comply with UFC 3-201-01, *Civil Engineering*. Locate parking areas so they do not dominate the main entrance and public image of the facility. Provide the following:

- Government vehicle parking. Provide two large, van-sized, paved parking spaces. If climate dictates and budget allows, provide enclosed or covered spaces. Accommodate any additional vehicle requirements associated with exclusive spaces, as required.
- Staff and reservist privately-owned vehicle (POV) parking. For a NOSC located on an Installation, provide paved parking spaces for 80% of reservist and full-time-staff population. If site space and budget permits, provide unpaved spaces for the remaining 20% of the population. For a NOSC located off Installation, provide paved parking spaces for 100% of reservist and full-time staff population. For both on- and off-Installation NOSCs, reservist population must be calculated based on the largest single drill weekend, not on total NOSC capacity.

CHAPTER 4 SPECIFIC DESIGN CRITERIA

4-1 INTRODUCTION.

This chapter identifies the specific design needs for each functional area outlined in this FC. Tables 4-1 through 4-40 provide this data in a standard Functional Data Sheet format.

- The interior construction specialties, equipment and furnishings criteria provided in these tables are broken down as follows:
- Casework/Built-in Equipment. This includes anything physically attached or plumbed to the building such as counters, cabinets, casework, toilet accessories, window treatments, laundry machines, and retractable overhead screens.
- Furnishings, Fixtures, and Equipment (FF&E). This includes contractor-furnished, contractor-installed loose items such as desks, tables, chairs, and bookshelves.
- User-provided FF&E. This includes all government-furnished, government-installed items, which are typically limited to office equipment such as computers, printers, copiers, projectors and flat screen monitors (if mounted, the projector and/or flat screen monitors mount is part of construction).

Table 4-1. ID Check

Description/ Usage	The ID check is a small space directly off the main entry that provides a transaction window to the security desk and access points to the NOSC and the recruiting office.
Ceiling Ht.	10 ft. (3.0 m).
Finishes	**Walls.** Provide a durable, impact resistant wainscot such as split-faced/ground-faced CMU, acrylic molded wainscot, etc. **Floor.** Provide a low-maintenance, durable finish suitable for this high-traffic area such as stone, terrazzo, or quarry tile. Provide a recessed walk-off mat/area at the entrance door. Provide a base that matches the flooring. **Ceiling.** Acoustical ceiling panel (ACP).
Plumbing	None required.
HVAC	Provide a system per the paragraph in Chapter 3 entitled, “HVAC”.
Fire Protection	Provide system per the paragraph in Chapter 3 entitled, “Fire Protection”.
Power	Provide outlets per the paragraph in Chapter 3 entitled, “Electrical Design”.
Lighting	Provide system per the paragraph in Chapter 3 entitled, “Electrical Design”.
Communication	**CCTV.** Provide one outlet for monitor location, if required. **CATV/Internal Video.** Provide a CATV outlet. **PA/Audio.** Provide a speaker. **Telephone.** Provide one line with internal two-way communication. If a security gate is provided for NOSC located off-base, provide telephone at exterior gate for communication with ID Check. **Data.** None required. **Security.** Provide an electronically locked door from the ID check to the NOSC with controls at the security desk. Provide door buzzer at main entrance door. For NOSC located off-base, provide electronically locked gate at the site perimeter that can be unlocked from ID Check.
Acoustics	No special provisions required.
Casework/Built-in Equipment	Provide a secure transaction counter to the full-time staff area security desk that serves as a security check-in point.
Furnishings Fixtures & Equipment (FF&E)	
User-provided FF&E	CCTV cameras at all building perimeter doors, at entry gates on site, and monitor and computer in ID Check room, if required.
Special Requirements	Where climate conditions dictate, provide an airlock at the exterior doors, and provide double doors leading into the NOSC. Provide door buzzer at main entrance door.

Table 4-2. Recruiting Office

Description/ Usage	This small suite is directly off the ID check/main entry and provides an environment for a recruiting officer to meet with prospective reservists. It includes a display area with brochure racks, table, two workstations with facing chairs for prospects, and storage. Provide a separate room to accommodate a table and chair for knowledge testing adjacent to the recruiting office. For larger NOSC with three recruiters or more, a small conference or meeting area for briefings must be provided. A small waiting area may be desired.
Ceiling Ht.	8 ft. (2.4 m) minimum.
Finishes	**Walls.** Painted gypsum wall board. **Floor.** Carpet tile with rubber base. **Ceiling.** Acoustical ceiling panels (ACP).
Plumbing	None required.
HVAC	Provide system per the paragraph in Chapter 3 entitled, “HVAC”.
Fire Protection	Provide system per the paragraph in Chapter 3 entitled, “Fire Protection”.
Power	Provide outlets per the paragraph in Chapter 3 entitled, “Electrical Design” and for all dedicated equipment. Provide at least one quad outlet per workstation.
Lighting	Provide system per the paragraph in Chapter 3, entitled “Electrical Design”.
Communication	**CCTV.** None required. **CATV/Internal Video.** None required. **PA/Audio.** Provide a speaker. **Telephone.** Provide one line with internal two-way communication at each workstation. **Data.** Provide data outlets to support each workstation and other required equipment. **Security.** None required.
Acoustics	Provide wall and door construction with a factory STC rating of 40. Rating does not need to be field verified.
Casework/Built-in Equipment	Provide marker board and bulletin board.
Furnishings Fixtures & Equipment (FF&E)	2 ft. (.61 m) diameter round table for display material, brochure racks, and display space. Workstations—systems furniture for 48 $ft.^2$ (4.5 m^2) workstation: desk chair and side chair. Workstation systems furniture must provide adequate space for filing and overhead storage.
User-provided FF&E	Computers and printer.
Special Requirements	Ensure this suite is well marked with signage and clearly visible from the facility entrance. Provide lockable door.

Table 4-3. Quarterdeck

Description/ Usage	The quarterdeck is directly off a corridor from the main entry and acts as an internal "lobby" of the facility. It provides for the main facility signage, the display of the flag, and display of Navy or unit memorabilia. It will also be used for staff gatherings of up to 15 people and as a ceremonial space.
Ceiling Ht.	10 ft. (3.0 m).
Finishes	**Walls.** Architectural Feature Wall Panel System using material such as acrylic, wood, metal or polished ground faced block. **Floor.** Provide a low-maintenance, durable finish such as stone, terrazzo, or quarry tile. Provide a base that matches the flooring. Provide recessed walk-off mat at entrance as an extension of the entrance vestibule. **Ceiling.** Provide a decorative acoustical ceiling.
Plumbing	None required.
HVAC	Provide system per the paragraph in Chapter 3 entitled, "HVAC".
Fire Protection	Provide system per the paragraph in Chapter 3 entitled, "Fire Protection".
Power	Provide outlets per the paragraph in Chapter 3 entitled, "Electrical Design".
Lighting	Provide system per the paragraph in Chapter 3 entitled, Electrical Design". Provide decorative and task lighting.
Communication	**CCTV.** None required. **CATV/Internal Video.** None required. **PA/Audio.** Provide speaker. **Telephone.** Provide one line with internal two-way communication. **Data.** Provide one outlet. **Security.** None required.
Acoustics	No special provisions required.
Casework/Built-in Equipment	Main facility signage
Furnishings Fixtures & Equipment (FF&E)	Cases to display Navy/unit memorabilia (display cases can be built-in). Provide chain of command board, with high quality finish, to include four 8 by 10 inch frames that can be easily changed.
User-provided FF&E	
Special Requirements	Consider a skylight or clerestory.

Table 4-4. Commanding Officer Office

Description/ Usage	This private office includes typical office accommodations and an adjacent private toilet.
Ceiling Ht.	8 ft. (2.4 m) minimum.
Finishes	**Walls.** Painted gypsum wall board in office and reception areas. In toilet, provide moisture and mildew resistant gypsum wall board with ceramic tile wainscot, and semi-gloss or better industrial latex-based paint. **Floor.** Carpet tile with rubber base in office and reception areas. Provide porcelain tile with flush cove base in toilet. **Ceiling.** Provide ACP in office and reception areas. Provide moisture resistant gypsum board ceiling in the toilet.
Plumbing	Provide water closet, shower, and lavatory.
HVAC	Provide system per the paragraph in Chapter 3 entitled, “HVAC”. Provide independent thermostat.
Fire Protection	Provide system per the paragraph in Chapter 3 entitled, “Fire Protection”.
Power	Provide outlets per the paragraph in Chapter 3 entitled, “Electrical Design”. Ensure an adequate number of circuits to power all equipment. Provide a minimum of one quad outlet in office area on at least three walls. Gang outlets with data and telephone. Provide outlets per code in the toilet.
Lighting	Provide system per the paragraph in Chapter 3 entitled, “Electrical Design”.
Communication	**CCTV.** None required. **CATV/Internal Video.** Provide one outlet. **PA/Audio.** None required. **Telephone.** Provide one line with internal two-way communication. **Data.** Provide data outlets to support required equipment. **Security.** None required.
Acoustics	Provide wall and door construction with a factory STC rating of 49. Rating does not need to be field verified.
Casework/Built-in Equipment	Provide vanity cabinet with lavatory and solid surface top in toilet.
Furnishings Fixtures & Equipment (FF&E)	Office desk, office chair, file cabinet, bookshelf, desk lamp, and two side chairs. Small conference table and four chairs, or sofa, two lounge chairs and two end tables.
User-provided FF&E	Computer and printer.
Special Requirements	Provide lockable door.

Table 4-5. Executive Officer and Senior Enlisted Offices.

Description/ Usage	These are one or two private offices adjacent to the CO office/command suite. Every NOSC has a Senior Enlisted office. NOSCs that accommodate over 500 reservists add the XO office.
Ceiling Ht.	8 ft. (2.4 m) minimum.
Finishes	**Walls.** Painted gypsum wall board. **Floor.** Carpet tile with rubber base. **Ceiling.** ACP.
Plumbing	None required.
HVAC	Provide system per the paragraph in Chapter 3 entitled, “HVAC”.
Fire Protection	Provide system per the paragraph in Chapter 3 entitled, “Fire Protection”.
Power	Provide outlets per the paragraph in Chapter 3 entitled, “Electrical Design”. Ensure an adequate number of circuits to power all equipment. Provide a minimum of one quad outlet on at least three walls. Gang outlets with data and telephone.
Lighting	Provide system per the paragraph in Chapter 3 entitled, “Electrical”.
Communication	**CCTV.** None required. **CATV/Internal Video.** Provide one outlet in the XO office. **PA/Audio.** None required. **Telephone.** Provide one line with internal two-way communication. **Data.** Provide data outlets to support required equipment. **Security.** None required.
Acoustics	Provide wall and door construction with a factory STC rating of 49. Rating does not need to be field verified.
Casework/Built-in Equipment	Provide markerboards.
Furnishings Fixtures & Equipment (FF&E)	Office desk, office chair,file cabinet, bookshelf, desk lamp, and two side chairs.
User-provided FF&E	Computers.
Special Requirements	Provide lockable doors.

Table 4-6. Open Office Area

Description/ Usage	The office area for the full-time staff includes workstations arranged in an open office plan with systems furniture. The offices should be free from frequent distraction, have a professional appearance, and provide a sense of work place. The square footage of this space may be divided into at least six different areas; Personnel Management, Mobilization, Career Counseling, Operations, Supply, and Command Services.
Ceiling Ht.	9 ft. (2.74 m) minimum.
Finishes	**Walls.** Painted gypsum wall board. **Floor.** Carpet tile with rubber base. **Ceiling.** ACP.
Plumbing	None required.
HVAC	Provide system per the paragraph in Chapter 3 entitled, "HVAC".
Fire Protection	Provide system per the paragraph in Chapter 3 entitled, "Fire Protection".
Power	Provide outlets per the paragraph in Chapter 3 entitled, "Electrical Design". Ensure an adequate number of circuits to power all equipment. Provide at least one quad outlet per workstation. Provide additional outlets as necessary to operate shared equipment such as printers, fax, etc.
Lighting	Provide system per the paragraph in Chapter 3 entitled, "Electrical Design".
Communication	**CCTV.** None required. **CATV/Internal Video:** None required. **PA/Audio:** Provide speaker and PA controls. **Telephone.** Provide one line per staff plus additional lines for fax and copier. **Data.** Provide one outlet per staff plus outlets for each printer, copier, scanner, etc. **Security.** None required.
Acoustics	Partition and floor materials must have a high Noise Reduction Coefficient (NRC) and be manufactured specifically for open office environments. Provide ceiling materials that have a high Articulation Class (AC) rating.
Casework/Built-in Equipment	Provide built-in cabinets under the transaction counters. Workcounter with under-counter storage in printer area. All countertops to be solid surface material.
Furnishings Fixtures & Equipment (FF&E)	Workstations—systems furniture for 64 $ft.^2$ (5.9 m^2) workstation: desk chair and side chair for open offices. Workstation systems furniture must provide adequate space for filing and overhead storage. Counters for work surfaces and equipment such as printers and cabinets for storage of administrative supplies. Provide lockable lateral file cabinets for secure personnel files.
User-provided FF&E	Computers, printers, and other office equipment as needed.
Special Requirements	**Mail Handling.** Provide a direct entrance into the mail distribution area. If the NOSC is located off Installation, provide a separate mail room that meets the requirements in UFC 4-010-01, *DoD Minimum Antiterrorism Standards for Buildings*. **Telecom Closet.** Near or adjacent to the administrative offices, provide a telecommunications room in compliance with the paragraph in Chapter 3 entitled, "Electrical Design".

Table 4-7. Service Counter/Waiting Area

Description/ Usage	This area provides space for reservists or other customers to interact with the full-time staff through the service/transaction counter. It includes a small waiting area and accommodates ID photography.
Ceiling Ht.	8 ft. (2.44 m) minimum.
Finishes	**Walls.** Painted gypsum wall board with durable acrylic wall system. **Floor.** Carpet tile with rubber base. **Ceiling.** ACP.
Plumbing	None required.
HVAC	Provide system per the paragraph in Chapter 3 entitled, “HVAC”.
Fire Protection	Provide system per the paragraph in Chapter 3 entitled, “Fire Protection”.
Power	Provide outlets per the paragraph in Chapter 3 entitled, “Electrical Design”.
Lighting	Provide system per the paragraph in Chapter 3 entitled, “Electrical Design”. Coordinate lighting with ID photography area.
Communication	**CCTV.** None required. **CATV/Internal Video:** Provide one outlet. **PA/Audio:** Provide speaker and PA controls. **Telephone.** Provide one line. **Data.** Provide one line. **Security.** None required.
Acoustics	No special provisions required.
Casework/Built-in Equipment	Provide work desk/service/transaction counter with ABA section. Include file and pencil drawer storage. Provide bulletin boards and/or tack surfaces for display of facility information.
Furnishings Fixtures & Equipment (FF&E)	Provide comfortable seating in waiting area. Provide child-sized tables and chairs for children waiting. Provide magazine and brochure racks.
User-provided FF&E	
Special Requirements	The entrance to this area should be directly off the corridor that runs from the main entrance to the quarterdeck and be easily visible to anyone who has entered the facility. Provide glass storefront walls between the waiting area and the corridor with glass entrance doors. A person standing in the corridor should be able to see the service counter and the staff administrative area behind it when looking through the storefront. Provide a lockable door from the waiting area into the open office area. Provide a photographic backdrop opposite the side of the service/transaction counter that includes the digital camera for ID issue.

Table 4-8. Navy Family Services Office

Description/ Usage	Family services offer a variety of private counseling functions such a financial planning or clinical counseling. Between sessions, staff will work on files and research cases.
Ceiling Ht.	8 ft. (2.4 m) minimum.
Finishes	**Walls.** Painted gypsum wall board. **Floor.** Carpet tile with rubber base. **Ceiling.** ACP.
Plumbing	None required.
HVAC	Provide a system per the paragraph in Chapter 3 entitled, “HVAC”.
Fire Protection	Provide system per the paragraph in Chapter 3 entitled, “Fire Protection”.
Power	Provide outlets per the paragraph in Chapter 3 entitled, “Electrical Design”.
Lighting	Provide system per the paragraph in Chapter 3 entitled, “Electrical Design”.
Communication	**CCTV.** Provide one outlet. **CATV/Internal Video.** None required **PA/Audio.** Provide a speaker. **Telephone.** Provide one line **Data.** Provide one outlet for each piece of equipment.
Acoustics	Provide wall and door construction with a factory STC rating of 49. Rating does not need to be field verified.
Casework/Built-in Equipment	Provide marker board and bulletin board.
Furnishings Fixtures & Equipment (FF&E)	Modular office furniture consisting of a desk or workstation, credenza with overhead storage, secure file cabinet, and desk chair. Provide an upholstered love seat, an upholstered arm chair, and a side table (see layout). As an option, the room can be utilized as a small conference room as needed.
User-provided FF&E	Computer and printer.
Special Requirements	Lockable door with a vision panel.
Special Requirements	The furniture configuration allows the staff member to meet with customers in a more intimate, less threatening setting. The desk should not divide the staff member from the customer. See illustration below.

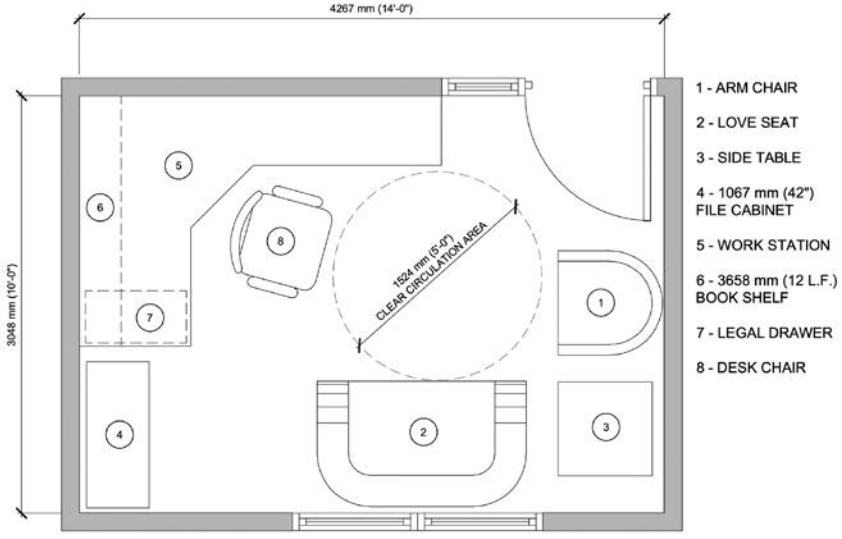

Table 4-9. Copier/Mail Nook and Mail Distribution

Description/ Usage	The copier/mail nook is directly off a main corridor and directly adjacent to the mail distribution area. It includes one or more copiers and office equipment for staff and reservists use and double-sided, lockable mailboxes for staff and reserve units. It should be easily accessible by both the full-time staff and the reservists. The mail distribution area is directly off the full-time staff open office area and includes a mail sorting table and access to the back of the mail boxes in the copier/mail nook.
Ceiling Ht.	8 ft. (2.44 m) minimum.
Finishes	**Walls.** Painted gypsum wall board. **Floor.** Resilient flooring with rubber base. **Ceiling.** ACP.
Plumbing	None required.
HVAC	Provide a system per the paragraph in Chapter 3 entitled, “HVAC”.
Fire Protection	Provide system per the paragraph in Chapter 3 entitled, “Fire Protection”.
Power	Provide outlets per the paragraph in Chapter 3 entitled, “Electrical Design”.
Lighting	Provide system per the paragraph in Chapter 3 entitled, “Electrical Design”.
Communication	**CCTV.** Provide one outlet. **CATV/Internal Video.** None required. **PA/Audio.** Provide a speaker. **Telephone.** Provide one line for a facsimile machine. **Data.** Provide outlets for each piece of equipment. **Security.** None required.
Acoustics	No special provisions required.
Casework/Built-in Equipment	Provide base and wall cabinets. Provide 4-in. x 10-in. (100-mm x 255-mm) double-sided, lockable mailboxes for each reserve unit plus 13 additional for full-time staff and operational divisions.
Furnishings Fixtures & Equipment (FF&E)	Provide sorting table and chairs in distribution area. Provide mail sorter and counter for large mail machine, if required by the size of the facility.
User-provided FF&E	Copiers and office equipment.
Special Requirements	If the NOSC is located off-base, provide a separate mail room in addition to the mail distribution area. This mail room must comply with the requirements in UFC 4-010-01, *DoD Minimum Antiterrorism Standards for Buildings*.

Table 4-10. Conference Room.

Description/ Usage	This conference room serves the CO and his/her staff and the Unit COs and senior enlisted personnel. It includes video teleconference (VTC) capability and is near the CO office and full-time staff area. (Note: NMCI does not support VTCs in NOSCs.)
Ceiling Ht.	8 ft. (2.4 m) minimum.
Finishes	**Walls.** Painted gypsum wall board. Provide durable wainscot with chair rail. **Floor.** Carpet tile with rubber base. **Ceiling.** ACP.
Plumbing	None required.
HVAC	Provide system per the paragraph in Chapter 3 entitled, “HVAC”.
Fire Protection	Provide system per the paragraph in Chapter 3, entitled, “Fire Protection”.
Power	Provide outlets per the paragraph in Chapter 3 entitled, “Electrical Design”. Ensure an adequate number of circuits to power all equipment. Provide a minimum of one quad outlet at table and on at least three walls. Gang outlets with data and telephone. Provide outlet above ceiling for projector.
Lighting	Provide system per the paragraph in Chapter 3 entitled, “Electrical Design”. Provide dimmable lighting.
Communication	**CCTV.** None required. **CATV/Internal Video.** Provide one outlet. **PA/Audio.** None required. **Telephone.** Provide one line with internal two-way communication. **Data.** Provide data outlets to support required equipment. **Security.** None required.
Acoustics	Provide wall and door construction with a factory STC rating of 49. Rating does not need to be field verified.
Casework/Built-in Equipment	A retractable overhead screen and ceiling mounted projector mount can be provided as an option to a 50 inch (1.27 m) video monitor/TV if desired. Provide two large marker boards and a bulletin board.
Furnishings Fixtures & Equipment (FF&E)	Conference table and chairs. Lectern.
User-provided FF&E	VTC equipment, including 50 inch (1.27 m) minimum video monitor/TV. (Note: NMCI does not support VTCs in NOSCs.)
Special Requirements	Consider the viewing angle when planning the location of the conference table, VTC camera, screen, and microphone.

Table 4-11. Funeral Honors Office

Description/ Usage	This office accommodates staff administrative functions for the oversight of military funeral honors and storage of coffins and other ceremonial equipment.
Ceiling Ht.	8 ft. (2.4 m) minimum.
Finishes	**Walls.** Painted gypsum wall board. **Floor.** Carpet tile with rubber base. **Ceiling.** ACP.
Plumbing	None required.
HVAC	Provide a system per the paragraph in Chapter 3 entitled, “HVAC”.
Fire Protection	Provide system per the paragraph in Chapter 3 entitled, “Fire Protection”.
Power	Provide outlets per the paragraph in Chapter 3 entitled, “Electrical Design”.
Lighting	Provide system per the paragraph in Chapter 3 entitled, “Electrical Design”.
Communication	**CCTV.** Provide one outlet. **CATV/Internal Video.** None required. **PA/Audio.** Provide a speaker. **Telephone.** Provide two lines. **Data.** Provide one outlet for each piece of equipment. **Security.** None required.
Acoustics	Provide wall and door construction with a factory STC rating of 49. Rating does not need to be field verified.
Casework/Built-in Equipment	Provide a storage closet with shelving for items such as uniform accessories, bugles, and other ceremonial equipment.
Furnishings Fixtures & Equipment (FF&E)	Two workstations—systems furniture for 64 $ft.^2$ (5.9 m^2) workstation: desk chair and side chair for open offices. Workstation systems furniture must provide adequate space for filing and overhead storage. Coffin dolly.
User-provided FF&E	
Special Requirements	

Table 4-12. Distance Learning Center

Description/ Usage	The distance learning center is an advanced classroom environment that supports synchronous or asynchronous learning where the student and the instructor may be in physically separate locations. It is designed to accommodate a minimum of 20 students. Space can be divided into two equally spaced separate rooms if desired.
Ceiling Ht.	10ft. (3.0 m) minimum.
Finishes	**Walls.** Painted gypsum wall board. **Floor.** Match ID Check area flooring. **Ceiling.** ACP.
Plumbing	None required.
HVAC	Provide system per the paragraph in Chapter 3 entitled, “HVAC”.
Fire Protection	Provide system per the paragraph in Chapter 3 entitled, “Fire Protection”.
Power	Provide outlets per the paragraph in Chapter 3 entitled, “Electrical Design”. Ensure adequate number of circuits to power all equipment. Provide utility AC outlets on separate circuits from the media equipment inside the room for portable media equipment and laptop computers. Provide at least one duplex outlet every 10 ft. (3.05 m) along the front wall of the classroom, on the underside of any teaching tables and on any fixed lecterns. Provide power outlet in ceiling for projector.
Lighting	Provide a minimum of three lighting zones: 1. One zone should control the classroom's general-use fluorescent lights that provide full brightness for general activities up to 50 ft. candles (540 Lux). 2. One zone should control low level, fully dimmable lights for note taking that provide 2 ft. candles (20 Lux) at the desktops. These lights must not shine on the screens and the eyes of the audience. 3. One zone should control presentation area lights (either incandescent or fluorescent) that illuminate the writing/display surface at the front of the room and provide 50 ft. candles (540 Lux).
Communication	**CCTV.** None required. **CATV/Internal Video.** Provide one outlet at the front of the room. **PA/Audio.** Provide speakers. **Telephone.** Provide one outlet at the front of the room near the lighting and media equipment controls. **Data.** Provide dual duplex data outlets at each of the following locations: the front of the classroom, the video monitor, and the media equipment rack. Provide one outlet for each student and coordinate location with selected furniture. Provide WIFI infrastructure and boosters. **Security.** None required.
Acoustics	Provide wall and door construction with a factory STC rating of 49. Rating does not need to be field verified. Provide ceiling materials that have a high Articulation Class (AC) rating.
Casework/Built-in Equipment	A retractable overhead screen and ceiling mounted projector mount can be provided as an option to a 50 inch (1.27 m) video monitor/TV if desired. Provide two large marker boards and bulletin board.
Furnishings Fixtures & Equipment (FF&E)	Provide tables that have C-legs on castors and wire management baskets. Tables must be 30 in. (762 mm) deep and long enough to accommodate two computers with 3-ring-binder space between. Provide mid-back upholstered task chairs with adjustable arms for each student and instructor. Provide a combination lectern to hold computer, monitor and keyboard connected to video monitor and camera control.

Table 4-12. Distance Learning Center

User-provided FF&E	Computers and projector.
Special Requirements	Provide two 1.25-in. (32-mm) conduits from each video projector location to the podium and to the location of the media equipment rack for low voltage projector control and signal cables. The distance learning center serves as a focal point of the facility. Provide an interior window to the corridor that runs from the main entrance to the quarterdeck. This window should be easily visible to anyone who has entered the facility.

Table 4-13. Mess

Description/ Usage	This space serves as a warming kitchen/staging area for catered events in the drill hall.
Ceiling Ht.	8 ft. (2.4 m) minimum.
Finishes	**Walls.** Provide a low maintenance, durable finish such as an epoxy based paint. **Floor.** Resilient sheet or tile such as linoleum, rubber or solid vinyl with rubber base. Do not use VCT. **Ceiling.** Gypsum wall board, semi-gloss latex paint.
Plumbing	Provide hot and cold water supply to a double-tub, stainless steel, commercial-grade kitchen sink. Provide cold water supply for refrigerator and coffee maker.
HVAC	Provide system per the paragraph in Chapter 3 entitled, “HVAC”.
Fire Protection	Provide system per the paragraph in Chapter 3 entitled, “Fire Protection”.
Power	Provide outlets per the paragraph in Chapter 3 entitled, “Electrical Design” and for all dedicated equipment.
Lighting	Provide system per the paragraph in Chapter 3 entitled, “Electrical Design”.
Communication	**CCTV.** None required. **CATV/Internal Video.** Provide one outlet. **PA/Audio.** Provide speaker. **Telephone.** Provide one line. **Data.** None required. **Security.** None required.
Acoustics	No special provisions required.
Casework/Built-in Equipment	Double-tub, stainless steel, commercial-grade kitchen sink, solid surface countertop, base cabinets with doors and drawers, and upper cabinets with doors. Provide a 6-ft. (1.83 m) wide pass-through window to drill hall.
Furnishings Fixtures & Equipment (FF&E)	One commercial microwave, one residential-style refrigerator, and commercial coffee maker.
User-provided FF&E	Provide warming cabinet if required by the size of the facility.
Special Requirements	A covered outdoor dining area may be considered.

Table 4-14. SIPRNET Room

Description/ Usage	Secure room housing equipment for secure Internet access.
Ceiling Ht.	8 ft. (2.4 m) minimum.
Finishes	**Walls.** Painted gypsum wall board. **Floor.** Resilient sheet or tile such as linoleum, rubber or solid vinyl with rubber base. Do not use VCT. **Ceiling.** ACP or none required.
Plumbing	None required.
HVAC	Provide system per the paragraph in Chapter 3 entitled, “HVAC”. Mechanical or other openings greater than 96 in.^{2} (0.06 m^2) must have bars in accordance with MIL HDBK 1013/1A, *Design Guidelines for Physical Security of Facilities*. Do not route other utilities through this space.
Fire Protection	Provide system per the paragraph in Chapter 3 entitled, “Fire Protection”.
Power	Provide outlets per the paragraph in Chapter 3 entitled, “Electrical Design” and for all dedicated equipment.
Lighting	Provide system per the paragraph in Chapter 3 entitled, “Electrical Design”.
Communication	**CCTV.** Provide outlet outside of room in corridor for surveillance of this room, if required. CCTV is not allowed inside the room, **CATV/Internal Video.** None required. **PA/Audio.** None required. **Telephone.** Navy to provide/install classified equipment. Provide one outlet for Secure Telephone Equipment. **Data.** Navy to provide/install classified equipment. **Security.** Navy to provide/install classified equipment.
Acoustics	Provide acoustical attenuation that meets SIPRNET requirements.
Casework/Built-in Equipment	Equipment racks.
Furnishings Fixtures & Equipment (FF&E)	Navy to provide computer racks. Provide desk, chair and class 5 safe.
User-provided FF&E	CCTV camera, if required.
Special Requirements	Navy to provide final fit-out of room based on "Technical Guide for the Integration of Secret Internet Protocol Router Network (SIPRNET),” latest version. Provide solid core wood or hollow metal door with a GSA-approved combination lock and an Intrusion Detection System (IDS).

Table 4-15. Supply Storage

Description/ Usage	The supply storage provides space for the storage of administrative supplies and new uniforms, a uniform fitting area for taking measurements, a workstation for supply staff, and a small receiving area directly off a service entrance.
Ceiling Ht.	8 ft. (2.4 m) minimum.
Finishes	**Walls.** Painted gypsum wall board. **Floor.** Resilient sheet or tile such as linoleum, rubber or solid vinyl with rubber base. Do not use VCT. **Ceiling.** ACP.
Plumbing	None required.
HVAC	Provide system per the paragraph in Chapter 3 entitled, “HVAC”.
Fire Protection	Provide system per the paragraph in Chapter 3 entitled, “Fire Protection”.
Power	Provide outlets per the paragraph in Chapter 3 entitled, “Electrical Design” and one additional quad outlet for the workstation.
Lighting	Provide system per the paragraph in Chapter 3 entitled, “Electrical Design”.
Communication	**CCTV.** None required. **CATV/Internal Video.** None required. **PA/Audio.** Provide speaker. **Telephone.** Provide one line at workstation. **Data.** Provide one outlet at the workstation. **Security.** None required.
Acoustics	No special provisions required.
Casework/Built-in Equipment	Provide a department-store style dressing room with minimum 6-ft. (1830 mm) high walls and a lockable door. Provide hooks in the dressing room. Provide a minimum 10 ft. (3.05 m) length of countertop/work surface for organizing/inventory of supplies.
Furnishings Fixtures & Equipment (FF&E)	Storage shelving for boxed uniforms and administrative supplies. Measuring platform and three-panel adjustable mirror at the fitting area. Workstation systems furniture for 64 ft.^{2} (5.9 m^2) workstation, desk chair and side chair. Workstation systems furniture must provide adequate space for filing and overhead storage.
User-provided FF&E	Computer, printer and copier.
Special Requirements	Provide a transaction counter open to the corridor with a coiling door or grille at the counter to serve as a security screen. The receiving area comprises open floor space for stacking of larger boxes until they can be unpacked and distributed appropriately. Provide lockable door.

Table 4-16. Fitness Room

Description/ Usage	The Fitness Room should accommodate the latest in fitness machines, as well as more traditional equipment. Design and size the room to provide free circulation between equipment while in use. Must conform to CNIC Instruction 1710.1.
Ceiling Ht.	10 ft. (3.0 m) minimum.
Finishes	**Walls.** Provide a low-maintenance, durable finish such as epoxy-based paint with wall graphics. **Floor.** Provide low-maintenance rubber sheet athletic flooring with rubber base. **Ceiling.** Provide acoustical ACP or gypsum board ceiling with a finish such as industrial egg-shell latex paint for gypsum board ceiling.
Plumbing	None required.
HVAC	Provide a system per the paragraph in Chapter 3 entitled, "HVAC". In addition, provide 68° F (20° C) minimum, 74° F (23° C) maximum, less than 60% relative humidity, 20 CFM (0.566 CMM) / person outside air and use CO_2 sensors to control outside air. Provide multi-speed ceiling fans.
Fire Protection	Provide system per the paragraph in Chapter 3 entitled, "Fire Protection".
Power	Provide outlets per the paragraph in Chapter 3 entitled, "Electrical Design" and provide wall or floor outlets to accommodate fitness machines such as treadmills, bikes, and stair-step machines.
Lighting	Provide system per the paragraph in Chapter 3 entitled, "Electrical".
Communication	**CCTV.** None required. **CATV/Internal Video.** Provide at least one outlet for a wall-mounted unit. **PA/Audio.** Provide a speaker. **Telephone.** Provide one line with internal two-way communication. **Data.** None required. **Security.** None required.
Acoustics	Provide partition and door construction with a minimum STC rating of 52 per the paragraph in Chapter 3 entitled, "Acoustics".
Casework/Built-in Equipment	Provide full-wall-height mirrors on at least one wall.
Furnishings Fixtures & Equipment (FF&E)	Provide fitness machines, treadmill, stationary bicycle, elliptical machine, weights, and mats.
User-provided FF&E	Provide a wall mounted flat screen video monitor.
Special Requirements	Determine if space is allowable in accordance with CNIC Instruction 1710.1. Consider an outdoor flat area for physical training (PT).

Table 4-17. Public Toilets

Description/ Usage	Male and female toilets for staff, reservists, and visitor use. Provide multiple toilet rooms for staff and units dispersed throughout building.
Ceiling Ht.	8 ft. (2.44 m) minimum.
Finishes	**Walls.** Epoxy painted, moisture-resistant, gypsum wall board with accent color and with a ceramic tile wainscot. **Floor.** Porcelain tile with flush cove base. **Ceiling.** Painted, moisture-resistant gypsum board.
Plumbing	Water closets, urinals, and lavatories. Floor drain.
HVAC	Provide system per the paragraph in Chapter 3 entitled, “HVAC”.
Fire Protection	Provide system per the paragraph in Chapter 3 entitled, “Fire Protection”.
Power	Provide outlets per the paragraph in Chapter 3 entitled, “Electrical Design”. Provide power to the air hand dryers.
Lighting	Provide system per the paragraph in Chapter 3 entitled, “Electrical Design”.
Communication	**CCTV.** None required. **CATV/Internal Video.** None required. **PA/Audio.** None required. **Telephone.** None required. **Data.** None required.
Acoustics	No special provisions required.
Casework/Built-in Equipment	Solid-surface countertop supported at both ends with either underhung or integral sinks. Wall-hung lavatories are also acceptable. Water closet and urinal partitions. Toilet accessories: air hand dryers, toilet paper dispensers, robe hooks, grab bars, soap dispensers and recessed waste receptacles. Mirror.
Furnishings Fixtures & Equipment (FF&E)	
User-provided FF&E	
Special Requirements	Provide a Janitor’s closet associated with or in proximity of these toilets. This closet includes a floor mop sink with hot and cold water and a hose connection, a floor drain, and storage for pails, mops, vacuums, and related cleaning supplies and equipment. Include a lockable door (which can be opened from the inside) with a vision panel. Provide lockable cabinets for cleaning supplies. Provide exhaust ventilation directly to the outside.

Table 4-18. Showers/Locker Room

Description/ Usage	The shower/locker room includes private water closets, lavatories, shower stalls with private changing area, and lockers for temporary storage of personal items for regular use by full-time staff and periodic use by reserve units during scheduled periods on drill weekends.
Ceiling Ht.	8 ft. (2.4 m) minimum.
Finishes	**Walls.** Provide a low-maintenance, durable finish such as epoxy paint. Provide full-height ceramic tile in showers. **Floor.** Provide slip resistant porcelain tile with flush cove base. **Ceiling.** Provide skim-coated cementicious backerboard ceiling.
Plumbing	Water closets, urinals, lavatories, and shower stalls. Provide a floor drain.
HVAC	Provide system per the paragraph in Chapter 3 entitled, "HVAC". In addition, provide 70° F (21° C) minimum, 78° F (26° C) maximum. Provide for air flow from the dry side (locker/dressing area) to the exhaust intakes in the wet (toilet/shower) area. Provide 0.50 CFM/ft.^{2} (0.154 CMM/m^2) of outside air and a minimum of 12 air changes per hour. Provide air supply as necessary to minimize air velocities while providing negative pressure. Limit relative humidity to under 50% through the use of humidistats. Humidistats may also be used to throttle back air changes as long as temperature and humidity remain within limits.
Fire Protection	Provide system per the paragraph in Chapter 3 entitled, "Fire Protection".
Power	Provide outlets per the paragraph in Chapter 3 entitled, "Electrical Design". Provide counter-height outlets at the vanity area.
Lighting	Provide system per the paragraph in Chapter 3 entitled, "Electrical Design". Lighting fixtures should have translucent, moisture resistant, non-breakable, protective covers. Minimize shadowing at face of lockers. Provide recessed fixtures with sealed lenses that are rated for wet applications in the shower areas. Provide lighting over lavatories.
Communication	**CCTV.** None required. **CATV/Internal Video.** None required. **PA/Audio.** Provide a speaker. **Telephone.** None required. **Data.** None required. **Security.** None required.
Acoustics	No special provisions required.
Casework/Built-in Equipment	Provide 24 in. (610 mm) deep minimum solid surface materials for countertops and shower and toilet partitions. Provide half-sized Z-shaped lockers and full-size lockers. Provide integral benches (usually part of the locker system) or free-standing benches at least 16 in. (406 mm) wide. Solid composite plastic lockers are strongly preferred. Provide wall-to-wall mirror over lavatories, and one full-length mirror in locker area..
Furnishings Fixtures & Equipment (FF&E)	
User-provided FF&E	
Special Requirements	Lockers should be configured as two half-sized lockers per one full-sized locker. Distribute the lockers throughout the area to prevent congestion during periods of heavy use. Provide a privacy screen at the entrance to this area.

Table 4-19. Break Room

Description/ Usage	The break room accommodates vending machines for snacks and drinks and a small seating area.
Ceiling Ht.	8 ft. (2.4 m).
Finishes	**Walls.** Provide acrylic wall panel system. **Floor.** Provide low-maintenance sheet vinyl flooring material with rubber base. **Ceiling.** Provide ACP or painted gypsum ceiling.
Plumbing	Provide a stainless steel sink in the counter.
HVAC	Provide system per the paragraph in Chapter 3 entitled, “HVAC”.
Fire Protection	Provide system per the paragraph in Chapter 3 entitled, “Fire Protection”.
Power	Provide outlets per the paragraph in Chapter 3 entitled, “Electrical Design”. Provide outlets and power required by equipment and vending machines.
Lighting	Provide system per the paragraph in Chapter 3 entitled, “Electrical”.
Communication	**CCTV.** None required. **CATV/Internal Video.** Provide one outlet **PA/Audio.** Provide speaker. **Telephone.** None required. **Data.** None required. **Security.** None required.
Acoustics	No special provisions required.
Casework/Built-in Equipment	Counter with base and upper cabinets.
Furnishings Fixtures & Equipment (FF&E)	Refrigerator, microwave, two four-top tables, eight chairs, and trash receptacles.
User-provided FF&E	Vending machines. Anchor vending machines to floor or walls.
Special Requirements	

Table 4-20. Recycling Area

Description/ Usage	This room is used for the collection, short-term storage, and separation of recyclables. Provide a direct access to receiving/service entrance.
Ceiling Ht.	8 ft. (2.4 m) minimum.
Finishes	**Walls.** Provide an acrylic wall panel system. **Floor.** Resilient sheet or tile such as rubber or solid vinyl with rubber base. Do not use VCT. **Ceiling.** ACP.
Plumbing	Provide a floor drain and a hose bibb.
HVAC	Provide system per the paragraph in Chapter 3 entitled, “HVAC”.
Fire Protection	Provide system per the paragraph in Chapter 3 entitled, “Fire Protection”.
Power	Provide outlets per the paragraph in Chapter 3 entitled, “Electrical Design”.
Lighting	Provide system per the paragraph in Chapter 3 entitled, “Electrical Design”.
Communication	**CCTV.** None required. **CATV/Internal Video.** None required. **PA/Audio.** None required. **Telephone.** None required. **Data.** None required. **Security.** None required.
Acoustics	No special provisions required.
Casework/Built-in Equipment	None required.
Furnishings Fixtures & Equipment (FF&E)	Receptacles for the separation of various products: glass, plastic, paper, etc. Heavy-duty, commercial shredder.
User-provided FF&E	
Special Requirements	Consider a location near the outdoor trash dumpster enclosure, if feasible.

Table 4-21. Medical Waiting/Check-In/Reception

Description/ Usage	The medical office and reception area accommodate medical staff general administrative work and the receiving and processing of personnel receiving medical examinations. The space includes a small waiting area, a transaction/reception counter and workstations.
Ceiling Ht.	8 ft. (2.4 m) minimum.
Finishes	**Walls.** Painted gypsum wall board. **Floor.** Resilient sheet such as rubber or homogeneous vinyl with rubber base. Do not use VCT. **Ceiling.** ACP.
Plumbing	None required.
HVAC	Provide system per the paragraph in Chapter 3 entitled, “HVAC”.
Fire Protection	Provide system per the paragraph in Chapter 3 entitled, “Fire Protection”.
Power	Provide outlets per the paragraph in Chapter 3 entitled, “Electrical Design” and for all dedicated equipment.
Lighting	Provide system per the paragraph in Chapter 3 entitled, “Electrical Design”.
Communication	**CCTV.** None required. **CATV/Internal Video.** None required. **PA/Audio.** Provide a speaker. Provide controls at the reception desk. **Telephone.** Provide one line with internal two-way communication at each workstation. **Data.** Provide one outlet at each workstation and additional outlets to support other required equipment. **Security.** None required.
Acoustics	No special provisions required.
Casework/Built-in Equipment	Provide transaction reception counter with solid surface top and desk. Provide file and pencil drawer storage.
Furnishings Fixtures & Equipment (FF&E)	Workstations—system furniture for 64 $ft.^2$ (5.9 m^2) workstations: desk chair and side chair for open offices. Workstation systems furniture must provide adequate space for filing and overhead storage. Seating for waiting area.
User-provided FF&E	
Special Requirements	Visually separate the transaction/reception counter from the workstations and the exam rooms to enhance staff, patient, and doctor privacy. Ensure privacy of workspaces for receipt of HIPAA protected information.

Table 4-22. Admitting/Vision

Description/ Usage	This area is directly adjacent to the reception/waiting area and accommodates private rooms or workstations for patient interviews and taking of vitals such as blood pressure, temperature, etc. It also includes an area with a vision chart and the proper stand-off distances for vision exams.
Ceiling Ht.	8 ft. (2.4 m) minimum.
Finishes	**Walls.** Painted gypsum wall board. **Floor.** Resilient sheet such as rubber or homogeneous vinyl with rubber base. Do not use VCT. **Ceiling.** ACP.
Plumbing	None required.
HVAC	Provide system per the paragraph in Chapter 3 entitled, “Medical Facility Requirements”, and the paragraph in Chapter 3 entitled, “HVAC”.
Fire Protection	Provide system per the paragraph in Chapter 3 entitled, “Fire Protection”.
Power	Provide outlets per the paragraph in Chapter 3 entitled, “Electrical Design” and for all dedicated equipment.
Lighting	Provide system per the paragraph in Chapter 3 entitled, “Electrical Design”.
Communication	**CCTV.** None required. **CATV/Internal Video.** None required. **PA/Audio.** None required. **Telephone.** Provide one line with internal two-way communication at each workstation. **Data.** Provide one outlet at each workstation.
Acoustics	Provide wall and door construction with a factory STC rating of 49. Rating does not need to be field verified.
Casework/Built-in Equipment	None required.
Furnishings Fixtures & Equipment (FF&E)	Provide partitions (or constructed walls) to accommodate privacy requirements for interviews. Provide tables and chairs. Provide lockable cabinets for supplies.
User-provided FF&E	
Special Requirements	Interview areas must accommodate Health Insurance Portability and Accountability Act of 1996 (HIPAA) Privacy Rules. Finishes must comply with the requirements in the paragraph in Chapter 3 entitled, “Medical Facility Requirements”, to meet the need for an aseptic environment.

Table 4-23. Medical Exam Room

Description/ Usage	Private room used to conduct routine medical examinations.
Ceiling Ht.	8 ft. (2.4 m) minimum.
Finishes	**Walls.** Painted gypsum wall board. **Floor.** Resilient sheet such as rubber or homogeneous vinyl with rubber base. Do not use VCT. **Ceiling.** ACP.
Plumbing	Provide one hand-washing sink with hot and cold water connections and health-care-style butterfly fittings on faucet.
HVAC	Provide system per the paragraph in Chapter 3 entitled, “Medical Facility Requirements”, and the paragraph in Chapter 3, “HVAC”.
Fire Protection	Provide system per the paragraph in Chapter 3 entitled, “Fire Protection”.
Power	Provide outlets per the paragraph in Chapter 3 entitled, “Electrical Design” and for all dedicated equipment.
Lighting	Provide system per the paragraph in Chapter 3 entitled, “Electrical Design”.
Communication	**CCTV.** None required. **CATV/Internal Video.** None required. **PA/Audio.** None required. **Telephone.** Provide one line with internal two-way communication. **Data.** Provide one outlet.
Acoustics	Provide wall and door construction with a factory STC rating of 49. Rating does not need to be field verified.
Casework/Built-in Equipment	Provide a solid-surface counter top with under-mount sink on floor-mounted storage cabinet. Paper towel dispenser, soap dispenser, and robe hook. Provide countertop surface with knee-space for computer and note taking.
Furnishings Fixtures & Equipment (FF&E)	Examination table, wheeled chair or stool for the doctor, and trash receptacle. Provide lockable cabinets for supplies/medications.
User-provided FF&E	
Special Requirements	Accommodate Health Insurance Portability and Accountability Act of 1996 (HIPAA) Privacy Rules. Finishes must comply with the requirements in the paragraph in Chapter 3 entitled, “Medical Facility Requirements”, to meet the need for an aseptic environment.

Table 4-24. Dental Exam Room

Description/ Usage	Private room used to conduct routine dental examinations. Dental cleanings are not performed.
Ceiling Ht.	8 ft. (2.4 m) minimum.
Finishes	**Walls.** Painted gypsum wall board. **Floor.** Resilient sheet such as rubber or homogeneous vinyl with rubber base. Do not use VCT. **Ceiling.** ACP.
Plumbing	Provide one hand-washing sink with hot and cold water connections and health-care-style butterfly fittings on faucet.
HVAC	Provide system per the paragraph in Chapter 3 entitled, “Medical Facility Requirements”, and the paragraph in Chapter 3 entitled, HVAC.
Fire Protection	Provide system per the paragraph in Chapter 3 entitled, “Fire Protection”.
Power	Provide outlets per the paragraph in Chapter 3 entitled, “Electrical Design” and for all dedicated equipment.
Lighting	Provide system per the paragraph in Chapter 3 entitled, “Electrical Design”. Provide power for X-ray light box and freestanding exam light.
Communication	**CCTV.** None required. **CATV/Internal Video.** None required. **PA/Audio.** None required. **Telephone.** Provide one line with internal two-way communication. **Data.** Provide one outlet.
Acoustics	Provide wall and door construction with a factory STC rating of 49. Rating does not need to be field verified.
Casework/Built-in Equipment	Provide a solid-surface counter top with under-mount sink on floor-mounted storage cabinet. Paper towel dispenser, soap dispenser, and robe hook. Provide a wall-mounted, flip-down writing table for note taking.
Furnishings Fixtures & Equipment (FF&E)	Dental exam chair and associated equipment, a wheeled chair or stool for the dentist, and trash receptacle. Wall mounted X-ray light box. Provide lockable cabinets for supplies/medications.
User-provided FF&E	
Special Requirements	Finishes must comply with the requirements in the paragraph in Chapter 3 entitled, “Medical Facility Requirements”, to meet the need for an aseptic environment.

Table 4-25. Doctor Library and Transcription Room

Description/ Usage	This office accommodates doctor and dentist administrative functions and includes a medical resource library.
Ceiling Ht.	8 ft. (2.4 m) minimum.
Finishes	**Walls.** Painted gypsum wall board. **Floor.** Carpet tile with rubber base. **Ceiling.** ACP.
Plumbing	None required.
HVAC	Provide a system per the paragraph in Chapter 3 entitled, “HVAC”.
Fire Protection	Provide system per the paragraph in Chapter 3 entitled, “Fire Protection”.
Power	Provide outlets per the paragraph in Chapter 3 entitled, “Electrical Design”.
Lighting	Provide system per the paragraph in Chapter 3 entitled, “Electrical Design.
Communication	**CCTV.** Provide one outlet. **CATV/Internal Video.** None required. **PA/Audio.** Provide a speaker. **Telephone.** Provide one line at each workstation. **Data.** Provide one outlet at each workstation. **Security.** None required.
Acoustics	Provide wall and door construction with a factory STC rating of 49. Rating does not need to be field verified.
Casework/Built-in Equipment	
Furnishings Fixtures & Equipment (FF&E)	Provide workstation systems furniture for 64 $ft.^2$ (5.9 m^2) workstations: desk chair and side chair for open offices. Workstation systems furniture must provide adequate space for filing and overhead storage. Provide bookshelves for medical resources.
User-provided FF&E	
Special Requirements	Note this is an administrative work area only; medical files are not stored here and patients will not occupy this space. Accommodate Health Insurance Portability and Accountability Act of 1996 (HIPAA) Privacy Rules.

Table 4-26. Dental X-Ray

Description/ Usage	Area to provide dental x-rays for all training reservists. Room is typically divided by shielding with the x-ray controls on one side and the chair for the reservist on the other side. Changes in equipment technology may alter the design of this room; coordinate the design with the planned equipment.
Ceiling Ht.	8 ft. (2.4 m) minimum.
Finishes	**Walls.** Painted gypsum wall board. **Floor.** Resilient sheet such as rubber or homogeneous vinyl with rubber base. **Ceiling.** ACP.
Plumbing	None required.
HVAC	Provide system per the paragraph in Chapter 3 entitled, “Medical Facility Requirements”, and the paragraph in Chapter 3, “HVAC.”
Fire Protection	Provide system per the paragraph in Chapter 3 entitled, “Medical Facility Requirements”, and the paragraph in Chapter 3, “Fire Protection”.
Power	Provide outlets per the paragraph in Chapter 3 entitled, “Medical Facility Requirements”, and the paragraph in Chapter 3, “Electrical Design”.
Lighting	Provide system per the paragraph in Chapter 3 entitled, “Electrical Design”.
Communication	**CCTV.** None required. **CATV/Internal Video.** None required. **PA/Audio.** Provide speaker. **Telephone.** Provide one line at x-ray control station. **Data.** Provide one outlet at x-ray control station. **Security.** None required.
Acoustics	No special provisions required.
Casework/Built-in Equipment	Counter with base and wall cabinets.
Furnishings Fixtures & Equipment (FF&E)	Dental chair.
User-provided FF&E	X-ray machine and control station and image developing equipment.
Special Requirements	Provide x-ray shielding as required in the paragraph in Chapter 3 entitled, “Medical Facility Requirements”, for the application. Finishes must comply with the requirements in the paragraph in Chapter 3 entitled, “Medical Facility Requirements”, to meet the need for an aseptic environment.

Table 4-27. Audio Room

Description/ Usage	Room to provide hearing tests for all training reservists. The booth may be set-up for testing of one or two reservists. If the booth is configured for two tests, the control station portion of the booth must be configured for a single technician to administer two tests simultaneously. The reservists are in a sound-proof booth with the technician at a control console with visual control of both reservists while the reservists do not have visual contact with each other.
Ceiling Ht.	8 ft. (2.4 m) minimum.
Finishes	**Walls.** Painted gypsum wall board. **Floor.** Carpet tile with rubber base. **Ceiling.** ACP.
Plumbing	None required.
HVAC	Provide system per the paragraph in Chapter 3 entitled, "Medical Facility Requirements", and the paragraph in Chapter 3 entitled, "HVAC". Provide connection to pre-fabricated audio booth.
Fire Protection	Provide system per the paragraph in Chapter 3 entitled, "Fire Protection". Provide connection to pre-fabricated audio booth.
Power	Provide outlets per the paragraph in Chapter 3 entitled, "Electrical Design" and electrical service designed specifically for the audio equipment.
Lighting	Provide system per the paragraph in Chapter 3 entitled, "Electrical Design".
Communication	**CCTV.** None required. **CATV/Internal Video.** None required. **PA/Audio.** Provide speaker. **Telephone.** Provide one line at the audio control station. **Data.** Provide one line at the audio control station. **Security.** None required.
Acoustics	Provide an acoustically-sealed environment specifically designed for audio testing. Doors, windows and partitions must all have acoustical sealing.
Casework/Built-in Equipment	Sound-proof partition with a vision panel to the control station.
Furnishings Fixtures & Equipment (FF&E)	One or two chairs for the reservists taking the exam. Workstation/control station for the technician and associated testing equipment.
User-provided FF&E	Pre-fabricated audio booth with ducted connection to building-wide HVAC, power, communications. Audio booth must conform to UFC 4-510-01, *Design: Medical Military Facilities*.
Special Requirements	Finishes must comply with the requirements in the paragraph in Chapter 3 entitled, "Medical Facility Requirements" to meet the need for an aseptic environment.

Table 4-28. Immunization Room

Description/ Usage	This area is for providing immunization shots to all training reservists. It may not be a fully-enclosed room.
Ceiling Ht.	8 ft. (2.4 m) minimum.
Finishes	**Walls.** Painted gypsum wall board. **Floor.** Resilient sheet such as rubber or homogeneous vinyl with rubber base. Do not use VCT. **Ceiling.** ACP.
Plumbing	Provide one hand-washing sink with hot and cold water connections and health-care-style butterfly fittings on faucet.
HVAC	Provide system per the paragraph in Chapter 3 entitled, “Medical Facility Requirements”, and the paragraph in Chapter 3 entitled, “HVAC”.
Fire Protection	Provide system per the paragraph in Chapter 3 entitled, “Fire Protection”.
Power	Provide outlets per the paragraph in Chapter 3 entitled, “Electrical Design” and dedicated electrical outlets for all the equipment.
Lighting	Provide system per the paragraph in Chapter 3 entitled, “Electrical Design”.
Communication	**CCTV.** None required. **CATV/Internal Video.** None required. **PA/Audio.** Provide speaker. **Telephone.** None required. **Data.** Provide one outlet. **Security.** None required.
Acoustics	No special provisions required.
Casework/Built-in Equipment	Solid-surface counter with base and wall cabinets.
Furnishings Fixtures & Equipment (FF&E)	Provide one medical grade refrigerator and freezer with lock and temperature alarm connected to remote monitor in accordance with UFC 4-510-01 for immunizations. Provide chairs designed for administering immunizations.
User-provided FF&E	
Special Requirements	Accommodate Health Insurance Portability and Accountability Act of 1996 (HIPAA) Privacy Rules. Finishes must comply with the requirements in the paragraph in Chapter 3 entitled, “Medical Facility Requirements”, to meet the need for an aseptic environment.

Table 4-29. Blood Draw

Description/ Usage	This room is for drawing, initial processing through a centrifuge, and storing blood samples. It is directly adjacent to the medical toilet to also allow processing of urine samples.
Ceiling Ht.	8 ft. (2.4 m) minimum.
Finishes	**Walls.** Painted gypsum wall board. **Floor.** Resilient sheet such as rubber or homogeneous vinyl with rubber base. Do not use VCT. **Ceiling.** ACP.
Plumbing	Provide one hand-washing sink with hot and cold water connections and health-care-style butterfly fittings on faucet.
HVAC	Provide system per the paragraph in Chapter 3 entitled, “Medical Facility Requirements”, and the paragraph in Chapter 3 entitled, “HVAC”.
Fire Protection	Provide system per the paragraph in Chapter 3 entitled, “Fire Protection”.
Power	Provide outlets per the paragraph in Chapter 3 entitled, “Electrical Design” and dedicated electrical outlets for all the equipment.
Lighting	Provide system per the paragraph in Chapter 3 entitled, “Electrical Design”.
Communication	**CCTV.** None required. **CATV/Internal Video.** None required. **PA/Audio.** Provide speaker. **Telephone.** None required. **Data.** Provide one outlet. **Security.** None required.
Acoustics	No special provisions required.
Casework/Built-in Equipment	Solid-surface counter with base and wall cabinets.
Furnishings Fixtures & Equipment (FF&E)	One refrigerator for blood samples. Refrigerator must be on alarm and kept at a constant temperature. Blood draw chairs.
User-provided FF&E	Centrifuge (counter or floor model).
Special Requirements	Provide a carousel from the medical toilet for transfer of urine samples. Locate carousel near the sink. Accommodate Health Insurance Portability and Accountability Act of 1996 (HIPAA) Privacy Rules. Finishes must comply with the requirements in the paragraph in Chapter 3 entitled, “Medical Facility Requirements”, to meet the need for an aseptic environment.

Table 4-30. Medical Toilet

Description/ Usage	Single-use, unisex toilet for patient use that is directly adjacent to the Blood Draw.
Ceiling Ht.	8 ft. (2.44 m) minimum.
Finishes	**Walls.** Epoxy painted moisture-resistant gypsum wall board with a ceramic tile wainscot with accent tiles and a flush cove base. Provide full-height ceramic tile on wet walls. **Floor.** Porcelain tile. **Ceiling.** Painted, moisture-resistant gypsum board.
Plumbing	One water closet and one wall-hung lavatory. Provide a floor drain.
HVAC	Provide system per the paragraph in Chapter 3 entitled, “Medical Facility Requirements”, and the paragraph in Chapter 3 entitled, “HVAC”.
Fire Protection	Provide system per the paragraph in Chapter 3 entitled, “Fire Protection”.
Power	Provide outlets per the paragraph in Chapter 3 entitled, “Electrical Design”. Provide power to the air hand dryer.
Lighting	Provide system per the paragraph in Chapter 3 entitled, “Electrical Design”.
Communication	**CCTV.** None required. **CATV/Internal Video.** None required. **PA/Audio.** None required. **Telephone.** None required. **Data.** None required. **Security.** Lockable door.
Acoustics	No special provisions required.
Casework/Built-in Equipment	Toilet accessories: air hand dryer, toilet paper dispenser, robe hook, grab bars, and soap dispenser. Mirror.
Furnishings Fixtures & Equipment (FF&E)	
User-provided FF&E	
Special Requirements	Provide a carousel to the blood draw area for transfer of urine samples. Finishes must comply with the requirements in the paragraph in Chapter 3 entitled, “Medical Facility Requirements”, to meet the need for an aseptic environment.

Table 4-31. Medical File Room

Description/ Usage	This room provides secure medical file storage. May include space for one to three personnel.
Ceiling Ht.	8 ft. (2.4 m) minimum.
Finishes	**Walls.** Painted gypsum wall board. **Floor.** Carpet tile with rubber base. **Ceiling.** ACP.
Plumbing	None required.
HVAC	Provide system per the paragraph in Chapter 3 entitled, “HVAC”.
Fire Protection	Provide system per the paragraph in Chapter 3 entitled, “Fire Protection”.
Power	Provide outlets per the paragraph in Chapter 3 entitled, “Electrical Design”.
Lighting	Provide system per the paragraph in Chapter 3 entitled, “Electrical Design”.
Communication	**CCTV.** None required. **CATV/Internal Video.** None required. **PA/Audio.** None required. **Telephone.** Provide one line with internal two-way communication per occupant. **Data.** Provide one outlet/line per occupant. **Security.** None required.
Acoustics	No special provisions required.
Casework/Built-in Equipment	Secure, high-density automated filing system with rotary or rolling units with base/track recessed into slab construction, if required. Must accommodate separate dental and medical records for each reservist.
Furnishings Fixtures & Equipment (FF&E)	If the secure, high-density, automated medical file storage system is not required, will include filing system of free-standing file units to accommodate separate dental and medical records for each reservist. May include workspace for one to three personnel. Smaller NOSC prefer rotary high-density (X2) filing.
User-provided FF&E	
Special Requirements	Accommodate Health Insurance Portability and Accountability Act of 1996 (HIPAA) Privacy Rules. Provide lockable door.

Table 4-32. Medical Supply Room

Description/ Usage	This room provides secure medical supply storage for non-perishable items such as gloves and needles.
Ceiling Ht.	8 ft. (2.4 m) minimum.
Finishes	**Walls.** Painted gypsum wall board. **Floor.** Resilient sheet such as rubber or homogeneous vinyl with rubber base. Do not use VCT. **Ceiling.** ACP.
Plumbing	None required.
HVAC	Provide system per the paragraph in Chapter 3 entitled, “Medical Facility Requirements”, and the paragraph in Chapter 3 entitled, “HVAC”.
Fire Protection	Provide system per the paragraph in Chapter 3 entitled, “Fire Protection”.
Power	Provide outlets per the paragraph in Chapter 3 entitled, “Electrical Design”.
Lighting	Provide system per the paragraph in Chapter 3 entitled, “Electrical Design”.
Communication	**CCTV.** None required. **CATV/Internal Video.** None required. **PA/Audio.** None required. **Telephone.** None required. **Data.** Provide one outlet/line. **Security.** Lockable door.
Acoustics	No special provisions required.
Casework/Built-in Equipment	None required.
Furnishings Fixtures & Equipment (FF&E)	Provide 18-in (455-mm) deep, adjustable shelving in lockable cabinets for medical supplies.
User-provided FF&E	
Special Requirements	Finishes must comply with the requirements in the paragraph in Chapter 3 entitled, “Medical Facility Requirements”, to meet the need for an aseptic environment. Provide lockable door.

Table 4-33. Medical Equipment Storage

Description/ Usage	This room provides storage for larger items such as CPR dummies, back boards and other deployable medical supplies.
Ceiling Ht.	8 ft. (2.4 m) minimum.
Finishes	**Walls.** Painted gypsum wall board. **Floor.** Resilient sheet such as rubber or homogeneous vinyl with rubber base. **Ceiling.** None required.
Plumbing	None required.
HVAC	Provide system per the paragraph in Chapter 3 entitled, “HVAC”.
Fire Protection	Provide system per the paragraph in Chapter 3 entitled, “Fire Protection”.
Power	Provide outlets per the paragraph in Chapter 3 entitled, “Electrical Design”.
Lighting	Provide system per the paragraph in Chapter 3 entitled, “Electrical Design”.
Communication	**CCTV.** None required. **CATV/Internal Video.** None required. **PA/Audio.** None required. **Telephone.** None required. **Data.** None required.
Acoustics	No special provisions required.
Casework/Built-in Equipment	Provide wall-to-wall 36-in (915-mm) deep adjustable metal shelving mounted to wall and floor for safety..
Furnishings Fixtures & Equipment (FF&E)	Provide 36-in (915-mm) deep, adjustable shelving for medical equipment.
User-provided FF&E	
Special Requirements	Provide lockable door.

Table 4-34. Unit Classrooms

Description/ Usage	Unit classrooms are used for meetings, training, testing, muster, etc. Rooms are sized to accommodate from 25 to 100 students at 20 $ft.^2$ (1.86 m^2) per student, and any room larger than for 25 includes movable partitions to divide the space into 25-student sections. See the paragraph in Chapter 2 entitled, "Layout and Adjacencies" for more information on sizing of individual rooms. The classrooms are directly adjacent to the unit administrative area.
Ceiling Ht.	10 ft. (3.0 m) minimum.
Finishes	**Walls.** Painted gypsum wallboard. **Floor.** Carpet tile with rubber base. **Ceiling.** ACP.
Plumbing	None required.
HVAC	Provide system per the paragraph in Chapter 3 entitled, "HVAC".
Fire Protection	Provide system per the paragraph in Chapter 3 entitled, "Fire Protection".
Power	Provide outlets per the paragraph in Chapter 3 entitled, "Electrical Design" and for all dedicated equipment. Provide power outlet above ceiling for projector, if provided.
Lighting	Provide system per the paragraph in Chapter 3 entitled, "Electrical Design".
Communication	**CCTV.** None required. **CATV/Internal Video.** Provide one outlet per room division. **PA/Audio.** Provide a speaker in each divided space. **Telephone.** Provide one line with two-way communication in each divided space. **Data.** Provide outlets for all dedicated equipment. **Security.** None required.
Acoustics	Provide wall and door construction with a factory STC rating of 49. Rating does not need to be field verified. Floors materials must have a high NRC and be manufactured specifically for open office environments. Provide ceiling materials that have a high AC rating. See Casework/built-in equipment for partition acoustics.
Casework/Built-in Equipment	A retractable overhead screen and ceiling mounted projector mount can be provided as an option to a 50 inch (1.27 m) video monitor/TV if desired. Provide heavy-duty, highly durable, operable walls with a 55 STC rating for the room dividers. To achieve the required STC, operable walls must extend above the dropped ceiling tiles and insulation provided in the ceiling around the operable wall openings. Powered operable walls are preferred, but the durability and acoustical criteria take precedence. One marker board and tack board per 25-student section.
Furnishings Fixtures & Equipment (FF&E)	Lectern; two-person, leg-powered activity tables; and stackable chairs.
User-provided FF&E	Provide 50 inch (1.27 m) minimum video monitor/TV in each room division.
Special Requirements	Permanent partitions and openings must be designed in accordance with ANSI/ASA S12.60.

Table 4-35. Unit Administrative Area

Description/ Usage	The unit administrative area groups all of the unit offices and workstations into a consolidated area. Each unit gets two private offices and three workstations that will be shared. Directly adjacent to the unit classrooms and the unit storage.
Ceiling Ht.	8 ft. (2.4 m) minimum.
Finishes	**Walls.** Painted gypsum wall board. **Floor.** Carpet tile with rubber base. **Ceiling.** ACP.
Plumbing	None required.
HVAC	Provide system per the paragraph in Chapter 3 entitled, “HVAC”.
Fire Protection	Provide system per the paragraph in Chapter 3 entitled, “Fire Protection”.
Power	Provide outlets per the paragraph in Chapter 3 entitled, “Electrical Design”. Ensure an adequate number of circuits to power all equipment.
Lighting	Provide system per the paragraph in Chapter 3 entitled, “Electrical Design”.
Communication	**CCTV.** None required. **CATV/Internal Video.** None required. **PA/Audio.** None required. **Telephone.** Provide one line with internal two-way communication for each office and one line in the open office area, plus as needed to accommodate required equipment. **Data.** Provide data outlets for each office and workstation and to support required equipment. **Security.** None required.
Acoustics	**Private offices.** Provide wall and door construction with a factory STC rating of 49. Rating does not need to be field verified. **Open offices.** Partition and floor materials must have a high Noise Reduction Coefficient (NRC) and be manufactured specifically for open office environments. Provide ceiling materials that have a high Articulation Class (AC) rating.
Casework/Built-in Equipment	Minimum 8 ft. (4.4 m) length of solid surface countertop for work surfaces and equipment such as printers and cabinets for storage of administrative supplies.
Furnishings Fixtures & Equipment (FF&E)	**Private offices.** Provide office desk, office chair, file cabinet, bookshelf, desk lamp, and one side chair. **Open offices.** Provide systems furniture for 48 $ft.^2$ (4.5 m^2) workstations: desk chair and side chair for open offices. Workstation systems furniture must provide adequate space for filing and overhead storage.
User-provided FF&E	Computers and other equipment.
Special Requirements	

Table 4-36. Unit Storage

Description/ Usage	A room for storage of equipment and unit supplies, directly off the unit administrative area.
Ceiling Ht.	12 ft. (3.7 m).
Finishes	**Walls.** CMU or painted gypsum wall board. **Floor.** Sealed concrete. **Ceiling.** None required.
Plumbing	None required.
HVAC	Provide system per the paragraph in Chapter 3 entitled, “HVAC”.
Fire Protection	Provide system per the paragraph in Chapter 3 entitled, “Fire Protection”.
Power	Provide outlets per the paragraph in Chapter 3 entitled, “Electrical Design”.
Lighting	Provide system per the paragraph in Chapter 3 entitled, “Electrical Design”.
Communication	**CCTV.** None required. **CATV/Internal Video.** None required. **PA/Audio.** None required. **Telephone.** None required. **Data.** None required. **Security.** None required.
Acoustics	No special provisions required.
Casework/Built-in Equipment	None required.
Furnishings Fixtures & Equipment (FF&E)	Freestanding shelving.
User-provided FF&E	
Special Requirements	Provide lockable door.

Table 4-37. Drill Hall

Description/ Usage	This is a multipurpose space that provides a large, open auditorium-like space for musters, training, drill assessment, team building scenarios, physical fitness, lectures, and ceremonies or presentations.
Ceiling Ht.	25 ft. (7.62 m).
Finishes	**Walls.** Painted CMU. **Floor.** Cushion underlayment and poured synthetic multi-purpose flooring system with rubber base. Provide game lines to include main court basketball and volleyball lines in different colors, if required by User. **Ceiling.** Exposed painted structure, except provide NRC (Average Sound Absorption Coefficient) of not less than 0.70).
Plumbing	None required.
HVAC	Provide system per the paragraph in Chapter 3 entitled," HVAC".
Fire Protection	Provide system per the paragraph in Chapter 3 entitled, "Fire Protection".
Power	Provide outlets per the paragraph in Chapter 3 entitled, "Electrical Design". Provide additional outlets in the stage floor.
Lighting	Provide Lighting System per the paragraph in Chapter 3 entitled, "Electrical Design".
Communication	**CCTV.** None required. **CATV/Internal Video.** None required. **PA/Audio.** Provide speakers and PA controls. **Telephone.** Provide four outlets. One on each wall. **Data.** Provide four outlets/lines. One on each wall. **Security.** None required.
Acoustics	Reverberation time must equal 1.0 second. Provide additional acoustical control with sound baffles, banners, and acoustical materials. Provide noise attenuation measures to mitigate acoustical problems resulting from mechanical systems, plumbing systems, and vibration transmitted through the facility structure. Design walls and openings to have an STC in accordance with ANSI/ASA S12.60.
Casework/Built-in Equipment	Provide a pass-through window to the mess room. Provide projector mount and electrical operated screen for presentations.
Furnishings Fixtures & Equipment (FF&E)	Folding chairs and tables on rolling carts for seating 200 people. Optional portable stage.
User-provided FF&E	
Special Requirements	Provide a stage (raised platform) at the end opposite the entrance from the mess. As budget and mission requirements dictate, design this space to accommodate large-audience audio-visual presentations, which may require items such as a built-in screen, built-in wiring, and additional controls. Provide a pair of 3'-6" (1.07 m) x 7'-0" (2.13 m) (7'-0" (2.13 m) clear width) hollow metal doors to exterior.

Table 4-38. Drill Hall Storage

Description/ Usage	Space behind the drill hall stage for storage of folding tables and chairs on rolling carts and other miscellaneous items such as flag poles and podiums.
Ceiling Ht.	25 ft. (7.62 m).
Finishes	**Walls.** Painted CMU. **Floor.** Sealed concrete. **Ceiling.** Exposed painted structure.
Plumbing	None required.
HVAC	Provide system per the paragraph in Chapter 3 entitled, “HVAC”.
Fire Protection	Provide system per the paragraph in Chapter 3 entitled, “Fire Protection”.
Power	Provide outlets per the paragraph in Chapter 3 entitled, “Electrical Design”.
Lighting	Provide system per the paragraph in Chapter 3 entitled, “Electrical Design”.
Communication	**CCTV.** None required. **CATV/Internal Video.** None required. **PA/Audio.** None required. **Telephone.** None required. **Data.** None required. **Security.** None required.
Acoustics	No special provisions required.
Casework/Built-in Equipment	
Furnishings Fixtures & Equipment (FF&E)	
User-provided FF&E	
Special Requirements	

Table 4-39. Mechanical Room

Description/ Usage	Space behind the drill hall stage for storage of folding tables and chairs on rolling carts and other miscellaneous items such as flag poles and podiums.
Ceiling Ht.	25 ft. (7.62 m).
Finishes	**Walls.** Painted CMU. **Floor.** Sealed concrete. **Ceiling.** Exposed painted structure.
Plumbing	None required.
HVAC	Provide system per the paragraph in Chapter 3 entitled, “HVAC”.
Fire Protection	Provide system per the paragraph in Chapter 3 entitled, “Fire Protection”.
Power	Provide outlets per the paragraph in Chapter 3 entitled, “Electrical Design”.
Lighting	Provide system per the paragraph in Chapter 3 entitled, “Electrical Design”.
Communication	**CCTV.** None required. **CATV/Internal Video.** None required. **PA/Audio.** None required. **Telephone.** None required. **Data.** None required. **Security.** None required.
Acoustics	Provide wall and door construction with a factory STC rating of 49. STC rating does not need to be field verified.
Casework/Built-in Equipment	
Furnishings Fixtures & Equipment (FF&E)	
User-provided FF&E	
Special Requirements	

Table 4-40. Urinalysis Area

Description/ Usage	Separate male and female toilets directly off the drill hall and designed to facilitate supervision during urinalysis testing.
Ceiling Ht.	8 ft. (2.44 m).
Finishes	**Walls.** Epoxy painted, moisture-resistant gypsum wall board with a ceramic tile wainscot. Provide full-height ceramic tile on wet walls. **Floor.** Porcelain tile with flush cove base. **Ceiling.** Painted, moisture-resistant gypsum board.
Plumbing	**Male.** One water closet, two urinals, and one wall-hung lavatory. **Female.** Two water closets and one wall-hung lavatory. Provide a floor drain in each toilet.
HVAC	Provide system per the paragraph in Chapter 3 entitled, “HVAC”.
Fire Protection	Provide system per the paragraph in Chapter 3 entitled, “Fire Protection”.
Power	Provide outlets per the paragraph in Chapter 3 entitled, “Electrical Design”. Provide power to the air hand dryers. Provide at least one duplex outlet in the drill hall wall to one side of the entrance to the urinalysis area to accommodate a registration table and equipment.
Lighting	Provide system per he paragraph in Chapter 3 entitled, “Electrical Design”.
Communication	**CCTV.** None required. **CATV/Internal Video.** None required. **PA/Audio.** None required. **Telephone.** None required. **Data.** Provide at least one outlet in the drill hall wall to one side of the entrance to the urinalysis area. **Security.** None required.
Acoustics	No special provisions required.
Casework/Built-in Equipment	Water closet and urinal partitions must not impede direct vision supervision during urinalysis testing. Water closet partitions must have doors for when the toilet is used at other times, but these doors must be securable in a fully-open position. Toilet accessories: air hand dryers, toilet paper dispensers, robe hooks, grab bars, and soap dispensers. Mirror.
Furnishings Fixtures & Equipment (FF&E)	
User-provided FF&E	
Special Requirements	Ensure the layout of the room provides adequate space behind each water closet and urinal for a supervisor to stand during urinalysis testing.

Table 4-41. Communications Room(s)

Description/ Usage	Secure room housing equipment for NMCI equipment. Additional rooms may be required for a multi-story building.
Ceiling Ht.	8 ft. (2.4 m) minimum.
Finishes	**Walls.** Painted gypsum wall board. **Floor.** Resilient sheet or tile such as rubber or vinyl with rubber base. Do not use VCT. **Ceiling.** ACP or none required.
Plumbing	None required.
HVAC	Provide system per the paragraph in Chapter 3 entitled, “HVAC”.
Fire Protection	Provide system per the paragraph in Chapter 3 entitled, “Fire Protection”.
Power	Provide outlets per the paragraph in Chapter 3 entitled, “Electrical Design” and for all dedicated equipment.
Lighting	Provide system per the paragraph in Chapter 3 entitled, “Electrical Design”.
Communication	**CCTV.** None required. **CATV/Internal Video.** None required. **PA/Audio.** None required. **Telephone.** Navy to provide/install equipment. **Data.** Navy to provide/install equipment. **Security.** Navy to provide/install equipment.
Acoustics	No requirement.
Casework/Built-in Equipment	Equipment racks. Provide 4 ft. (1.2 m) x 8 ft. (2.4 m) painted plywood panel on wall.
Furnishings Fixtures & Equipment (FF&E)	
User-provided FF&E	Computer servers and equipment.
Special Requirements	Provide lockable door.

APPENDIX B SPACE PLANNING

B-1 SPACE PLANNING GUIDELINES.

The NOSC space program is determined by a detailed planning analysis to be conducted according to UFC 2-000-05N (P-80), *Facility Planning Criteria for Navy/Marine Corps Shore Installations.* Figures B-1.1 through B-1.2 illustrate sample interactive spreadsheets completed for hypothetical Navy facilities and programs that are defined by their respective Form DD1391.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD(AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the more stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Civil Engineer Support Agency (AFCESA) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request (CCR). The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://dod.wbdg.org/.

Hard copies of UFC printed from electronic media should be checked against the current electronic version prior to use to ensure that they are current.

CHAPTER 1

INTRODUCTION

1-1 **PURPOSE AND SCOPE**. This UFC is comprised of two sections. Chapter 1 introduces this UFC and provides a listing of references to other Tri-Service documents closely related to the subject. Appendix A contains the full text copy of the previously released Military Handbook (MIL-HDBK) on this subject. This UFC serves as criteria until such time as the full text UFC is developed from the MIL-HDBK and other sources.

This UFC provides general criteria for the design of firefighting school facilities.

Note that this document does not constitute a detailed technical design, maintenance or operations manual, and is issued as a general guide to the considerations associated with the design of firefighting school facilities.

1-2 **APPLICABILITY**. This UFC applies to all Navy service elements and Navy contractors; Air Force service elements should use the references cited in paragraph 1-3 below; all other DoD agencies may use either document unless explicitly directed otherwise.

1-2.1 **GENERAL BUILDING REQUIREMENTS**. All DoD facilities must comply with UFC 1-200-01, *Design: General Building Requirements*. If any conflict occurs between this UFC and UFC 1-200-01, the requirements of UFC 1-200-01 take precedence.

1-2.2 **SAFETY**. All DoD facilities must comply with DODINST 6055.1 and applicable Occupational Safety and Health Administration (OSHA) safety and health standards.

NOTE: All **NAVY** projects, must comply with OPNAVINST 5100.23 (series), *Navy Occupational Safety and Health Program Manual*. The most recent publication in this series can be accessed at the NAVFAC Safety web site: www.navfac.navy.mil/safety/pub.htm. If any conflict occurs between this UFC and OPNAVINST 5100.23, the requirements of OPNAVINST 5100.23 take precedence.

1-2.3 **FIRE PROTECTION**. All DoD facilities must comply with UFC 3-600-01, *Design: Fire Protection Engineering for Facilities*. If any conflict occurs between this UFC and UFC 3-600-01, the requirements of UFC 3-600-01 take precedence.

1-2.4 **ANTITERRORISM/FORCE PROTECTION**. All DoD facilities must comply with UFC 4-010-01, *Design: DoD Minimum Antiterrorism Standards for Buildings*. If any conflict occurs between this UFC and UFC 4-010-01, the requirements of UFC 4-010-01 take precedence.

1-3 **REFERENCES**. The following Tri-Service publications have valuable information on the subject of this UFC. When the full text UFC is developed for this

subject, applicable portions of these documents will be incorporated into the text. The designer is encouraged to access and review these documents as well as the references cited in Appendix A, MIL-HDBK 1027/1B.

HANDBOOK

FIREFIGHTING SCHOOL FACILITIES

AMSC N/A AREA FACR

DISTRIBUTION STATEMENT A. Approved for public release; distribution is unlimited.

ABSTRACT

This handbook provides basic design guidance developed from extensive reevaluation of facilities necessary to support new firefighting devices. It is intended for use by experienced architects and engineers. The contents cover the technical and environmental requirements of the structures that house them.

FOREWORD

This handbook has been developed from an evaluation of facilities in the shore establishment, from surveys of the availability of new materials and construction methods, and from selection of the best design practices of the Naval Facilities Engineering Command (NAVFACENGCOM), other Government agencies, and the private sector. This handbook was prepared using, to the maximum extent feasible, national professional society, association, and institute standards. Deviations from these criteria cannot be made without prior approval of the NAVFACENGCOM Criteria Office.

Design cannot remain static any more than can the functions it serves or the technologies it uses. Accordingly, recommendations for improvement are encouraged and should be furnished to Commanding Officer, Atlantic Division, Naval Facilities Engineering Command (LANTNAVFACENGCOM), Code 403, 1510 Gilbert Street, Norfolk, VA 23511-2699; telephone (757) 322-4243.

DO NOT USE THIS HANDBOOK AS A REFERENCE DOCUMENT FOR PROCUREMENT OF FACILITIES CONSTRUCTION. IT IS TO BE USED IN THE PURCHASE OF FACILITIES ENGINEERING STUDIES AND DESIGN (FINAL PLANS, SPECIFICATIONS, AND COST ESTIMATES). DO NOT REFERENCE IT IN MILITARY OR FEDERAL SPECIFICATIONS OR OTHER PROCUREMENT DOCUMENTS.

GLOSSARY.....284

Section 1: INTRODUCTION

1.1 Scope. This military handbook prescribes design criteria necessary to support new firefighting training devices and to outline technical and environmental requirements of structures which house them.

1.2 Application. Training facilities covered by this handbook as identified by the devices contained within are as follows:

a) 19F1A and 19F1B - Advanced Shipboard Firefighting Trainers

b) 19F3 and 19F3B - Basic Shipboard Firefighting Trainers, which consist of four training structures:

(1) B1 - Engine Room - Bilge Fire Trainer

(2) B2 - Galley/Berthing Fire Trainer

(3) B3 - Pit Fire Trainer

(4) B4 - Pit Fire Trainer

c) 19F3A and 19F3C - Combined Basic/Advanced Shipboard Firefighting Trainers, which consist of a 19F1A portion and 19F3-B3 trainers

d) 19F4 and 19F4A - Basic Shipboard Aircraft Firefighting Trainers

e) 19F5 and 19F5A - Basic Recruit Shipboard Firefighting Trainers

f) 21C12 and 21C12A - Submarine Firefighting Trainers

g) Gas Chamber - Chemical Warfare Trainer

h) Seawolf

1.2.1 Types of Trainers. There are two types of trainers: warm and cold weather designs. Cold weather design is applicable to sites in climates where annual heating degree days are 1100 or greater. Warm weather design is applicable to sites in climates where annual heating degree days are less than 1100.

Section 2: DESIGN CRITERIA

2.1 Site Development

2.1.1 Flooding Considerations. When planning the site for a new 21C12 and 19F series facility, the finished floor area of the crawl space should be high enough to preclude flooding during a 100-year storm. The training device equipment that will be installed in the crawl space is expensive and would be destroyed if the crawl space were flooded.

2.1.2 Prevailing Wind. Prevailing wind direction should be one of the first considerations in selecting a site. Heat and products of combustion may be objectionable to adjacent buildings located downwind. Show prevailing wind direction on drawings.

2.1.3 Drainage. Rainwater should be channeled away from device structures because water that enters the structure should be first treated and then disposed of in the sanitary sewer. Since firefighting agents are collected in the structures, surface runoff can be disposed of in the storm system without treatment.

2.1.4 Circulation Patterns. Design the site layout to allow for personnel circulation patterns between each of the various support facilities and trainers.

2.1.5 Support Facilities. There are various support facilities that must be provided with the 19F and 21C12 series trainers. Provide classroom space, restrooms, showers, and changing area to support the students and instructors. In addition, provide a maintenance area, utilities space, storage area, and wastewater treatment system. Design initial planning to allow for bulk deliveries of fuel and dry storage.

2.1.6 Security. Fence the grounds around a firefighting school to restrict entry of unauthorized personnel. Fence each fuel and CO_2 storage area, and exterior doors to firefighting school facilities should be of the lockable type.

2.1.7 Setbacks and Clearances. The exterior of firefighting structures should have a clearance of 16 m away from any

obstruction, trees, building, structure, etc., to allow free access of natural ventilation air to the crawl space, and to allow access for snow and ice removal.

2.1.8 Pollution Permits. The preliminary design should include the initiation of air and water pollution permit applications.

2.1.9 Contaminated Soil. As a result of several firefighting trainer sites having contaminated soil, evaluate selected firefighting trainer sites for soil and groundwater contamination during the planning stage of the project. Permits may be required for the site cleanup.

2.1.10 Design for Accessibility of Physically Handicapped Personnel. Provisions for physically handicapped personnel are not required in firefighting training facilities. Firefighting trainers are required to be designed for able-bodied naval personnel.

2.1.11 Energy Conservation. Normal building energy conservation measures are not a consideration in the firefighting facilities because of the facilities application, i.e., because heat is generated by the fires, energy conservation measures are not feasible. Energy studies are not required to be performed for firefighting trainers because the trainers are the same as trainers at other locations, and each trainer has the same mechanical and electrical systems. The one area of the firefighting facilities that will have conditioned air is the instructor station and the electrical room, which should be designed to conserve energy in compliance with the latest techniques and applicable standards. Refer also to MIL-HDBK-1190, Facility Planning and Design Guide.

2.1.12 Design Similarity. Design and construct firefighting training structures the same from site to site (i.e., firefighting training structures should have the same internal dimensions, internal arrangements, similar functions, similar equipment, etc.). Design similarity is required to ensure that all naval personnel are exposed to similar training environments.

2.2 Utility Design

2.2.1 General

2.2.1.1 Service. The various services, water, fuel, 100 percent foam (surrogate) concentrate, and, possibly, compressed air should be routed to each training structure by underground pipe. Each service should include a manual shutoff valve for maintenance purposes. The valves to a given structure should be grouped together in a valve pit with a cover small and light enough to be lifted by two men. No cover should weigh more than 57 kg and each cover should have lifting handles. The propane valve should be in a separate pit.

2.2.1.2 Design for Simultaneous Operation. Design and size utilities for the firefighting training school to allow for training structures to operate simultaneously.

2.2.1.3 Freeze Protection and Snow. Firefighting facilities should be protected against freeze damage. Because training structures are not usually heated, interior and exterior water-based utilities located aboveground should be protected. Large valve pits with many valves should also include protection for freezable utilities. Refer also to pars. 3.2.3 and 3.11.8 for additional requirements. Methods of freeze protection include drain-down, heat tracing, and air purge. The following criteria applies to this handbook:

a) When a drain-down system employs some method of automatically sensing ambient temperature and controlling a valve, install a manual valve in parallel with the automatic valve. The manual valve will provide an added measure of protection.

b) Provide freeze protection at any location where there is the possibility of freezing temperatures. Sites as far south as Mayport, Florida, should have freeze protection.

c) In those locations subjected to regular snow accumulations, ensure that the design will not impede the operation of exterior equipment. Design facilities to accommodate snow removal procedures.

d) Since the foam stations and foam reels cannot be adequately drained they should be freeze-protected by a removable, insulated and electrically heated cover. The cover should be completely removable so that during training the hose stations maintain a shipboard appearance.

2.2.1.4 Breathing Air. The quality standard for compressed air to be used for breathing air is Federal Specification (Fed. Spec.) BB-A-1034, Compressed Air, Breathing. Breathing air is not a requirement in surface fleet training facilities; however, it is a requirement for submarine fleet trainers. Refer to par. 3.12.4.6 for requirements. Breathing air for instructors by the use of personal "SCOTPAK" units is not covered by this handbook.

2.2.1.5 Fire Department. Training facilities are designed on the basis that experienced instructors with adequate fire control equipment will be present at--all times that training is being conducted. The fire suppression capability will be supplemented by a municipal or military fire department whenever possible, with fire department notification provided by properly spaced exterior fire alarm boxes, fire telephones, or other approved means. Provide fire hydrants at each firefighting school site in accordance with the National Fire Protection Association (NFPA) 24, Installation of Private Fire Service Mains and Their Appurtenances.

2.2.1.6 Electromagnetic Interference (EMI). Test firefighting project sites for EMI to determine required EMI protection for trainers. EMI testing should be accomplished by the Naval Air Warfare Center Training Systems Division (NAWCTSD) during preliminary design to determine cost impact. If NAWCTSD test results indicate EMI shielding is required, NAWCTSD should determine if the device equipment can be shielded. If device EMI shields are determined to be inadequate, then NAWCTSD should notify the Engineering Field Division (EFD) or Engineering Field Activity (EFA), NAVFACENGCOM, and LANTNAVFACENGCOM of facility EMI shielding requirements.

2.2.2 Equipment Outages

2.2.2.1 Standby. There is no requirement for standby equipment in excess of full design capacity for the systems supporting a firefighting training facility. Critical support

systems, those whose downtime would affect a large portion of the training, should be designed with parts totaling full capacity, e.g., two 50 percent fans or two 50 percent pumps. Then while a piece of equipment is not operating and being repaired, the second piece of equipment can be carrying 50 percent of the load. In all cases, critical equipment should be designed to provide as much reliability and maintainability as possible.

2.2.2.2 Emergency Power. Emergency power is generally not a requirement for firefighting facilities. The fuel and CO2 systems are required to be failsafe, shutting off fuel and CO2 when electrical power is lost. Without a continuous source of fuel, there can be no fire, because there is no combustible material inside a training structure. For this reason the propane entry station consisting of the "block and vent" (Appendix J, Figure J-2) should be located outside of the training structure.

The availability of electricity at most training facilities is reliable enough that periodic outages will not adversely affect training. In the event of electrical power outage at a trainer, provide a battery backup annunciation and alarm at the 24-hour duty desk and at the instructor's station. Provide capability to silence the alarm at both locations.

2.2.2.3 Emergency Water. Emergency water should be water supplied under sufficient pressure to fight fires without the use of electrical energy. Water flow tests should be performed to determine the adequacy of the water supply system. A separate emergency water system is not necessary for the 19F series trainers for the same reasons stated above under emergency power. The Navy's portable gasoline powered P-250 pumps and the Municipal Fire Department are available for non-trainer structure fires.

2.2.2.4 Lightning Protection. As a minimum, the requirements of NFPA 78, Lightning Protection Code, should be followed. Lightning protection is not required for the propane tanks.

2.2.2.5 Lighting. The fenced-in grounds and parking area around the firefighting facility should be lighted to provide general security.

2.2.3 Fuel

2.2.3.1 Propane. Propane should be the fuel for the 19F and 21C12 series trainers. It has a standard and reliable chemical composition as opposed to natural gas which is a blend of chemicals. Propane gives the desirable flame characteristics and has been tested for environmental acceptability in the training situation. Complete stoichiometric burning of propane requires 23 cubic meters (cu. m) of air for each cubic meter of fuel at atmospheric pressure. The following criteria is provided pertaining to propane as outlined in NFPA 58, Storage and Handling of Liquefied Petroleum Gases:

a) Properties and characteristics of liquefied petroleum (LP) gases. Propane has certain properties and characteristics which must be understood by the persons handling and processing these products.

(1) They are normally gases but are changed to liquid state by the application of moderate pressure. At atmospheric pressure commercial propane boils at minus 42.2 degrees C. It is evident that at normal atmospheric temperatures and pressures, propane will be in a gaseous form. Propane in liquid state and open to the atmosphere will evaporate (not boil) although the atmospheric temperature may be below its boiling point.

(2) LP gases contain no toxic components such as carbon monoxide. However, the vapors should not be inhaled as serious accidents could occur from ignition of gases contained in the lungs.

(3) LP gases are heavier than air. With air equal to 1.0, the specific gravity of propane is 1.52. LP gas will, therefore, collect in low places but will eventually diffuse into the atmosphere.

(4) The explosive range of propane-air mixture is lower and narrower than with other fuel gases and is 2.15 (lower explosive limit) to 9.6 (higher explosive limit) percent in air. The lower explosive limit is the limit at which combustion of propane can be sustained. The higher explosive limit is the limit at which the combustion of propane cannot be sustained.

(5) In accordance with requirements of NFPA 58, LP gases are effectively odorized to positively indicate presence of gas down to concentration in air of not over one-fifth the lower explosive limit.

(6) The pressure exerted by propane gas in a container is entirely dependent upon the temperature of the contents. Excessive pressure may be relieved by discharging gas from above the liquid thus reducing the temperature of the liquid or by application of a cooling agent to the outside of the container. In the interest of safety, it is preferable to reduce the temperature of the liquid rather than permit the escape of high pressure gas with resultant potential hazard.

b) Propane data as listed in NFPA 58:

Total heating value after vaporization:	25 140 kJ/L (liquid) 92 430 kJ/cu. m 50 000 kJ/kg
.271 cu. m of vapor per L of liquid at 15.56 degrees C	

Vapor pressure in kPa at:

20 degrees C	895
40 degrees C	1482
55 degrees C	1980

Specific gravity of liquid at 15.56 degrees C:	0.504
Initial boiling point at 1.00 atmosphere, degrees C:	-42

Flammability limit, percent of propane gas in air:

Lower	2.15
Upper	9.60

c) The design of the fuel system should be in accordance with NFPA 54, National Fuel Gas Code and NFPA 58 and NAVFAC Design Manual DM-22, Petroleum Fuel Facilities. NFPA 58 covers the LP gas system including the container, the vaporizer,

the unloading station, and tank and pipe appurtenances up to the double block and bleed valve at each building. NFPA 54 covers any part of the system where the propane gas pressure is less than 1370 kPa.

d) Fuel should be stored in a single location which provides easy access for tank trucks. This is to facilitate inventory taking, reduce installation costs, and increase safety. Use a minimum of two tanks to store the fuel. This allows for tank maintenance without interruption to the training. The total storage should equal 30 days' consumption. Design a full storage tank to contain 80 percent liquid equivalent to 30 days' storage and 20 percent vapor. The vapor space allows for thermal expansion and must never be used for liquid storage. Fence the storage area to restrict pedestrian and vehicular traffic. The fence should have a main entrance gate and a second gate on the opposite fence from such gate for emergency exit. At fence openings, provide a remote shutoff station for the emergency shutoff valves, refer to subpar. o). The fence area should have anti-vehicle barricade posts to protect tanks from an accidental collisions from vehicles or trucks. In accordance with NFPA 58, the storage area should not have walls, barricades, curbed areas, etc., which would prevent access and lateral ventilation from flushing the area. Provide the tanks in accordance with the American Society of Mechanical Engineers (ASME), Boiler and Pressure Vessel Code, Section VIII, unfired pressure with a minimum working pressure of 2100 kPa. Propane storage tanks should have an American Society of Mechanical Engineers stamp of approval on the tanks. No used tanks are allowed. Tank foundations should be proper for the soil bearing conditions and the weight of the tank plus its full weight of water because of the future hydrostatic testing of each tank. Tank exterior shells should be coated with proper corrosion protective material where the tank shell rests on the foundation. This may be accomplished with a properly saturated pad. The tank should be adequately grounded.

e) The tank valves and other appurtenances should be listed and approved for LP gas use by Underwriters Laboratories, Inc. (UL), Factory Mutual Research Corporation (FM), or other qualified testing facility. The tank pressure relief valves should be in accordance with the specifications of UL or ASME. The vent outlet from such valves should be a minimum of 2150 mm

in height and should discharge vertically upward. The discharge vents should be equipped with a loose rain cap so that it will not restrict the flow of propane vapor through such vent. The rain cap or end of the vent should be installed to direct the discharge vertically upward only. It is preferable to install the pressure relief valves on a multiport manifold so that one valve at a time can be shut off for repair or replacement while the tank is properly protected by the remaining valve or valves which are still in service and cannot be shut off, thus, ensuring full required relieving capacity. The vertical discharge of propane vapor 2150 mm above the top of the container assists in dispersing propane in a general safe manner.

f) Storage tank liquid and vapor operating connections are to be equipped with internal valves. These internal valves function as a primary shutoff valve and have built-in excess flow protection. The valves are to be operated manually at the installed location, or from a remote location via pneumatic actuator. Provide a fusible plug at the valve location to close the valve in the event of fire.

g) The water drain discharge opening of the pressure relief valves must be equipped with a diverter to deflect any product flow when the valve operates away from impingement on the tank or an adjoining tank. This is necessary to prevent a hot spot and a possible tank shell failure if such discharge would become ignited.

h) Each connection to the storage tank should be equipped with an excess flow valve or a backflow check valve as required in NFPA 58 except for the pressure relief valve and openings of 1 mm or smaller. The container should also be equipped with a pressure gauge.

i) Liquid piping between shutoff points should be equipped with a hydrostatic pressure relief valve to relieve the pressure caused by an increase in the liquid temperature resulting in an increase in pressure when the shutoff valves are in a closed position.

j) Accuracy in filling the tanks is important because of the expansion of the liquid as its temperature rises. The

amount of propane that can be placed in a tank over 4550 L water capacity as shown in Table 4-5.2.1 of NFPA 58 is 45 percent of the water weight capacity of the container. Then Table 4-5.2.3(b) shows that at 15.9 degrees C temperature the container can be filled to 88 percent. It is, thus, important to have accurate gauging devices. Such tanks generally have a variable gauge for general inventory control. The gauging devices are generally a float magnetic gauge with an indicator dial to show the percentage full of the contents at different temperatures; however, the gauging devices are not accurate enough to use them for maximum fill control because the float arm may become bent or other malfunction may occur that throws off the accuracy. As a result, a fixed liquid level gauge is required. This is a tube into the tank with the tube length made to extend down to the proper liquid level of 88 percent. There is a small valve with a restricted opening at the outer end. On filling of the container, the operator opens this valve and vapor will flow out during loading until the liquid reaches the bottom of the tube where a white cloud will appear at the outlet valve. This is not liquid propane but rather it is a water vapor cloud which is created when liquid propane expands to vapor and resulting refrigeration condenses the moisture in the air and creates the white cloud as fog. When this occurs, the operator should immediately shut off the flow of propane into the container and then shut off the gauge valve. Generally, at firefighting schools, transport trucks will be used.

k) Propane will be delivered to the containers by transport truck or, in some cases, by tank car. Generally at firefighting schools, truck transport will be used. Truck transports are generally 30 000 to 42 000 L capacity. Usually, such transports are equipped with an unloading pump. In such cases, the unloading hose is connected to the storage unloading station liquid line for unloading. The vapor return hose is also connected to the storage tank vapor line. This connection assists in the liquid transfer as it prevents a buildup of vapor pressure in the receiving tank. The transport might be equipped with a vapor compressor instead of a pump to use for off-loading. Off-loading involves vapor being drawn off the storage tank and discharged into the transport tank which creates a higher pressure differential in the transport tank and thus forces the liquid to flow into the storage tank. When the

liquid has been off-loaded from the transport to the storage, there will be some residual propane vapor in the transport. The vapor is recovered by switching the compressor valving so that it will then draw vapor from the transport and discharge it into the storage tank. This vapor piping to the storage tank should discharge into the liquid of the tank and not into the vapor space. This assists in condensing the vapor to liquid and thus speeds up the transfer. The recovery of the vapor results in an economic benefit.

l) Propane or water may be delivered to the storage by tank cars. In such cases, a proper tank car unloading facility must be installed. The facility should be a platform facility adjacent to the tank car unloading location. The facility should be equipped with liquid and vapor pipe lines and a hose connection at the platform. The hose connection should be of proper length to properly reach the tank car valve dome. There will be two liquid hoses so that a connection can be made to both liquid eduction valves on the tank car. These will be connected to the platform liquid piping at a three-way fitting. At the hose connection to this fitting, a backflow check valve should be installed at each hose connection to prevent backflow into the tank car. The tank car liquid education and the vapor openings on the manhole cover plate are equipped with excess flow valves on the underside of the manhole cover. Hose connections are also equipped with shutoff valves in the protective dome. A pressure relief valve is installed in the center of the protective dome with an opening in the dome cover above the relief valve. The tank car is equipped with a sampling tube extending down from the manhole cover to the sump at the tank bottom so that a sample of the propane or water may be drawn off. There is also a thermometer well extending into the car tank. The thermometer well have an antifreeze solution in it to a height of about 310 mm to provide conductivity of propane liquid temperature to the thermometer when it is inserted in the well.

m) The transport trucks or tank cars should always have the wheels blocked by chock blocks to prevent movement while parked and especially while unloading. The transport truck or tank car unloading point must be equipped with an emergency shutoff valve to prevent a discharge from the storage

tank(s) in case of a pullaway or break of the unloading hose or other equipment. Refer to NFPA 58. The emergency shutoff valve should be installed in the fixed piping between the tank and a substantial bulkhead with hose or swivel-type piping connections on the opposite side of the bulkhead from the emergency shutoff valve.

n) The bulkhead should be substantial and should be of concrete. The piping should be fully anchored to the bulkhead not just by inserting the pipe through a sleeve.

o) Provide emergency shutoff with three modes of operation: manually; remote control; and thermally. A preferable installation can be made which provides both thermal and remote control. The installation entails the running of plastic tubing to strategic points in or near the storage and unloading points pressurized with air, carbon dioxide (CO_2), etc., so that the pressure holds the valve open. Then if there is a fire, the plastic will melt, thus, enabling the valve to be closed. Install the plastic tubing so that it will be activated at all potential points of a flame. Install the tubing at a point where the emergency valve will be activated if there is a flame downstream beyond the bulkhead. For remote control, there may be a snap action release valve at several strategic locations in the tubing so that activation of valves releases the pressure and closes the emergency shutoff valve. The plastic tubing must be tied to the unloading hose so that a pullaway of the hose will break the tubing. In this way, a pullaway of the hose will activate the emergency shutoff valve and close the discharge from the tank storage. The excess flow valves in the transport piping should stop the flow from its tank. If it is a pullaway break, the transport tank valves should always have been closed before moving the vehicle.

p) After unloading the liquid from either a transport truck or a tank car, bleed the liquid propane from the connection after shutting off the valve at both the hose end and at the unloading piping. Many accidents have occurred because such bleeding has not been done. There should be a bleed attachment built into the unloading equipment for this purpose. If the attachment is not provided then bleeding can be done by only partially disconnecting the hose, thus, creating some additional hazards.

Remote shutoff control should be located at the 24-hour duty station and at each fence opening. The truck unloading station emergency shutoff should have a dual control of cable release and remote shutoff.

q) Normally vapors for use will be drawn off of the container from the vapor space above the liquid. Propane boils from a liquid to a vapor at a liquid temperature of minus 42.2 degrees C or above and thus replaces the vapor being used. However, this evaporation creates heavy refrigeration which cools down the temperature of the liquid. If the draw is heavy enough it will result in insufficient vaporization thus requiring the use of a vaporizer to convert the liquid to vapor.

r) There are two basic types of vaporizers. One is the indirect type which is heated by a heating unit remote from the vaporizer. The indirect type should furnish heat by steam, hot water, or other heating medium. The other is a direct-fired type. The standards for vaporizers is detailed in NFPA 58. Many times a pump is necessary to provide the necessary flow from the storage tank to the vaporizer because if the vapor pressure in the storage tank gets low, the proper quantity of liquid will not flow to the vaporizer, thus the need for the liquid pump. The installation should be in accordance with NFPA 58 and should have the electrical equipment in accordance with NFPA 70, National Electrical Code. Waterbath and indirect-fired vaporizers are both acceptable for use at firefighting training facilities. Use an indirect-fired vaporizer when there is a sufficient sized central steam or high temperature hot water heating plant or system available. In this case, the indirect-fired vaporizer would be less expensive than the waterbath vaporizer. Use a waterbath vaporizer when there is no central heating plant or system available. In this case, the waterbath vaporizer would be less expensive than an indirect-fired vaporizer and a new heating plant. No direct-fired vaporizers other than the waterbath type are to be used.

s) When using indirect-fired vaporizers, NFPA 58 applies. FM Loss Prevention Data, Section 7-55/12-28, Liquefied Petroleum Gas apply. In addition, install and design the waterbath vaporizer in accordance with the following:

(1) Waterbath vaporizers should be FM approved.

(2) Waterbath vaporizers should be located to maintain the space clearances as required by FM.

(3) Provide emergency shutoff valves with fusible links. Provide the following emergency shutoff valves in accordance with NFPA 58 and FM Loss Prevention Data:

(a) Liquid propane supply from the truck unloading station to the storage tank.

(b) Liquid propane supply from the storage tank to the vaporizer.

(c) Gas propane supply from the vaporizer. Regardless of which type of propane vaporizer is used, the truck unloading station should be located 23 m minimum from the tank and vaporizer. Refer to Appendix J, Figure J-1.

t) Indirect-fired vaporizers can be located indoors in specially designed vaporizer rooms. Refer to NFPA 58 for requirements. If a vaporizer room is provided then provide a separate propane alarm detection system for the room. This alarm detection system should provide an alarm (sound and flashing warning sign) in the instructor's station at the 24-hour duty desk, and locally at the vaporizer room entrance. Provide a 24-hour battery backup.

In addition to the alarm detection system, for propane vaporizers installed indoors, provide the following safety features:

(1) The exhaust fan should be located near the floor and should vent to the outside with high and low intakes in the door. The exhaust fan should be energized by an on-off switch located outside of the room.

(2) Doors with panic hardware.

(3) A leak detector readout with the readout outside.

(4) A leak detector kit located outside.

u) A totalizing, vapor type meter should be provided at the tank installation, at the vaporizer discharge, to record fuel used at the facility. The fuel system should be sized by

adding the demand rates listed herein for each trainer to be constructed. Flow meter should be a turbo meter with temperature and pressure compensation. Provide meter with digital interface connections.

(1) The propane will be delivered to the individual structures by underground pipe with a single entry to each structure. The propane piping at the site should be routed in a closed loop so as to maintain a constant supply pressure. Do not use galvanized steel pipe for underground installation. Underground pipe and fittings should be carefully coated for protection from corrosion and should be equipped with cathodic protection.

(2) The propane entry should consist of the apparatus and piping as shown in Appendix J, Figure J-2. Install a totalizing consumption meter on the structure side of the "house valve" to record the amount of propane used by that building. The device contractor will tie into the propane entry as shown in Appendix J, Figure J-2. Provide the propane entry outside. A list of valves, fixtures, appurtenances, and controls required for the propane system are shown in Appendix J, Figures J-3 through J-7.

(a) Provide underground piping located under roadways, parking areas, etc., in a vented protective conduit in accordance with API 2510, Design and Construction of LP Gas Installations at Marine and Pipeline Terminals, Natural Gas Processing Plants, Refineries, Petrochemical Plants, and Tank Farms.

(b) Propane piping should be welded and should be provided in accordance with ANSI B31.3, Chemical Plant and Petroleum Refinery Piping, and should be Schedule 80. On existing facilities, propane piping with threaded fittings should be back-welded.

(3) In addition to the above, provide a bank of two gaseous propane strainers with isolation valves at the propane entry for each training structure. The strainer bank should be located upstream from the isolation valve serving the flow meter. Each strainer should be sized and designed as follows:

(a) The propane demand flow rate, L/s.

(b) Stainless steel 1000 kPa basket type in-line strainer with flanged connections and ASME code stamp.

(c) Provide with a 30 micron filter screen.

(d) Support large basket strainers on outside reinforced structural concrete pads. Provide fence with locked gate and warning sign displaying "WARNING - PROPANE. NO SMOKING WITHIN 15 M."

(e) Designed for outside use.

(f) Provide means for cleaning including relieving propane pressure prior to opening the strainer.

(g) A potential manufacturer who can provide this strainer is Stream-Flow-Strainers, Inc., Buffalo, NY, (800) 263-8251, or Haywood Industrial Products Inc., Elizabeth, NJ (201) 351-5400. Other manufacturers are also available.

v) Safety precautions to be observed in handling LP gases:

(1) Smoking and open flames are prohibited in areas of storage tanks, unloading stations, and vaporizer.

(2) Motor vehicles are prohibited from entering the storage area. Motor vehicles should be prohibited from entering or leaving unloading area while transport trucks or tank cars are being unloaded.

(3) Test for leaks with soapsuds and a pressure drop test.

(4) Connect ground wire to tank cars and truck trailers before any unloading or loading operation is started.

(5) Wear rubber (neoprene) gloves when gauging tank cars, truck trailer, and storage tanks and when performing other operations.

(6) Keep vapor or liquid off skin and clothing. Liquid in contact with skin produces the same injury as a freeze burn.

(7) Thorough ventilation is required in buildings, especially at floor level.

(8) Use spark proof tools and explosion proof flashlights.

(9) Open valves slowly. If excess flow valves are closed, they may be opened by closing the line discharge valve for a few minutes, thus permitting pressure above and below excess flow valve to equalize internally through the small hole provided for this purpose, enabling the excess flow valve disk to drop into the open position.

(10) The coefficient of thermal expansion of the liquefied gas is high, therefore, liquid should not be confined in any isolated section of pipe except where a pressure relief valve is provided.

(11) Do not overfill storage tanks. The maximum allowable fill is 80 percent full, refer to NFPA 58 for exact fillage amounts.

(12) Do not pressurize tank cars above the safety valve setting as stenciled on the car. If faulty equipment on the car prevents normal unloading do not loosen or remove car valves under any circumstances. Fill in "Bad Order Tag" and attach to defective car part. Inform firefighting school supervisor of defective car and await further instructions on disposition of the car.

(13) Bleed vapor and liquid unloading and loading hoses before uncoupling from tank cars or truck transports.

(14) Bleed pressure from vapor compressor crankcase before removing oil fill plug.

(15) Before undertaking repairs the container or section of pipe to be repaired must be isolated by closing valves or physically disconnecting the involved section from communicating lines, as the situation warrants, followed by thorough purging with CO2.

(16) Hoses and fittings must be maintained in good order. Damaged or unsafe hoses must be removed from unloading area and must not be used for any purpose.

w) The propane interconnection at the device contractor tie-in point will be a block and vent propane entry as shown in Appendix J, Figure J-2. This interconnection will then meet the requirements set forth in NFPA 54 and also the FM insurance requirements.

x) The two most hazardous events associated with the gaseous fuel burning trainers are the fuel handling operations and the accumulation of unburnt fuel in the trainer. The risk of fuel handling operations is mitigated by strict adherence to NFPA 58, DM-22, and this handbook. The risk should be further reduced by having the receiving and storage systems maintained by the device maintenance contractor or someone experienced with large propane systems. The danger from accumulated unburnt fuel in the trainer is adequately eliminated during the occupied period by a system of ventilation, sensors, and interlocks. During the unoccupied period, the risk is reduced by natural ventilation and the proper operation of the key operated Hands-Off Automatic (HOA) switch in the instructor's station. Proper operation requires air flushing and purging the crawl space prior to energizing the crawl space electrical circuits. (Refer to par. 3.6.4)

y) The maximum fill level (fixed liquid level) gauge on the top of the tank is inconvenient at times to read. Thus, a backup variable liquid level rotogauge may be installed in the center of the tank head. If the float type liquid level gauge is not operating or if you want to check its accuracy, the rotogauge may be used. The rotogauge has a manually operated arm which traces the inside circumference of the tank. When

installed and maintained properly, the rotogauge will give you a true reading.

z) The firefighting training facility will have a 24-hour propane detection system provided by the device contractor. Refer to par. 2.6.a). The facility contractor is required to interface with the detection system via the data terminal cabinet (DTC) as follows:

(1) For 19F series trainers, provide an alarm system to alarm by sound and flashing warning sign at the quarterdeck or other 24-hour duty station. The warning sign should state "DANGER - PROPANE ALERT."

(2) For 21C12 series and Seawolf trainers, refer to par. 3.12 for requirements.

(3) In addition to propane alarms, the 24-hour duty station should be equipped with remote shutoff capability of propane from storage tanks and vaporizers.

2.2.3.2 Natural Gas. Natural gas is largely methane but includes ethane, propane, and butane. It has two disadvantages in regards to its use as a fuel for 19F series devices. First, the device would have to be modified. Natural gas has less than one-half of the Btu content of propane based on heating value of 93 MJ/cu. m of propane and 37 MJ/cu. m of natural gas. Therefore, pipes, nozzles, and other components, would have to be larger to accommodate the increased flow rate. The flame characteristics so important to realism also would be different. Additionally, natural gas is lighter than air, with air having specific gravity equal to 1, natural gas has a specific gravity between .58 and .70. Trainer architectural and safety aspects would have to be redesigned for this lighter than air hazard. Second, tests have not been run to determine the effect that using natural gas would have on the training environment. Therefore, natural gas cannot be used for the device training fires. Natural gas, however, can be used as heating fuel.

2.2.3.3 Oil and Gasoline. Oil and gasoline are no longer preferred as firefighting school fuels. These liquid hydrocarbon fuels produce many kinds of air and water pollution which can only be partially treated at great cost and may not be

acceptable by the local, State, or Federal environmental regulations.

2.2.4 Water

2.2.4.1 Potable Water. Potable water should meet the following criteria:

a) Firefighting facilities based on the 19F and 21C12 series trainers should use fresh water throughout. Salt water cannot be used because of the corrosive effect on the expensive device.

b) Recycled water can be used. Previous tests have indicated that wastewater treatment would be required to provide recycled water. The training structure effluent contains a large chemical oxygen demand (COD) that would have to be removed before delivering it back to the fire field. Refer to par. 5.3.3 for wastewater characteristics.

c) Water delivered to the site should be metered and supplied through a backflow preventer in accordance with AWWA C506, Backflow Prevention Devices--Reduced Pressure Principle and Doublecheck Valve Types. The pressure drop of this equipment must be considered when calculating the availability of water.

d) The range for water or foam pressure at the hose nozzle for the 19F series trainers is 820 to 965 kPa). Submarine trainers (21C12) should also require a minimum nozzle pressure of 820 to 965 kPa. The total discharge head of each pump should allow for hydraulic losses and wear.

e) The water system should be sized by summing the demand and consumption listed herein for each 19F and 21C12 series trainer.

f) During the development of the project, the EFD Code 16 (Utilities Division) should verify a reliable source of potable water. Water usage rates should be determined based on a once-through water system. Water flow tests should be conducted to determine the adequacy of the water supply system.

g) Other than the firefighting water, potable water for drinking and cool-down showers should be supplied to each device structure. The drinking fountain should be a pipe which shoots the water in an arch to a drain and the shower should be an emergency shower. Eyewash showers are not required.

h) Emergency water is defined as water delivered under pressure, over 700 kPa during a power outage. Emergency water is not required for the 19F and 21C12 series trainers because water could not extinguish the fire in an emergency.

i) Due to previous problems of piping failure from bursting under pressure, do not use PVC or other plastic materials for firefighting water piping. Piping should be suitably rated for 2100 kPa.

2.2.4.2 Water Storage. Sufficient water storage should be provided to ensure that the water demand can be met under all operating conditions without starving the pump suction. Water storage should be available on the site or in the vicinity. Water storage should be sufficient to supply the facility needs such that once a class is started (including classroom time), it can be finished. Design the water storage tank in accordance to AWWA standards. Tank should include the following: level gauge, automatic means for filling, vent, manways, OSHA approved ladders, etc.

2.2.5 Wastewater. Effluent from the training structures should be collected in an equalization tank, treated, and pumped at a metered rate into the sanitary sewer system. The ultimate disposal of the effluent should be through a biological treatment process. If the public owned treatment works (POTW) does not incorporate that degree of treatment, the fire facility should biologically treat the wastewater prior to discharging it (refer to Section 5).

2.2.6 Electrical Power. Provide sufficient electrical power in underground conduit to each structure to meet the needs of the building and device equipment, including the computer. Demand quantities are listed herein. Provide spare capacity in both power and control conduits. Separate conduits should be

used for power and control wiring. Spare conduits for the device contractor's use are identified under the respective trainer's requirement.

2.3 Supporting Facilities. Firefighting facilities should have a utilities building and a bulk storage building with an agent bottle refill.

2.3.1 Utilities Building. The utilities building design should conform to the following criteria:

a) The utilities building should have a minimum floor area of 232 sq. m.

b) The utilities building should include water pumps, foam concentrate mixing station, motor control centers, wastewater treatment monitoring equipment, central utility annunciator panel, and a maintenance area.

c) Provide a minimum of two pumps piped in parallel to supply 965 kPa water to the farthest hose. For submarine trainers, provide one full-sized pump for standby when existing potable water pressure is sufficient; when potable water pressure is low, provide two full-sized booster pumps in parallel. Design the pumping system as an industrial process system and not to meet normal fire protection requirements. Provide a flow sensor to turn on the second pump, based on demand. The second pump should be protected from short cycling with a timer which keeps the pump running for at least 10 minutes, regardless of demand. Each pump should be rated for continuous duty and should include a non-slam check valve. The design of the water system should be such that the pumps are protected from "dead head" during erratic demand variations experienced at a firefighting training facility. The method of relieving "dead head" pressure should ensure that the pump cannot overheat during this condition. The pressure relief should be by diaphragm relief valve. Provide a manual lead pump select switch and the lead pump should be started manually. Process water piping serving the hose stations should be painted red. Provide pumps with mechanical seals.

d) Aqueous film-forming foam (AFFF) are concentrates, based on fluorinated surfactants plus foam stabilizers, usually

diluted with water to a 3 to 6 percent solution. The foam formed acts both as a barrier to exclude air or oxygen, and to develop an aqueous film on the fuel surface capable of suppressing the evolution of fuel vapors. The foam produced with AFFF concentrate is dry chemical compatible and thus is suitable for combined use with dry chemicals. At firefighting training facilities, an AFFF surrogate is used in lieu of real AFFF for cost and environmental reasons. The foam surrogate concentrate, Calsoft, Ultrawet K, or equivalent, will be delivered and stored in bulk form. Refer to par. 4.2 for details on AFFF. It will be pumped to the utilities building concentrate mixing tank where it will be diluted with potable water to a strength equal to 100 percent AFFF concentrate. A batch process should be used and provisions for mixing should be included to prepare the solution. The method chosen for mixing should consider the potential foaming problem. The 100-percent solution will be pumped as required to each proportioner holding tank on the fire field. It will also be used to fill 19 L foam concentrate cans for use in the training structures. Carbon steel cannot be used for piping and storage of AFFF surrogates. Acceptable materials are stainless steel and copper piping. AFFF concentrate piping tanks and appurtenances should be painted green. All 6 percent and 3 percent AFFF piping should be painted green and red striped. AFFF pumps should be positive displacement type with internal relief and mechanical seals.

e) An electrical room should be provided in the utilities building to house electric controls and utilities related motor control centers, such as, water, fuel, chemicals, waste pumps, and others.

f) Utility system information, such as pressures, temperatures, liquid levels, run status, and flows should be brought to a central annunciator panel. The fuel information should be sensed indirectly so that no fuel is piped inside the building. Tanks and reservoirs should have level indicator devices.

2.3.2 Storage and Refill. Storage and refill facilities should meet the following criteria:

a) Provide a minimum floor area of 232 sq. m for bulk storage for all trainers, except the 21C12 trainer which should have a minimum of 111 sq. m of floor area.

b) Provide bulk storage for large CO_2 bottles, palletized purple potassium powder (PKP) containers, 19 L cans of foam concentrate, PKP and CO_2extinguishers, and OBA canisters. This storage should be kept from freezing and kept dry. The maximum temperature should not exceed 54.2 degrees C. The layout should consider the handling of material by fork truck. A minimum of 9.2 sq. m of well ventilated space should be provided for filling empty PKP and CO2 fire extinguishers. This area should contain scales and support jigs to facilitate the filling operation which should be done in accordance with NAVSHIPS Technical Manual, Chapter 55, Section 555-4.1.

c) Additional storage may be required for storing of collateral equipment and spare parts. Contact the using activity for requirements.

d) The dry storage and refill areas should contain floor drains which lead to the equalization tanks.

2.4 Other Facilities

2.4.1 P-250 Demonstration. Provide the P-250 demonstration with all 19F type trainers. The P-250 pump cannot be mounted on the 19F4 trainers. P-250 demonstration facilities should meet the following criteria:

a) The P-250 is a gasoline-powered, portable water pump. For demonstration, provide an in-ground sump of a minimum 4200 L along with bleachers for the trainees (see Appendix A, Figure A-15). The sump should have a drain and a 50 mm fill valve. Provide a chain rail for personnel safety. During the demonstration, the pump should take suction from the sump and discharge back to it.

b) When the installation is located inside an enclosed structure, the exhaust from the gasoline engine should be removed. The P-250 pump uses process water for bearing lubrication. This water should be discharged through the exhaust pipe. Provide an exhaust system to carry away the

exhaust including a trapped drain to carry the lubrication water to the equalization tanks. Refer to par. 5.3.3 on pretreatment and equalization tanks. For outside P-250 locations, provide means to drain the lubrication water to the equalization tanks. The lubrication water could contain small amounts of oil and gasoline. The drains serving the P-250 pump should be piped to an oil and water separator for removal of gasoline and oil from the P-250 pump lubrication water. A new P-250 pump has been introduced which eliminates oil and gasoline in the lubrication water.

2.4.2 Wild Hose. Provide the wild hose demonstration with 19F type trainers. The wild hose cannot be mounted on the 19F4 and 19F4A trainers. The wild hose demonstration area should meet the following criteria:

a) The wild hose demonstration area should include access to a 40 mm hose station, 30 480 mm of 40 mm hose, 65 mm to 40 mm adapter, another small section of 40 mm hose, and a 3048 mm high steel pipe column. A section of 40 mm hose should be strapped to the column with 2438 mm hanging loose from the top. The other end of the 40 mm hose section should be at ground level to allow coupling of the longer hose. (See Appendix A, Figure A-13.)

b) The wild hose should be installed outdoors except in extreme climate locations where an enclosed area is a necessity for year-round training. Provide enclosed areas inside training structures with Plexiglas barriers to facilitate viewing the wild hose without getting personnel wet.

> Caution: The length of the free end of hose with the nozzle should always be less than the distance to the walls, ceiling, and floor to prevent damage to the structure.

2.4.3 Smoke House. A separate facility for smoke training has not been identified.

2.4.4 Hose Drying Area. Provide a rack for laying out twelve 15 000 mm lengths of hose to dry. It should be located in an open area if possible to take advantage of natural air

movement. Hoses should lay on an angle to promote drainage. Provide one rack per training structure.

2.4.5 Maintenance Contractor Area. The maintenance contractor area should be a work or office type room with a 2450 mm high ceiling to be used by the device maintenance contractor. The minimum floor areas should be as follows:

a) For 19F5, 19F5A, 21C12, and 21C12A trainers, 11 sq. m.

b) For 19F1A, 19F1B, 19F3, 19F3B, 19F3A, 19F3C, 19F4, or 19F4A trainers, 45 sq. m.

c) For other training devices, locate the maintenance contractor area at the utility building or other support building.

2.4.5.1 Room Provisions. Provide the room with the following:

a) Telephone connection

b) Air conditioning, heating, and ventilation

c) 120 volt, single phase, heavy duty electrical outlet

d) Lighting

e) Lockable door

2.5 Interfaces

2.5.1 General. Firefighting training facilities are procured through two separate contracts. The first is a construction contract which provides the training structure, the site development, the supporting facilities, and the utilities. The second is a device contract which provides the trainer, computer, and its related equipment. Everything discussed in this handbook should be provided by the facilities contractor unless indicated otherwise. Two copies of military construction (MILCON) project facility drawings and any changes thereof, and as-builts should be supplied to NAWCTSD when available.

2.5.2 Device Contractor. The device contractor should provide the following equipment:

a) Fireplace mockups

b) Nonfireplace mockups

c) Telltale and obscuration smoke systems

d) Halon and aqueous potassium carbonate (APC) agent simulators

e) Explosive gas monitoring system (propane detectors)

f) Temperature and safety monitors

g) Training and maintenance communication devices

h) Ventilation devices used by the trainee

i) Shiplike labelings

j) Power ventilation necessary to distribute smoke

k) Equipment necessary to "clean up" electrical service

l) Equipment necessary for electromagnetic shielding

m) Special compartment lighting

n) Bulkhead rib insulation (21C12)

o) Partitions in 21C12 instructor's station

p) Flush deck nozzle system (19F4)

q) Bulkhead flapper (21C12 and 21C12A)

r) Red Devil blower and adapter (21C12 and 21C12A)

2.5.3 Facility Contractor. Unless indicated otherwise, device services should be brought to a single point close to the exterior of the training structure. The device contractor should make final connections after the facility contractor leaves the site.

2.5.3.1 Electric. Electrical service designated for the device and computer should terminate in a single-fused disconnect in the electric room near the instructor's station. For those buildings without an instructor's station, the disconnect should be located in a ground-level burner room.

Power for facilities installed equipment, such as, lights and exhaust fans, should be run through a separate, fused disconnect and wired ready for use. This disconnect should be located in a ground-level burner room.

Power provided should be directly from the station or municipal grid system. If the power source needs to be modified or "cleaned up" to protect the computer equipment, the device contractor will provide the necessary equipment.

2.5.3.2 Data Terminal Cabinet (DTC). Exhaust fans, motorized dampers, and motorized valves located in, a trainer should be controlled by individual, HOA switches in the instructors station. The automatic mode should have the necessary relays to be energized by a 24-Vac, 100 mA, binary signal from the future device computer. Wire each relay to the DTC. The DTC should be located in the instructor's station, except the DTC for the 19F4 trainer should be located in the electrical space below the instructor's station. Controls which are recommended to be wired to the DTC should include the HOA switches and relay mentioned above. The 24-Vac relays associated with HOA switches wired to the DTC should be provided with arc suppression protection. The use of non-suppressed relays can produce a large voltage spike which is detrimental to the device computers.

The DTC should include a terminal strip where these controls are wired to unique lugs. Mating lugs on the terminal strip should be ready for the device contractor to tie into to complete the installation. Each lug should be identified by the

facilities contractor by the function connected to it. For typical control interface, see Appendix A, Figures A-18 through A-20D.

2.5.3.3 Fuel. Refer to par. 2.2.3.

2.5.3.4 Fireplace. Areas indicated on the floor plans as fireplace areas should have no floor grating or plate and should be free of any structural members. Acceptable tolerance should be plus or minus 6.4 mm maximum. Provisions for supporting the future device are shown in Appendix A, Figures A-9A and A-9B. Provide a temporary bolted post and chain railing around the opening for safety until the device is installed.

2.5.3.5 APC Extinguishing Agent Simulation. Provide a 40 mm fire water line to the deep fat fryer fireplace and terminate with a globe valve below the floor grating.

2.6 Device. (For information only and does not pertain to the device contract.) The device equipment provided in the trainers consist of the following:

a) Fireplaces should be computer-controlled propane burners hidden in a mockup which is designed to represent the item burning. See Appendix A, Figures A-1, A-2, and A-3. Most fireplaces will be floor-mounted and fed from the crawl space. Fireplaces which are not fed from the crawl spaces, such as: electrical panel, wire bundle, and vent duct fires, should include propane equipment in their electrical cabinets. Each of these cabinets will contain a propane sniffer which will detect any propane which has leaked into the cabinet. There will also be propane sensors on both sides of the wall underneath electrical cabinets containing burners. When activated, this sniffer will shut down its fireplace until the propane is removed from the area.

b) Design device equipment to go through a 914 mm personnel door unless other provisions are made.

c) The artificial smoke generator (provided by the device contractor) is started at the beginning of a training session and runs continuously. Air at 538 degrees C should be discharged from bypass ducts which keep the system at operating

temperature. The unit requires one-half hour at the start to attain operating temperature. When smoke is required, the chemical is injected into the hot air and ducted to the proper location. The building ventilation should remain on even during the application of smoke. The bypass duct should discharge into the ventilation system or be controlled so that no artificial smoke can exit through it. Different smoke generation rates are obtained by relieving air before the chemical is injected into it.

d) The smoke generator should be powered by propane and electricity and located on the ground adjacent to the training structure.

2.7 Gas Chamber

2.7.1 General. Use the gas chamber to provide chemical warfare countermeasures training; it is not part of the 19F and 21C12 series firefighting structure. However, the gas chamber should usually be provided with the 19F5 facility. The chemical agent to be used for training is tear gas. Use the gas chamber to train 1 class of 100 personnel at a time, 2 to 3 classes per day, and 20 classes per week.

2.7.2 Training. Recruits and instructors will enter into the gas chamber wearing the MCU2/P gas masks. Prior to their entrance in the chamber, tear gas is made on a hot plate and is subsequently exposed to the recruits as they remove their gas masks. When gas training is complete, the recruits and instructors march out of the chamber to an area where they can get fresh air. After completion of gas training, an instructor opens the emergency exit/vent doors and energizes the exhaust system to exhaust the tear gas-laden air from the gas chamber. During winter, the instructor will deenergize the heating system prior to energizing the exhaust system. When tear gas has been removed from the gas chamber, the exhaust system will be deenergized and the heating system will be energized, as required. After each use, the gas masks will be sterilized by the recruits by dipping or wiping the masks with a 2 percent iodine and 98 percent water solution. The masks are then rinsed or wiped with water and wiped dry.

2.7.3 Site Development. The gas chamber should be a separate structure and should be located at least 15 m away from any building or facility to prevent the migration of tear gas into an occupied area or building. Consideration should be given to the prevailing wind direction. The gas chamber discharge should be sited so that tear gas is not blown to occupied areas or buildings located downwind.

2.7.4 Architectural. The floor plan for the gas chamber is provided in Appendix H, Figure H-2.

2.7.4.1 Layout. Layout of the gas chamber should conform to the following criteria:

a) The gas chamber should be a 120 sq. m based on inside dimensions, one-story building consisting of a 9144 mm by 9144 mm gas chamber room, a decontamination station, a storage room, and a mechanical room.

b) The building should consist of concrete masonry unit wall construction. Ceiling should be a 2450 mm high gypsum-board type. Protective sealant should be applied to both the walls and the ceiling of the gas chamber room. Sealant should be chemically-resistant to tear gas (vapor and powder) and capable of preventing migration of tear gas and water through the walls and the ceiling of the gas chamber room. Protective sealant should be an epoxy or urethane coating system.

c) There should be means of access to the space above the ceiling, which will be used for maintenance purposes. Access to the ceiling should be via the storage locker or the mechanical room. The doors should be the insulated, hollow metal type. Each door should be provided with a clear 460 mm by 460 mm shatterproof window. There should be no windows in the walls. Provide emergency exit doors with panic hardware.

2.7.4.2 Decontamination Station. Use the decontamination station for sterilizing the gas masks. The decontamination should consist of an iodine-water solution sink for sterilizing the gas masks, a rinse water sink for rinsing the gas masks, and a drying counter or table for hand drying the masks. The sinks and counter or table should be stainless steel.

2.7.4.3 Storage Locker. Store gas masks, tear gas powder or capsules, and collateral equipment in the storage locker separated from the gas chamber. Provide built-in wall storage consisting of pigeon-hole type compartments in the storage locker for storing 200 gas masks with haversacks. See Appendix H, Figure H-2, for detail information pertaining to wall storage.

2.7.4.4 Collateral Equipment. Collateral equipment to be furnished by the station are:

a) Washdown hose and storage rack

b) Hot plates

c) Hot plate counters

d) Gas masks

2.7.5 Plumbing. Provide hot and cold water to the sinks in the decontamination station. Provide floor drains in the gas chamber room and decontamination room. Provide a 20 mm hose bib in the gas chamber room for hose washdown of floors, walls, and ceiling. Drains should connect into piping leading to equalization basin.

2.7.6 Mechanical. Provide a mechanical exhaust and winter heating system for the building (heat the building to 10 degrees C inside. Do not provide air conditioning. The mechanical exhaust system should be separate from the heating system and should be provided for the gas chamber room. The exhaust system should be sized for 60 air changes per hour. A sign should be placed on the gas chamber room wall, near the exhaust system controls, stating, "IMPORTANT - WHEN OPERATING EXHAUST SYSTEM, TURN OFF HEATING SYSTEM AND OPEN ALL DOORS." The exhaust fan should have a non-overloading wheel. The exhaust system should contain a discharge stack to disperse the tear gas high enough into the air above the building to prevent recirculation back into the gas chamber and migration to other areas and buildings. The exhaust system should contain a motorized damper which will be closed during gas training to prevent the loss of tear gas. Do not use an air heating system for heating the building. The heating system should consist of unit heaters or fin tube

radiation. The heating equipment should be designed for water cleaning by hose and should also be able to withstand the accumulation of tear gas powder.

During tear gas training, when the recruits are entering the gas chamber room, the heating will be turned off by the instructor. When recruits are in the gas chamber, the instructor will turn the heating systems back on. The exhaust system will be off throughout the gas training. After completion of gas training, the instructor will turn the heating system off in the gas chamber room, open doors, and energize the exhaust system to rid the gas chamber of tear gas. After exhausting the tear gas out of the chamber, the instructor will turn the exhaust system off and energize the heating system.

2.7.7 Electrical. Provide lighting in gas chamber rooms. Provide waterproof, surface-mounted, incandescent light fixtures in the gas chamber room. Provide three heavy-duty, waterproof wall outlets in the gas chamber room. Two of the wall outlets should be located near the hot plates. Provide a red, rotating beam light outside at the main entrance to the chamber to serve as a warning light during training. A sign should be placed on the building, near the main entrance, stating, "CAUTION - GAS TRAINING IN PROGRESS WHEN RED LIGHT IS FLASHING." Electrical power to the building should be 120/208 Vac/single phase/60 Hz.

2.7.8 Tear Gas Characteristics. Tear gas is available in two forms: powder and powder-in-capsule. Approximately 6.5 to 20 grams of powdered tear gas will be used per class for the gas chamber.

a) Chemical: alpha-chloroacetophenone, $C_6H_5COCH_2C_1$

b) Threshold Limit Value (TLV): 0.3 mg/m^3

c) Melting Point: 59 degrees C

d) Density: 1.324 gram/ml (powder)

e) Vapor Pressure: 1.6 Pa

Section 3: TRAINING STRUCTURE

3.1 Training Courses. The various 19F and 21C12 series firefighting trainers have been designed to support the following courses:

a) J-495-0418 - General Shipboard Firefighting Training Course: Taught in the 19F3 and 19F3A trainers, a 2-day course for a maximum of 108 students in the 19F3 and 60 students in the 19F3A. Students are exposed to Class A, B, and C type fires.

b) J-425-0424 - Advanced Shipboard Firefighting Team Evaluation Course: Taught in the 19F1A and 19F3A trainers, a 2-day course for a maximum of 30 students. Students should locate, identify, and extinguish the classes of fires and communicate with Damage Control Central.

c) J-495-0413 - Shipboard Aircraft Firefighting Training Course: Taught in the 19F4 trainer, a 2-day course for a maximum of 60 students. Students should conduct firefighting and rescue exercises with fixed wing and helicopter crash fires.

d) J-495-0414 - Aviation Facility Ship Helicopter Firefighting Team Training Course: Taught in the 19F4 trainer, a one-day course for a maximum of 29 students. Students should conduct firefighting exercises with helicopter crash fires.

e) J-495-0424 - Advanced Shipboard Firefighting Team Training Course: Taught in the 19F1A and 19F3A trainers, a 4-day course for a maximum of 30 students.

f) A-495-2071 - Submarine Basic Firefighting.

g) A-495-2072 - Submarine Advanced Firefighting.

h) A-495-2073 - Submarine Team Firefighting.

Subpars. f) through h):

(1) The basic course is a 2-day course: 8 hours of classroom and 8 hours of trainer instruction. Maximum class size is 25 students.

(2) The advanced course is a 2-day course: 16 hours of combined classroom and trainer instruction. Maximum class size is 12 students.

(3) The team course is a one-day course: 4 hours of trainer instruction. Maximum class size is 14 students.

3.2 General. Design the training structure to house the various 19F and 21C12 series devices and provide realistic training situations. It should be ruggedly constructed to withstand the temperature cycling from the intense heat of the flame to a stream of cold water from a hose. It should withstand the impact of a high velocity hose stream.

3.2.1 Heat Protection. Building structural components should have sufficient room for thermal expansion. The maximum flame temperature of the device is 899 degrees C when using propane fuel. Assume the products of combustion reach 349 degrees C and an individual compartment may reach 204 degrees C. Any item located in a compartment should be able to withstand the radiant heat or be shielded from it. It takes about 5 minutes for a small fireplace and about 20 minutes for a large fireplace, such as a bilge fire, to return to the starting temperature assuming 2 minutes of cooling water spray.

3.2.2 Personnel Spacing. There will be approximately 1550 mm of spacing between trainees on a hose team.

3.2.3 Weather and Freeze Protection. Weather protection of the training structure should meet the following criteria:

a) Structures should be sufficiently enclosed and heated to allow training in subfreezing weather (where this is a requirement) without adverse effects, such as, ice buildup on grating or doors. Other than for training and water freeze protection, there is no low temperature limit on the structure or associated equipment during off hours.

b) Crawl space should be heated to 4.4 degrees C during unoccupied hours to maintain the structure above freezing. Unit heaters should be used to provide heat.

c) During occupied hours, enclosed staging areas should be heated to 10 degrees C and also should be ventilated for summer heat removal. The staging area ventilation should be the forced type so the pressure there is always above the compartment pressure. This will ensure that the smoke stays in the training compartments.

d) When roof staging areas and second story emergency walkways are enclosed, a 1850 mm by 2450 mm high removable wall panel in the staging area should be provided. This will allow larger equipment to be hoisted during installation and maintenance.

e) Staging areas should drain into the structure to ensure that firefighting agents and rainwater are collected. Staging areas should be provided with trench type drains. Rainwater from roofs does not have to go to the crawl space.

3.2.4 Drainage. The area around exterior trainee entries to a fire space should be provided with an apron which slopes to a drain. The drain should lead to the wastewater treatment system. This apron will collect the firefighting agent used to cool the door prior to student entry and should be large enough for that purpose. If the apron will be subject to collecting rainwater, a pair of post indicator valves should be placed on the drain line; one should lead to the storm drain, the other should lead to the wastewater treatment. It will be the instructor's responsibility to correctly position the valves so the rainwater goes to the storm drain when the structure is not in use and the training water goes to treatment when the structure is occupied.

3.2.4.1 Drainage Piping Material. Because of exposure to heat and AFFF, the drainage piping in the training structure should be capable of withstanding 400 degrees C and should be constructed of either copper or stainless steel. When piping is not exposed to heat, PVC piping can be used.

3.2.5 Escape Trunks. Escape trunks should be 1550 mm on a side and should descend from the roof to the first floor by way of a vertical wraparound ladder. The roof entry should be a small hatch and the lower entry should be an Ellison door. A horizontal safety net should be stretched across the escape

trunk at a maximum of 2450 mm intervals. The safety net in escape trunks should be first quality parachute nylon webbing in accordance with BUSHIPS Dwg. 804-5184163. Webbing should have 800 kg test load and should be waterproof. Borders should have safety snaps for attachment to wall-mounted eyelets. The net should be fastened to the walls so it can be removed for maintenance. Provide a 900 mm by 900 mm opening in the safety net where the ladder passes through. Provide door in escape trunk for access from crawl space area for maintenance. The door should have louvers for ventilation. The escape trunk should be provided with 950 L/s mechanical ventilation with the supply air coming from the crawl space. Refer to par. 3.11.9.2.

3.2.6 Consumables. Each 19F and 21C12 series trainer was designed to handle a specified student loading as indicated herein. The training schedule and demand and consumption of consumables are also indicated. When the student loading of a proposed project differs substantially from the indicated values, the design demand and consumption may be proportioned up or down to suit the project.

3.2.7 Burner Rooms. Burner rooms should have a minimum ceiling height of 2134 mm and a floor level with the crawl space floor. The device contractor will provide necessary hardware for mounting and maintaining training components away from air intake louvers. For access into the burner room where a change in elevation occurs, provide stairs with a landing and railing.

3.2.8 Obstructions. Provide obstructions where they are indicated on the floor plan drawings in the appendices. Obstructions should be constructed of 4.8 mm steel plate, making a solid top and sides and having an open bottom. Obstructions should be bolted to the floor grating from underneath in such a way that they can be positioned anywhere in the room.

3.2.9 Separation Chamber and Piping Traps

a) Effluent coming from a fire training structure should dump into a separation chamber. The primary purpose of the chamber is to separate the propane which accumulates in the pipe peripheral air space from the remainder of the wastewater piping. The chamber should be open at the top or covered with a 150 mm diameter vent pipe. The inlet should be valved with a

lockable post indicator type valve, and should be high enough above the outlet invert so the influent can fall even in freezing weather. The inlet should be baffled. Both inlet and outlet should terminate inside the chamber with a pipe flange and sufficient room for a future pipe fitting. The outlet should be a dip tube which draws from the bottom of the chamber. A running trap should be provided in the outlet line adjacent to the chamber (see Appendix A, Figure A-16 for separation chamber detail).

b) "NO SMOKING" signs should be posted facing all directions around the separation chamber since it is a source of propane.

c) No traps should be provided in the piping leading from the crawl spaces. Floor drains leading from other spaces in the training structure should have vented traps or should tie into the wastewater line upstream of the separation chamber running trap. This precaution will prevent propane migration through the piping.

3.2.10 Fireplace Compartment Dimensions. Dimensions given for fireplace compartment sizes are inside clear dimensions. These inside clear dimensions are critical and should be maintained; allowable tolerance should be plus or minus 6.35 mm maximum. For example, if a fireplace compartment has refractory coatings and steel plate liners on the walls, then the inside clear dimensions are from liner to liner of the walls.

3.3 Repair or Crash Lockers. Each structure, except the 21C12 and 21C12A trainers, should have at least one repair locker to house the paraphernalia required for firefighting. Unless indicated otherwise, repair lockers should be 3048 mm on a side with a 2438 mm sloping roof and gutter. Repair lockers should have natural ventilation at floor and roof and should have a floor drain. Hollow metal doors should be used on repair locker entries. The following repair locker equipment should be provided by the respective training school:

a) Damage control plotting board to track status of the fire and extinguishment process

b) OBA canisters and OBA's

c) CO_2 bottles

d) PKP bottles

e) Repair parts

f) Nozzles

Crash lockers should be the same as repair lockers.

3.4 Doors and Hatches. Various types of entryways defined here are used throughout firefighting training structures. Doors used for emergency exits should be adequately marked and should have panic hardware.

3.4.1 Watertight Doors. Watertight doors should be provided in accordance with NAVSHIPS Dwg. 805-1400066, galvanized steel with three dogs unless indicated otherwise, see Appendix A, Figure A-12. Refer to NAVSHIPS Dwg. 805-1400074 for details of airtight doors. Airtight doors as shown on NAVSHIPS Dwg. 805-1400074 can be used in lieu of watertight doors since submergence in water is not a requirement. Airtight doors are a good simulation to watertight doors. No hasp assembly is required. Three dogs are used instead of eight because the door will warp when subjected to heat and many of the dogs would not work. Since the door will have to be replaced periodically because of warping, it is desired to keep the door as inexpensive as possible. Quick-acting watertight doors should be a watertight door provided with a single lever to operate the three dogs at once. Refer to Appendix A, Figure A-7. Quick-acting, airtight doors should be provided in accordance with NAVSHIPS Dwg. 805-1400074.

3.4.2 Hollow Metal Doors. Hollow metal doors should be standard exterior doors with standard door knobs. Panic hardware should be used on doors labeled "Emergency Exit." Typically, doors should be 900 mm wide except that doors to instructors' stations, burner/electrical rooms, and electrical equipment rooms should be 1200 mm minimum width doors to allow for equipment access.

3.4.3 Wire Mesh Doors. Wire mesh doors should be constructed of 38 mm angle steel with 9.5 mm by 12.7 mm steel wire mesh fastened to it.

3.4.4 Automatic Closing (Ellison) Doors. Automatic closing (Ellison) doors should be in accordance with NAVSHIPS Dwg. 803-5184129. Refer to Appendix A, Figure A-8. Ellison doors are nonwatertight, steel, balanced doors which close automatically by the action of an internal spring. Ellison doors should be shielded from the radiant heat of the fireplaces. The door should be 900 mm wide. These doors are considered to be proprietary and are provided by Ellison Bronze Co., Inc.

3.4.5 Large Hatch. A large hatch should be provided in accordance with BUSHIPS Dwg. 805-1624089. This hatch should be 900 mm by 1550 mm with six wrench-operated dogs, spring-balanced and should include a 635 mm, quick-acting, spring-balanced, raised scuttle.

3.4.6 Small Hatch. A small hatch should be provided in accordance with BUSHIPS Dwg. 803-1645097. This hatch is 900 mm by 1070 mm raised, oval, quick-acting, and spring-balanced. It should include 330 mm diameter handwheels on both sides which operate four dogs. Provide safety chains or rails around the top of hatches.

3.5 Ladders

3.5.1 Inclined Ladders. Inclined ladders should be designed in accordance with NAVSHIPS Dwg. 805-1749113. The weight of the ladder should be supported from floor beams instead of deck grating. The slope of the ladder should not exceed 60 degrees from the horizontal and unless indicated otherwise, should have landings at either end with a minimum of 1070 mm clear space. When the ladder rises more than 6100 mm of vertical height, an intermediate landing should be provided in accordance with OSHA.

a) The top tread of an inclined ladder should be 225 mm wide and start 51 mm away from the deck cowling. Other treads should be 150 mm wide. Non-slip treads, within wet conditions, should be used exclusively. Head room clearance

anywhere on the ladder should be maintained at 2150 mm in accordance with OSHA. The inclined ladder should be constructed of hot-dipped galvanized steel.

b) Where an inclined ladder passes through a crawl space, an airtight barrier should be provided so the crawl space air cannot enter the inclined ladder space.

c) Where the inclined ladder leaving Compartment 1 passes through the first floor concrete ceiling, it should be surrounded by a barrier. The barrier should be tight to the ceiling and extend into the compartment to 2150 mm above finished floor. This barrier will keep any products of combustion higher than 2150 mm from entering the inclined ladder space.

3.5.2 Vertical Ladders. Vertical ladders should be designed in accordance with NAVSHIPS Dwg. 804-1749235. Following standard shipboard design, the wraparound ladder rungs should be 177.8 mm from the wall. The rungs should be of serrated 316 stainless steel to provide a nonslip surface. A 0.83 sq. m opening should be provided in the safety net where the ladder passes through.

3.6 Lighting and Electrical

3.6.1 General Lighting. General lighting should be provided for each space in a firefighting structure using appropriate building type fixtures and switches.

The fireplace areas should use indirect lighting from the crawl space areas. The fixture should be wall mounted at 900 mm above finished floor (AFF), facing outward or with a (25 degree) stanchion. Luminaires should not be floor mounted, facing upward. Provide a fixture similar to that shown in Appendix A, Figure A-22. Specify the particular type and lamp wattage appropriate for the design (Type 1 or 2). Luminaires should meet Underwriters Laboratories Inc. (UL) 595, Marine-Type Electric Lighting Fixtures, for marine locations. A globe guard should be provided. The above requirements will: (a) protect the fixtures from heat and direct spray of the water; (b) allow for the water to drain away from the fixture; and (c) avoid letting water penetrate the fixture and conduit

system. These lighting levels are not intended for use with training personnel. The lights in the crawl spaces are only intended to aid and supplement maintenance and inspection personnel who carry individual task lighting. Provide approximately 53.8 Lx of illumination level. The light switches associated with the crawl space lights should be located outside the entryway(s) for the compartments.

It is requested that the following requirement be added to the operation and maintenance support information (OMSI) for the facility:

Perform monthly inspection of the two gaskets (ballast and globe) associated with each fixture. Replace gasket when deterioration is evident.

Staging areas should be provided with general lighting for nighttime operation.

3.6.2 Special Compartment Lighting. Special compartment lighting should be provided for use by the trainee and should be provided and controlled by the device contractor.

Every attempt should be made to minimize the length of conduit in the compartment. When conduit is run in the compartment it should be shielded from the fire and water spray and should contain wire with high temperature insulation suitable for greater than 260 degrees C. High temperature wire should be in accordance with Military Specification MIL-W-25038, Wire, Electrical, High Temperature and Fire Resistant, Type 1.

3.6.3 120-Volt Alternating Current (Vac) Convenience Outlets. The 120-Vac convenience outlets should be provided in the crawl spaces, burner rooms, and instructor's station.

3.6.4 Electrical Interlocks in Crawl Space and Burner Rooms. The electrical interlocks in crawl spaces and burner room should meet the following criteria:

a) Provide a lockable, key operated HOA switch in the instructor's station to disable lighting circuits, receptacle circuits, and power circuits in the crawl space(s) and burner room(s). The HOA switch should be wired to the DTC in the same

manner as the other HOA switches. After the device is installed, the computer will interlock these circuits with the ventilation such that they remain deenergized until after a preset purge time. The computer will deenergize these circuits again at the end of the occupied time. The HOA switch should remain locked in the automatic mode after the device is installed. Provide a minimum of one HOA switch for each burner room and crawl space; (two total) for the 19F5 or 19F5A; provide one for each 19F3 or 19F3B building (four total); (one total) for the entire 19F1A or 19F1B building. The key operated feature of this switch should prevent accidental changing of the position and the key should only be in the possession of the senior person in the instructor's station. The positions of this switch function are as follows:

(1) Hand - The fans must be operating for a preset time of 3 minutes before the power and lighting circuits noted above can be energized from this position. Prior to the installation of the trainer device, this position is used to provide light and power for construction and testing work in the crawl space. After installation of the trainer, this position can be used to provide utilities for normal maintenance work or to provide power and lighting in the event of a computer malfunction.

(2) Off - Power and lighting circuits deenergized.

(3) Automatic - The computer starts the purge cycle by operation of the ventilation fans and checks the sensors in the crawl space and central cabinets containing propane piping prior to energizing the power and lighting circuits. Exact sequence and timing of this operation is completed by NAVAIRWARCEN Training Systems Division at the time the trainer device and the computer are installed. The switch will then be locked in the automatic position.

b) Crawl space should contain propane burners, piping, valves, and regulators. As discussed above, the ventilation system will be interlocked with the main propane valve. Propane will not be introduced to the trainer until the

crawl space is purged. In addition, the crawl space will contain propane detectors (provided by the device contractor) which will prevent the introduction of propane if 10 percent of the lower explosive limit (LEL) of propane is detected in the crawl space or burner rooms.

c) Electrical receptacles, lighting fixtures, and other electrical equipment in crawl space and burner rooms should normally be deenergized and can be energized only after the above interlocks are satisfied.

d) The crawl space exhaust fan and power enable controls should include the following features:

(1) Detect fan run status via a differential pressure sensor.

(2) Detect a closed damper (with fan running) via a differential pressure sensor.

(3) Transmit the analog fan differential pressure to the device computer.

(4) Turn off fan upon detection of failure or closed damper.

(5) Indicate when fan fails to respond to a control action.

(6) Latched fan start circuit in hand control mode (upon restoration of power after a failure, fan will be off).

(7) Use the fan status in purge timer interlock with crawl space power. Timer interlocks should be provided with adjustable settings from 0 to 30 minutes, and set at 3 minutes.

(8) Indicate when crawl space power enable fails to respond to a control action.

(9) Crawl space power indicator light.

(10) Latched crawl space power enable circuit in hand control mode (upon restoration of power after a failure, crawl space power will be off).

3.6.5 Alarm for Loss of Electrical Power. (For all trainers.) Provide a battery backup annunciation and alarm at the 24-hour duty desk and the instructor's station which will activate in the event of an electrical power outage at a trainer. Capability to silence the alarm should be provided at both locations.

3.7 Floors. There should be five types of floors in a fire training device structure: a training floor, a staging floor, a crawl space floor, a maintenance floor, equipment floor, and a computer room floor. Consider Occupational Safety and Health Administration (OSHA) requirements for walking surfaces. Floors should be designed for a floor loading of 292.8 kg/sq. m except for the computer area, which should use standard computer floor design, and the deck surrounding the fireplace of the 19F4 and 19F4A. Additional support should be provided by the device contractor to mount any equipment which exceeds the indicated loading.

3.7.1 Training Floor. The training floor is the floor inside the fire compartment that the trainees walk on. This floor should be steel grating to give sure footing, good distribution of ventilation air which comes from below, and instant removal of firefighting agents. Unburned propane can be introduced into the compartment during flame suppression; therefore, even distribution of ventilation air is important to dilute it and flush it away. This floor should be supported from the crawl space floor below and the walls. Grating should be made of mild steel and should be hot-dipped galvanized with a maximum vertical depth of 25 mm and holes that are 19 mm by 50 mm maximum, from centerline to centerline. Benefits of high temperature steel grating material are not cost effective in the firefighting facilities. A nonskid surface should be provided on the grating. Grating should be sectionalized and securely fastened so it can easily be removed for maintenance. Two men should be able to handle each section. Refer to par. 3.7.6 for additional requirements for grating. The training floor should meet the following additional criteria:

a) Floor support steel should be indirectly attached to the walls and crawl space floor to allow room for thermal expansion. Connections should have slotted bolt holes to allow for thermal expansion. Floor support steel should be hot-dipped galvanized.

b) Areas designated as fireplace locations should be free of lights, equipment, flooring, and floor support members. The perimeter of the fireplace area should be designed, as shown in Appendix A, Figure A-9, to support the future device mockup around its perimeter. Fireplace support should be 70 mm below the trainer floor. Since this area will remain open until the device contractor installs the mockup, a temporary post and chain railing should be provided around the perimeter.

Design Note: Drawings should show locations of sectionalized grating. Grating sections should be dimensioned and sized on drawings. A note should be provided on drawings to indicate the contractor should use the dimensions given as a guide only. Adjoining grating sections should match and be at the same elevation.

3.7.2 Crawl Space Floor. The crawl space floor should be located directly under each training floor. Each crawl space floor should be at or above grade for safety reasons. It should be constructed of concrete. The functions of the crawl space floor are to collect agents which come through the training floor grating, to separate training compartments in the case of two-story structures and provide a platform for the maintenance of burner and sensor equipment. The crawl space floor should have chamfers where the walls meet the floors. The cants should be 150 mm high and 150 mm wide.

a) Where the crawl space floor meets any wall, provide a 150 mm high by 150 mm wide cant strip, fillet or curb. The purpose of this cant strip is to prevent propane gas from accumulating in the corners of the floor or wall interface. The cant strip will allow the propane gas to flow away from the walls.

Caution: Wastewater piping leading from a crawl space should be routed to a separation chamber prior to discharging into the piping leading to the propane in the piping. The separation chamber should be provided as shown on Figure A-15 of Appendix A.

b) There should be 1372 mm of clear space between the structure of the training floor and the crawl space floor, unless noted otherwise. This area should remain clear of obstructions to allow for burner tubes and burner equipment. The perimeter of the crawl space should be as open as possible for burner tube installation and access to ventilation air. However, for heating, ventilating, and air conditioning (HVAC) equipment placement, ductwork, and piping runs in the crawl space, should be limited to a space 600 mm wide above the louvers, along the exterior wall. Space in front of the crawl space louvers should not be used, since it is the path of the ventilation air. In addition, the heated supply air duct for cold weather trainers can be located outside.

c) Personnel access should be provided to crawl space areas. Ground level accesses should be ramped to facilitate dolly traffic.

3.7.3 Staging Floor. The staging floor is the area where the students are organized before starting a firefighting sequence. The staging floor can be made of concrete or grating. The concrete design should have generous slopes to channel away water and collect it for treatment. If the area is exposed to the rain, the collection piping should be configured to allow rainwater to bypass the treatment system. The staging floor should be designed to meet the following additional criteria:

a) A catchment should be provided by each trainee door to ensure that the agent used by the trainee to cool the door is directed to the treatment system. Rainwater should be handled as stated above.

b) When the staging area is above a fireplace compartment, as in the case of roof staging, the flooring must be separated from the heat generated in the space below. Galvanized steel grating should be provided in these areas. The grating floor should be at least 508 mm above the concrete

ceiling of the fireplace compartment. This concrete ceiling should be sloped to drains located above each fireplace compartment.

c) Trench drains should be provided.

3.7.4 Maintenance Floor. The maintenance floor is used in the electrical rooms and should be constructed of concrete with no covering.

3.7.5 Computer Floor. The computer floor is a raised computer deck conforming to MIL-F-29046, Flooring Raised, General Specification for. Twelve inches of clear space should be provided under the decking. This flooring should be used in the instructor's station(s). The adjacent electrical room does not require a raised computer deck.

3.7.6 Grating Floors and Platforms. For grating floors and platforms located outside, provide galvanized steel grating with a non-skid surface. Grating should be hot-dipped galvanized, open type, 25.4 mm by 4.7625 mm bars, welded with section modulus of 5625 cu. mm, moment of inertia of 71,552 mm^4, and maximum weight of 36.112 kg/sq. m.

3.8 Walls. Walls around training compartments should resist thermal cycling from 538 degrees C in the fire area to the coldest ambient temperature at the site, plus the effect of cold water applied during the extinguishment of the fire. Walls should not be porous because, in colder climates, the wetted wall could be damaged when the water freezes. Walls should withstand the mechanical stress of a stream of high-pressure water.

3.8.1 Wall System. Walls directly behind the cable raceway, electrical panel, trash can, storage compartment, and dryer fireplaces should not have columns in them and the crawl space directly below should also be free of columns. Holes up to 0.18 sq. m will be cut through the walls in these areas by the device contractor. Holes any larger will be structurally reinforced by the device contractor.

In addition, walls surrounding fireplaces should be lined with a steel panel. The panel and its supports should

allow for thermal expansion. Weathering steel (ASTM A588/A588M, Standard Specification for High-Strength Low-Alloy Structural Steel With 50 psi (345 MPa) Minimum Yield Point to 4 in. (100 mm) Thick or ASTM A242/A242M, Standard Specification for High-Strength Low-Alloy Structural Steel should not be used because the rust is not self-limiting in this application. Steel liners protect the refractory coating from the effects of the water spray and raise the training compartment temperature by reflecting the heat back into space.

a) The refractory system should be a one-inch thick calcium silicate board like "Westtemp" as manufactured by Fire Facilities, Inc. of Antioch, IL.

3.8.2 Windows. Windows should be provided in training compartment walls as shown on the floor plans in Appendix B, Figures B-3 and B-4; Appendix C, Figures C-2 and C-3; Appendix D, Figures D-1, D-2, and D-3. These windows provide a means for spectator viewing. Windows should be 139 sq. m be made of heat strengthened glass, and have hinged, sheet metal covers on the outside.

3.8.3 Cool Down. Walls adjacent to fireplaces will probably overheat, so a method to cool them down between training exercises should be provided. The preferred method is a water spray system consisting of nozzles and a motorized valve wired back to the data terminal cabinet, which will have manual control. The motorized valve should have a manual bypass which will be used for the trickle cooling flow control. Nozzles should be located so that water dripping from them will not detract from the training. These nozzles and their piping will require an adjustable flow rate of water to maintain a trickle to protect them from the heat.

The main purpose of the cool-down system is to provide cooling of the wall and ceiling steel plate liners after a training scenario. The spray nozzles are controlled by a solenoid valve via the DTC/device computer. There should also be manual control by the hand/off/automatic switch. Dripping is accomplished by a manual bypass globe or needle valve. This valve bypasses the solenoid. The spray nozzle should be open type, stainless steel (316 SS) with 125 degree spray pattern, 10 mm orifice. Install cooling nozzle in pendant position.

Cooling spray nozzles should be directed horizontally or 30 degrees down from the horizontal and towards the wall at the fireplace with the spray hitting ceiling and wall liners. The nozzle should not be located over fireplace openings because the constant water drip is not desired over the device equipment. A minimum flow of 1.893 L/s is used for each nozzle.

Note: NAVAIRWARCEN Training Systems Division has the final say as to the location of these nozzles. They do not want direct spray onto their device equipment. They may require some of the nozzles be relocated during their facility (construction site survey) inspections. Some of the manufacturers that can meet the above requirements are:

Spraying Systems Co., (312) 665-5000
Bete Fog Nozzle, Inc., (413) 772-0174

3.9 Roofs and Ceilings

3.9.1 Training Compartment Ceilings. Ceilings in the training compartments should be constructed of reinforced, lightweight concrete with a refractory coating of sprayed on calcium aluminate cement. No alternates are acceptable. When a steel false ceiling is required, it is to help control trainer compartment heat and to protect the refractory coating.

3.9.2 Staging Area Roofs. Roofs over staging areas should protect trainees from the elements, such as the hot sun in the south and the snow in the north. Staging areas should have a roof.

In those structures where the roof access enters the fireplace compartment directly, the access way should be shielded to impede the escape of hot gases. The shield should be constructed of steel plate which should form a rectangular box. The box should surround the inclined ladder. The bottom edge of the box should stop 2000 mm above the training floor in Compartments 1 and 2 of the 19F1A and 2750 mm above the floor in the 19F3-B1 structure. The forward side of the box should be far enough in front of the ladder so a person descending the ladder cannot bump his head. The shield should be airtight where it meets the ceiling.

3.10 Instructor's Station and Electrical Space. Each 19F series trainer has its own instructor's station which, along with the adjacent electrical space, houses most of the electronic equipment associated with the device. Operations of buildings associated with a given device are controlled from the instructor's station. A single point ground plate is required for trainers. Grounding plates are required in the instructor's station and its accompanying electrical room under the raised computer room flooring. The instructor's station and electrical space should be waterproof from the outside weather.

3.10.1 Air Conditioned Space. The instructor's station and adjacent electrical space should be designed as an air conditioned office. When the instructor's station is adjacent to a training compartment, it should be thermally insulated from it, including structural members.

3.10.2 Temperature and Relative Humidity. Environmentally control the instructor's station and the adjacent electrical room to 25.5 degrees C and 50 percent relative humidity in the summer and 20 degrees C and 30 percent relative humidity in the winter. Wintertime humidification and reheat for summertime dehumidification is not a requirement. In accordance with NAVFAC MIL-HDBK-1012/1, Electronics Facilities Engineering, dehumidification should not be provided in the air conditioning unit for an electronic equipment space. The instructor's station and adjacent electrical room should be individually controlled by independent thermostats.

3.10.3 Fire Protection. A fixed, fire protection system is not required for the instructor's station or the adjacent electrical space. However, portable CO_2 extinguishers should be provided by the facility contractor. Refer to par. 4.4 for the requirements of portable CO_2 extinguishers.

3.10.4 Window Glass. The window glass size and location should be as indicated in the specific device sections. Glass should be the insulated, shatter-resistant type. The bottom of the window should be 900 mm above the floor.

3.10.5 Plugged Tap. Each instructor's station will have an analog pressure indication for the firefighting water supplied

to the structure. Its location should be clearly indicated on the facility drawing. The sensor should provide the analog pressure signal to the gauges in the instructor's station and should have a DTC connection.

3.11 Ventilation

3.11.1 General. The facility exhaust system serves three main functions:

a) Continuously purges the structure of unburned fuel;

b) Provides the secondary air necessary for complete combustion and realistic fire characteristics; and

c) Collects products of combustion for possible treatment.

Ventilation air should be induced into each building by the exhaust fans. Provide air test ports throughout the system for testing and balancing. Burner rooms should be ventilated to control heat buildup and to cool the room for summer temperature control. Ventilation flow rates (L/s) come from NAVAIRWARCEN Training Systems Division and fleet project teams. Provide details on how to seal space around high temperature ducts at wall, floor, and roof penetrations. High temperature exhaust fans should have total enclosed fan cooled motors, when located outside in the weather.

3.11.2 Purge. Purging of the facility exhaust system should meet the following criteria:

a) Ambient air should enter the building through louvers in the crawl space perimeter. When there is a burner room adjacent to the crawl space, the crawl space perimeter should be left open to the burner room and the louvers located in the burner room exterior wall. The building design should allow free air movement in the burner room and crawl space and prohibit the possibility of any stagnant air spaces where unburned fuel could accumulate. Fuel is heavier than air and could create an explosive situation if not flushed away.

b) Purge air should flow at the full design rate.

3.11.3 Combustion Air. The exhaust system should deliver sufficient air to allow complete combustion. In the case of propane, it takes 23 parts of air for each part of fuel for theoretical complete combustion. Device burners do not provide any primary air therefore combustion air must be provided by the facility ventilation. In addition, enough excess air must be delivered to provide realistic flame characteristics. When a fuel is burned in the open, the flame induces into it approximately 10 times the air needed for perfect combustion. The trainer should be capable of providing this air to produce a natural looking fire. This excess air should enter the compartment at low velocity and not be directed at the flame.

3.11.4 Exhaust. The exhaust system should be designed to conform to the following criteria:

a) Once inside the compartment, the air should be heated, collected at the ceiling, ducted to a common point then to the exhaust fans and then to the treatment if necessary. The duct and fan layout should allow for the future addition of a pollution control device. Every attempt should be made during the design of the structure to ensure that air is collected and leaves the structure through the exhaust system. Minimize leaks. Roof entries provide another escape path for the products of combustion and should be ducted into the exhaust system through manual dampers.

b) Each training compartment should have a separate duct to carry away the products of combustion.

c) The exhaust stack should be designed to have a height of 1.4 to 2.0 times the training structure height, which would eliminate short circuiting and contamination of fresh air entering the trainer. The stack should be designed to meet the American Conference of Governmental Industrial Hygienists (ACGIH) 2080, Industrial Ventilation, A Manual of Recommended Practice.

d) A low velocity area should be provided prior to the exhaust fan inlet to allow the PKP particulate to settle

out. The duct system should have provisions for cleaning out the PKP particulate which will settle out. Access doors and low velocity areas should be used in long horizontal runs and at the base of vertical runs. Provide a 50 mm trapped drain in the duct section.

3.11.5 Dilution Air. Dilution air should be required to protect the compartment environment from a buildup of products of incomplete combustion, unburned fuel, and heat. Air specifically for dilution is not needed. This requirement is satisfied by secondary air.

3.11.6 Equipment

3.11.6.1 Louvers. Louvers should run continuously around the perimeter of crawl spaces. They should be sized for a maximum pressure drop of 25 Pa at the design "air in" flow and be a minimum of 460 mm high. Louvers should be of corrosion-resistant material and designed so they can be removed individually for maintenance. Louvers should be designed to meet the following additional criteria:

a) In areas where snow accumulation can be expected on a regular basis, the design of the louver system should prevent drifting snow from blocking the openings.

Caution: The structure should never be operated with any portion of louver openings blocking the free entrance of air. Unburned propane could easily build to the LEL in pockets if ventilation is impeded.

b) In climates where the annual heating degree days are greater than 1093 degrees C, perimeter louvers should be provided with motorized dampers. Motorized dampers allow the crawl space to be closed during unoccupied hours so the crawl space can be maintained above freezing.

3.11.6.2 Dampers. Where more than one compartment is connected to the exhaust fan system, the air from each duct should be controlled by a motorized, modulating, floating point damper from the instructor's station. In the "automatic" mode, the damper should be controlled by the device computer. In the

"hand" mode, the damper should be controlled by an open-stop-close pushbutton set. The damper should be capable of infinite positioning in either mode of operation.

a) Motorized dampers connected to the DTC in the instructor's station should be provided with a positive feedback control. Damper position status should be provided in the instructor's station. Floating point dampers should be provided with a modulating control output and the two position dampers should have binary control. See Appendix A, Figures A-18 and A-19.

b) Variable speed motor should be provided for the primary fan in each system, so the fan can be economically turned down during periods of no fire. This control would operate from reduced flushing flow to fully open when directed by the device computer. Any control used should have the following requirements:

(1) Modulation controls should have positive feedback and interface with the DTC.

(2) Exhaust fan controls should provide means to indicate in the instructor's station the following status:

Fan on-off condition
Damper position
Fan modulation - rpm (only if variable speed control is used)
Alarm air temperature
Exhaust air temperature

(3) The exhaust system should be provided with safety warning signs to indicate personnel hazard from heat of ducts.

c) A manual damper should be located in the duct leading from all compartments so the maximum exhaust flow from that space can be limited.

d) Dampers should be designed for high temperature operation at 538 degrees C. High temperature dampers should be constructed of stainless steel, same material as the ductwork.

Bronze bearings should not be used in high temperature dampers. Bronze bearings have a maximum temperature rating of 149 degrees C. Other bearing materials which should not be used in high temperature dampers are: nylon, Teflon, and stainless steel. The following bearing is acceptable for use with 538 degrees C high temperature dampers:

MATERIAL	BEARING TYPE	MAXIMUM TEMPERATURE RATING DEGREES C
Carbon and/ or Graphite	Sleeve	538

e) Dampers should be electrically operated and should be installed in the exhaust ductwork outside of the training compartment. Damper actuators for high temperature dampers should be accessible for maintenance.

f) Dampers should have a quick opening and closing time. The maximum time of operation of the dampers from any position to another position should be 15 seconds.

3.11.6.3 Fan. The exhaust system for each building should be sized to pull approximately two times the "air in" rate due to volumetric expansion of the heated air. These values are listed in Table 1 entitled "Main Ventilation Air for Fireplace Compartment" for each structure. Design temperature for flow calculations should be 315.5 degrees C. The design temperature for materials should be 538 degrees C. The fan and the exhaust system should meet the following criteria:

a) The exhaust system should consist of at least two fans totaling 100 percent of the ventilation requirement. The exhaust system should be designed for operation at 538 degrees C and should be provided with high temperature expansion joints suitable for operation at 538 degrees C in lieu of flexible duct connectors. The exhaust system ductwork should be constructed of low carbon stainless steel, 304L or 316L. Carbon steel should not be used because of high temperatures; the corrosion rate is increased and its structural strength is reduced due to the segregation of carbon. Ductwork design pressure should be noted on the drawing and should be based on the addition of the following:

(1) Maximum suction pressure of the exhaust fan at no flow conditions.

(2) Wind loads.

(3) Live load of 100 kg/sq. m on the top of horizontal exterior duct and inside horizontal duct areas of access.

(4) Interior horizontal duct loading of 14 g dust/(System L/s) equally distributed across the duct system horizontal surfaces.

(5) High temperature ductwork should be designed and constructed in accordance with Sheet Metal and Air Conditioning Contractors' National Association, Inc. (SMACNA), Industrial Duct Construction Standards and ACGIH, Industrial Ventilation Guide. Ductwork should be welded. Welding procedures should be carefully specified and should be either American Society of Mechanical Engineers (ASME) or American Welding Society, Inc. (AWS) and should incorporate pure argon shielding gas. Suitable procedures are described in AWS B2.1.005, Standard Welding Procedure Specification (WPS) for Gas Metal Arc Welding of Austenitic Stainless Steel (for austenitic stainless steel) and AWS B2.1.006, Standard Welding Procedure Specification (WPS) for Gas Metal Arc Welding of Carbon Steel to Austenitic Stainless Steel (for carbon steel to stainless steel), except use pure argon shielding gas. Procedure AWS B2.1.006 is used for welding the duct to any structural support member. Use a low carbon and low hydrogen welding rod.

b) Several factors should be considered in the selection of a fan type. The fan horsepower and energy consumption should be as low as possible. Motors for exhaust fans should be sized for the lowest outside ambient temperature. The fan should be able to ride the fan curve to 50 percent of its design flow rate without adverse effects.

c) Noise is a consideration. A fan should be chosen for quiet operation and located in a sufficiently remote area so as to not interfere with training.

d) Manually adjustable inlet dampers should be provided for flow adjustment and segregation for maintenance.

e) Provide pressure drop indication across each fire compartment exhaust fan. The analog indication signal should be routed to a remote indicator in the instructor's station and then to the DTC. In addition, a pressure switch(es) should be provided which will sense the differential pressure across each fire compartment exhaust fan. The switch should have an adjustable setpoint that when reached will shut off the fan and send a binary signal to the DTC. The setpoint should be chosen to indicate impending fan surge or to ensure that the ductwork will not implode. If the airflow is restricted too much, the switch will stop the fan before equipment is damaged.

Table 1
Main Ventilation Air for Fireplace Compartment
of 21C12 and 21C12A Structures

PROPANE DEMAND L/s	VENTILATION AIR OUT AT 315 degrees C L/s
96	34 456

Notes: 1. Fan static pressure should be determined by comparing two modes of operations:

a. During burner operation: bring 15 degrees C air through the louvers and exhausting 315 degrees C air through the exhaust system.

b. Between firefighting scenarios (burners off): bring 15 degrees C air through the louvers and exhausting 15 degrees C air through the exhaust system.

2. The fan motor should be sized for bringing the lowest ambient air temperature expected through the louvers and exhausting it at the same temperature.

3.11.7 Control. Control of the ventilation should be performed as follows:

a) Before the start of training each day, the ventilation system should be energized with motorized dampers open and doors closed (in those structures with doors) to purge the structure of any unburned fuel which may have accumulated overnight. The purge should last at least 3 minutes.

b) When treatment equipment is required, a ventilation system control scheme should be provided to satisfy the device requirements discussed above, plus the treatment equipment in an economical manner.

c) Any motorized airflow adjustment device should be controllable by the device computer. The fans should run continuously or be off if not needed for extended periods of time. Floating point motors are for future sophistication.

d) To prevent back spin during startup of exhaust fans, provide the following:

(1) Individual controls for each fan and have it interfaced with the DTC.

(2) Each fan should have a two position back spin prevention motorized damper at the fan inlet. The damper should remain closed until the fan is started.

3.11.8 Preheat. In extreme climates where the annual heating degree days is greater than 2000, the ventilation air will require preheating. In trainers where the trainee walks into the path of the ventilation air, such as, bilge, berthing, or trash can fires, the air must be preheated. Where the trainee does not walk in the air path, as in the pit fire, the preheat temperature can be reduced for energy savings. The air passing through the burner rooms in extreme climates should be preheated. The preheating system should meet the following criteria:

a) Heating equipment should be sized to heat the design airflow from the low ambient design temperature to 10 degrees C. (This temperature was chosen because the heating

design temperature is at night and only occurs during a small percentage of the time. Such a system would provide 15.5 degrees C air 95 percent of the time.)

b) Design of the preheat system should not compromise the crawl space purge requirement. The preferred preheat system is to heat outside air and to distribute air over the louver, motorized damper, and backdraft damper combination in the crawl space. Air should be heated from outside ambient temperature to a temperature hot enough to allow a mixed air temperature of 10 degrees C. Mixed air is comprised of cold outside air from the louver combination units and hot air from the preheat system. The preheat system should be designed to heat the ventilation air by adequately mixing the air coming from louver combination units and the preheat system when the fire compartment exhaust fans are either exhausting 315.5 degrees C air (burners operating) or 10 degrees C air (burners off).

3.11.9 Other Rooms

3.11.9.1 Burner and Electrical Rooms. Some training structures have separate burner and electrical rooms. These rooms should be provided with filtered ventilation air which can be discharged directly to the outside, separate from the facility ventilation system. Fans in these rooms should run continuously while training is being conducted in that portion of the building. Control for this system should be by an HOA switch wired to the DTC. When there is no propane burner in the electrical room, the ventilation is for summer heat removal and should be controlled by a local wall switch in parallel with a thermostat. This ventilation does not apply to air conditioned electrical rooms associated with the instructor's station. Doors for electrical rooms should be 1200 mm wide.

3.11.9.2 Escape Trunks. Escape trunks should be provided with an exhaust fan located just below the roof hatch. This wall mounted fan should be wired to the DTC in the instructor's station so that anytime the escape trunk becomes too hot for training, the instructor can activate the fan. The exhaust fan for the escape trunk should be thermostatically controlled and should interface with the DTC.

3.11.10 Safety

3.11.10.1 Fuel Sensors. Ventilation should be designed to eliminate the possibility of any accumulation of unburnt fuel. Because fuel settles in low unflushed areas, careful crawl space and facility ventilation design can preclude this. To monitor this condition, the device includes fuel sensors located in the crawl space and in the electrical rooms which contain burners. These sensors sample their immediate location for fuel in excess of a percentage of the LEL. If an excess is registered, they shut down the control console in the instructor's station and sound an alarm. These sensor systems, installed by the device contractor and maintained by the using activity, should be located in strategic places.

> Caution: Sensors and the ventilation system should be kept in good working order to prevent an incident.

3.11.10.2 24-Hour Propane Alarm. If the trainer is not in operation and 24-hour propane sensing is in effect, a means for remote alarm activation should be provided (by device computer) at the DTC. Any alarms or other indicators are the responsibility of the facility contractor. The DTC will be the interface where the facility contractor will receive the 24 Vdc continuous signal. A 24-hour propane alarm from the DTC should be provided at the 24-hour duty watch station. Refer also to par. 2.2.3.1.

3.11.10.3 Fan Interlock. Another level of safety should be provided to prevent the danger of accumulated unburned fuel in the trainers. Danger from accumulated unburned fuel in the trainer during the occupied period can be adequately eliminated by a system of ventilation fans, sensors, and interlocks. During unoccupied periods the risk is reduced by natural ventilation and proper operation of the purge fan. Proper operation during occupied periods requires flushing the crawl space prior to energizing crawl space electrical circuits. Crawl space electrical circuits therefore, should be interlocked with main exhaust fans. At least one fan should be operating during the maintenance period before training. Fans and dampers as interlocked in the sequence in par. 3.11.9.1 should be further interlocked to include a timer relay to energize electrical circuits after a 3-minute delay from the key operated

HOA switch. The timer relay will alleviate the human error of energizing the crawl space electrical circuit prematurely. Refer to Appendix A, Figure A-20.

3.11.10.4 Insulation or Shielding. Where exhaust ducts pass from one fire compartment into the occupied space of another, they should be shielded or insulated or otherwise outfitted to ensure that personnel cannot be burned. If insulation is used, its jacket should be able to withstand the heat and force of a hose jet.

3.12 21C12 and 21C12A Structures

3.12.1 General. The 21C12 and 21C12A structures will be used to provide hands-on practical firefighting, training for submarine personnel. The structure is designed to train a class of 25 students maximum. Refer to par. 3.1, subpars. f) through h) for class types.

3.12.2 Siting. On some projects, the 21C12 and 21C12A will be combined with the 21C6, submarine damage control trainer. Criteria for the 21C6 device is maintained by NAVAIRWARCEN Training Systems Division in Orlando, Florida. The 21C6 may only be physically attached to the 21C12 and 21C12A trainers at the bulk storage room. However, access to the bulk storage room via ramp and truck platform is required. Other exterior walls of the 21C12 and 21C12A should remain exposed to the outside.

3.12.3 Architectural. Floor plans for the 21C12 and 21C12A structures are provided in Appendix G.

3.12.3.1 Layout. The 21C12 and 21C12A structures should consist of one fireplace compartment containing three fireplaces. The compartment is accessed from staging areas on either side through a submarine watertight door. There are two submarine doors in the 21C12 and 21C12A structures. All three fireplaces should be able to run simultaneously.

Mechanical Equipment Room: A 232.25 sq. m (floor area) mechanical equipment room should be provided as a second floor above the bulk storage area.

3.12.3.2 Fireplace Compartment. The fireplace compartment should meet the following criteria:

a) Bulkhead should be located to maintain a clearance from the backwall of 228 mm plus or minus 12.7 mm. One wall should simulate a curved bulkhead. There should be two 3000 mm lengths of bulkhead, 3810 mm high with a curve radius of 4572 mm supported by ribs. Bulkheads should be spaced 4572 mm apart. Each bulkhead should have three support ribs spaced 900 mm apart. Ribs should be T-shaped, 254 mm high with a 203 mm top and constructed of 6.4 mm steel plate. Bulkheads and ribs should be made of steel in accordance with ASTM A36, Structural Steel. Wall ribs will be insulated by the device contractor to give a submarine-like appearance. The wall on the opposite side should be a vertical wall because it is hidden from the trainees by a 2150 mm, steel partition. This partition should contain two emergency air breathing (EAB) outlets located in 304 stainless steel housings which will shield the EAB outlets from the fires. EAB outlet housings are designated as "EO" in Appendix G. The emergency corridor is behind this partition. The corridor is not part of the training compartment and therefore does not have to retain a submarine-like appearance. Provide a 102 mm high steel kickplate around the edge of the training floor by mockups and fireplaces at the grating floor as shown in Appendix G, Figure G-1. The kickplate should minimize the trainee's feet from slipping into mockups and fireplaces. Broom finish concrete floors located in fireplace compartments. Provide two floor drains in the emergency corridor.

b) Short masonry walls opposite the partition should support the SHS1 hose station and EAB cabinets. The main walkway and emergency corridor floors should be concrete while the 1200 mm wide walkways leading to fireplaces should be steel plate. A grating equipment floor should be 310 mm below the training floor which should be continuous under the mockup. Mockups should be mounted on the grating equipment floor. Mockups should be located within 76 mm of steel walkway to preclude someone from getting their foot caught in the void. The device contractor should provide a personnel safety barrier between the mockups to prohibit a person from falling onto the grating equipment floor.

c) The facility contractor does not have to provide a temporary railing around the walkway since the grating equipment floor will be only 310 mm below. A chain railing should be provided by the facility contractor around the bilge fireplace.

3.12.3.3 Crawl Space. There should be a crawl space below the grating portion of the training compartment which maintains a 1372 mm clear space between the equipment floor and the floor of the crawl space. The concrete crawl space floor should be approximately 1550 mm below the equipment floor. The crawl space should extend below the fireplace compartment and part of both staging areas are as shown on Figure G-1 of Appendix G. Refer to floor plans in Appendix G for additional details.

3.12.3.4 Staging Areas. Staging areas should be at the training floor elevation and should be made of concrete. Each staging area should include 1 combined SHS1 and SHS3 hose station, 1 EAB cabinet, 2 oxygen breathing apparatus (OBA) canister racks, 10 OBA cabinets, 1 shower with hot and cold potable water, 1 water cooler, and doors leading to the outside and the bulk storage area. A portion of the staging area should be set aside for storage of many fire extinguishers required during training. Broom finish concrete floors in staging areas.

a) Hose drying in the 21C12 and 21C12A should be provided in the staging areas. Hose drying consists of naturally drying the hoses on the staging area floor between training classes.

b) Staging areas should be enclosed at the sites. No artificial smoke should be introduced into the staging area. Because of the fireplace compartment ventilation, its artificial smoke should never drift into the staging area.

3.12.3.5 Burner Room. Directly behind fireplaces should be a burner room. Across from each burner is the computer electrical cabinet which operates it. The bilge fire burner will be located in the crawl space.

3.12.3.6 Bulk Storage

a) Directly adjacent to staging areas should be a bulk storage area with the same floor elevation as staging area

floors. This storage space will take bulk deliveries of consumables, store them, and prepare them for use. Extinguishers should be passed between staging and bulk storage, refilled, and returned for use. There should be at least enough extinguisher bottles for three classes.

b) The bulk storage room should include an extinguisher fill station capable of replenishing CO_2, PKP, and AFFF extinguisher bottles. A truck platform should be provided for receiving bulk materials. The configuration should suit the type of packaging expected for the consumables for a given site. Refer to Section 4 for characteristics of CO_2, PKP, AFFF, and their systems.

3.12.3.7 AFFF Fill Station. The foam fill station for the 21C12 and 21C12A structures should consist of a mixing tank, measuring tank, pump, water supply, spill containment, and drain. Foam concentrate should be delivered in 200 L gal drums. A single .631 L/s low head pump should be piped to pump concentrate from the drum to the .631 L/s measuring tank and supply the extinguisher's fill hose. The concentrate should then flow to the mixing tank by gravity. Water should be supplied to the 1137 L mixing tank through an open sight funnel. The mixing tank should have a closed top with a hinged cover, liquid level sight glass, and drain located at the bottom of the tank. A restricted bypass should ensure that there is flow through the pump during extinguisher fill operations when the trigger fill nozzle is closed. Mixing of the solution should be done manually.

a) Hoses 15 mm in diameter should be provided for concentrate suction, solution discharge, and cold water washdown.

b) The fill station should be provided with 820 kPa shop air to supply the propellant charge for the extinguishers. This air should not be supplied from the EAB system compressor but from a separate 820 kPa shop air compressor. Each AFFF extinguisher takes 2 L of air at 689 kPa for a full charge. The compressed air supply for the AFFF extinguisher fill should be

sized for a minimum airflow of 2.36 L/s at 820 kPa. Piping, a means for filling the extinguishers, and a suitably sized air receiver should also be provided.

c) The entire foam fill station should be surrounded by a containment to collect spills. Ramps should be provided for access to the containment. Floor drains should be provided in the containment and in two sites in the bulk storage area where filled bottles will be stored. A room designated as an extinguisher washdown room should be located adjacent to the fill station. The AFFF fill station should be in accordance with Appendix G, Figure G-10.

d) EAB and AFFF fill compressors are sources of loud noise and vibration and should be located to minimize noise and vibration interference with training. Noise control for these compressors should be provided.

3.12.3.8 CO_2 Extinguisher Fill Station. A CO_2 extinguisher recharging station should be provided for the 21C12, 21C12A, 19F5, and 19F5A structures. The recharging system should consist of low-pressure refrigerated bulk storage tank and system with CO_2 at -17.8 degrees C and 2100 kPa, and a manual extinguisher fill pump. The system should be insulated and should have safety valves between isolation valves. Safety valves should vent outdoors. Ensure isolation valves are operable without interference with piping insulation. See Appendix I, Figures I-1 through I-7 for CO_2 details.

3.12.3.9 Repair Lockers. Repair lockers are not required for the 21C12.

3.12.3.10 Ceilings. The ceiling in the fireplace compartment should be 2438 mm above the training floor and constructed of grating hung from the roof. Access to the space above the ceiling should be provided. The roof should be a minimum of 3658 mm above the training floor.

3.12.3.11 Doors. Doors in the training structure should be 44.45 mm, hollow, metal doors unless indicated otherwise. Submarine doors between staging areas and the training compartment should visually simulate the watertight door on a

SSB(N) 616 Class Submarine. However, the door should retain only those functions which are necessary for firefighting training. The submarine door should be mounted in a steel frame bulkhead, located in the concrete wall of the fireplace compartment. Provide stainless steel grip rails with non-slip surface above the submarine doors, on both sides of the walls. Also provide support plates for smoke curtains at the submarine doors in the trainer compartment. The using command activity should provide smoke curtains. A support and door stop should be provided to secure the submarine door when in the open position. The submarine door should be as shown on BUSHIPS Dwg. 805-1400064. The submarine door should be specified as follows:

- Watertight quick-acting (WTQA)
- 316 stainless steel material
- 103.4 kPa test pressure
- Right-hand or left-hand operation
- 457 mm by 914 mm size
- Lever operation - six rotating dogs on frame

3.12.3.12 Fireplaces. The exact dimension of the burn areas are:

	FIRE TYPE	DIMENSIONS
a)	Bilge/ Oil Spray Combination Fireplace	3048 mm by 1219 mm 1548 mm by 610 mm
b)	Hull Insulation Fireplace	4572 mm wide by height of bulkhead (mounted between bulkheads)
c)	Electrical Panel Fireplace	305 mm by 1219 mm

The bilge fireplace should be in the equipment floor of the training compartment. The hull insulation fireplace, oil spray fireplace, and electrical fireplace should be openings in the burner room wall. The oil spray fireplace should penetrate the curved bulkhead or wall behind the bilge fireplace.

3.12.3.13 Instructor's Station. A space 6706 mm by 6096 mm should be provided as a combined instructor's station, electrical, and maintenance room. A raised computer floor should be provided throughout, with 310 mm clear space below the raised floor. Lightweight partitions will be added by the device contractor. These partitions will not support any device equipment without having additional bracing provided beneath the raised floor. There should be no windows in the instructor's station. The instructor's station should be heated and air conditioned.

3.12.3.14 Miscellaneous. Artificial smoke will be introduced in the training compartment only. There will be no artificial smoke in the staging areas or in the emergency corridor.

3.12.4 Mechanical

3.12.4.1 Use Rate. Utilities for the 21C12 and 21C12A structures (see Table 2) are designed to support ten 4-hour classes of 25 students each week (2 classes per day). A class will be divided equally into two groups. Each group will go to a staging area and remain there for the class duration. Fires should be fought by the teams separately and simultaneously. However, only one fire hose will be used at a time since a majority of submarine firefighting is done with portable extinguishers. Table 2 is based on training 250 students per week, 1000 students per month, and 11,000 trainees per year.

3.12.4.2 Firefighting Agents. The 21C12 and 21C12A training structures should contain four hose stations, two stations are the combined type and the other two stations are the individual type. Each of the two combined hose stations should consist of hose stations SHS1 and SHS2. The combined hose stations are located in the staging areas. The two individual hose stations are SHS1 and SHS2 and are located in the fire training compartment. The hose stations should be served by one 40 mm angle-globe valve. Provide a bronze end hose cap with the angle-globe valve for thread ends. The valve should have male hose threads at the cap connection. The angle-globe valve should be perpendicular to the wall and should be served by piping routed in or through the wall. Refer to Section 4 regarding details of hose stations.

Fifteen-lb CO_2, 8.2 kg PKP, and 9.46 L AFFF extinguishers should also be used. Since the use rate for extinguishers will be high, ready storage is located in the staging area. After beneficial occupancy, instructors should locate the extinguishers in the trainer compartment.

Table 2
21C12 and 21C12A Structures

CLASS NO.	NO. OF CLASSES PER YEAR	NO. OF PERSONNEL
A-495-2071	288	(25 PER CLASS)
-2072	24	(12 PER CLASS)
-2073	24	(14 PER CLASS)

PROPANE USAGE

BASIC COURSE A-495-2071

CLASS OF FIRE	NO. OF FIRES/ CLASS (25 STU)	FIREPLACE TYPE	PROPANE DEMAND L/S	PROPANE USE PER FIRE (L)	TOTAL PROPANE L/CLASS
A	13	Hull insulation	49.6	8915	115 889
B	13	Bilge/Oil Spray	42	7471	97 126
C	13	Electrical	4.7	368	4783
	39 Fires per class		203		217 796/ class;

803/class

Notes:
1. Propane demand is based on a gas pressure at the bilge and hull fires of 14 kPa.
2. The design propane demand for the building is 96 L/s.
3. It was assumed that although there are more fires in the 2071 course they do not burn as long; therefore, the total consumption 217 796 L/class, based on the 2071 course, is the design maximum.

Table 2 (Continued)
21C12 and 21C12A Structures

AGENT USAGE

WATER

NO. OF FIRES/ CLASS	NO. OF HOSES/ FIRE	WATER L/s	WATER TIME/ FIRE min	WATER/4 HOUR CLASS L
36	2	13	6	27 288

EXTINGUISHERS

NO. OF FIRES/ CLASS	PKP BOTTLES/ CLASS	PKP L/CLASS	AFFF BOTTLES/ CLASS	AFFF L/CLASS	CO_2 BOTTLES/ CLASS	CO_2 kg/ CLASS
25	12	98	25	98	25	170

Notes:
1. Water is used at the design rate during an 0010 course fire.
2. Extinguisher sizes are 8.2 kg, 9.5 L, 6.8 kg for PKP, AFFF, and CO_2 respectively.
3. AFFF indicated is based on 56.6 g of 40 percent concentrate in 9.5 L of water.
4. Extinguishers are used at the design rate during an 0011 course fire.
5. PKP extinguishers will use 40 CO_2 charges per class.
6. Though water is used for firefighting, extinguishers are the primary method for fighting fires on submarines.

Table 2 (Continued)
21C12 and 21C12A Structures

TOTAL UTILITIES			
	DAILY	WEEKLY	MONTHLY
Propane	305 cu. m	1525 cu. m	6098 cu. m
Water	81 864 L	272 880 L	682 200 L
AFFF Concentrate (100%)	14 L	68 L	212 L
PKP	98 kg	588 kg	2354 kg
CO_2	511 kg	2384 kg	7661 kg

Notes: 1. Daily rates assume three 4-hour classes in the trainer a day.
2. Weekly rates for water assume (10)-0010 and five -0011 classes a week; for extinguishers, assume five -0010 and (10)-0011 classes a week.
3. Monthly rates assume (25) 0010 and (25) 0011 classes.
4. AFFF Concentrate (100 percent) is 20 percent AFFF, 80 percent water.

Caution: Any extinguisher located inside the training compartment must be shielded from fires. If it were exposed to the radiant heat, pressure inside the extinguisher could build to unsafe levels.

3.12.4.3 Ventilation for 21C12 and 21C12A Structures. Ventilation for the 21C12 and 21C12A structures should conform to the following criteria:

a) The design ventilation for the 21C12 and 21C12A should be based on the simultaneous operation of all three fireplaces or 34 456 L/s "air out."

b) The training compartment should have a 330.2 mm diameter ventilation duct which should be used for training purposes. This duct should run above the main walkway and terminate with a cap above the ceiling in staging area 1. The other end should lead to the fan room above staging area 2. There should be a bulkhead flapper at both staging area wall penetrations. A 200 mm branch leading to the fire area should be fitted with a 200 mm female blower adapter to allow the trainees to connect a Red Devil blower. The blower should be used to aid in evacuating smoke from the space during the training exercise. Bulkhead flappers and blower adapter should be provided by the device contractor. The horizontal run and the elbow in staging area 2 should have access panels for cleanout. Device contractor should provide the Red Devil blower and adapter.

c) In the fan room, the trainee vent duct should connect to the main compartment exhaust system through a motorized damper and a manual damper. During a training scenario when the trainee secures the mockup compartment ventilation, the motor damper should close automatically, stopping the flow of smoke into the branch duct. Note the actual compartment ventilation should be unaffected. The fan should run continuously. When the trainee attaches the Red Devil blower to the branch duct and reactivates the trainer ventilation, the motor damper should reopen, discharging into the main exhaust duct.

d) The main ventilation system for the fireplace compartment should have intakes above the ceiling level at the bilge and hull fireplaces, above the entrance to the emergency corridor at the ceiling level at the bilge and hull fireplaces, above the entrance to the emergency corridor at the ceiling level, and at the roof level above the emergency corridor door leading to staging area 2. Each of the intake ducts should have manual dampers for volume control. The main ventilation system should be provided with a floating point damper in the main exhaust duct run serving the fireplace compartment.

e) The main ventilation system duct work should be oversized as follows:

(1) The main duct run should be sized for 100 percent of the fireplace compartment ventilation.

(2) The intake and ductwork for each of the two fireplaces, bilge and hull, should be sized for 100 percent of the fireplace compartment ventilation. The manual damper for each of the two intakes should be set to exhaust 826 m^3/min) at 316 degrees C of exhaust gases.

(3) The intakes and ductwork for the roof level and emergency corridor exhaust point should each be sized for 25 percent of the fireplace compartments ventilation. The manual damper for each of the two intakes should be set to exhaust 207 m^3/min) at 316 degrees C of exhaust gases.

(4) Ventilation exhaust equipment and systems should be designed and selected for continuous operation at 399 degrees C.

3.12.4.4 Air Conditioning and Heating. The electronic equipment in the instructor's station is expected to add 11 237 W to the air conditioning load. This can be broken down into 6629 W in the operator station and 4608 W in the electrical room. Design for five people in the instructor's station rooms. One staging area should be heated during the unoccupied times. The staging area should be designated as a hose drying area where wet hoses can be stored until the next training session.

3.12.4.5 Cooling Spray. Cooling spray nozzles should be located above the grating ceiling aimed to direct water on the mockups. The single water supply pipe leading to the nozzles should have a motorized valve with a manual bypass controlled from the DTC. The cooling will be activated between exercises whenever the training compartment becomes too hot. The cooling system should not be part of the training scenario. Each cooling spray nozzle should have a constant dripping of water to cool compartment walls. Refer to par. 3.8.3.

3.12.4.6 Breathing Air. Two types of breathing apparatus are used in the 21C12 and 21C12A structures, the OBA and EAB devices. The OBA canisters for this structure should be racked in accordance with Appendix G, Figure G-5. There should be two such racks in each staging area for a ready storage of 44 OBA canisters per team. The OBA headpiece should be stored in lockers constructed in accordance with Appendix G, Figure G-7. There should be 10 OBA lockers in each staging area. The EAB outlet housings should be constructed in accordance with Mare Island Dwgs. 612-1889964A1 and 612-1889964A2, see Appendix G, Figure G-11. Housings should have doors. There should be eight EAB outlet housings, four in the fireplace compartment, two in the emergency corridor, and one in each of two staging areas.

> Caution: Care must be taken during design and construction of the breathing air system to eliminate any possibility of the air in the EAB system rising in temperature such that it would be hazardous to health. The EAB system piping should not be routed in the fireplace compartment.

a) Store EAB head gear in a cabinet in accordance with Appendix G, Figure G-6. Two cabinets must be located in each staging area and two cabinets must be located in the fireplace compartment.

b) The EAB system must be in accordance with the schematic shown on LANTDIV Sketch No. SK-M-43-86. The EAB system must be a 689 kPa system. Naval Facilities Guide Specification (NFGS) 15484, Medical Gas and Vacuum Systems, on nonflammable medical gas systems can be used; however, modify the guide specification to suit requirements of this 21C12 and 21C12A criteria.

c) The EAB system should meet: (1) Fed. Spec. BB-A-1034, Source II and (2) 29 CFR 1910, OSHA Safety and Health Standards for General Industry Grade D breathing air requirements. Delete reference to Table II. The EAB compressor should be an oil-free, breathing air compressor: single-stage, positive displacement, non-pulsating, and liquid ring type, Nash Engineering Company, Model OC-5C or equal. To meet breathing requirements, the EAB system may require use of a refrigerated

air dryer and a high purity air filter/cleaner. Fresh air intake to the EAB compressor should be located away from any potential air contamination sources.

d) Air samples taken from the completed system should be tested and approved in accordance with: (1) Fed. Spec. BB-A-1034, Source II and (2) 29 CFR 1910 Grade D breathing air requirements prior to system acceptance and twice per year. The EAB system is not required to be certified per Naval Material Command (NAVMAT) P-9290, System Certification Procedures and Criteria Manual for Deep Submergency System.

3.12.5 Electrical

3.12.5.1 Power. The power requirement for the device should be 35.5 kVA. It should be 120/208 Vac, three-phase, 60 cycle and include 21.4 kVA in the burner room and 14.1 kVA in the instructor's station.

There should be two heavy duty type electrical outlets in the training compartment located on the edge of the main walkway. One outlet should be 480-Vac, three-phase, 60 cycle and the other should be 120-Vac, single-phase service.

3.12.5.2 Lighting. The 21C12 and 21C12A structures parking lot and grounds should be lighted for nighttime operation. The training compartment should be lighted for maintenance from underneath the grating.

Emergency egress corridors should be lighted with low wall fixtures located to be shielded from the fires. Locate switches on both sides of emergency exit doors. These lights should only be used for maintenance purposes so that the lights should not interfere with training.

The device contractor should provide training compartment lighting which is remotely controlled from the instructor's station.

3.12.6 Propane Alarm System. The firefighting training facility should have a 24-hour propane detection system in the trainers. The detection system should be provided by the device contractor and monitored by device computers.

The facility contractor is required to interface with the detection system via a DTC and an alarm system. The facility contractor should provide the following:

a) A DTC for the trainer, refer to par. 2.5.3.2.

b) An alarm system with audible alarms, warning lights (backlighted signs), and manual pull stations.

The alarm system should be wired to the DTC and should consist of the following: (See Appendix G, Figure G-17 for the alarm system schematic.)

3.12.6.1 Central Control Panel. Provide a central control panel at the quarterdeck or 24-hour duty station. The panel should be wired to the DTC, should be UL listed, and should have indicating lights indicating the source of alarm from the DTC, auxiliary control stations, and manual pull stations.

a) Provide manual control on the central control panel for actuating and deenergizing the audible alarms and warning signs.

b) The DTC should be capable of energizing and deenergizing the alarm system.

c) The central control panel with the appropriate label should contain connections for future propane to the fire department.

d) A propane alarm condition can be actuated by the DTC, manual pull stations, central control panel, or auxiliary control stations. The alarm condition can be deenergized only by the DTC, central control panel, or auxiliary control stations. Audible alarms can be deenergized only by auxiliary control stations.

e) In the event of an alarm condition, appropriate warning signs, audible alarms, and the DTC should be alarmed by the central control panel.

3.12.6.2 Audible Alarms. Provide audible alarms at the following locations:

a) Classrooms and offices

b) Locker rooms and restrooms

c) Storage rooms

d) Staging and training areas

e) Quarterdeck or 24-hour duty station

f) Main corridors and vestibules

g) Mechanical and fan rooms

h) Propane storage areas

3.12.6.3 Propane Warning Signs. Provide separate propane warning signs at the following locations:

a) Front entrance

b) Loading dock

c) Quarterdeck or 24-hour duty station

d) Instructor and operator station

e) Propane storage area

Warning signs should be the backlighted type and should flash when there is an alarm condition. Propane warning signs should state "DANGER - PROPANE ALERT."

3.12.7 Manual Pull Stations. Provide separate manual pull stations which actuate an alarm condition at the following locations:

a) Outside propane tank storage area

b) Mechanical rooms

3.12.8 Auxiliary Control Stations. Provide auxiliary control stations which consist of manual pull stations. Auxiliary

control stations should be capable of deenergizing the audible alarms. Provide auxiliary control stations at the following locations:

a) Instructor and operator station

b) Quarterdeck or 24-hour duty station

3.12.9 Intercom System. Provide an intercom system to include the following:

a) Audible alarms should override the intercom system until the alarms have been secured. When audible alarms have been secured, the intercom system should be operable. Intercoms should not be provided in fireplace compartments, crawl space, and burner rooms.

b) The intercom system should have public announcement capability with speakers located in all rooms of the facility, except as noted above.

3.13 19F1A and 19F1B Structures

3.13.1 General. The 19F1A and 19F1B structures should be used to train in the Advanced Shipboard Firefighting Team Evaluation Course, J-425-0424. The structure is designed to train an 0424 class of 30 students and can train two classes or 60 students each week operating a single shift.

3.13.2 Architectural. Floor plans for the 19F1A and 19F1B structures are in Appendix B.

3.13.2.1 Layout. The 19F1A and 19F1B structures contain eight training quadrants on two floors accessible by a centrally located corridor. Staging should be done on the upper level. The structure, including the corridor, should be divided in half by a smoke tight wall allowing for separate and independent training to proceed simultaneously. To better control the products of combustion, the second floor crawl space floor should also be smoke tight. Corridor walls and the escape trunk enclosure should be continuous from the crawl space floor to the concrete ceiling over the training compartment. Provide

ventilation openings at the base of these corridor enclosures on three walls. Personnel access to the space below the corridor floor should be by removing a grating section.

Except for the aforementioned walls, the crawl spaces should remain open and clear. Partition walls should stop at the training floor. Grating should be used exclusively for the training floors in the 19F1A structure.

3.13.2.2 Ceilings. A steel barrier or false ceiling should be provided in Compartments 1 and 2 below the second floor crawl space to facilitate buildup of residual heat so the room stays hot during the whole exercise. The ceiling shields the crawl space floor above from direct radiant heat, keeping it cooler. A clearance of approximately 310 mm should be maintained between the barrier and the walls.

3.13.2.3 Doors and Hatches. The door type should be as shown on the floor plan. Exterior doors on the first and second training levels are for emergency use only. Their location may be shifted to accommodate structural requirements. Hollow metal doors should be used for non-training doors for identification purposes. During search and identification classes, the trainee should be instructed to use only watertight doors.

a) Access to the first floor from the second floor should be through a horizontal large hatch. These hatches are to be located between floors instead of on the roof because the roof location would require the roof to be 2438 mm wider. Also the hatch will get hotter located between floors which is a plus for training.

b) The heat shield for the Ellison door is a definite requirement, however, the shield restricts access to Compartment 1 from the escape trunk. For trainee safety, the bilge fire will be programmed to be off, or in the low fire position, in that corner during escape trunk training so the trainees can walk in that area of the fireplace.

3.13.2.4 Fireplaces. Exact dimensions of burn areas are given in Table 3 incrementally by compartment.

Table 3
Dimensions of Burn Areas for 19F1A and 19F1B Structures Figures

COMPARTMENT	TYPE	SIZE
Compartment 1 5791 by 5791 mm	Bilge Fire	2 rectangular areas 1524 by 3658 mm, 610 by 1524 mm
	Oil Spray	610 by 1524 mm above bilge
Compartment 2 5791 by 5791 mm	Bilge Fire	2 rectangular areas 1524 by 3048 mm, 1524 by 3048 mm
	Obstruction	914 by 1829 mm (914 mm H)
Compartment 3 4572 by 5486 mm	Clothes Dryer	1981 mm H by 1372 mm W by 1016 mm D
	Electrical Panel	305 by 1219 mm (Note 1)
	Obstruction - Laundry Table	762 mm by 1524 mm (762 mm H)
Compartment 4 4572 by 5486 mm	Deep Fat/Stack	610 by 1524 mm (Note 1)
	Wire Bundle (Cable Raceway)	3048 by 457 mm (Note 1)
Compartment 5 4572 by 5791 mm	Radar Display Console	610 by 914 mm
Trash Can		1829 by 1829 mm
	Escape Trunk (No exit)	1524 by 1524 mm
Compartment 6 4572 by 5791 mm	Weapons Fire Enclosure	2134 mm by 2134 mm by 2438 mm H
	Storage Room	2134 mm by 2134 mm by 2438 mm H

Table 3 (Continued)
Dimensions of Burn Areas for 19F1A and 19F1B Structures Figures

COMPARTMENT	TYPE	SIZE
Compartment 7 4572 by 5486 mm	Mattress Fire	2134 by 1067 mm
	Locker Fire	914 by 1067 mm
	"Dummy" Mattress Mockup	2134 by 1067 mm
Compartment 8 4572 by 5486 mm	Motor Generator	914 mm off each wall 914 by 1219 mm
	Vent Duct	3658 by 610 mm (Note 1)

Notes: 1. No hole in floor is required for these fireplaces.
2. Dimensions for fireplace compartment sizes should be clear dimensions. When compartments have refractory coatings and steel plate liners on walls, the inside clear dimension should be from liner to liner.
3. Facility to provide fireplace steel gratings. NAWCTSD will supply drawings and cost estimate to the facility architect during design phase.

3.13.2.5 Enclosures

a) The enclosure in Compartment 4 is designed to complicate the training associated with the cable raceway fire. The enclosure should be 2134 mm by 2134 mm and should have 2600 mm high steel walls, a grating floor, a wire mesh door, and no ceiling. The raceway fireplace should be located 2150 mm above the floor and should be installed by the device contractor who should cut the necessary holes in the steel walls.

b) There are two enclosures in Compartment 6. One encloses the storage room fireplace and the other is the weapons enclosure. The storage room should be 2150 mm by 2150 mm. Walls and the door should be steel frame with heavy chain link fence fabric sides. Walls should be 2438 mm high. No ceiling should be provided. The floor should be a standard fireplace floor which means it should be open until the device is installed. Provide a chain inside the door to prevent entry until the floor is installed. The 2134 mm by 2134 mm weapons enclosure should be 2438 mm high steel in front and adjacent to the storage room. No ceiling. Provide a watertight door. The floor should have a fireplace floor perimeter, however, a temporary grating floor with associated temporary supporting structure should be provided. The weapons fireplace or fire enclosure should be installed sometime in the future, therefore, a temporary floor is more appropriate than a drained entry.

3.13.2.6 Instructor's Station. The instructor's station should conform to the following criteria:

a) The instructor's station should have two personnel doors and two windows with dimensions of 2438 mm by 762 mm.

b) The instructor's station and electrical room below it should be 3048 mm wide and air conditioned. Contractors should be cautioned to seal wall penetrations airtight. Note that other maintenance areas should be ventilated only.

c) Provide a 1550 mm diameter circular stairway between the two floors. The stairway provides secondary access, is circular to save space, and is too narrow for equipment passage. The transferring of equipment can be accomplished by exterior doors and stairs.

3.13.2.7 Miscellaneous. The following are additional architectural criteria pertaining to 19F1A structures:

a) Local OBA cabinets should not be used in the 19F1A structure. The OBA's should be stored in the repair lockers.

b) An escape trunk should be provided in Compartment 1.

c) The inclined ladder leading to Compartments 1 and 2, and 3 and 4 descends greater than 4300 mm, however, no intermediate landing is required. The inclined ladder should be slip resistant.

d) The Foam Reel Station (FR) and Halon systems between Compartments 1 and 2 should be protected from the fire by 1200 mm high heat shields. Heat shields should be constructed of pipe and sheet metal and be sized so radiant heat from the fire cannot reach the firefighting equipment.

3.13.3 Mechanical

3.13.3.1 Use Rate. The 19F1A and 19F1B structures are designed to house 13 distinct fireplaces to instruct a one-day course for two ship's teams of up to 24 members per team. The ship's teams are organized inport duty section fire parties, repair parties, rescue and assistance details and at-sea fire parties (average team size is 18). Each team should be assigned a building half for training. Each side of the building should have three training exercises per hour. Each team should fight a minimum of five fires with a sixth fire as the graded exercise for the course. The graded exercise for the team should be on the opposite building half from which the team trained. A typical schedule should consist of three classes (A, B, C) per week, 108 trainees per week or 5,400 trainees per year.

3.13.3.2 Firefighting Agents. The first and second training floors should have HS1 type hose stations while HS2 hose stations should be installed on the roof staging area. In addition, one foam hose station (FS) and one FR type hose station for foam, should be installed on the roof staging area. The FS by the escape trunk should supply foam to the FR in Compartment 2 and to the FR on the roof. Provide six 6.81 kg CO_2 cylinders, four 13.6 kg PKP cylinders and one 9.08 kg PKP cylinder. These cylinders should be provided by the facility contractor and located and installed by station personnel. Halon 1301 (device contractor installed) should be simulated in Compartment 1 and a foam reel FR, should be provided in Compartment 2. Foam should be used throughout the structure from hose reels and 18.95 L cans.

Provide a 40 mm fire water line to the deep fat fryer fireplace and terminate it with a globe valve below floor grating. The water should be used for APC extinguishing agent simulation.

For propane usage, agent usage, and total utilities, see Table 4.

Table 4
19F1A and 19F1B Structures

FIRE CLASS		TIME	NO. OF FIRES
A	Wednesday	AM	12 fires
		PM	12 fires
B	Thursday	AM	12 fires
		PM	12 fires
C	Friday	AM	12 fires
		PM	12 fires

PROPANE USAGE

CLASS OF FIRES	NO. OF FIRES/ GROUP (15 MEN) 2 DAYS	TOTAL FIRE TYPE	PROPANE DEMAND L/s	PROPANE USE PER FIRE L	PROPANE/ GROUP FOR 2 DAYS
A	3	Trash Can	4.75	425	1274
	3	Mattress/Locker	19.5	849	2547
	3	Steam Clothes Dryer	4.75	425	1275
	3	Storage Compartment	19.5	849	2547
	3	Vent Duct	4.75	425	1274
B	4	Bilge/Oil Spray (Note 1)	66	9905	39 620
	4	Bilge (Note 2)	83	12 395	49 582
	3	Deep Fat Fryer/ Fryer Hood	19.5	849	2547

Table 4 (Continued)
19F1A and 19F1B Structures

PROPANE USAGE (Continued)

CLASS OF FIRES	NO. OF FIRES/ GROUP (15 MEN) 2 DAYS	FIRE TYPE	PROPANE DEMAND L/s	PROPANE USE PER FIRE L	PROPANE/ GROUP FOR 2 DAYS
C	1	Electrical Panel	2.4	212	212
	1	Motor Generator	4.75	425	425
	1	Radar Display	4.75	425	425
	1	Cable Raceway	4.75	425	425
Alternate	6	A, B, or C		849-12 395	56 600
	36 fires/group				158 763 L/ group 580 L/ group

Notes:
1. Compartment 1.
2. Compartment 2.
3. There should be 12 fires per group, 24 fires per class, 72 fires per week.
4. Propane demand is based on a gas pressure at the burner of 7 kPa except for bilge fires which are based on 14 kPa.
5. The design propane demand for the structure is 66 + 83 + 9 = 158 L/s.

AGENT USAGE

CLASS OF FIRE	NO. OF FIRES/ GROUP	NO. OF HOSES 40 mm	WATER L/s	AFFF 6% L/s	PKP FIRE kg	CO2 FIRE	TIME min
A	15	2	4.4				3-5
B	8	1		95	5-9		8-10
C	4					(2)7 kg Bottles	

Table 4 (Continued)
19F1A and 19F1B Structures

AGENT USAGE (Continued)

CLASS OF FIRE	NO. OF FIRES/ GROUP	NO. OF HOSES 40 mm	WATER L/s	AFFF 6% L/s	PKP FIRE kg	CO2 FIRE	TIME min
Deep Fat	3	1	4.4		9		3-5
Alternate	6	1		95	9		

Notes: 1. Bilge fires should be fought sometimes using AFFF and portable PKP bottles.
2. The design water demand for the structure is 4.4 + 4.4 + 6, or 15 L/s.

TOTAL UTILITIES

	DAY 3/	WEEKLY	MONTHLY
Propane	311 300 L	622 600 L	9096 L
Water	166 760 L	333 520 L	1 334 080 L
AFFF Concentrate (100%)	3032 L	6064 L	24 256 L
PKP	227 kg	454 kg	1816 kg
CO_2	114 kg	227 kg	908 kg

Notes: 1. The water category includes the water portion of AFFF (94 percent water, 6 percent AFFF for design).
2. 67 percent of water usage occurs on Tuesday and Thursday.
3. Values listed equal two times the group rates for "19F1A Propane Usage" and "19F1A Agent Usage."
4. The monthly consumption equals four times the weekly values.

3.13.3.3 Ventilation

a) There should be an exhaust duct leading from each compartment with a separately operated motorized floating point damper. These ducts should terminate at the concrete ceiling and not penetrate the ceiling liner. These ducts should come

together above the roof staging area and lead to the exhaust fan system. The collection duct can be as much as 2438 mm wide and the bottom should be no closer than 2134 mm to the staging floor.

b) The design capacity of exhaust fans should be based on the simultaneous operation of compartments or 46 256 L/s "air out." For ventilation air per compartment, see Table 5.

c) The anticipated control is by device computer and is as follows: When a fire is initiated, the building exhaust system should control from flushing to full design ventilation. The damper for the functioning compartment should open to a full design ventilation position. Dampers in nonfunctioning compartments should remain in their minimum flushing position.

d) Although smoke should not be admitted directly into corridors, roof entryways should have an exhaust duct to capture any stray smoke. The duct should discharge into the main exhaust duct through a manual damper.

3.13.3.4 Air Conditioning. Electronic equipment in the instructor's station is expected to add 5274 W to the air conditioning load. Normal occupancy should be eight people. The electronic room below the instructor's station has an air conditioning load of 9816 W due to equipment. Individual thermostatic control of each area is required.

3.13.4 Electrical. The power for the device should be 75 kVA. Provide 120/208-Vac, three-phase service. Provide four lights for each training compartment switched by compartment. Locate a switch for each compartment by the closest crawl space door and another outside by the emergency door. These light fixtures should be provided to light the training compartment by shining up. There should be six lighting circuits per crawl space.

Table 5
19F1A and 19F1B Ventilation Air

COMPARTMENT	PROPANE DEMAND L/s	VENTILATION AIR OUT AT 316 degrees C L/s
1	66	11 942
2	83	14 774
3	5	2171
4	9	4342
5	5	2171
6	9	4342
7	9	4342
8	5	2171

Notes: 1. The design ventilation is the sum of compartments or 46 256 L/s "air out." The minimum flushing ventilation should be as low as the fans can turn down but never lower than 3776 L/s "air in."
2. Fan static pressure should be determined by bringing 10 degrees C air through the louvers and exhausting 315.5 degrees C through the exhaust system.

3.14 19F3 and 19F3B Structures

3.14.1 General. The 19F3 and 19F3B structures should be used to train the General Shipboard Firefighting Training Course, J-495-0412. The structure is designed to train an 0412 class of 108 students and can train three classes or 324 students each week operating a single shift. Approximately 15,500 students can be trained in a year.

a) The location of the four buildings of the 19F3 and 19F3B trainers are flexible; however, consideration should be

given to clustering them around the instructor's station located in the bilge fire building, to minimize control wiring lengths. No building should be further than 18 m horizontally from the instructor's station.

b) Line of sight is not a requirement between the instructor's station and pit fire buildings.

3.14.2 Architectural. Floor plans for the 19F3 and 19F3B structures are in Appendix C. The 19F3 and 19F3B devices are housed in four structures: the bilge fire building, galley/berthing building, and two pit fire buildings.

3.14.2.1 Bilge Fire Building (19F3 and 19F3B). The bilge fire building should have interior dimensions of 9144 mm by 9144 mm with a ceiling height of 4600 mm. This area should house a generalized mockup of a shipboard engineering space to provide realism while exposing students to a major Class "B" bilge fire. Staging should be on the roof and at one ground level entrance. One topside entrance should include a dogged watertight door built into a vestibule, leading to an inclined ladder. Provide reinforcing of the landing to prevent swaying when six students with fire hoses are descending. The ladder should have a 1550 mm long landing midway down its length. At bilge area 1, the dimension from the corner to the shield should be 3124 mm clear. At bilge area 2, the dimension from the corner to the escape truck liner should be 7163 mm clear.

a) The bilge fire building should have a second topside entrance by way of a watertight hatch and emergency escape trunk.

b) A ground level entry with staging area should be located under the vertical ladder in the bilge fire building. The staging area should include a 4572 mm by 4572 mm OBA locker with a ground level entry. The design of the OBA locker should be similar to a repair locker.

c) A 1219 mm wide walkway should be provided around the exterior of the building to allow for emergency egress and to allow exterior viewing of the training scenario. Two sets of stairs should provide access to the roof.

d) A metal false ceiling should be provided in the B1 building to facilitate the buildup of residual heat so the room stays hot during the whole exercise.

e) The perimeter dampers on the B1 building should be 609.6 mm high.

3.14.2.2 Galley/Berthing Fire Building. The galley berthing building should have interior dimensions of 9144 mm by 9144 mm and a ceiling height of 3048 mm. It should be divided in half with one half having mockups to represent a berthing space and having a weapons fire enclosure. The other half should contain a deep fat fryer fire, a cable raceway fire, and an electrical panel fire. Staging and access to the structure should be from staging area at same level as training floor through watertight doors.

a) Provide a 40 mm process water line to the deep fat fryer fireplace and terminate it in a globe valve under trainer floor. This water line should be used for APC extinguishing agent simulation.

b) A 1219 mm wide walkway should be provided around the exterior of the structure for emergency egress and viewing.

3.14.2.3 Pit Fire Building. The pit fire building should be 9449 mm by 7620 mm and contain a 4572 mm by 4572 mm fireplace to teach basic firefighting techniques. The ceiling should be 9144 mm above the training floor. A staging area should be provided so the students enter the structure through a 6096 mm wide by 3658 mm high opening in the wall. No door is required.

a) The floor around the fireplace should be steel plate with a non-slip surface. The floor should slope to the fireplace so agents are channeled to the crawl space. The rear perimeter plate should be 610 mm wide. There is no training requirement for the decking on either side or to the rear of the B3 or B4 building.

b) Columns used to support the fireplace perimeter should be located at each corner, one on each side in the center

and two in the front and back on 1524 mm centers. A vertical barrier should be provided around the perimeter of the fireplace to prevent water from getting beyond the perimeter.

c) Students will walk on the fireplace grating but this grating must be provided by the device contractor along with the weapon mockup ramp. When a device contractor supplied weapon mockup is indicated it must be stored inside the building.

3.14.2.4 Doors. Doors leading to the fire areas of the 19F3 and 19F3B structures must be quick-acting watertight doors. Doors leading to non-fire areas must be hollow metal doors. In the galley/berthing building, the door between Compartments 1 and 2 must be watertight.

3.14.2.5 Fireplaces. Dimensions of specific fireplace locations are listed in Table 6.

3.14.2.6 Instructor's Station. An instructor's station should be located on the roof of the bilge fire building and should control the 19F3 buildings. The instructor's station should be 3658 mm by 7315 mm. Directly below the instructor's station should be an air conditioned electrical space. Window dimensions should be 2591 mm with the bottom 1219 mm above the floor.

3.14.3 Mechanical

3.14.3.1 Use Rates

a) The 19F3 and 19F3B structures are designed to house eight distinct fireplaces to instruct a 2-day course for a class of 108 trainees. The afternoon of the first day, the class is split into two groups of 54 students each. Each group goes to a deck fire building, B3 or B4, where group is further divided into two groups of 27. First group is divided into four hose teams. All four hose teams fight the fire at one time. The second group of 27 is given lectures. Each group will receive a "dropped weapon" fire demonstration at the end of their deck fires. Once fires and demonstrations are completed for each group, the two groups on each building should rotate and repeat lectures and fires.

Table 6
Dimensions for 19F3 and 19F3B Structures Fireplace Locations

Bilge fire building B1	
2 rectangular areas:	2134 x 2438 mm; 1219 x 5182 mm
3 rectangular areas:	1524 x 2438 mm; 1524 x 2438 mm; 2743 x 1524 mm
Obstructions:	610 x 3048 mm x 2438 mm H 3048 x 2743 mm x 1829 mm H
Pit fire building, B3:	4572 x 4572 mm
Pit fire building weapon, B4:	4572 x 4572 mm
Galley/berthing building, B2	2134 x 2134 mm x 2438 mm H
Mattress/locker fire	3048 x 1067 mm
Dummy mattress mockup	2134 x 1067 mm
Mattress/locker mockup	4572 x 1067 mm
Deep fat/stack hood	610 x 1524 mm (Note 1)
Electrical panel	3048 x 1219 mm (Note 1)
Cableway	3048 x 914 x 2438 mm AFF (Note 1)

Notes: 1. No hole in floor is required for this fireplace.
2. Dimensions for fireplace compartment sizes must be clear dimensions. When compartments have refractory coatings and steel plate liners on walls, the inside clear dimension must be from liner to liner.
3. Facility to provide fireplace steel gratings. NAWCTSD will supply drawings and cost estimate to the facility architect during design phase. For Buildings B-3 and B-4, facility to provide fireplace steel grating supports. NAWCTSD will supply drawings and cost estimate to the facility architect during design phase.

b) The second day the class is divided into two groups of 54 students each. Each group then goes to either the B1 or B2 structure. In the B1 building, the group is divided into two groups of 27 students. One group goes to the top level of B1 and one group goes to the bottom level of B1. The top group performs a vertical entry into the space and attacks the oil spray-bilge fire. The lower group should attack the prop shaft bilge fire alternately with the top level group. When both levels have completed fires, groups alternate from the top to the bottom and bottom to the top and repeat. In the B2 building, the group of 54 is also split into two groups of 27 each. The first group of 27 is then split into two groups and each attacks the mattress and metal storage locker fires together from two separate entrances until each member has fought a Class "Alpha" fire as a nozzleman. The second group of 27 fights the electrical panel and the wire bundle fires until each member has extinguished a Class "Charlie" fire. The second group should also watch a demonstration on the deep fat fryer and stack hood fire. Once both groups are finished with their first part of B2, they should alternate with the other group until students have completed B2.

Until completion of each building, the group from B1 should go to B2 and the B2 group should go to B1 until students have completed both buildings.

For propane usage, agent usage and total utilities, see Table 7.

3.14.3.2 Ventilation. (See Table 8). Provide an exhaust outlet above each bilge area and in each compartment. Ducts from one fireplace should not run horizontally through the compartment of another fireplace. The design capacity of exhaust fans for the B1, B2, B3, and B4 buildings should be equal to the maximum building ventilation L/s "air out."

3.14.3.3 Air Conditioning. Electronic equipment in the instructor's station is expected to add 7800 W to the air conditioning load. Normal occupancy should be six people. The electrical room below the instructor's station has an air conditioning load of 7102 W due to equipment. Individual thermostatic control is required for each area.

Table 7
19F3 and 19F3B Structures

CLASS SCHEDULE

BUILDING	MON AM	MON PM	TUE AM	TUE PM	WED AM	WED PM	THU AM	THU PM	FRI AM	FRI PM
B1			X		Y		Z			
B2			X		Y		Z		MAINTENANCE	
B3		X		Y		Z				
			2/	2/		2/				
B4		X	X	Y	Y	Z	Z			

Notes: 1. Day 1 AM, Classroom lecture
2. Day 2 PM, Demonstrations
3. Three classes: X, Y, Z

PROPANE USAGE

BLDG	CLASS OF FIRES	NO. OF FIRES/ CLASS	FIRE TYPE	PROPANE DEMAND L/s/min	PROPANE USE PER FIRE/L	TOTAL PROPANE/ CLASS L
First Day PM						
B3	B	30	Pit	186	16 725	501 759
B4	B	30	Pit	186	16 725	501 759
Second Day						
B1	B	13	Bilge Area 1	79	9509	123 614
	B	14	Bilge Area 2	187	10 584	148 207
B2	A	9	Mattress/ Locker	9	849	7641
	B	9	Deep Fat Fryer/ Fryer Hood	9	849	7641
	C	9	Elect. Panel	2	212	1924
	C	9	Cable Raceway	5	425	3821

Table 7 (Continued)
19F3 and 19F3B Structures

PROPANE USAGE (Continued)

BLDG	CLASS OF FIRES	NO. OF FIRES/ CLASS	FIRE TYPE	PROPANE DEMAND L/s/min	PROPANE USE PER FIRE/L^3	TOTAL PROPANE/ CLASS L^3
Second Day (Continued)						
B3 or B4	D	12	Pit/Weapon	186	16 725	200 704
Alternate		9	A, B, or C	89	10 584	95 258
		144 fires/class				715 000 Class for 2 Days
						43 639 Class for 2 Days

Notes:
1. Propane demand is based on a gas pressure at the burner of 6.89 kPa except for the bilge and pit fires which are based on 13.78 kPa.
2. The design propane demand for each building is:
   B1 79 + 88 or 167 L/s
   B2 9 + 9 or 18 L/s
   B3 186 L/s
   B4 186 L/s
3. The design propane demand for the four buildings together is: 168 + 19 + 186 + 186 = 559 L/s

Table 7 (Continued)
19F3 and 19F3B Structures

AGENT USAGE

BLDG	CLASS OF FIRE	NO. OF FIRES/ CLASS	NO. OF HOSES 40 mm	WATER L/s	AFFF 6% L/s	PKP/ FIRE kg	CO2/ FIRE kg	WATER TIME min
First Day PM								
B3	B	30	51	8				3
B4	B	30	51	8				3
Second Day								
B1	B	27	25	6				3
	B		25		6	114		1
B2	A	9	51	6				3
	B	9	25	6		3		3
	C	9 7.5						
	C	9 7.5	-					
63 B3 or								
B4	D	12	51		8			1
Alternate		9	25	6				3
			25		6	5		1

Notes:
1. PKP should be used in 9 of the 27 fires in the B1 building.
2. The design water demand for each building is:
   B1 (6 + 6) x 2 or 24 L/s
   B2 6 x 2 + 6 or 18 L/s
   B3 8 x 2 or 16 L/s
   B4 8 x 2 or 16 L/s
3. The design water demand for the four buildings together is:
   24 + 18 + 16 = 58 L/s
4. B1 should have nine fires/hour.
5. B2, B3, and B4 should have 15 fires/hour.
6. In B1 each team (12 men) should approach a fire from each of three entryways.
7. B1 fire heights 3048 to 3658 mm.
8. B2 fire heights 3658 to 4572 mm.

Table 7 (Continued)
19F3 and 19F3B Structures

Notes (Continued):

9. PKP and CO_2 in B2 should come from portable extinguishers; 9 CO_2 charges for PKP bottles required per class.
10. Each class should use 72 OBA canisters with each canister being used three times.
11. B3 should have foam provisions similar to B4 so they can be used interchangeably.

TOTAL UTILITIES

	CLASS DAY 2	WEEKLY	MONTHLY
Propane	1 584 800 L	4 754 400 L	69 584 L
Water	265 300 L	795 900 L	3 183 600 L
AFFF Concentrate	5738 L	4548 L	18 192 L
PKP	687 kg	545 kg	2179 kg
CO_2	64 kg	191 kg	763 kg

Notes:
1. The water category includes the water portion of the AFFF (94 percent water, 6 percent AFFF for design).
2. 70 percent of the water usage for a class occurs on the first day of class. However, since the successive classes overlap, the design daily water consumption equals the values for one 2-day class.
3. The monthly consumption equals four times the weekly values.

Table 8
19F3 and 19F3B Ventilation Air

BUILDING COMPARTMENT		MAXIMUM PROPANE DEMAND L/s	VENTILATION AIR OUT AT 315 degrees C L/s	BUILDING VENTILATION AIR OUT L/s
B1	Area 1	79	14 113	63,500
	Area 2	88	15 859	
B2	Area 1	9	4342	8685
	Area 2	9	4342	
	Area 3	2	1086	
B3		186	56 640	56 640
B4		186	56 640	56 640

Note: Fan static pressure should be determined by bringing 16 degrees C air through the louvers and exhausting 315 degrees C through the exhaust system.

3.14.4 Electrical

a) Provide 120/208 V, three-phase service to each of the structures as follows:

B1 building	70 kVA
B2 building	37.5 kVA
B3 and B4 building	25 kVA each

b) Provide the following spare conduits from the instructor's station located at the of building B1 to B2, B3, and B4 buildings as follows:

B2 Building	3 - 76 mm conduit
B3 Building	3 - 76 mm conduit
B4 Building	3 - 76 mm conduit

The above conduits should be used only by the device contractor for both power and control wiring. Power and control wiring should be run in separate conduits.

3.15 19F3A and 19F3C Structures

3.15.1 General. The 19F3A and 19F3C structures will be used to train the General Shipboard Firefighting Training Course, J-495-0412; Advanced Shipboard Firefighting Evaluating Course, A-495-0419; and Advanced Shipboard Firefighting Team Training Course, J-495-0424. The structure is designed to train in a single shift an 0412 class of 60 students and can train up to four classes or 240 students each week; an 0419 class of 30 students and can train up to one class or 30 students each week; and an 0424 class of 30 students and can train up to two classes or 60 students each week. Splitting the year evenly, this trainer can teach 6000 students the general course and 1500 students the advanced team course annually.

3.15.2 Architectural. Floor plans for the 19F3A and 19F3C structures are in Appendix D.

3.15.2.1 Layout

a) The 19F3A and 19F3C structures are a single building which includes 19F1A and 19F1B type structures and 19F3 and 19F3B-B3 buildings connected by a large covered staging area. The respective portions of the 19F3A and 19F3C structures should duplicate the 19F1A, 19F1B, 19F3, and 19F3B-B3 buildings with the exceptions presented herein.

b) Compartments in the 19F1A and 19F1B portions of the structure have been enlarged and fireplaces have been relocated to accommodate the larger General Firefighting Course classes. The 0412 students should stage at ground level and in adjacent compartments on the second floor. Students should not travel between floors during a training scenario. Trainees in the 0424 course should travel between floors and a landing should be provided midway in the inclined ladder leading to Compartments 1 and 2. Doors leading from fireplace compartments in the 19F1A and 19F1B portions should be watertight. Those used by the trainees should be quick acting.

c) The pit fire, B3, or B4 portion is the same as for the 19F3 and 19F3B structures.

d) A 4572 mm by 4572 mm locker with an exterior access should be provided for OBA storage and should be designed as a repair locker. Standard OBA cabinets should be provided in the OBA locker. A wild hose demonstration area is required for teaching in the 19F3A and 19F3C structures. Where the climate allows year around training outside, the wild hose demonstration area should be outside. Trainees would watch the demonstration from the open sides of the staging area. In severe weather locations, the wild hose area should be provided in an area enclosed on three sides with the trainee side open. Means with unrestricted visibility should be provided to protect the bleacher from the hose water spray (a Plexiglas barrier meets this requirement). Refer to par. 2.4.2. Water should come from the HS2 hose station on the opposite side of the staging area.

e) Bleachers should be required in the 19F3A and 19F3C structures and should be capable of seating 120 people.

f) Demonstrations of portable extinguishers should be conducted on the B3 side of the staging area.

g) The staging area should be constructed of concrete or steel grating with appropriate floor drains. If bulk dry storage is to be located underneath the staging area, then a waterproof construction should be used. Subsurface storage should not be considered where there is a high water table or where flooding is probable. At least one-third of ventilation air for pit fireplace exhaust fans should be supplied into staging area.

h) The ventilation system should be manifolded such that Compartments 1, 2, 5, and 6 are on a separate system served by two equal sized exhaust fans. Compartments 3, 4, 7, and 8 should be on a separate system served by one exhaust fan.

3.15.2.2 Doors and Hatches. Doors leading from Compartments 1 and 2 to the staging area should be quick acting and watertight with 180 degree swing. The door leading to Compartment 2 should be installed in a removable panel such that when the door and panel are removed, a 914 mm by 2134 mm minimum opening is

available for the transfer of large equipment. The door should be used for installation and maintenance. A 1829 mm wide, 2134 mm high door should be located in the staging area to accommodate large equipment on hand trucks. The door should have a ramp access. Forklift truck access is not required.

a) First floor burner room doors should be located at each end of the burner rooms. They should be exterior doors except for the northwest corner which should be in the extended stair column. Second floor burner room doors should be accessed from the stair columns as in the 19F1A.

b) A large hatch should be provided at the top of the inclined stairs leading from the first floor and the second floor.

3.15.2.3 Fireplaces. For exact dimensions of fireplaces incrementally by compartment, see Table 9.

3.15.2.4 Instructor's Station. The instructor's station and the electrical room below the instructor's station should be similar to the rooms of the 19F1A and 19F1B. Interior dimensions should be approximately 13 411 mm by 3048 mm. Controls for the pit fire, B3, or B4 portion should be installed in the instructor's station.

3.15.2.5 Miscellaneous

a) No hose drying area is required but provide the following two items for hose drying: an outside hose drying rack and a heated storage for rolled up 15 240 mm long hoses. Rolled hoses should be stored vertically in storage racks. Racks should be designed to hold two rolls high and be located in the OBA locker.

b) P-250 training is a part of the 0412 course; therefore, a facility is required. P-250 training is a requirement for 19F3A and 19F3C structures.

Table 9
Dimensions for 19F3A and 19F3C Structures Fireplaces

COMPARTMENT	TYPE	SIZE
Compartment 1 7620 x 6096 mm	Bilge Fire, Oil Spray	2 rectangular areas 1524 x 3658 mm, 6096 x 1524 mm
Compartment 2 7620 x 6096 mm	Bilge Fire	2 rectangular areas 1524 x 3048 mm, 1524 x 3048 mm
	Obstruction	914 x 1829 mm, 914 mm H
Compartment 3 5487 x 6096 mm	Clothes Dryer	1981 mm H x 1372 mm W x 1219 mm D
	Electrical Panel	305 x 1219 mm (Note 4)
	Obstruction-Laundry Table	762 x 1524 mm (762 mm H)
Compartment 4 5487 x 6096 mm	Deep Fat/Stack Hood	610 x 1524 mm (Note 4)
	Wire Bundle (Cable Raceway)	3048 x 457 mm (Note 4)
	Closet	1219 x 1829 mm
Compartment 5 7620 x 6096 mm	Escape Trunk (No exit)	1524 x 1524 mm
	Weapons Enclosure	2134 x 2134 x 2438 mm H
	Storage Room	2134 x 2134 x 2438 mm H
Compartment 6 20 726 x 7620 x 6096 mm	Mattress/Locker Fire	3048 x 1067 mm
	“Dummy" Mattress Fire	2134 x 1067 mm
Compartment 7 5487 x 6096 mm	Motor Generator Wall	914 mm off each wall
	Vent Duct	3658 x 610 mm (Note 4)
	Enclosed Pit Fire	4572 x 4572 mm
Compartment 8 5487 x 6096 mm	Radar Display Console	610 x 914 mm

Table 9 (Continued)
Dimensions for 19F3A and 19F3C Structures Fireplaces

Compartment 8 (Continued):	
Trash Can	1829 x 1829 mm

Notes:
1. The cable raceway fire should be mounted 2438 mm above the grated floor and should be installed in an enclosure with 2591 mm high walls.
2. Bilge fire heights - Maximum 2743 mm.
3. Pit fire heights - 3658 x 4572 mm.
4. No hole in the floor is required for these fireplaces.
5. Dimensions for fireplace compartment sizes should be clear. When compartments have refractory coatings and steel plate liners on walls, the inside clear dimension should be from liner to liner.
6. Facility to provide fireplace steel gratings. NAWCTSD will supply drawings and cost estimate to the facility architect during design phase for all compartments and pit fireplace. Facility will also provide grating supports for pit fireplace.

3.15.3 Mechanical

3.15.3.1 Use Rate. Utilities for the 19F3A and 19F3C structures (see Table 10) are designed to support four general classes of 60 trainees each week. During the first session, the class should go to the pit fire location. The class should be divided into four hose teams of 15 trainees each. Two hose teams at a time should fight the fire alternately at a rate of 15 fires per hour.

a) During the second session this class should again be divided into four groups of 15 trainees. One group should go to Compartment 1, one should go to Compartment 2, one should go to Compartments 3 and 4, and one should go to Compartments 5, 6, 7, and 8. Each group should stay at a location for one hour then rotate to a different location. Each group should go to either Compartment 1 or 2 but not both.

Table 10
19F3A and 19F3C Structures

PORTION OF BUILDING	MON AM	MON PM	TUE AM	TUE PM	WED AM	WED PM	THU AM	THU PM	FRI AM	FRI PM
Classroom	V	W				X	Y			
Pit Fire/		V	W				X	Y		
Demonstration				V	W				X	Y
Bilge Fire				V	W				X	Y

Notes: 1. The 2 day-course includes a classroom session before fire training and a demonstration session after it.
2. Demonstration should be in front of the pit fireplace, therefore during the second day, another class should not be using this area.
3. Classes, 60 trainees each, are designated as V, W, X, and Y.

PROPANE USAGE

CLASS OF FIRES	NO. OF FIRES/ CLASS (60 MEN) 2 DAYS	FIRE TYPE	PROPANE DEMAND L/s	PROPANE USE PER FIRE L	TOTAL PROPANE/ GROUP FOR 2 DAYS
First Day PM					
B	30	Pit	186	16 725	501 759
Second Day AM					
B	20	Bilge Compartments 1 and 2	83	12 395	247 908
B	32	Deep Fat Fryer/ Fryer Hood	9	849	27 168
A	24	Mattress/Locker, Trash Can, etc.	9	849	20 376
C	24	Radar Display, Elect. Panel, etc.	5	425	10 188
	130 fires/class			807 116 L/class	
				22 046 L/class	

Table 10 (Continued)
19F3A and 19F3C Structures

Notes:
1. Propane demand is based on a gas pressure at the burner of 7 kPa except the bilge and pit fires require 14 kPa.
2. The design propane demand for the building is: 186 + 83 + 83 + 9 + 9 = 370 L/s.

AGENT USAGE

CLASS OF FIRE	NO. OF FIRES/ CLASS	NO. OF HOSES 40 mm	WATER L/s	AFFF 6% L/s	PKP/ FIRE Kg	CO_2/ FIRE kg	WATER TIME min
First Day PM							
B	30	51	8				3
Second Day AM							
B	20	25	6				2.5
		25		6	11		1
B	32	25	6		3		3
A	24	51	6				3
C	24					3	-
	130						

Notes:
1. PKP should be used in 7 of the 20 bilge fires.
2. The design water demand is: (8) 2 + (6 + 6) 2 + 6 + (6) 2 = 58 L/s.
3. PKP and CO_2 used on the fryer and electrical fires respectively should come from portable extinguishers; 32 - CO_2 charges for PKP bottles should be required for each class.
4. Each 0412 class should use 72 OBA canisters. Each canister should be used by three students.

Table 10 (Continued)
19F3A and 19F3C Structures

TOTAL UTILITIES

	CLASS 2 DAY	MONTHLY
Propane	792 400 L	7 414 600 L
Water	197 080 L	23 376 330 L
AFFF Concentrate (100%)	432 L	21 224 L
PKP	182 kg	2633 kg
CO_2	76 kg	1226 kg

Notes:
1. The water category includes the water portion of the AFFF (94 percent water, 6 percent AFFF for design).
2. 45 percent of the water usage for a class occurs on the first day of class. However, since the successive classes overlap, the design daily water consumption equals the values for one 2-day class.
3. The greatest weekly consumption is four times that for a single class.
4. The 2-day class totals are for a 0412 class.
5. The weekly rate is four times the 2-day class rate.
6. The monthly consumption includes seven 0412 classes and six 0424 classes.

b) The following utility rates should easily support the 0419 and 0418 courses because both have fewer fires per class. The 0418 course, when it is taught in the 19F3A and 19F3C, should be similar to when it is taught in the 19F1A and 19F1B. Only one course type can be taught in the 19F3A and 19F3C at any given time.

3.15.3.2 Firefighting Agents

a) There should be a foam reel in Compartment 2 which should get its foam from the FS on the east side of the roof and a FR between the Compartment 1 and 2 exterior doors. This second FR should get its foam from the FS on the west side of

the roof. The interior FR is fed from the east FS because both stations serve the same group during 0418 training. During 0412 training, each FR should be served by a separate FS.

b) Provide six 6.81 kg CO_2 cylinders, four 14 kg PKP cylinders, and one 9 kg PKP cylinder. These cylinders should be provided by the facility contractor and located and installed by the station personnel. Halon should be simulated in Compartment 1.

3.15.3.3 Ventilation. The design ventilation less the pit fire or the 19F1A, 19F1B portion of the structure should be based on the simultaneous operation of compartments or 49 088 L/s "air out." The minimum ventilation should be 3776 L/s. The design ventilation for the pit fire, B3, or B4 portion of the structure should be 56 640 L/s "air out." For ventilation air per area, see Table 11.

3.15.3.4 Air Conditioning. The electronic equipment in the instructor's station is expected to add 6739 W to the air conditioning load. Normal occupancy should be six people. The adjacent electrical room should have an air conditioning load of 9669 W due to equipment and a two-person occupancy. Individual thermostatic control for each area is required.

3.15.4 Electrical

3.15.4.1 Power. The power for the device is 100 kVA. Provide 120/208 V, three-phase service.

3.15.4.2 Lighting. The staging area should be lighted for training after dark. When walkways and stair columns associated with the 19F1A and 19F1B portions of the structure are enclosed, they should be lighted.

3.16 19F4 and 19F4A Structures

3.16.1 General. The 19F4 and 19F4A structures should be used to train the Shipboard Aircraft Firefighting Course, J-495-0413 and the Aviation Facility Ship Helicopter Firefighting Team Training Course, J-495-0414. The structure is designed to train

two 2-day 0413 classes of 60 students and one 1-day 0414 class of 30 students a week. Approximately 6000 students can be trained a year.

3.16.2 Architectural. Floor plans for the 19F4 and 19F4A structures are in Appendix E.

Table 11
19F3A and 19F3C Ventilation Air

COMPARTMENT	PROPANE DEMAND L/s	VENTILATION AIR OUT AT 316 Degrees C L/s
1	83	14 774
2	83	14 774
3	5	2171
4	9	4342
5	9	4342
6	9	4342
7	5	2171
8	5	2171
Pit	186	56 640

Note: Fan static pressure should be determined by bringing 16 degrees C air through the louvers and exhausting 316 degrees C through the exhaust system.

3.16.2.1 Layout. The 19F4 and 19F4A structures are designed to simulate aircraft fires onboard ship. The structure consists of an open training deck measuring 34 138 mm by 20 117 mm with one fireplace. The training deck should be constructed of concrete. The fireplace should be 15 850 mm by 10 973 mm centered leaving two 9144 mm wide and two 4572 mm wide areas for staging. These 4572 mm wide areas are acceptable even though the fire should be fought from any one of the four sides. There should be no more than three to five trainees on a 40 mm hose and 7 to 10 trainees on a 65 mm hose. The remainder of the class should observe the exercise. The perimeter of the fireplace should be lined with

70 mm thick refractory and a vertical stainless steel plate in accordance with Appendix A, Figure A-9 and should be designed for a load of 295 kg per linear foot. No coaming should be required around the outside perimeter of the training deck; however, a safety rail should be provided. This rail should be constructed of 38.1 mm steel pipe with two horizontal rails. Horizontal rails should line up vertically to prevent personnel from falling off the training deck. The safety rail should not have any netting or webbing.

a) The training deck should consist of a 102 mm lightweight heat-resistant concrete topping on a 6 mil polyethylene bond breaker, on a concrete structural slab. The topping slab should be designed to be sacrificial, provided in sections, and capable of thermal expansion. Expansion joint material should consist of a ceramic fiber blanket capable of resisting temperatures of 1093 degrees C minimum. The training deck elevation should be 2438 mm above grade to allow air access to the underside of the fireplace and to allow space for the electrical, foam, and storage rooms (each with a 2134 mm minimum ceiling height) beneath. Where the training deck is located above the first floor rooms it should be waterproofed. The crawl space under the training deck should maintain 1829 mm of clear height. There should be no doors leading from the ground level rooms directly into the crawl space and utility penetrations should be sealed airtight. Stairs should be provided at three locations to afford personnel access to the training deck. Additional ground access should be provided at each foam training deck. The area under the foam decks and stairs should allow free air access to the wire mesh covered openings.

b) Walls between the first floor rooms and the crawl space should be airtight. Any utility penetrations should be sealed. This precludes propane from drifting into these rooms. The crawl space should be bounded by two walls with floor to ceiling wire mesh covered openings. The other two walls should contain 4572 mm wide air tunnels with similar wire mesh covered openings.

c) Columns used to support the perimeter of the fireplace should be no greater than 5487 mm on center. These columns should be located as indicated on the floor plan in

Appendix E. Refer to par. 3.16.2.6 for other structural features pertaining to the fireplace opening.

3.16.2.2 Foam Deck. Eight identical foam decks should be located around the perimeter of the training deck. The floor of the foam deck should be constructed of steel grating and located 1067 mm below the training deck. The foam deck should include firefighting equipment found on both a destroyer deck (DD) and an aircraft carrier deck (CV). Each deck should be configured in accordance with Appendix E, Figure E-3. Although this combined deck is not set up to duplicate a station found on ships, appropriate gear is available for use. Included should be a foam reel with 38 100 mm of 40 mm hose, two faked hose racks, with 30 480 mm of 65 mm hose each, a stand pipe (SP) hose station with 1219 mm applicator, two faked hose racks, each with 30 480 mm of 40 mm hose, an electrical foam pump start station, and a communications station. Communications should be provided by the device contractor. Foam should be delivered to the deck through a 80 mm pipe with a 40 mm branch leading to the reel through a ball valve. The 80 mm pipe should terminate in a 65 mm service valve, in accordance with NAVSHIPS Dwg. 803-1385712. Both the foam pipe and the SP hose station should be deactivated by a valve out of sight of the trainee which can be operated by the instructors. The safety rail can be used for supports for the faked 60 960 mm of 40 mm hose. The deck steel grating should be sectionalized and securely fastened so it can be easily removed for maintenance.

a) The foam station is activated by depressing the electric foam pump start button which opens the water control valve and starts the proportioning pumps pressurizing the system with proportioned (3 percent) foam. See Figure E-6 in Appendix E. The fire can then be fought with both 40 mm and 65 mm hoses. The amount of foam used for any one training exercise should be 500 gpm or two 65 mm hoses. To depressurize the system, the electric foam pump stop button should be depressed.

b) On the smaller ships the foam reel is supplied by an FS station using an FP-180 foam proportioner; however these reels are not on the flight deck. The device 19F4 is for training firefighting techniques on aircraft decks; the FP-180 training should be accomplished onboard ship.

c) Access to the foam deck should be by inclined stairs from the training deck and a vertical ladder from the ground. The foam deck should have a safety railing around its perimeter. Two safety chains should be provided at the access openings for the ladder to grade and at access to training deck. The vertical ladder should only be used as an emergency exit from the foam deck.

3.16.2.3 Crash Lockers. Adjacent to main access stairs to the training deck should be two crash lockers with dimensions 3048 mm by 4572 mm each. These lockers should be constructed the same as repair lockers. They should be used to store hoses, proximity suits, porta saws, jaws of life, etc. These items should be procured by the using activity through collateral equipment. Ventilation is required in the crash lockers at a rate of 6 air changes per hour.

3.16.2.4 Instructor's Station

a) A two-story high instructor's station should be located 15 240 mm from a corner of the fireplace. Its siting should consider the prevailing wind. It should be upwind of the fireplace and the sun should not interfere with the view of the training deck.

b) The instructor's station and electrical room below should be 3048 mm by 4572 mm, have 2743 mm high ceilings and a computer floor. A computer floor is not required for the electrical room. Access to the second floor should be by exterior stairs. The instructor's station should have a 2438 mm by 762 mm high window overlooking the training deck mounted 610 mm off the computer floor.

c) The DTC is located in the electrical room.

d) The exterior wall and windows of the instructor's station facing the fireplace should be designed to be capable of withstanding a surface temperature of 74 degrees C.

3.16.2.5 Doors. Doors associated with the 19F4 structure should be 914 mm wide hollow metal doors. This structure is not an all weather trainer. The 19F4 structure is open to the

elements and has no provisions for removal of ice and snow; however, associated liquid systems should be freeze protected.

3.16.2.6 Structural Features

a) A device contractor supplied steel framing should support the mockups and grating in the fireplace opening and at the ground storage area. The foundation for this steel framing should be provided with the facility as follows:

(1) A reinforced concrete mat foundation should be provided in the crawl space at the 15 850 mm by 10 973 mm fireplace opening and should support concentrated loads from device support columns. The concrete mat should be pile or grade supported as required by the site soil conditions. The concrete mat should be designed for the following column reactions and spacings:

Location	Column Grid Spacing	Column Reaction
Center 4877 mm by 4877 mm area	1067 mm on center	3405 kg
Remaining fireplace area	1905 mm on center	4812 kg

(2) Column bearing area should be approximately 305 mm square and should be set in a grout bed and anchored directly to the mat foundation. Minimum column distance to edge of mat should be 610 mm. The mat should be designed to give the device contractor the flexibility to locate columns anywhere on the mat subject to minimum column grid spacing, maximum column reactions, and minimum edge distance.

(3) Minimum mat thickness should be 203 mm. Provide a 13 mm minimum expansion joint at the mat perimeter isolating the mat from the remainder of the crawl space slabs. Minimize the crack control joints in the mat foundation. Slope mat from center high point to drains. Refer to Appendix E.

b) The training deck should be designed as a standard training floor, 27 kg per square foot live load. There should be no wheeled vehicles on the deck of the 19F4 structure. Aircraft carriers use a forklift truck to aid in rescuing the

pilot. The 19F4 trainer should have a 91 kg mannequin strapped in a seat 2438 mm above the deck which should be rescued using a portable ladder.

c) Some of the larger ships use a P-16, self-propelled fire truck, to fight deck fires. Because the trainer deck should be above grade due to the propane fuel, resulting size limitations prohibit the use of the P-16. Another negative aspect of P-16 use with this structure is that it would require automotive type maintenance which is not normally associated with firefighting schools.

3.16.2.7 Miscellaneous. Ordnance mockups should weigh approximately 45 kg and be positioned manually by the trainees.

3.16.3 Mechanical

3.16.3.1 Use Rate. The 19F4 structure (see Table 12) has utilities designed to support three classes of 60 trainees each week. The class should be divided into four teams of 15 trainees each with two team leaders and one center leader. Two teams at a time should fight fires alternately at a rate of three fires per hour. The structure should be used for half a day each day of the week for two 2-day classes and one 1-day accelerated class. Each class should receive 5 hours of fire exposure time.

3.16.3.2 Firefighting Agents

a) Flush deck nozzles are used on the flight deck of a ship as a countermeasure to prevent accumulation of contaminants during a chemical biological radiation (CBR) attack and with foam to aid in fighting fires. On the 19F4 structure, use deck nozzles for demonstration purposes only and supply with water only. Nozzles must be installed in the fireplace grating by the device contractor. A 152 mm water line must terminate near the edge of and below the trainer deck with a motorized valve. The water line must have a manual shutoff valve and a pressure regulator valve prior to the motor operated valve. The water pressure for the flush deck nozzles should be the fire main pressure. The tie-in point for the device contractor should be the outlet of the motorized valve.

Table 12
19F4 and 19F4A Structures

CLASS SCHEDULE

	MON		TUE		WED		THU		FRI		
	AM	PM	AM	PM	AM	PM	AM	PM	AM	PM	
Classroom	X	X					Y	Y			Z
Structure			X	X					Y	Y	Z

Note: Classes are designated as X, Y, Z.

PROPANE USAGE

CLASS OF FIRE	NO. OF FIRES/ CLASS OF 63 MEN	FIRE TYPE	PROPANE DEMAND L/s		PROPANE USE PER FIRE L^3	TOTAL PROPANE/ CLASS
First Day PM	6	Fixed Wing	2549	5/	283 000	1 698 000
B						
Second Day PM	6	Helicopter	2549	5/	283 000	1 698 000
B						
B	3	Gas Tank	34		6198	18 593
	15 Fires/ Class					3 414 593 L/ class 12 496 L/ class

Notes:
1. Propane consumption and demand for the 1-day class are the same as those for the 2-day class.
2. The design propane demand for the bldg. is 2549 L/s.
3. Propane is based on a gas pressure at the burner of 14 kPa.
4. Propane supply pressure at the trainer entry (device contractor hookup) should be 69 kPa.
5. The average propane demand is 944 L/s.

Table 12 (Continued)
19F4 and 19F4A Structures

AGENT USAGE

CLASS OF FIRE	NO. OF FIRES/ CLASS	NO. OF HOSES	AFFF 3% L/s	WATER TIME min
First Day PM				
B	6	2 - 65 mm	16	5
Second Day PM				
B	6	2 - 65 mm	16	5
B	3	2 - 65 mm	16	3

Notes: 1. The design water demand should be 8 + 8 + 16 + 16 = 48 L/s for the occasional times when two 64 mm and two 38.1 mm cooling water hoses are used together. This is the total demand for the structure. Do not add in the water for foam.
2. The maximum 3 percent foam solution demand should be 16 + 16 = 32 L/s.

TOTAL UTILITIES

	CLASS	WEEKLY
Propane	3 414 593 L	10 243 779 L
Water	136 440 L	409 320 L
AFFF Concentrate (100%)	3923 L	15 160 L
PKP	None	

Notes: 1. The water category includes the water portion of the AFFF (97 percent water, 3 percent AFFF for design) and the flush deck nozzle water.
2. 46 percent of the water usage for a 2-day class occurs occurs on the first day of class. However, since the whole course is taught in one day to the accelerated students, the design daily water consumption equals the full class value.

b) The flush deck nozzles should be controlled from the instructor's station only, by activating the motorized valve. The water demand for the 19F4 structure should not be affected by these nozzles. Deck nozzles should not be used simultaneously with other agents.

c) Agents used to fight aircraft deck fires should come from the foam deck. Foam should be used exclusively to fight aircraft fires. Water should be used to cool ordnance after the fire is out and used to wash contaminate off the deck.

d) PKP should not be used as a firefighting agent with this structure.

3.16.3.3 Ventilation

a) The wind generator should not be used because of crosswind problems, safety, noise and power consumption. Natural wind should be used to provide the air movement required. In an effort to retain the advantage of training with a upwind or downwind approach to the fire, the device should be configured so the fire can be attacked from any one of its four sides with equal realism. Foam decks are also located so the fire can be approached from any side.

b) Wire mesh covered openings bordering the crawl space should be as large as the structure will allow to provide as much air under the fireplace as possible. Louvers and backdraft dampers for the 19F4 trainers are not required since neither artificial smoke nor PKP is used.

3.16.3.4 Air Conditioning. The electronic equipment in the instructor's station is expected to add 1000 W to the air conditioning load. There is no electronic equipment (device) cooling load for the electrical space below the instructor's station. This electrical space should be cooled and heated.

3.16.3.5 Miscellaneous

a) Artificial smoke should be used to help trainees determine wind direction and to indicate, along with the sound of an explosion, ordnance that has heated beyond its cook-off point.

b) The courses taught on the 19F4 and 19F4A trainers require exposure to the wild hose facility. The wild hose may be taught on the ground adjacent to the 19F4 structure. Only one wild hose facility should be required at a firefighting school.

c) The propane supply should terminate at the side of the structure as shown in Appendix E, Figure E-1.

3.16.3.6 Foam Proportioning

a) The foam for foam decks should be proportioned in the foam room with less than 3 percent AFFF solution being piped to each foam standpipe. Concentrate should be pumped to the mixing tank in the foam room. An industrial type proportioner should take 100 percent solution from the mixing tank and produce less than 3 percent solution. A balanced pressure system should be used as shown on Figure E-6 of Appendix E.

b) The high capacity fog foam generator (HCFF) or FP-1,000 are used aboard ship to proportion firefighting foam. There are aspects of this equipment which are not conducive to firefighting training. The HCFF or FP-1,000 should not be incorporated in the 19F4 or 19F4A for training purposes. This equipment type training should be accomplished aboard ship.

3.16.4 Electrical

3.16.4.1 Power

a) Power required for the device is 85 kVA. Provide 120/208 V, three-phase service.

b) Provide eight 50 mm spare conduits from the two-story instructor's station building to the 19F4 training structure. These conduits should be used only by the device contractor for both power and control. Power and control wiring should be run in separate conduits.

3.16.4.2 Lighting. The 19F4 structure should be lighted for nighttime operation. However, provide security lighting. The crawl space should be fully lighted with switches by doors.

3.17 19F5 and 19F5A Structures

3.17.1 General. The 19F5 and 19F5A structures should be used for initial exposure or indoctrination firefighting training. The structure is designed to train one class of 160 students and can train five classes each week operating on a single shift.

3.17.2 Architectural. Floor plans for the 19F5 and 19F5A structures are in Appendix F.

3.17.2.1 Layout. The 19F5 and 19F5A structures should consist of six fireplace compartments, three on either side of a large staging area. Students should line up in the staging area in front of each compartment and fight the fire through the doorway. Fireplaces should run simultaneously.

Two storage rooms should be located off of the staging area which should provide access to the burner room. Both of the storage rooms should be permanently heated to 10 degrees C.

3.17.2.2 Ceilings. Ceilings in the fireplace compartment should be 3658 mm high. The roof over the staging area should be high enough to provide line of sight between the second story instructor's station and the compartments. The roof over the compartments should allow 2438 mm clearance for maintenance of the exhaust system and smoke generation equipment. An equipment space over the burner room may also be required. The ceiling height in the egress chamber should be 2438 mm minimum.

3.17.2.3 Doors. Doors leading to fireplace compartments and associated with the egress chamber should be quick-acting watertight doors. Other doors should be hollow metal. A 1829 mm wide by 2134 mm high door should be located in the staging area to accommodate large equipment on hand trucks. The door should have ramp access. No forklift trucks should be used.

3.17.2.4 Fireplaces. Exact dimensions of burn areas are listed in the table below by fire type. Compartments are 3048 mm by 3048 mm clear in the plan.

Trash Can	1829 mm by 1829 mm (floor opening), located 305 mm from the back wall liner
Bilge	3048 mm by 3048 mm clear (floor opening)
Electrical Panel	406 mm (wall mounted)

Fireplace compartments should have refractory lined walls and ceilings. In addition, compartment walls should have steel plate liners to protect walls from the water hose stream and to maintain compartment temperature. The bilge fireplace compartment ceiling should also have steel plate liner. The electrical panel and trash can fireplaces should have grating floors. The bilge fireplace should have a chained doorway, floor, and a fireplace support as shown on Appendix A, Figure A-9. Required compartment dimensions should be clear dimensions from refractory wall coating to steel plate wall liner. Fireplace compartments should be thermally isolated from the facility structure to allow for thermal expansion.

Note: Facility to provide fireplace steel gratings. NAWCTSD will supply drawings and cost estimate to the facility architect during design phase.

3.17.2.5 Instructor's Station. The 19F5 and 19F5A structures should include two 3658 mm by 3658 mm instructor's stations. One for each set of fireplace compartments. The 19F5 and 19F5A structures should be separated by an electrical room measuring 3658 mm by 7925 mm. All three rooms should be located on the second floor along the side of the staging area and should have a 305 mm high raised floor. Access to the instructor's stations should be by stairway or through the electrical room. Each instructor's station should have a 3048 mm by 762 mm window overlooking the staging area. The lower edge of window should be 610 mm off of the computer floor.

3.17.2.6 Egress Chamber. An emergency egress chamber should be provided which should present the trainee with a loss of light and a high temperature, smoky environment. The trainee should enter and leave the chamber through smoke filled entryways. These entryways should be designed to block light from entering

the main chamber. Ventilation should be such that no smoke is allowed to enter the staging area. Smoke should not be introduced in the main chamber.

a) Once inside the dark chamber, the trainee should follow a rope lanyard which should eventually lead him to the smoke filled exit. The main chamber should be heated to 43.3 degrees C during the training scenario.

b) Provide a watertight door in the steel partition between side 1 and side 2 of the chamber and watertight openings without doors in the steel partitions making up the entryways, refer to Appendix F, Figure F-1, for details. Walls and the ceiling should be sealed with a coating chemically resistant to triphenyl phosphate.

3.17.2.7 Miscellaneous

a) No OBA's should be used by trainees, therefore a fixed OBA disposal area is not required.

b) Provide a hose drying rack capable of storing twelve 15 240 mm lengths of hose. Once loaded, the hose drying rack should be hoisted electrically to a mezzanine located 2743 mm above the floor. The mezzanine should be accessible from the second floor. Material for the hose drying rack should be lightweight. A heavy duty wrench-hoist system should be provided.

c) The P-250 portable, gasoline engine driven water pump should be demonstrated in front of the bleacher area. Refer to the requirements stated herein. No raised platform is required.

d) Provide bleachers for seating 250 students.

e) Provide a wild hose demonstration area. The space should be approximately 6096 mm by 6096 mm by 6096 mm high with an opening facing the bleachers to allow observation from the staging area. Means with unrestricted visibility should be provided to protect the bleachers from the wild hose water spray.

3.17.3 Mechanical

3.17.3.1 Use Rate. Utilities for the 19F5 and 19F5A structures are designed to support five classes of 160 students each week. A class should be divided into two groups (A, B) of 80 men. Group A should spend the morning fighting fires in the six fireplace locations while group B watches the demonstration, e.g., wild hose, P-250 pump, portable extinguishers, etc., and goes through the emergency egress chamber. In the afternoon the two groups switch. A typical schedule should consist of five classes per week, 800 trainees for 52 weeks or 40,000 students per year. For class schedule and utilities requirements, see Table 13.

3.17.3.2 Firefighting Agents. Firefighting water entering the structure should come through a motorized valve. This valve should be controlled from the DTC and act as an emergency shutoff valve in case of an uncontrollable hose.

a) Six standpipes, two foam stations, and two foam reels should be located in the center of the staging area. Only the reels and agents should be used for training purposes. The foam proportioning equipment which feeds the reels should be operated by instructors. Therefore, it can be standard commercial. The design should allow for any two reels to operate simultaneously, one for each bilge compartment.

b) Provide a 9 kg portable PKP extinguisher outside of each bilge compartment. Provide a 6.81 kg portable CO_2 extinguisher outside of each electrical panel compartment. Additional extinguishers which should be used as replacements should be purchased as collateral equipment.

c) Hose stations in the 19F5 structure do not require the instructor operated hose station disabling valve.

Table 13
19F5 and 19F5A Structures

CLASS SCHEDULE

A	Monday	AM	240 fires
B		PM	240 fires

Note: The 2-day course includes a classroom session before the fire training.

PROPANE USAGE

CLASS OF FIRES	TOTAL NO. OF FIRES/ CLASS	FIRE TYPE	PROPANE DEMAND L/s	AVERAGE FIRE DURATION min	PROPANE USE PER FIRE L	PROPANE/ CLASS FOR 1 DAY L
A	160	Trash Can	5	2	566	67 920
B	160	Bilge	31	2	4528	724 480
C	160	Electric Panel 480 fires/class	2	2	283	33 960 826 360/ class

Notes:
1. Each fireplace should have 10 fires/hour.
2. Maximum fires per shift is 480 fires. Classes larger than 160 students can be accommodated by reducing student fire exposure or extending the shift.
3. Great Lakes should train additional students with the same number of fires.
4. The propane demand is based on a gas pressure at the burner of 7 kPa except for the bilge fire which is 14 kPa.
5. The design propane demand for the structure is (5 + 31 + 2) x 2 = 76 L/s.

Table 13 (Continued)
19F5 and 19F5A Structures

AGENT USAGE

CLASS OF FIRE	NO. OF FIRES/ CLASS	NO. OF HOSES 40 mm FIRE	WATER L/s	AFFF 6% L/s	PKP/ FIRE kg	CO_2/ FIRE kg	WATER TIME min
A	160	2	6				2
B	160	1	6				2
		1		6	5		1
C	160	5					

Notes:
1. The design water demand is: ((6)2 + 6 + 6)2 = 48 L/s.
2. Portable PKP extinguishers should require 80 CO_2 charges per class.
3. No OBA's should be used.
4. Portable extinguishers should be used for fighting fires with PKP.

TOTAL UTILITIES

	CLASS 1 DAY	WEEKLY
Propane	820 700 L	4 103 500 L
Water	379 950 L	1 989 750 L
AFFF Concentrate (100%)	3456 L	17 282 L
PKP	73 kg	363 kg
CO_2	363 kg	1816 kg

Notes:
1. The water category includes the water portion of AFFF (94 percent water, 6 percent AFFF for design).
2. Continuous operation can be assumed for weekly and monthly consumption.

3.17.3.3 Ventilation

a) There should be an exhaust duct leading from each fireplace compartment with a separately operated motorized floating point damper. These ducts should come together above the compartment ceiling. The design capacity of exhaust fans for each side of the structure should be based on the simultaneous operation of fireplaces or 8686 L/s "air out." The minimum ventilation should be 472 L/s per fireplace or 1416 L/s for each side of the structure. For ventilation air per area, see Table 14.

b) Artificial smoke, butylated triphenyl phosphate, should be used in fireplaces and in the emergency egress chamber.

c) Each entryway of the egress chamber should be provided with 472 L/s of ventilation which should keep it under negative pressure so that the smoke should not migrate to the staging area. Exhaust grills should be located above the entry and exit on the inside and should draw air from the staging area through the doorway. Motorized dampers should be provided to allow remote adjustment of the entryway ventilation rate. A second fan should draw 472 L/s from each inner room of the egress chamber. The inner room fan should be used to clear stray smoke from inner rooms only after the exercise is complete. The inner room fan should not be on while trying to maintain 37.7 degrees C in the chamber. Interlock the fans to the entryway doors so they cannot run with the doors closed. The open door is the source of makeup air for the inner room exhaust fan. Heating of the egress chamber to 43.3 degrees C during training should be provided by the device contractor. Normal building heating should be provided.

3.17.3.4 Air Conditioning. Electronic equipment in each instructor's station is expected to add 1172 W to the air load. The air conditioning to the electric room adjacent to the instructor's station has an air conditioning load of 5860 W due to the equipment. The normal occupancy for each of the three rooms should be two people.

Table 14
19F5 and 19F5A Ventilation Air

COMPARTMENT	PROPANE DEMAND L/s	VENTILATION AIR OUT AT 316 degrees C L/s
Trash Can	5	2171
Bilge	31	5428
Electric Panel	2	1086

Notes:
1. The design ventilation for each side is 8685 L/s "air out." The minimum flushing ventilation should be as low as the fan can turn down but never lower than 1416 L/s "air in."
2. Fan static pressure should be determined by bringing 15.5 degrees C air through the louvers and exhausting 316 degrees C through the exhaust system.
3. Provide two 944 L/s fans for the egress chamber.

3.17.4 Electrical

3.17.4.1 Power. The power for the device is 50 kVA. Provide 120/208 V, three-phase service.

3.17.4.2 Lighting. The staging area should be lighted for training after dark. Fireplace compartments should be lighted for maintenance from underneath the grating. No shipboard type lighting is required in compartments of the 19F5 structure. Install guards on lights in staging area at the ceiling to protect lights from hose spray.

The egress chamber should have interior lighting for maintenance purposes only. The light switch should be exterior and away from the entry and exit doors.

Section 4: AGENTS AND APPARATUS

4.1 General. Substitute materials have been found to replace AFFF foam, PKP, and smoke. These substitutes were chosen to improve the trainee's environment, the treatability of the air and water effluents, and the economics of training. Equivalents other than brand names are acceptable as long as the substitute material meets the given chemical formula requirement.

Any reference to the use of the above agents in this document should be understood to mean the substitute mentioned below unless stated otherwise.

4.2 Aqueous Film-Forming Foam (AFFF)

a) AFFF is used extensively in the Navy for fighting fires aboard ship. Its main disadvantage in firefighting training is its toxicity to treatment plant bacteria and receiving stream oyster larva. The toxic characteristic did not respond to various treatment processes as measured by methylene-blue-active substance (MBAS). Therefore, the only two methods of disposal for AFFF contaminated waste water was hauling it away as a toxic waste or diluting it to under 200 ppm. The first option was prohibitively expensive and the latter alternative restricted the amount of foam to where it could only be used for demonstration purposes not for training.

b) Dilution is, however, the method of disposal of AFFF used by the fleet during the routine testing of shipboard firefighting equipment. When testing is done in harbor and coastal areas, the effluent is collected and stored until it can be transferred to shore. Once shoreside, it is metered into the municipal sanitary sewer system under permit.

4.2.1 Substitute

a) The substitute for AFFF is sodium dodecylbenzine sulfonate manufactured by Pilot Chemical Company of Avenel, New Jersey and marketed as Calsoft. It is also marketed by Whitco under the name Ultrawet K, by Textile Chemical Company under the name Calsoft, and by Stephan Chemical Company under the name

Nacconal 35SL. It is a common industrial surfactant. Of the many types of surfactants on the market, Calsoft was chosen because it was:

(1) Readily available in large quantities

(2) Nonflammable

(3) Disposable in effluent

(4) Biodegradable

(5) Acceptable for human health and safety

(6) Adequate in foaming action

(7) Stable at high temperature

(8) Minimally corrosive

(9) Cost effective for training

(10) Compatible with the flame control logic

b) Another substitute should not be attempted without thoroughly considering each of these characteristics.

c) Calsoft can be delivered in a wide variety of forms. The solid form comes in bags and drums. The liquid form comes in cans, drums, and by tank truck in varying concentrations. The liquid form is preferred for fire training.

d) Liquid Calsoft is sold in different concentrations because higher concentrations contain less water therefore less bulk for efficient shipping. However, 60 percent and higher concentrations of liquid Calsoft should increase handling problems for the user. In 60 percent concentrated form, Calsoft should be heated to be transferred. If 60 percent Calsoft ever cools below 10 degrees C, it should be heated and mechanically mixed before it can be used. Calsoft should be bought as a 40 percent concentrate which does not have to be kept heated except

for freeze protection. The concentrate is mixed half and half with water to make a 20 percent solution of surfactant which is referred to as 100 percent AFFF in this handbook.

e) Concentrates are diluted with water to the maximum extent practicable, consistent with maximizing realism, activating AFFF sensors, and minimizing cost. Foaming action should vary from site-to-site, based on water hardness. Experimentation at each site is required. The diluted AFFF surrogate is referred to as 100 percent AFFF in this handbook.

4.2.2 Handling System. The foam system for fire training should consist of bulk storage for concentrate, a mixing tank for preparing 20 percent solutions, a proportioning device (see hose stations), and suitable transfer means between each. Where usage rates are practical and tank truck deliveries are available, bulk tank storage may be the most economical method. The 40 percent concentration, used for the design delivery quantity should ensure that the concentrate remains pumpable without heating under possible ambient conditions. Provide spill prevention provisions around the bulk storage area. If the bulk storage tank is underground, ensure that the pump design includes a provision for pump priming.

a) If bulk tank storage is inappropriate, provisions should be made for 204 kg bulk 208 L drum storage and handling.

b) A solution tank should be provided in the utilities building for mixing the concentrate with water to make 100 percent solution (20 percent active surfactant, 80 percent inert). The tank should be sized to hold 120 percent of the maximum daily 100 percent AFFF usage. Supporting equipment should facilitate manual batch mixing. Each day the design amount of concentrate should be pumped into the solution tank from the bulk tank or from 208 L drums after which the calculated amount of water should be added.

c) The solution tank should have, but not be limited to, a graduated sight glass, a gage port, inlets and outlets, high level alarm, low level pump shutoff, drain, and a vent. Tank inlets should extend to the bottom of the tank and have expansion nozzles to reduce foaming. Aspects of the design

should consider the fluid's propensity to foam and the fluid's viscosity. Refer to Appendix A, Figures A-17 and A-18 for the AFFF viscosity characteristics curves.

d) Carbon steel cannot be used with the AFFF surrogate because the chemical picks up iron molecules. Tanks, pumps, piping, and appurtenances should not be carbon steel, irrespective of the solution concentration of the chemical. Copper piping or 316L stainless steel is an acceptable piping material.

e) From the solution tank the foam concentrate should be pumped in underground pipes to the hose station day tank. The flow rate should allow the day tank(s) to be filled in approximately 15 minutes. The concentrate distribution pump should be controlled by start-stop push-button stations at each hose station. The solution tank should include provisions for filling 19 L cans to be used with the portable foam proportioner.

f) The device sensors can distinguish between 3 percent AFFF and pure water. However, instructors feel that a 6 percent solution is more realistic in appearance. The proportioner is field adjustable. A 6 percent solution should be used for design purposes unless indicated otherwise. The 19F4 trainer uses 3 percent solution.

g) The 21C12A trainer requires a AFFF mixed solution for extinguishers of 59 ml. of 40 percent concentrate in 9 L of water.

4.2.3 Portable AFFF Fire Extinguishers. Portable AFFF fire extinguishers are only required on submarines, therefore, only used in the 21C12 and 21C12A trainers. These extinguishers are stainless steel cylinders that store 9 L of a premixed solution of AFFF concentrate and water. Cylinders are pressurized with air to 689 kPa at 21 degrees C. The AFFF is discharged from the bottom of the cylinder through the siphon tube, extinguisher valve, and discharge hose to the nozzle. The AFFF fire extinguisher weighs approximately 12 kg when fully charged and has a 55- to 65-second continuous discharge time. The AFFF

solution undergoes an expansion of 6.5 to 1 when passing through the nozzle, which produces around 61 L of expanded AFFF/water solution (foam) after discharge.

4.3 Potassium Bicarbonate. Potassium bicarbonate, PKP, is a dry chemical extinguishing agent. PKP has two main undesirable characteristics for use in fire training. It is extremely diffusive, that is it spreads in all directions like smoke and remains airborne, and it is corrosive to metal and painted surfaces.

a) Substitute. A substitute was identified as grade No. 2 sodium bicarbonate powder with an apparent density of approximately one g/cm^3. Sodium bicarbonate is similar to PKP in all respects. However, No. 2 grade powder is composed of large particles, i.e., 90 percent of the particles are larger than 44 microns whereas 90 percent of PKP particles are smaller than 44 microns. PKP has an apparent density of approximately 2 g/cm^3. Larger particles make sodium bicarbonate less diffusive. The substitute powder is coated with silicon and therefore not soluble in water. The silicon coating should breakdown in time and then the sodium bicarbonate should dissolve in the water. Sodium bicarbonate powder's chemical composition is:

COMPONENTS	WEIGHT/PERCENT
Sodium bicarbonate, No. 2 grade	93.4
Attaclay	4.0
Mica	2.0
Silicone fluid	0.6
	100.0

b) Sodium bicarbonate is available in a variety of dry containers. It should be delivered and stored in bulk quantities. Storage should be kept dry.

c) Sodium bicarbonate should then be transferred to the refill station where the proper weight is poured through a funnel into portable extinguishers. The same scales can be used for PKP and CO_2 refill. PKP cylinders come in 8 and 12 kg sizes

and are provided in accordance with MIL-E-24091, Extinguisher, Fire, Portable, Potassium Bicarbonate, Dry Chemical, Cartridge-Operated Type.

4.4 Carbon Dioxide (CO_2). CO_2 should be used for fire training in the form of portable 7 kg extinguishers. The portable 7 kg extinguishers should be in accordance with MIL-E-24269, Extinguisher, Fire, Carbon Dioxide, 15 Pound, Portable, Permanent Shutoff, Navy Shipboard Use. There are no fixed pipe CO_2 systems for training purposes. Extinguishers should be purchased as collateral equipment and stored in repair lockers for use by the trainees. As an exception to collateral equipment requirements, portable CO_2 extinguishers should be provided with the training facility for the electrical room and instructor's station.

a) The 19F5, 19F5A, 21C12, and 21C12A trainers should use a low pressure refrigerated, CO_2 bulk storage tank system. For other trainers, consideration should be given to using either a low pressure refrigerated, CO_2 bulk storage tank system or high pressure 23 kg storage cylinders for recharging the extinguishers.

b) The high pressure recharging system should consist of 23 kg cylinders which are 1295 mm long by 215.9 mm in diameter and weigh 72 kg when full. Cylinders contain CO_2 gas at 5857 kPa at 21.1 degrees C. The recharging station should consist of the following collateral equipment: tilt racks, a scale, 220 V, single-phase motor and pump, fill hose, and valves. For details, refer to Appendix A, Figure A-11. The 23 kg cylinders should be stored in a bulk storage area located near the recharging area. The bulk storage area should be suitable for storing 1 month's supply of cylinders plus 2 weeks of empty cylinders. Sufficient access should be provided in the bulk storage area for moving the cylinders.

c) The low pressure recharging system should consist of a low pressure refrigerated CO_2 storage tank, fixed supply and

return piping system, and a manual extinguisher fill pump capable of receiving CO_2 at 2067 kPa, and an oxygen monitor and alarm system.

d) The system should be in accordance with NFPA 12, Carbon Dioxide Extinguishing Systems. The storage tank should contain CO_2 at -17.7 degrees C and 2067 kPa and should be sized to provide a minimum of 30 days of CO_2. For details, refer to Appendix I, Figures I-1 through I-7.

> Caution: Extra care should be taken when recharging the extinguisher with low pressure liquid CO_2. Too much liquid CO_2 in an extinguisher will cause an explosion when the CO_2 changes state from a liquid to a gas due to expansion as the liquid heats up from -17.7 degrees C ambient temperature.

e) CO_2 is also used in cartridges for propelling PKP from portable extinguishers. These cartridges are not refillable.

f) Due to the potential for CO_2 gas leakage, provide an oxygen (O_2) monitoring and alarm system in enclosed spaces containing the CO_2 recharging system. The O_2 monitoring and alarm system should tie into the main propane alarm control panel so as to provide alarm and annunciation to the 24-hour duty desk, instructor's station, and to the DTC. Local alarm and flashing warning sign should also be provided. The warning sign should state "DANGER, CO_2 CONDITION."

g) At the closest outside entrance to the CO_2 recharging system, provide the following in weatherproof lockers with the appropriate labels:

(1) A portable CO_2 and O_2 detection kits.

(2) An emergency air breathing "SCOTPAK."

h) Doors for the spaces containing the CO_2 recharging system should be provided with panic hardware.

4.5 Halon. Halon is an invisible gas which is used in the Navy community. Where it is called for in the training structure it should be simulated and necessary equipment should be provided by the device contractor. No facility services are required. The Halon simulator should look like a shipboard installation but there should be no pressurized containers inside the structure. Halon is now limited by the Navy due to possible ozone depletion.

4.6 Aqueous Potassium Carbonate (APC). APC is a type of extinguishment that is used as a fixed range guard system on kitchen exhaust hoods. It should be simulated on the deep fat fryer fireplace by the use of a water spray.

4.7 Nozzles. Hose end nozzles used for firefighting training should be provided by the user as collateral equipment. The preferred water fog nozzle is NAVSHIPS Dwg. 805-860089.

4.8 Oxygen Breathing Apparatus (OBA). OBA are used by the Navy to protect firefighters from the toxicity of the products of combustion. They contain a replaceable cartridge. Oxygen is produced by chemical reaction in the cartridge. The OBA's should be stored in repair lockers associated with each structure. Chemicals in the spent cartridge should be completely finished producing oxygen prior to disposal. This is done by letting them set in the air a minimum of one hour, then recapping them and wrapping them in double poly bags. Wrapped cartridges are then stored in drums to be hauled away as hazardous waste.

4.9 Hose Stations. In the 80 mm service pipe supplying each hose station, provide a shutoff valve so the instructor can disable the station. The valve should be out of sight of the trainee where possible but in a location convenient to the instructor. The instructor's shutoff valve should be a 80 mm commercial ball valve with a locking handle.

a) Consult the using activity and when requested, provide a hose drying rack. Where the climate allows, the hose drying rack should be out in the open for maximum use of natural air movement.

b) The word "faked" in faked hose station refers to the method used to store the hose. See Appendix A, Figure A-4 for an example of a faked hose.

c) The following types of hose stations have been identified for the 19F series trainers.

4.9.1 Hose Station 1 (HS1). A 40 mm hose station, supplied with water. Refer to Appendix A, Figure A-4.

a) A 40 mm hose globe valve with one end flanged and one end threaded, NAVSHIPS Dwg. 803-1385712.

b) A marine strainer and valve with connection coupling on one end and threaded on the other end is no longer required.

c) A 15 240 mm steel hose rack with strap, NAVSHIPS Dwg. 805-860089.

d) A 40 mm hose, 15 240 mm long, Fed. Spec. ZZ-H-451, Hose, Fire, Woven-Jacketed Rubber or Latex or Rubber-Coated Fabric-Lined With Couplings.

e) A 1219 mm applicator.

f) Spanner wrench.

4.9.2 Hose Station 2 (HS2). A 65 mm hose station, supplied with water. Refer to Appendix A, Figure A-5.

a) A 65 mm hose angle valve with one end flanged and the other end threaded, NAVSHIPS Dwg. 803-1385712.

b) A marine strainer and valve with connection coupling on one end and a threaded connection on the other end is no longer required.

c) A 65 mm by (2) 40 mm wye gate.

d) Two 30 480 mm steel hose racks with strap, NAVSHIPS Dwg. 805-860089.

e) Four 40 mm hose, 12 240 mm long Fed. Spec. ZZ-H-451.

f) Two 1219 mm applicators.

g) Spanner wrench.

4.9.3 Foam Station (FS). Foam hose station, supplied with water. Refer to foam station diagram Appendix A, Figure A-21.

a) Single agent hose reel

b) A 40 mm hose, 38 100 mm long, MIL-H-24580, Hose Assemblies, Synthetic Rubber, Noncollapsible, Firefighting

c) Foam nozzle

d) Concentrate tank

(1) 19F1A - 303 L

(2) 19F3-B1 - 303 L

(3) 19F3-B3, 19F3-B4, and 19F5 - 379 L

e) Electric foam proportioning pump (Blackmer pump Model BXL - 1-1/4, Manufacturer Dwg. E-4638)

f) Controls as found on damage control deck

The 100 percent AFFF concentrate line should have a valved bypass before it enters the concentrate tank arranged so 19 L AFFF cans can be filled at that location.

4.9.4 Foam Reel (FR). Foam reel station, supplied with foam. Refer to Appendix A, Figure A-21.

a) Single agent hose reel, Appendix A, Figure A-6.

b) A 40 mm hose, 38 100 mm long, MIL-H-24580

c) Foam nozzle

d) Manual control valve

e) Ball valve

f) Controls

The foam reel is supplied with 6 percent foam from the nearest FS type hose station.

4.9.5 Stand Pipe (SP). A 65 mm stand pipe, supplied with water.

a) A 65 mm hose angle valve with one end flanged and the other end threaded, NAVSHIPS Dwg. 803-1385712.

b) A marine strainer and valve with connection coupling on one end and a threaded connection on the other end is no longer required.

c) A 65 mm by (2) 40 mm wye gate.

4.9.6 Submarine Hose Station 1 (SHS1). Hose station is supplied with water and is wall mounted.

a) A 40 mm angle globe valve with one end flanged and the other end threaded, NAVSHIPS Dwg. 803-1385712. The valve should be located 457 mm above the floor next to the hose station. The valve should be perpendicular to the wall and should be served by piping routed in or through the wall.

b) A 40 mm hose, 7620 mm long, MIL-H-24580.

c) Wall mounted fire hose locker in accordance with Appendix G, Figure G-8. The hose is rolled up and stored in the locker.

d) No strainer, wye gate, or applicator is required.

4.9.7 Submarine Hose Station 2 (SHS2). Hose station is supplied with water and is floor mounted.

a) A 40 mm angle globe valve. Refer to SHS1 above.

b) A 40 mm hose, 15 240 mm long, MIL-H-24606, Hose Assemblies, Chlorosulfonated Polyethylene Impregnated, Double Synthetic Jacket, With Couplings, Firefighting and Other Water Service

c) Floor mounted hose cabinet in accordance with Appendix G, Figure G-9. The hose is rolled up and stored in the locker.

4.9.8 Submarine Hose Station 3 (SHS3). Hose station is supplied with water and is recessed into the wall. Hose station should consist of the following as shown on NAVSEA Dwg. 608-4674414: (SHS3 is part of the combined submarine hose station.)

a) A 40 mm hose, 15 240 mm long, MIL-H-24606

b) Fire hose rack per NAVSEA Dwg. 608-4674414

c) One applicator per BUSHIPS Dwg. 810-1385834

d) Two spanner wretches per NAVSHIPS Dwg. 810-4444647

Spanner wrenches and the applicator should be clamped in the recessed area of the station. Clamps should be per NAVSEA Dwg. 608-4674414. SHS3 should be recessed into a space of the wall with dimensions of 1270 mm height from the floor to top of the opening by 762 mm wide by 203 mm deep.

4.9.9 Combined Submarine Hose Station (CSHS). Hose station is supplied with water and consists of SHS3 recessed into the wall with SHS1 on a metal plate mounted to cover SHS3. The metal plate should be removable and should be provided over SHS3 to hide SHS3. The plate should be designed to be removed by one or two men. Clips or other methods of attachment should be provided for attaching the plate over SHS3. SHS1 should be

permanently attached to the metal plate. A 40 mm angle globe valve normally furnished with SHS1 should be provided next to the combined hose station.

4.9.10 PKP Fire Extinguisher (PFE). A 12 kg portable PFE should be provided with single AFFF foam reels, as shown on appendixes floor plans, and should be in accordance with MIL-E-24091.

4.9.11 Twin Agent Reels (TAR). The TAR and system have been replaced by a single AFFF FR and a 12 kg portable PFE which should provide a similar function to the TAR system.

Section 5: PROTECTION OF THE ENVIRONMENT

5.1 Permits

a) OPNAVINST 5090.1, Environmental and Natural Resources Protection Manual, Chapter 6, Air Pollution Abatement states the firefighting schools should comply with state open burning regulations or have prior Chief of Naval Operations (CNO) approval for a delayed compliance request.

b) Discharge permits for air and water should be negotiated with the state for each site. This should be done early in the project so the scope of monitoring and treatment can be determined. It is important to have discharge information adequately prepared and use a positive approach. Water usage permits may also be required depending on locality, municipal, or State regulations. For typical air emissions, see Table 15; for wastewater characteristics, see Table 16.

5.2 Air. The 19F series trainers use propane for fuel, dramatically reducing criteria (PM1O/TSP, VOCs, CO, SOX, etc.) and other hazardous air pollutants. However, benzene as a combustion by-product is still emitted in sufficient concentrations to require emission control devices under some circumstances. In addition, the surrogate PKP and artificial smoke training agents generate regulated emissions as discussed below. Continuous monitoring of the air effluent may be required to determine code compliance. This should be negotiated with local air pollution control authorities.

5.2.1 PKP. One of the parameters used to choose the PKP surrogate was particle size. Grade No. 2 sodium bicarbonate was chosen. Ninety percent of its particles are larger than 44 microns with an average particle size of 100 microns. Ninety percent of normal PKP particles are smaller than 44 microns with an average particle size of 20 microns. For comparison, a human hair is approximately 100 microns in diameter. The large particle PKP substitute is less diffusive than PKP with most particulate falling out before the effluent leaves the training compartment. For maximum particulate emission rates see Appendix A, Figure A-10.

Table 15
Typical Air Emissions

EMISSION	MAXIMUM EMISSION RATE	TYPICAL EFFLUENT
CO	(1)	negligible
VOCs	(1)	negligible
SOX	(1)	none
NOX	(1)	negligible
TSP/PM1O	(1)	see Figure A-10, Appendix A
Lead	(1)	none
Ozone	(1)	negligible
Benzene	(2) 0.325 mg/cu. m (0.1 mg/kg)	(3)
Tear Gas	(2) 0.3 mg/cu. m (0.05 mg/kg)	19.5 gm (4)
Triphenyl Phosphate	(2) 3 mg/cu. m	(5)

Notes: (1) Emission rates of criteria pollutants vary by locality, primarily due to each locality's compliance with National Ambient Air Quality Standards established by the Clean Air Act Amendments of 1990.

(2) Values listed are threshold limit values (TLVs) as established by the National Institute for Occupational Safety and Health (NIOSH), American Conference of Governmental Industrial Hygienists (ACGIH), or Occupational Safety and Health Administration (OSHA).

(3) Source emissions testing/monitoring for the 21C12 trainer at STF Norfolk were conducted in the Fall of 1993. This data will be promulgated as an amendment to this handbook as soon as data is available. Such information may be useful for local EFD's in projecting air permit application data and generating cost certification/concept design cost estimates for necessary control devices required by local authorities for other types of trainer devices.

(4) Tear gas chambers are normally only included in 19F5 recruit training facilities.

(5) TPP emission data is largely dependent on local training requirements for each facility.

NOTES:

1. These tests were performed by LANTNAVFACENGCOM Code 1812. These bench tests were performed on mixed solutions containing the required constituents at concentrations given in this handbook.

2. The 19F3 test is the combination of the B1, B2, B3, and B4 trainers.

3. The composite test is for the combination of 19F1A, 19F3 (B1, B3, B4), and 19F4 trainers.

5.2.2 Artificial Smoke. Artificial smoke agent is butylated triphenyl phosphate ester hydraulic fluid which contains varied amounts of the toxic substance triphenyl phosphate (TPP). Several states regulate the emission of this substance as a hazardous air pollutant. Artificial smoke as generated is a hot air or aerosol mixture which produces a negligible residue.

Visible emission from a training structure consists of artificial smoke (a white colored hot air or aerosol mixture) and water vapor both of which evaporate to a colorless gas with no particulates. Where visible emission is not permissible, treatment should consist of allowing the effluent to evaporate prior to discharge.

5.2.3 Benzene. Although propane fuel eliminates most emissions of criteria pollutants, benzene is still emitted in trace amounts and concentrations. In some installations, additional stacks have been required by local air pollution authorities to lower ground level plume concentrations of benzene. Emissions testing of 21C12 facilities at STF Norfolk and 19F5 facilities at RTC San Diego were conducted in Fall of 1993. Test results will be published as an amendment to this handbook as soon as results are available.

5.3 Wastewater

5.3.1 General. The water effluent from training structures contains two major contaminants in varying degrees depending on the training being given. Sodium bicarbonate and excessive concentrations of biodegradable surfactant are the contaminants. Wastewater is channeled to a collection tank for pretreatment. Surface runoff from fire training facility pavement can go directly to the storm drain since firefighting agents used outside each structure are also collected and sent to pretreatment.

a) Wastewater effluent characteristics are as noted below in Table 16. These wastewater characteristics are based on actual bench tests performed by LANTNAVFACENGCOM. Limitations for each of these characteristics may vary on a local or state level. Typical wastewater surcharge limits are provided in Table 17. It should be the responsibility of the local EFD's to:

(1) Determine the required level of wastewater treatment.

(2) Determine applicable regulations necessary to obtain the wastewater permit.

(3) Determine the necessity of additional environmental studies of the projected wastewater (if required) to identify:

(a) BOD - biological oxygen demand

(b) COD - chemical oxygen demand

(c) pH

(d) TSS - total suspended solids

(e) TDS - total dissolved solids

(f) Priority pollutant scans

(g) EPA priority pollutant scans

b) The effluent is not toxic as the high COD could imply and is completely biodegradable when combined with acclimated bacteria. Surfactant quantities in excess of 200 mg/kg should require the addition of an anti-foaming agent to suppress foaming. A typical anti-foaming agent is Betz No. 300 defoamer.

c) Firefighting trainer wastewater should always require secondary treatment before being discharged to the environment because of high BOD and COD.

d) Provisions for onsite biological treatment should be provided where the receiving stream does not include secondary treatment. At those sites where Navy owned secondary treatment will be required, the design should consider the effect of precipitate on the treatment process. High surfactant effluent generates a precipitate so it may be desirable to reduce the precipitate in the biological section by flocculating and sedimentation prior to treatment.

e) Alternative AFFF surrogate agents may be available to reduce or eliminate local effluent discharge problems. Although discharge limits will vary at each trainer location, LANTNAVFACENGCOM Code 1811 has conducted a study of several agents to determine amounts of each which can be discharged as part of the effluent stream for the Fleet Training Center (FTC) Norfolk facilities. This information is available upon request from Mr. Ken Clark, Mr. Steve Azar, or Mr. Jim Bailey at (804) 322-4736 or DSN 262-4736.

f) Modifications to the pretreatment process described below may be required to comply with local discharge limitations. If pretreatment is not required by local authorities, it may be deleted.

Table 17
Wastewater Surcharge Limits

	TYPICAL LIMITS (Based on domestic sewage) (maximum)
BOD - Biological Oxygen Demand	230 mg/kg*
COD - Chemical Oxygen Demand	550 - 700 mg/kg*
pH - measure of acidity or alkalinity of a solution	6.5 - 8.5*
Oil and Grease	100 mg/kg
TSS - Total Suspended Solids (consists mostly of siliconized sodium bicarbonate particles)	250 mg/kg*
MBAS - measure of surfactant quantity	200 mg/kg

*Note: These are typical surcharge limits, not compliance limits.

5.3.2 Separation Chamber. The large particle siliconized sodium bicarbonate is partially soluble in water; however, its density is so close to that of water it should stay in suspension with the slightest agitation. Grit and sludge from other sources should accumulate in tanks associated with the wastewater stream and a method for its removal should be included in the tank design. Training wastewater from the fire training structure should be piped to a separation chamber to remove the propane. For details refer to par. 3.2.9 and Appendix A, Figure A-15.

5.3.3 Pretreatment. Fire training wastewater should be collected in an equalization tank sized to hold 125 percent of the largest one day's effluent. This should allow various firefighting agent concentrations to mix and dilute each other. It should also allow a homogeneous batch of wastewater to be monitored and then discharged to the sanitary sewer system at a controlled rate. There should be two equal size equalization tanks so that one can be discharging while the second is receiving. During maintenance periods the active tank can discharge at night. Each of the equalization tanks should have draft marks in increments sufficient for operators to estimate tank contents to the nearest 1900 L.

a) Piping and valves associated with equalization tanks should be designed for flexibility of use. Tanks should overflow to each other. Each tank should have provisions for mechanical agitation and sludge removal. The agitation should be a high volume low head pumped recirculation system with a 90-degree elbow and length of pipe at the discharge so the operator can manually adjust between submerged or open discharge. The open discharge would afford some aeration. Sludge handling provisions may consist of a sump or trough to which the grit can be hosed for removal by shovel and bucket. The sump should have a drain piped directly to the exterior of the tank for future addition of a pumped system if it becomes practical. Provide permanent personnel access to the bottom of tanks and a standpipe, SP, so tanks can be hosed down with a 40 mm fire hose.

b) Consideration should be given to the option of using a covered reservoir. The trade-offs are the cost of disposing of collected precipitation and freeze protection.

c) A chemical addition system should be provided for addition of acid, caustic, and defoaming agent. These three chemicals should be separately pumped at an adjustable rate to either equalization tank. The injection rate should be determined manually. Prior to discharging the wastewater to a secondary treatment plant, the operator should determine the pH of the effluent and make adjustments as necessary. Automatic pH adjustment with manual override can also be used. Provide a separate containment for each of the three chemicals used for the pretreatment. The containment basin should be designed to keep chemicals from mixing and to control chemicals in the event of spillage. A drain should not be provided. The containment should be designed to hold 125 percent of the amount of chemical drum storage intended for the area. Provide local exhaust in the chemical containment area. The exhaust system should manually operate from the local area.

d) When the pH is adjusted, the wastewater is ready for discharge. If monitoring is required by local authorities, it should be done at this time. A daily log of sampling data and chemical additions should be maintained by the user. Discharge to the sewer system should be controllable and verifiable because the rate should be used for billing purposes. The preferred system is dual sump pumps designed to evacuate the tank in 8 to 10 hours.

e) Local municipal treatment plants will periodically want a chemical analysis of the effluent being discharged to it. The reporting period may be short at first but then lengthened as confidence in the pretreatment process is gained. A sampling should best be done by a contract laboratory since its purpose is to determine permit compliance and its final frequency should not justify funding "in-house" capability. An automatic sample taking machine should be provided at fire training sites to facilitate the sample taking process. The controls for sump and recirculation pumps should include level controls, lead-log capability, alarm conditions for high-high and pump failure. Alarm conditions should be sent to the central annunciator panel in the utility building and to the 24-hour duty desk.

f) The inlet to the discharge and recirculation pumps should be provided with readily cleanable strainer to catch leaves and frogs, etc., which have been a problem in the past.

g) Pumps which take suction from the equalization tank should be protected by a low level shutoff switch.

5.3.4 Recovery. Wastewater recovery normally cost more than purchase, treatment, and disposal of potable water. In some instances, however, water use may be restricted and the more expensive route will be necessary. Recycled water should not cause a health hazard and should be compatible with device sensors. To avoid a health hazard, organic materials added during firefighting should be removed and the water should then be made clear since the device sensors use opacity to differentiate between foam and water. A carbon absorption procedure would be required to remove the organic material followed by a reverse osmosis system to remove the remaining dissolved solids and clear up the water. Since there are chemical compounds which are not removed by the above processes, the addition of new water and blow down would still be required. If recycling water is a serious consideration, more study would be required by the cognizant EFD to derive an acceptable system.

a) Wastewater associated with firefighting structures have low suspended solids, high dissolved solids (DS), high BOD, high COD, high pH, and high total toxic organics (TTO) levels. Recycling will arithmetically escalate the untreated portions of the wastewater (DS, BOD, COD, pH, and TTO), after each training scenario, to such high levels that device sensors and training personnel's health could be effected. Also, high levels of TDS, BOD, COD, pH, and TTS may prevent direct discharge into a sanitary sewer. The recycling system should consider each of the portions. The device sensor water requirements are given in the chart below:

pH Range	7.5 (max) - 6.5 (max)
Particle Size	40 microns
Color	None
Refoaming	Should not foam when sprayed
Safety	Not harmful to personnel

b) Recycling of water does not effect the storage requirement for potable water. The EFD environmental quality division should determine the required wastewater treatment, applicable regulations necessary to obtain the wastewater permit, and the necessity of required environmental studies of

the projected wastewater to identify: BOD, COD, pH, TSS, TDS, priority pollutant scans, Environmental Protection Agency (EPA) priority pollutant scans as required; water reclaim.

Fireplace Support

APPENDIX A (Continued)

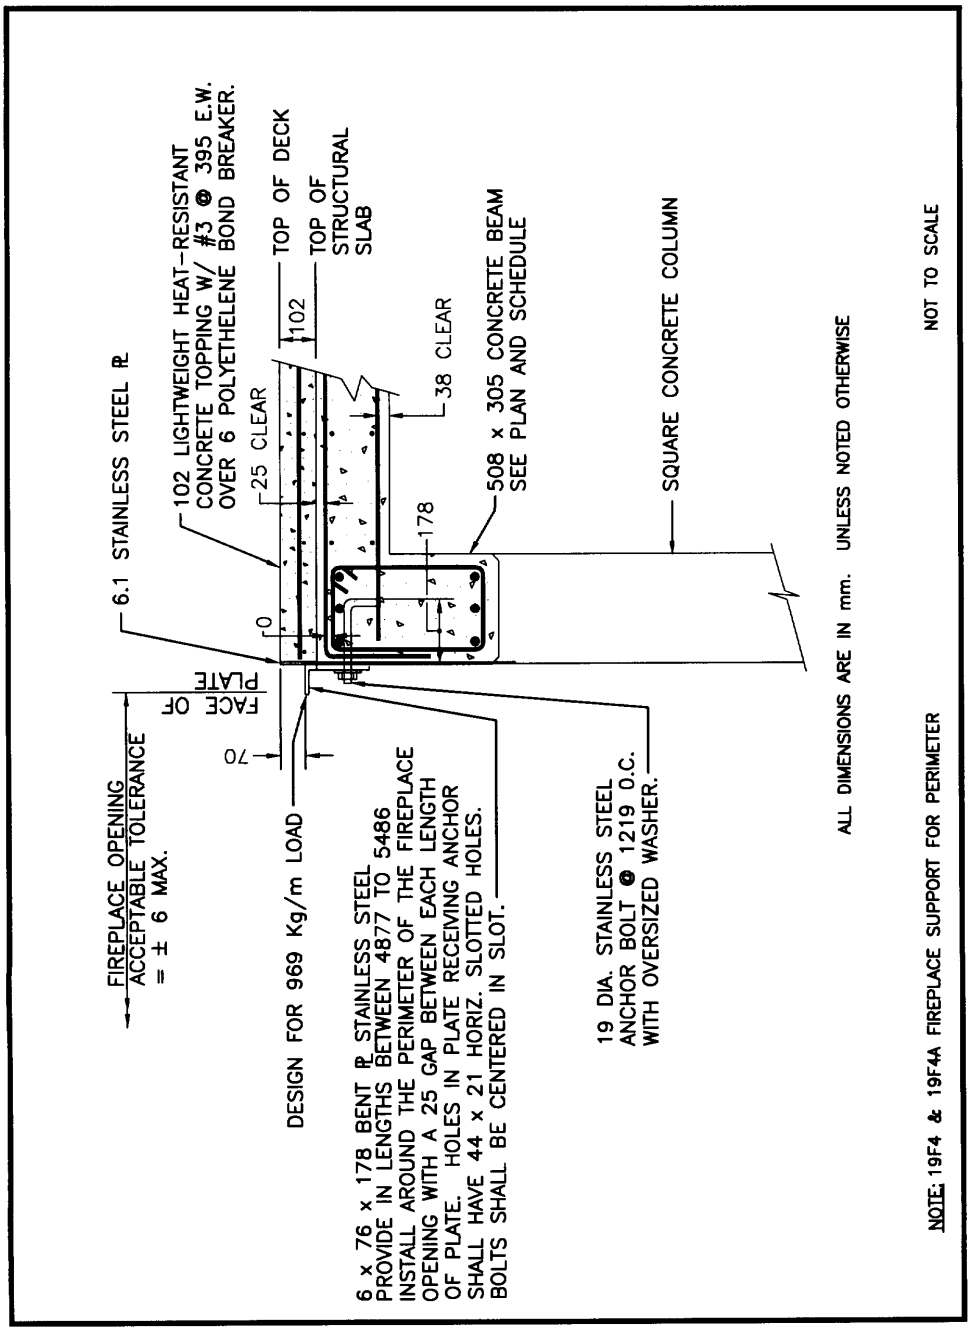

Figure A-9B

FIREPLACE SUPPORT

APPENDIX A (Continued)

DEEP FAT FIRE

PKP emission 0.0690 kg in 6 runs during test
0.011 kg E/run
PKP discharge 2 kg D/run during test
PKP emission rate 0.011 ÷ 2 = 0.005 kg E/kg D

3 Deep fat fires + 4 discretionary fires = 7 fires/class
*2 classes running together x 7 = 14 fires/day
9 kg discharge/fire x 3 fires/hr = 27 kg D/hr
x 14 fires/day = 127 kg D/day
27 kg D/hr x 0.005 kg E/kg D = 0.14 kg E/hr
127 kg D/day x 0.005 kg E/kg D = 0.64 kg E/day

BILGE FIRE

PKP emission 0.011 kg in 6 runs during test
0.002 kg E/run

PKP discharge rate 0.002 ÷ 7 = 0.0003 kg E/kg D
8 bilge fires/class x 2 classes = 16 fires
**9 kg discharge/fire x 6 fires/hr = 54 kg D/hr
x 16 fires/day = 144 kg D/day

54 kg D/hr x 0.0003 kg E/kg D = 0.016 kg E/hr
145 kg D/day x 0.0003 kg E/kg D = 0.048 kg E/day

TOTAL Maximum

***0.14 kg E/hr + 0.016 kg E/hr = 0.156 kg E/hr
27 kg D/hr + 54 kg D/hr = 81 kg D/hr

*0.64 kg E/day + 0.043 kg E/day = 0.684 kg E/day
127 kg D/day + 145 kg D/day = 272 kg D/day

*This represents the worst day where PKP fires for 2 classes were run in 1 day. This is very unlikely.

**7 kg D/run was used during test but figure 9 kg D/run for training purposes.

***Three 20 minute exercises per hour on the deep fat fire and the bilge fire for a total of 6 fires is the maximum training rate.

Figure A-20A
EXHAUST FAN/CRAWL SPACE
POWER CONTROLS & INTERLOCKS

APPENDIX A (Continued)

EXHAUST FAN SEQUENCE OF OPERATION:

HAND MODE: WHEN THE START PUSHBUTTON, PB1A, IS PRESSED, THE FAN CONTROL RELAY, CR1, ENERGIZES AND LATCHES IN THE CIRCUIT. AS THE FAN COMES UP TO SPEED, MINIMUM AIRFLOW DIFFERENTIAL PRESSURE IS GENERATED, ACTIVATING R1A. THIS CAUSES THE RUN INDICATOR, L1A, TO LIGHT. PRESSING THE STOP BUTTON, PB1B, UNLATCHES THE CIRCUIT WHICH DEENERGIZES THE FAN CONTROL RELAY AND RUN INDICATOR.

AUTO MODE: WHEN THE REMOTE CONTROL RELAY, R1C, IS ENERGIZED, THE FAN CONTROL RELAY, CR1, IS ALSO ENERGIZED. AS THE FAN COMES UP TO SPEED, MINIMUM AIRFLOW DIFFERENTIAL PRESSURE IS GENERATED, ACTIVATING R1A. THIS CAUSES THE RUN INDICATOR, L1A, TO LIGHT. DEENERGIZING THE DEVICE COMPUTER CONTROL RELAY RELEASES THE FAN CONTROL RELAY AND TURNS OFF THE RUN INDICATOR.

INTERLOCKS AND ALARMS (HAND AND AUTO MODES): IF NORMAL DIFFERENTIAL PRESSURE IS SENSED (FAN IS RUNNING), RELAY R1A IS ENERGIZED. EXCESSIVE DIFFERENTIAL PRESSURE (FAN RUNNING WITH DAMPER CLOSED) CAUSES R1B TO ENERGIZE. WHEN THE FAN IS COMMANDED ON AND EITHER INSUFFICIENT OR EXCESSIVE DIFFERENTIAL PRESSURE IS SENSED FOR 15 SECONDS, RELAY TR1A (TR2A) ENERGIZES AND LATCHES IN. THIS DEENERGIZES THE FAN CONTROL RELAY, CR1 AND LIGHTS THE FAN FAILURE INDICATOR, L1B. WHEN THE FAN IS COMMANDED OFF AND NORMAL DIFFERENTIAL PRESSURE IS SENSED FOR 15 SECONDS, RELAY TR1B ENERGIZES AND LATCHES IN. THIS ALSO CAUSES INDICATOR L1B TO LIGHT.

NOTES: 1. CONTROL LOGIC MAY BE IMPLEMENTED IN DISCRETE HARDWARE OR IN A SMALL PROGRAMMABLE LOGIC CONTROLLER.
2. TIMER RELAYS PROVIDE A DELAY AS NOTED AFTER POWER IS APPLIED. WHEN POWER IS REMOVED THE CONTACTS RESET IMMEDIATELY.

Figure A-20B
Exhaust Fan/Crawl Space Power Controls and Interlocks

APPENDIX A (Continued)

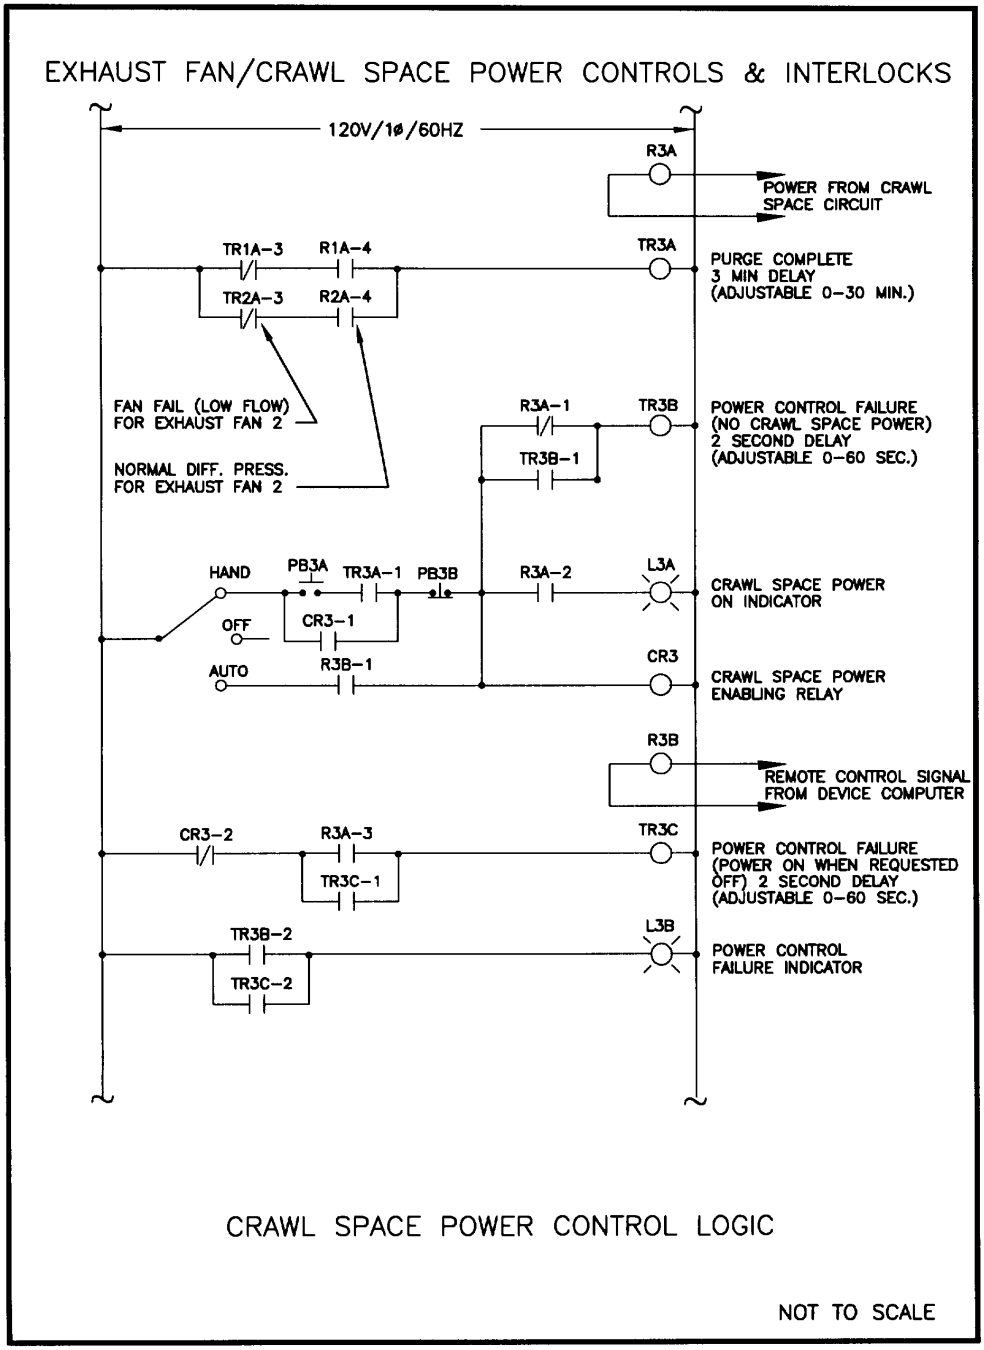

Figure A-20C
EXHAUST FAN/CRAWL SPACE
POWER CONTROLS & INTERLOCKS

APPENDIX A (Continued)

CRAWL SPACE POWER SEQUENCE OF OPERATION:

HAND MODE: WHEN EITHER FAN IS ON FOR 10 MINUTES WITHOUT A DETECTED FAILURE, THE PURGE COMPLETE RELAY, TR3A, IS ENERGIZED. WHEN THE ON PUSHBUTTON, PB3B, IS PRESSED AND TR3A IS ENERGIZED, THE CRAWL SPACE POWER RELAY, CR3, ENERGIZES AND LATCHES IN THE CIRCUIT. THIS PROVIDES POWER TO THE CRAWL SPACE, ENERGIZING RELAY R3A AND LIGHTING THE POWER INDICATOR, L3A. PRESSING THE OFF PUSHBUTTON, PB3B, UNLATCHES THE CIRCUIT WHICH DEENERGIZES THE POWER CONTROL RELAY AND POWER INDICATOR.

AUTO MODE: WHEN THE REMOTE CONTROL RELAY, R3B, IS ENERGIZED, THE FAN CONTROL RELAY, CR3, IS ALSO ENERGIZED. THIS PROVIDES POWER TO THE CRAWL SPACE, ENERGIZING RELAY R3A AND LIGHTING THE POWER INDICATOR, L3A. WHEN THE DEVICE COMPUTER CONTROL RELAY RELEASES, THE CRAWL SPACE POWER RELAY AND INDICATOR DEENERGIZE.

ALARMS (HAND AND AUTO): IF RELAY R3A DOES NOT ENERGIZE WITHIN 2 SECONDS AFTER POWER IS COMMANDED ON, POWER FAILURE RELAY TR3B ENERGIZES AND LATCHES ON. IF RELAY R3A DOES NOT DEENERGIZE WITHING 2 SECONDS AFTER POWER IS COMMANDED OFF, POWER FAILURE RELAY TR3C ENERGIZES AND LATCHES ON. WHENEVER EITHER POWER FAILURE RELAY IS COMMANDED THE POWER CONTROL FAILURE INDICATOR, L3B, LIGHTS.

NOTES: 1. CONTROL LOGIC MAY BE IMPLEMENTED IN DISCRETE HARDWARE OR IN A SMALL PROGRAMMABLE LOGIC CONTROLLER.
2. TIMER RELAYS PROVIDE A DELAY AS NOTED AFTER POWER IS APPLIED. WHEN POWER IS REMOVED THE CONTACTS RESET IMMEDIATELY.

APPENDIX A (Continued)

NOTES:

1. LOCATE SAMPLE COCK SO IT CAN FILL A 19 L AFFF CAN.

2. ALL PIPES SHOULD BE PIPED TO ALLOW DRAINING FOR FREEZE PROTECTION. PROVIDE DRAINS AT LOW POINTS.

3. TANK SIZE: 19F1A-303 L
19F3-B1-303 L
19F3-B3-379 L
19F3-B4-379 L
19F3A -379 L
19F5 -379 L

4. SOURCE OF SUPPLY IS THE REQUIRED SOURCE OF SUPPLY.

5. PAINT WATER PIPING RED AFFF CONCENTRATE PIPING GREEN, 6% AFFF PIPING RED AND GREEN STRIPED, EXCEPT AT FOAM STATION WHERE ONLY THE VALVE HANDLES SHOULD BE COLOR CODED.

6. THE TANK SHOULD HAVE:

(A) AN EXTERNALLY MOUNTED LIQUID LEVEL INDICATOR ASSEMBLY PROTECTED FROM BREAKAGE BY AN EXPANDED METAL CASE.

(B) A GOOSENECK PIPE VENT 25 MM IN DIAMETER.

(C) TWO 200 MM INSIDE DIAMETER TANK FILL FUNNEL TAPERING TO 80 MM DIAMETER WITH A FLANGED TOP RIM BOLTED INTO A 80 MM TALL BOSS ON THE TANK TOP. PROVIDE 80 MM STAINLESS STEEL PIPE SCREENS, RUN PIPING TO 80 MM ABOVE TANK BOTTOM.

(D) A FUNNEL TOP THREADED TO RECEIVE A SCREW-IN FUNNEL COVER REQUIRING NO MORE THAN THREE TURNS TO REMOVE/REPLACE.

(E) A FUNNEL COVER FITTED WITH 102 MM WIDE U-SHAPED HANDLE TO FACILITATE USE.

(F) A 80 MM PIPE EXTENDING FROM THE FUNNEL BOTTOM TO WITHIN 51 MM OF THE TANK BOTTOM.

Figure A-21C
AFFF Station

APPENDIX A (Continued)

NOTES (Continued):

(G) A PUMP SUCTION CONNECTION WITH A WELDING REDUCER HAVING ITS LARGER END WELDED FLUSH WITH THE BOTTOM OF THE TANK. THE INLET AREA HAVING NOTES APPROXIMATELY FOUR TIMES THE FLOW AREA OF THE SUCTION PIPING.

(H) TANK SHOULD BE CONSTRUCTED OF STAINLESS STEEL (SS 316).

(I) A BOLTED ACCESS PLATE WITH GASKET IN THE TANK SIDE TO ALLOW A MINIMUM OF 305 MM CLEARANCE FOR CLEANING.

7. TRAINER REQUIREMENTS:

19F1A HAS 1 FOAM STATION SERVING 2 FOAM REELS
19F3-B1 HAS 1 FOAM STATION SERVING 2 FOAM REELS
19F3-B3 HAS 1 FOAM STATION SERVING 1 FOAM REEL
19F3-B4 HAS 1 FOAM STATION SERVING 1 FOAM REEL 19F3A HAS 1 FOAM STATION SERVING 3 FOAM REELS (USE OF STD. COMM. FOAM PROPORTIONING EQUIPMENT WITH 4 FOAM REELS IS APPROVED).

8. MOTOR CONTROLLER: (NEMA 4 ENCLOSURE)

(A) SEE SHEET 4 FOR PHYSICAL REQUIREMENTS

(B) SWITCHES SHOULD BE APPROVED FOR WET LOCATIONS

9. MASTER SOPV

(A) USE 480 V SOLENOIDS

10. AFFF PIPING, VALVES AND FITTINGS SHOULD BE STAINLESS STEEL OR COPPER.

11. PUMP IS BLACKMER PUMP MODEL BXL-1-1/4 (MFG. DWG. NO. E-4638) WITH STD. ELECTRIC MOTOR (7-1/2 HP, TOTAL ENCLOSED FAN COOLED).

12. PROVIDE VIBRATION ISOLATORS FOR AFFF STATION SUPPORTS.

Figure A-21D
AFFF Station

APPENDIX A (Continued)

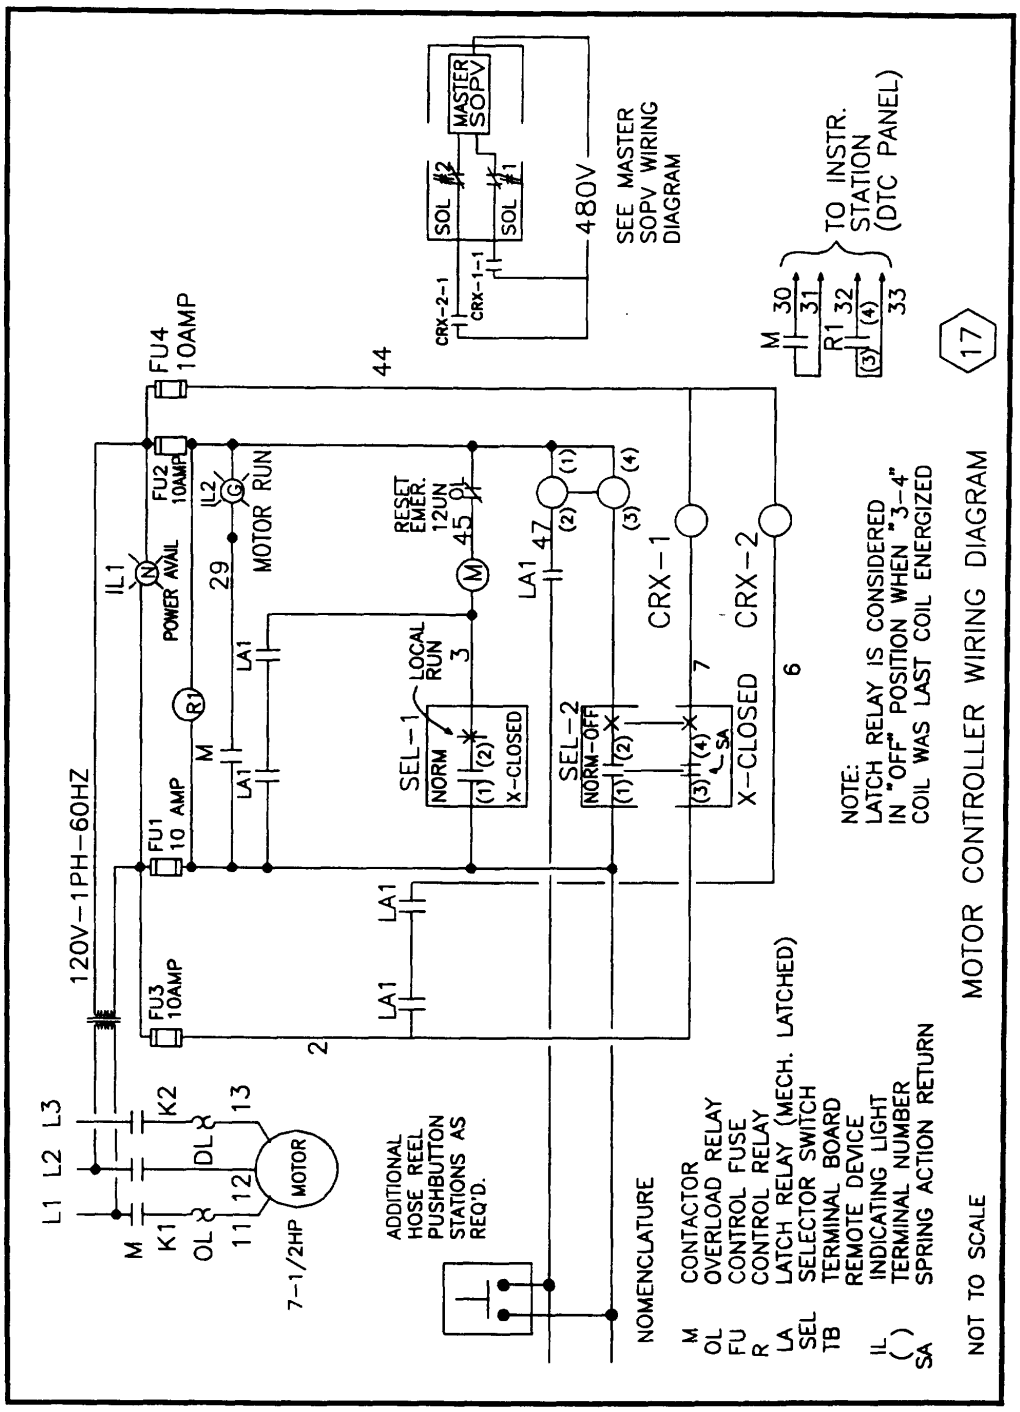

Figure A-21E
AFFF Station

APPENDIX A (Continued)

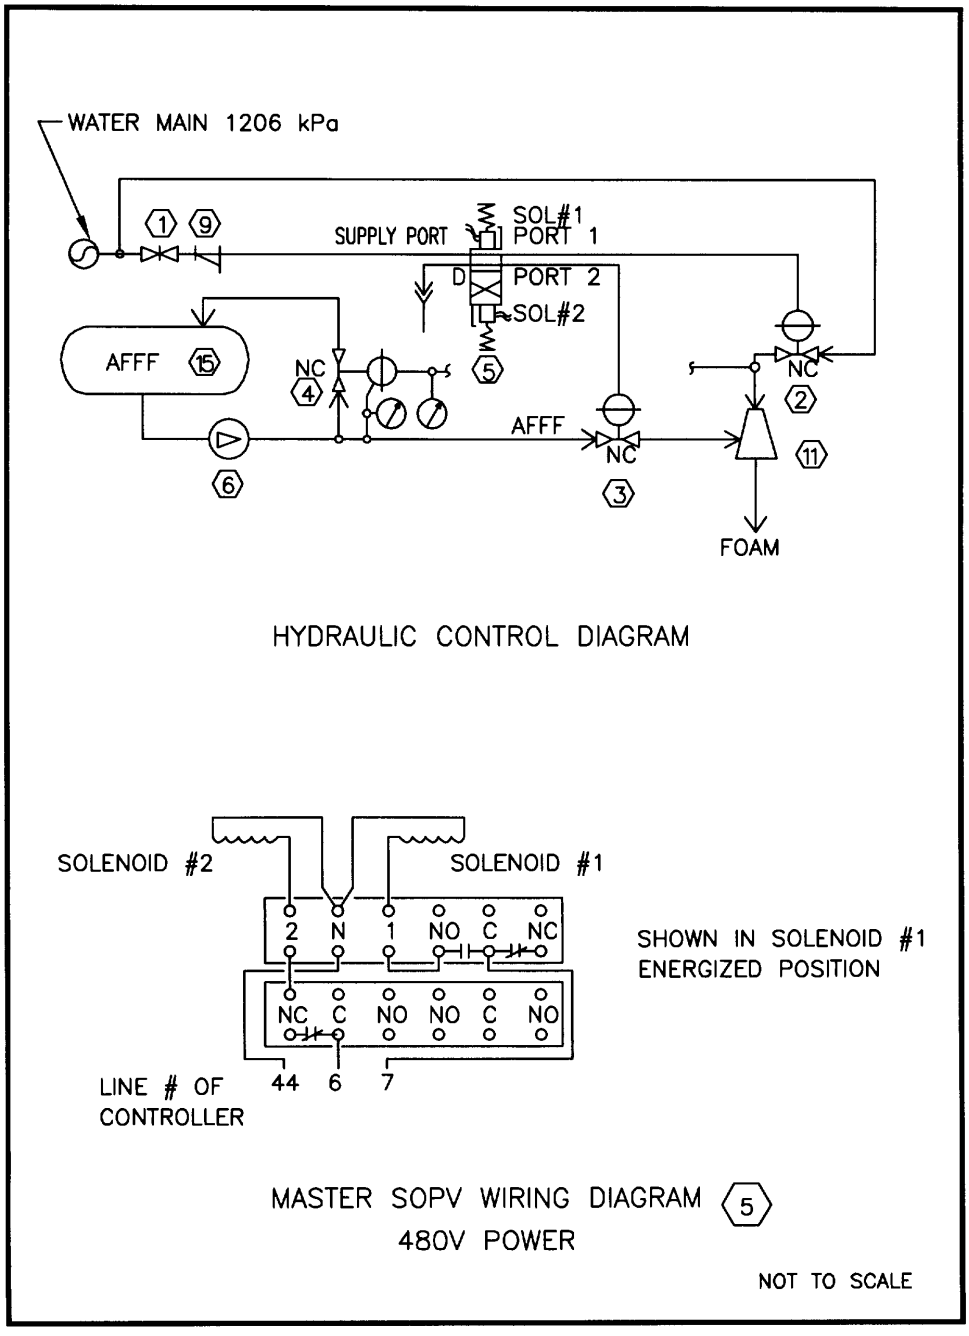

Figure A–21F
AFFF Station

APPENDIX A (Continued)

SEQUENCE OF OPERATION:

1. SUPPLY POWER TO MOTOR CONTROLLER CONTROL TRANSFORMER. THE WHITE POWER AVAILABLE LIGHT (IL 1) IS LIT. BOTH SELECTOR SWITCH ONE (SEL 1) AND SELECTOR SWITCH TWO (SEL 2) ARE IN "NORMAL" POSITION AND BOTH AFFF CONCENTRATE AND BACK PRESSURE GAGES SHOW NO PRESSURE.

2. IN NORMAL MODE BOTH SEL 1 AND SEL 2 SHOULD BE IN "NORMAL" POSITION, MASTER SOPV CONNECTS SUPPLY PORT TO PORT #2 WHICH SUPPLIES PRESSURE TO (2) WATER CONTROL VALVE (PRESSURE TO CLOSE) AND CONNECTS DRAIN PORT TO PORT #1 WHICH RELIEVES PRESSURE TO (3) AFFF CONCENTRATE DISCHARGE CONTROL VALVE (RELIEF TO CLOSE). (4) BACK PRESSURE REGULATING VALVE IS IN FULL RECIRCULATING MODE TO AFFF TANK.

3. TO START PUMP

A. LOCAL OPERATING MODE: PLACE "NORMAL/LOCAL RUN" SWITCH (SEL 1) IN THE LOCAL RUN POSITION THE PUMP WILL START AND GREEN MOTOR RUN LIGHT (IL 2) ON THE CONTROLLER IS LIT.

B. REMOTE OPERATING MODE ((7) HOSE STATION PUSHBUTTON): MOMENTARILY PUSH HOSE REEL PUSHBUTTON. THE PUMP WILL START AND GREEN MOTOR RUN LIGHT (IL 2) ON THE CONTROLLER IS LIT. IN ORDER TO ENERGIZE SOLENOID #2, MOMENTARILY PRESS THE PUSHBUTTON. THE PURPOSE OF THE LOCAL MODE IS TO ALLOW THE AFFF PUMPS TO RUN, READY FOR ACTION, WITHOUT INJECTING FOAM INTO THE WATER MAIN. WHEN THE FOAM REEL STATIONS ARE READY FOR FOAM, THE TRAINEE PRESSES THE REMOTE PUSHBUTTON.

4. WHEN PUMP IS RUNNING, THE MOTOR CONTROLLER ENERGIZES SOLENOID #2 OF THE (5) MASTER SOPV, WHICH CONNECTS SUPPLY PORT TO PORT #1 WHICH SUPPLIES PRESSURE TO (3) AFFF CONCENTRATE CONTROL VALVE WHICH GOES TO FULL OPEN POSITION AND CONNECTS DRAIN PORT TO PORT #2 WHICH RELIEVES PRESSURE TO (2) WATER CONTROL VALVE WHICH GOES TO FULL OPEN POSITION. SOLENOID #2 IS DEENERGIZED AT THE END OF ITS STROKE.

5. THE (4) BACK PRESSURE REGULATING VALVE SHOULD SELF REGULATE SO THAT THE PRESSURE OF THE AFFF CONCENTRATE IS EQUAL TO THE WATER AT THE FLOW PROPORTIONER.

Figure A-21G
AFFF Station

APPENDIX A (Continued)

SEQUENCE OF OPERATION (CONTINUED):

6. TO STOP PUMP

A. LOCAL OPERATING MODE:

(1) PLACE "NORMAL/LOCAL RUN" SWITCH (SEL 1) TO "NORMAL" POSITION.

(2) MOMENTARILY PLACE "NORMAL/OFF" SWITCH (SEL 2) TO "OFF" POSITION. TO ENERGIZE SOLENOID #1 TO CLOSE (3) AFFF CONCENTRATE VALVE AND (2) WATER CONTROL VALVE, AND RESET LATCH RELAY.

B. REMOTE OPERATING MODE:

(1) MOMENTARILY PLACE "NORMAL/OFF" SWITCH TO "OFF" POSITION TO ENERGIZE SOLENOID #1 TO CLOSE (3) AFFF CONCENTRATE VALVE AND (2) WATER CONTROL VALVE AND RESET LATCH RELAY.

TYPE 1 & 2

LUMINAIRE REQUIREMENTS

1. LUMINAIRE SHALL MEET U.L. 844 OR FACTORY MUTUAL (FM) STANDARD FOR HAZARDOUS LOCATIONS.

2. LUMINAIRE SHALL MEET U.L. 595 FOR MARINE LOCATIONS.

3. HOUSING SHALL BE COPPER FREE CAST ALUMINUM WITH LACQUER OR EPOXY FINISH.

4. ALL JOINTS SHALL BE OF THE THREADED TYPE.

5. HEAT AND IMPACT RESISTANT PRESTRESSED GLASS GLOBE.

6. PROVIDE GLOBE GUARD INDICATED.

7. PROVIDE LAMPS AS INDICATED.

8. MOUNTING AS INDICATED.

9. PROVIDE INTERNAL GREEN GROUNDING SCREW.

TYPE 1 TWO 9 WATT COMPACT FLURESCENT LUMINIRES RATED FOR CLASS 1 DIVISION 2 GRUOP D ATOSHPHERE.

TYPE 2 70-250WATT HPS OR 175-400 WATT MET. HALIDE LUMINAIRE RATED FOR CLASS 1 DIVISON 2 GROUP D ATOSHPHERE.

Record of Changes (changes are indicated by **\1** ... **/1/**)

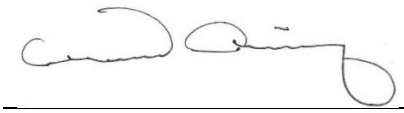
Change No.	Date	Location
1	13 Mar 2025	Multiple CCRs, allowed granular rubber traps for all Services, and clarified the criteria for prohibiting A/C in most indoor ranges.

This UFC supersedes MIL-HDBK 1027/3B, dated November 1992 and ETL 11-18 dated November 2018.

This Page Intentionally Left Blank

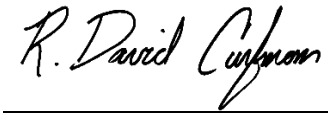
FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States, its territories, and possessions is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA). Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.



UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Military Department's responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Systems Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Technical content of UFC is the responsibility of the cognizant DoD working group. Defense Agencies should contact the respective DoD Working Group for document interpretation and improvements. Recommended changes with supporting rationale may be sent to the respective DoD working group by submitting a Criteria Change Request (CCR) via the Internet site listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:



- Whole Building Design Guide website https://www.wbdg.org/dod.

Refer to UFC 1-200-01, *DoD Building Code*, for implementation of new issuances on projects.

UNIFIED FACILITIES CRITERIA (UFC)

NEW SUMMARY SHEET

Document: UFC 4-179-02, Small Arms Range Criteria.

Superseding: Navy MIL HNDBK 1027/3B and Air Force ETL 11-18.

Description: This UFC-4-179-02 replaces the superseded documents above and provides Tri Service criteria applicable all new DoD indoor, outdoor, and steel close quarter combat small arms range facilities. This UFC establishes existing Army and USMC Surface Danger Zone criteria as Tri Service criteria and references other Department of Defense (DoD) range criteria where appropriate.

Reasons for Document:

- The new UFC updates and consolidates various service range guidance into one Tri Service document and addresses many areas not covered in existing DoD range criteria.
- The superseded documents included requirements that were inconsistent between each other and other service practices.

Impact:

This unification effort will result in more consistent requirements across DoD and will increase DoD range safety, improve training, and reduce costs in the following ways:

- Provides new and updated criteria that is consistent throughout DoD and a centralized source to share and apply lessons learned.
- Improves indoor range ventilation designs which in turn reduces the chance of overexposure to airborne contaminants.
- Improves indoor range noise attenuation designs which in turn reduces the impacts of harmful noise to personnel at the range.
- Highlights exterior noise concerns and thus reduces noise to neighboring areas.
- Increases awareness of indoor range options and capabilities. This allows for facilities that improve training to warfighters.
- Provides criteria on steel CQC facilities which is currently absent in DoD.
- Provides suppliers with consistent standards thus simplifying procurement of range equipment for both DoD and contractors.

Unification Issues:

General:

Several service specific planning and layout requirements are included since:

- The Army has extensive planning criteria for outdoor ranges. The Air Force has detailed planning requirements for the indirect support area of indoor ranges. The Navy has no separate range planning criteria.

- Training requirements vary between the services, and this dictates different range requirements and layouts.

Outdoor ranges:

The Army, Navy, and USMC use DA PAM 385-63 and MCO 3570 for SDZ criteria. The Air Force uses horizontal distances listed in these criteria but different distances for the vertical component of the Surface Danger Zone. A separate table with vertical components is included for Air Force use.

Services have different access, signage, and marking requirements. A statement is made to use service installation guidance.

The Army, USMC, and Air Force allow machine gun training on tube ranges. These tube ranges do not support traverse firing that is required for maritime machine gun training. A statement is made not to use tube ranges for Navy machine gun qualifications.

Indoor Ranges:

\1\ /1/

The Air Force requires a raised floor in the range control booth. The other services do not. A note is included to use raised floors on Air Force projects.

CQC Facilities and Shoothouses:

The Army allows an option to glue splatter protection directly to the ballistic panels in steel shoothouses. The Navy requires an air gap between steel panels and the splatter protection to facilitate inspections and to increase the life of the splatter protection. Service specific guidance is provided.

The Army uses Shock Absorbing Concrete (SACON) as an option for ballistic walls and does not require a ballistic roof when an SDZ waiver is obtained. The Navy only uses steel shoothouses with steel ballistic panels and overhead ballistic containment. This criteria only covers steel shoothouses with a ballistic roof and refers to Army when designing SACON shoothouses.

CHAPTER 1 INTRODUCTION

1-1 PURPOSE AND SCOPE.

This Unified Facility Criteria (UFC) provides requirements for DoD small arms range facilities.

1-2 APPLICABILITY.

This UFC follows the same applicability as UFC 1-200-01, paragraph 1-3, for indoor, outdoor, and steel Close Quarter Combat (CQC) small arms range facilities (also known as shoothouses).

1-3 OTHER CRITERIA.

1-3.1 General Building Requirements.

Comply with UFC 1-200-01, *DoD Building Code*. UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

1-3.2 Antiterrorism and Security.

UFC 4-020-01 supports the planning of DoD facilities that include requirements for security and antiterrorism. Use UFC 4-020-01 in conjunction with UFC 4-010-01 to establish the security and antiterrorism design criteria that will be the basis for DoD facility designs. All DoD facilities must also comply with Geographic Combatant Commander antiterrorism construction standards for antiterrorism requirements.

1-3.3 Sustainability.

For indoor ranges, the indirect support areas must meet UFC 1-200-02. The design of the training and direct support areas is driven by containment and ventilation criteria and must meet UFC 1-200-02 to the extent practical.

1-3.4 Service Specific DoD Range Criteria.

- AR 350-19.
- AR 350-52.
- DA PAM 385-63.
- TC-25-8.
- MCO 3570.1.
- FC 4-179-03F.

- AF 36-2654. **\1** (Soon to be replaced with DAFI31-131 and DAFMAN31-131 V1) **/1/**

1-3.5 Army Ranges.

Range layouts, target distances, lane widths, target systems, and baffle effects are standard and defined by the Training Circular TC 25-8. Specific range design requirements are as defined in the Range Design Guide (RDG).

1-3.6 Non-Standard Ranges.

For non-standard ranges that do not have applicable criteria in this UFC, consult with the specific service range subject matter expert.

1-4 CYBERSECURITY.

All facility-related control systems (including systems separate from a utility monitoring and control system) must be planned, designed, acquired, executed, and maintained in accordance with UFC 4-010-06, and as required by individual Service Implementation Policy.

1-5 BEST PRACTICES.

Appendix A contains best practices.

1-6 WEAPONS AND AMMUNITION.

Appendix B contains a general description of common weapons and ammunition used by DoD.

1-7 GLOSSARY.

Appendix C contains acronyms, abbreviations, and terms.

1-8 REFERENCES.

Appendix D contains a list of references used in this document. The publication date of the code or standard is not included in this document. Unless otherwise specified, the most recent edition of the referenced publication applies.

CHAPTER 2 GENERAL

2-1 PLANNING.

Design ranges to meet the need of the intended training. Consider the number of shooters and firing lanes, anticipated weapons and ammunition, target systems, target distances, scoring accuracy required, shooting directions and angles, and components necessary to maintain and support the range. Establish a team to review range requirements and develop the project. The team composition will depend on the service but in general should include service range experts, weapons and range safety officers, organizational range safety personnel, trainers, industrial hygienists, activity planners, project managers, fire protection and environmental personnel, and others that will be involved in operations and maintenance of the facility. For outdoor ranges plot the proposed Surface Danger Zone (SDZ) and check for conflicts early in the planning phase. Check aircraft operations and contact the Federal Aviation Administration (FAA) if there is a vertical weapon component that could endanger aircraft.

2-2 BASIS OF DESIGN.

For the initial design submittal include a separate document outlining the parameters and assumptions on which the range design is based. All range design parameters should be provided or verified by the service's range safety program. This information will help ensure the range is operated and maintained with appropriate restrictions and should include:

All Ranges:

- The most powerful rounds in terms of energy and maximum distance.
- A sketch for indoor ranges and a Geographic Information System (GIS) map for outdoor ranges showing location of all firing lines, target lines, direction of fire, and left and right limits.
- Maximum target distance provided.
- Target systems.
- Assumptions used for sizing range support areas including the number of targets, weapons, and students.

Outdoor Ranges:

- A Surface Danger Zone (SDZ) map provided by the government annotated to show the location of SDZ enforcement features including topography, range fencing, base limits, signage, and road barriers.
- A list of recommended best management practices.

Indoor Ranges and CQC Facilities:

- A sketch showing the location and maintenance access to all range equipment and controls including targeting systems, ventilation equipment, filters, trap equipment, dust collection system, bullet collection components, and lighting controls.
- A floor plan showing live fire areas with direction of fire and any limitations imposed such as areas or walls not designed for live fire.
- A floor plan showing range support functions such as classrooms armories, offices, simulators etc.
- Bullet trap and ventilation operation and maintenance manuals provided at end of project.

2-3 MATERIAL.

2-3.1 Concrete.

All concrete that may receive bullet strikes must be minimum 3500 psi (24 MPa). Structural design may require higher strengths.

2-3.2 Ballistic and \1\ Abrasion Resistant (AR) /1/ Steel Plate.

Ballistic steel plate and AR Steel Plate must be tested in accordance with ASTM E10-08, meet MIL-A-46100, and certified as having the following Brinell Hardness (HBW):

- AR500: HBW between 470 and 544.
- AR525: HBW between 500 and 544.

In addition, require:

- Certifications for all ballistic steel plates.
- **\1** Only steel bullet trap component exposed to bullet impact are required to meet both ASTM E10-08 and MIL-A-46100 certification requirements.**/1/**
- Connection made in such a manner as to maintain ballistic properties.
- All cuts made in a manner that does not alter or reduce hardness.
- Ballistic integrity maintained across all joints.

2-3.3 Splatter Protection for Overhead Baffles and Safety Ceiling.

Splatter protection must have spacers providing minimum 1-1/2” (38 mm) air gap between splatter protection and the underlying material with the exception that Army ranges may have splatter protection glued directly to the underlying material. Splatter

protection material must be fire resistant and must not contain any metal or metal fibers, excluding fasteners. Design splatter protection to allow for removal and replacement without damage to the splatter protection, spacers, or underlying material. Choose from among the following:

- 0.375 in. (9.5 mm) two-ply rubber conveyor belt material. Must not contain any metal.
- 2 in. (50 mm) thick vulcanized rubber.
- 2 in. (50 mm) cold-pressed ballistic rubber.
- Minimum 0.75 in. (19 mm) fire-retardant plywood.
- Other material may be used when approved.
- Acoustic material with tests results showing material can stop splatter from rifle rounds after striking underlying steel plates.
- Spacer material may be wood, light-gauge steel channels, or recycled plastic lumber.

2-3.4 Splatter Protection for Steel CQC Facilities.

Choose splatter protection options that provide:

- Containment of splatter within wall.
- Capability to easily remove and replace to allow inspection of ballistic steel.
- Ease of maintenance.
- Fire resistance.

For Navy projects, use spacers that provide a 1.5-in. (37 mm) air gap between steel and splatter protection to reduce damage to backside of splatter protection and simplify removal for routine inspection of ballistic steel panels. Army facilities may have splatter protection glued directly to the ballistic panels.

2-4 AIR FORCE RANGES.

The Air Force allows only outdoor non-contained, machine gun tube, or fully enclosed indoor ranges for new construction. The following applies to Air Force indoor and outdoor small arms ranges.

2-4.1 Firing Line Positions and Platforms.

All small arms ranges should have a minimum of seven positions at the firing line. Additional positions may be added in increments of seven. The width of the firing

position must be at least 5 ft. (1.5 m) center-to-center. The firing line must be located on a stable horizontal surface with a clear distance that is at least 14 ft. (4.3 m) in depth for the length of the firing line. For most ranges, the firing platform is a concrete slab on grade. For ranges that have fighting positions dug in the ground, sandbags, or other definite structures to identify the firing line, the firing platform can be an earth surface. For special weapons, Combat Arms (CA) personnel will specify the number of firing positions and the widths of each position based on training requirements.

2-4.2 Position Numbering.

Number each firing position beginning from the left when facing the target line. The numbers must be at least 8 in. (200 mm) tall and displayed on rectangular backgrounds attached to the position barricade or other location that is clearly visible to all shooters and range officials. Mark odd-numbered positions with white numbers on a black background. Mark even-numbered positions with black numbers on a white background.

2-4.3 Position Barricades.

Install a wooden barricade, or equivalent, in the form of a cross at the left edge of each firing position with the following requirements:

- The nominal dimensions of the wood horizontal member must be the 2 in. (50 mm) by 6 in. (150 mm).
- The top surface of the horizontal member must be 48 in. (1220 mm) above the floor with a 12 in. (300 mm) resting surface on each side of the post.
- Post member may be nominal 2 in. (50 mm) by 6 in. (150 mm) or 4 in. (100 mm) by 4 in. (100 mm) wood.

2-4.4 Firing Line.

Paint a red line a minimum of 4 in. (100 mm) wide on the leading edge of the firing line on the target side. For ranges without firing line platforms or concrete floor, a firing line may be marked in red on the downrange side of the firing positions with treated timber embedded along the firing line. If not painted in red, this can also be a line of safety cones or other method that clearly marks the location. This is the stationary firing line and must be continuous for the full length of all firing positions. For move and shoot courses, the firing line is relocated downrange as appropriate for the training scenarios.

2-4.5 Light Anti-Tank Weapons (LAW) and 40 mm Grenades.

See Chapter 3 paragraphs on “Surface Danger Zones”.

2-5 ARMY AND USMC RANGES.

For planning Army ranges follow AR 350-19. Army ranges must be approved and included on the installations Range Complex Master Plan (RCMP).

- Use US Army TC 25-8 and DA PAM 385-63 for range layout.
- Use the RDG for range design details, standard features, and target system interface.

This Page Intentionally Left Blank

CHAPTER 3 OUTDOOR RANGES

3-1 PLANNING AND DESIGN.

Safety is the primary concern when selecting a site for an outdoor small arms range. Other critical concerns include training capability, compatible use, travel distance, location of utilities, and unexploded ordinance (UXO) risk assessment.

3-2 SURFACE DANGER ZONES.

Surface Danger Zones (SDZs) include both horizontal and vertical components and will be developed by the Government during the planning phase in accordance with DA PAM 385-63/MCO 3570. The designer should familiarize themselves with the SDZ as it impacts the location and layout of the firing lines, target lines, berms, supporting features, and downrange features. Orient the SDZ horizontal and vertical components to minimize the effect of range operations on populated areas, watercraft operations, public waterways, aircraft ground and air operations, and land uses within the maximum range of the ammunition. Available land for the SDZ controls the type and size of the range. Consider future expansion when choosing the site and developing SDZs. As weapons and ammunition improve, they are often more powerful than their replacements and therefore require larger SDZs. All mapping must be done using a geographic information system (GIS).

3-2.1 Air Forces Ranges.

The Vertical Danger Zone (VDZ) component of the SDZ will be developed using Table 3-1. For VDZ in excess of 200 ft. (61 m) in height, coordinate with the local airfield manager. In some cases, Light Anti-Tank Weapons (LAW) and 40 mm grenade launchers are employed adjacent to, or overlapping, the small arms range footprint. For specialized weapons such as the LAW and 40 mm grenades on outdoor non-contained small arms ranges, DA PAM 385-63 will be used to develop surface danger zone and range design criteria.

Table 3-1 Air Force Minimum VDZ Height Requirements

Weapon/Caliber	DOD Identification Code (DODIC)	Ammunition Nomenclature	Minimum VDZ Height[5] Feet (Meters)
Pistol, 9 mm (M9, M11, GLOCK 19) and Submachine Gun, 9 mm (MP5 and UZI)	A363, A360	Cartridge (Ctg), 9 mm Ball NATO and Cartridge 9 mm Ball Parabellum (M882, M1)	2215 (675)
Pistol, 9 mm (M9, M11, GLOCK 19)	AA16	9 mm Ctg Frangible (MK254-0)	2215 (675)[1]
Pistol, 9 mm (M9, M11, GLOCK 19)	AB13, AB14	9 mm Blue (Red) Marking Ctg (M1041)	328 (100)[4]
Handgun, .44 magnum		Commercial Local Purchase	2965 (904)[2]
Shotgun, 12 Gauge	A011, AA51, AA82	Ctg 12 Gauge (GA) Shotgun 00 Buckshot, Frangible, Non-Lethal Fin Stabilized (M19/M162, M1012)	1083 (330)
Shotgun, 12 Gauge	A023	Ctg 12 GA 1 OZ Slug	2706 (825)[2]
Shotgun, 12 Gauge	AA52	Ctg 12 GA Non-Lethal Crowd Control (M1013)	328 (100)
Rifle/Carbine, 5.56 mm (M4, M4A1 and all M16 series weapons)	A071, A068	Ctg 5.56 mm Ball, Ctg 5.56 mm Tracer (M193, M196)	3347 (1020)
Rifle/Carbine/Automatic Rifle, 5.56 mm (M4, M4A1, all M16 series weapons and M249)	A059, A063/Linked A062, A064, AA01	Ctg 5.56 mm Ball, Ctg 5.56 mm Tracer (includes ball, tracer, armor piercing [AP] and AP tracer linked) (M855, M856, M995)	3674 (1120)
Rifle/Carbine, 5.56 mm (M4, M4A1 and all M16 series weapons)	AA68	5.56 mm Plastic (M862)	328 (100)[4]
Rifle/Carbine/Automatic Rifle, 5.56 mm (M4, M4A1, all M16 series weapons and M249)	AA40/Linked AA85	Ctg 5.56 mm Frangible Ball and Ctg 5.56 mm Frangible Linked	3347 (1020)[1]
Rifle/Carbine/Automatic Rifle, 5.56 mm (M4, M4A1, all M16 series weapons and M249)	AB09, AB10/Linked AA85	5.56 mm Blue (Red) Marking Ctg/Blue (Red) Linked Marking Ctg (M1042)	328 (100)[4]
Rifle/Carbine/Automatic Rifle, 5.56 mm (M4, M4A1, all M16 series weapons and M249)	AB67, AB66	5.56 mm, XM1037 Short Range Training Ammunition (SRTA) (Includes Single Round and Linked) (M1037)	656 (200)[4]

Weapon/Caliber	DOD Identification Code (DODIC)	Ammunition Nomenclature	Minimum VDZ Height[5] Feet (Meters)
Rifle/Machine Gun, 7.62 mm (M110, M14, MK14 EBR, M21, M24 and M240)	A122, A130, A140, A146, AB50/ Linked A168, A127, A128, A131, A143, A151, A164, A165, A168, A257	Ctg 7.62 mm Ball (M80) and Ctg 7.62 mm Tracer (M62) (Includes Linked and Ball/Tracer Linked) (M80, M62, M276, MK319-0)	4478 (1365)
Rifle/Machine Gun, 7.62 mm (M110, M14, MK14 EBR, M21, M24 and M240)	AA11	Ctg 7.62 mm NATO M118 Special Ball (M118)	4856 (1480)
Machine Gun, 7.62 mm (M240)	AA37, AB60	7.62 mm, M973/M974 Short Range Training Ammunition (SRTA) 4/1 and (Includes Ball Linked) (M973 and M974)	656 (200)[4]
Rifle, .50 caliber (M107)	A525, A552, A571, AA50, A606, A605	Ctg Cal .50 Ball, Tracer, Armor Piercing (AP), AP Incendiary (I) and API Tracer (Mark 211 Mod O, M2, M1, M10, M33, M17, M8, M20)	6365 (1940)
Machine Gun/Rifle, .50 caliber (M2)	A530, A532, A533, A543, A545, A546, A555, A557, A564, A575, A576, A584, A602, A606, A641, AA06	Ctg Cal .50 Ball, Tracer, AP, Incendiary (I), API and API Tracer Linked (M8 API, M2 AP, M20, M1, M33 Ball, M2 Ball, M17, M10, M17, Spotter Tracer)	6365 (1940)
Grenade Launcher, 40mm (M203, M320)	B470, B472, B506, B508, B509, B519, B535, B536, B537, B538, B542, B546, B568, B576, B584	40mm Ctg, HE, HEDP, TP, Practice, Smoke, Illumination (M381, M384, M385, M386, M406, M407A1, M430, M433, M441, M661, M662, M583A1, M992, M713, M715, M716, M781, M918)	708 (216)[3]
Grenade Launcher, 40mm (M203, M320)	BA06	40mm Ctg Non-Lethal Sponge (M1006)	328 (100)
Grenade Launcher, 40mm (M203, M320)	B534	40mm Ctg, Multi Projectile (M576)	246 (75)
Machine Gun, 40mm Linked (MK19)	BA30, B542, B576, B584, BA32, BA21, BA12	Ctg 40mm Linked HEDP, TP, Practice, Mixed (M430/M918/M385/M385A1/M918 & M385/ MK281)	1565 (477)[3]
Light Anti-armor Weapon (LAW), 35mm Sub-Caliber (M72-Series LAW)	H708	Rocket, 35mm, Practice (M73)	666 (203)[3]

Weapon/Caliber	DOD Identification Code (DODIC)	Ammunition Nomenclature	Minimum VDZ Height[5] Feet (Meters)
LAW, 66mm RKT HEAT (M72-Series LAW)	HX01	Launcher, Rocket, 66mm (M72 Series)	3116 (950)[3]
LAW, 84mm RKT HEAT (M136 [AT-4])	C995	Rocket, HE 84mm M136 AT-4 (M136)	3116 (950)[3]

[1] same as ball
[2] calculated plus 1.25 safety factor
[3] From DA PAM 385-63
[4] From SRTA ballistic graph - General Dynamics Ordinance
[5] Historical data based on 30° projectile trajectory plus safety factor

3-2.2 Access Restrictions, Warning Signs, Markers, and Flags.

Use service specific installation criteria.

3-2.3 Surface Danger Zones Over Navigable Water.

Use DA PAM 385-63/MCO 3570.1 when shooting over navigable water. A U.S. Army Corps of Engineers permit and citation in 33 CFR Part 334 are required.

3-2.4 Baffled Ranges.

When approved, overhead baffles can reduce the size of the SDZ but require special consideration that are not addressed in this UFC:

- Containment: Baffles designed to completely block line of sight out of the range may be used to eliminate direct fire from leaving the range but may not necessarily contain ricochets, ground skips, and splatter from leaving the range.
- Surface Danger Zone: The size and shape of the SDZ will need to be established on a case-by-case basis by the Government.
- Air movement: Baffles can significantly block natural air flow and increase potential for exposure to lead and other airborne contaminants. Unlike indoor ranges where negative pressure can be achieved, any ventilation system on baffled ranges will be influenced by outdoor air movement.

3-3 TYPES OF OUTDOOR RANGES.

Outdoor ranges may be configured in various ways to accomplish training goals.

3-3.1 Single Fixed Firing Line.

These ranges have one fixed firing line with targets placed along one or more target lines downrange. A moving target system may also be provided to vary target distance.

3-3.2 Multiple Firing Lines.

These ranges vary target distances using multiple firing lines used for shooting at one target line at the end of the range.

3-3.3 Maneuver Areas.

Maneuver ranges allow fire and movement in multiple directions. These ranges may or may not have permanent firing positions or firing trails. They may have single or multiple targets or target arrays. The complexity of maneuver ranges varies significantly. Simple maneuver ranges train movement and firing while moving techniques to individuals and teams. Complex maneuver ranges train movement, engagement, and support techniques to larger, or multiple, maneuver elements using a variety of weapons and weapon systems. Maneuver ranges often use Short Range Training Ammunition (SRTA), Standard Operating Procedures (SOPs) or Observer/Controllers to limit the firing locations and target engagement in order to limit SDZs.

3-3.4 Skeet and Trap Ranges.

Skeet and trap ranges are a type of outdoor recreational range that are typically limited to shot size Number 7.5 and smaller. Follow the United States Army Corps of Engineers (USACE) Centers of Standardization (CoS) Outdoor Sports Facility Standard.

3-4 SITING.

3-4.1 Mandatory Requirements and Issues to Address.

- The range must be accessible by road. Vehicle access is required to the range area for maintenance, grass mowing, emergencies, and delivery of weapons and ammunition.
- Travel distance to the range.
- Storm water management.
- Protection of wetlands, ground water, and surface water.
- Suitability of terrain.
- Historical and archaeological features.
- Previously contaminated sites, including unexploded ordnance contamination.
- Endangered species habitat.

3-4.2 Considerations.

When siting and orienting the range consider:

- Allowing for future expansion.
- Orienting north to south to minimize glare for the shooters.
- Orienting the firing away from sensitive and inhabited areas.
- Taking advantage of existing impact areas and natural backstops.
- Eliminating drainage structures on the range surface whenever possible.
- Using natural drainage with no flowing water courses near the range floor or impact berm.
- Avoiding areas that are subject to flooding.
- Minimizing noise to surrounding areas both on and off the installation. Noise models such as those provided in the Army's Range Management Toolkit (RMTK) may be used to develop potential noise contours.
- Taking advantage of any natural barriers and base restricted areas to prevent access by personnel and animals to the SDZ.
- Taking advantage of any natural topography such as hills and mountains to help contain rounds.
- Selecting site to minimize grading of range surface to produce a smooth surface of homogeneous material. A rocky surface will increase ricochets.
- For areas where wind predominantly blows in one direction, orienting with wind blowing downrange.
- Taking advantage of local topography to assist with runoff removal.
- In cold climates minimizing snow drifts and ice buildup and facilitating snow removal on range.

3-5 SUPPORT FACILITIES.

Supporting facilities include roads, drainage structures, and utilities. Design and locate these features to protect them from direct fire.

3-5.1 Roads and Parking.

Design for access by all vehicles that will use the range. Provide surfaced all-weather connector roads from the installation road network to the range complex. Provide range access roads that approach the range complex from behind the firing line and outside the SDZ.

3-5.2 Utilities.

3-5.2.1 Electricity.

Size service to accommodate power requirements for target systems, lighting, support facilities, and range maintenance.

3-5.2.2 Telephone and Radio Communication.

Include two forms of communication between the Range Control Facility, Range Safety Officer (RSO), instructors, beach guards, and any others involved in the operations of the range and security of the SDZ. For Army, follow DA PAM 385-63 and installation's SOPs.

3-5.2.3 Water.

Coordinate with the local utility and Designated Fire Protection Engineer (DFPE), as defined in UFC 3-600-01 to determine requirements. Consider fire protection, drinking, hand washing, and sanitary uses. If a water system is not feasible, consider a well and tank system. If this is not feasible, consider portable fire protection such as fire extinguishers or tanker trucks as required by the DFPE in collaboration with the installation fire department.

3-5.2.4 Restroom Facilities.

Restroom facilities are required adjacent to or within a reasonable distance from the range. Where sewage and running water are not feasible, other options such as composting or commercial portable latrines may be used.

3-6 GEOMETRY FOR NAVY AND AIR FORCE RANGES.

Typical geometry for a flat rectangular outdoor range may be adjusted when necessary to accommodate different types of training.

3-6.1 Measurement Control.

For vertical control define the firing line floor surface (FLFS) elevation as 0.00 and set other features based on this. Base horizontal control on measurements taken from the rearmost firing line (FL).

3-6.2 Target Centers.

Locate the center of the target at an elevation between the upper limit of fire (ULF) equal to 6 ft. (1.8 m) above FLFS for standing shooting and lower limit of fire (LLF) equal to 6 in. (152 mm) above FLFS for prone shooting.

3-6.3 Lanes.

Lane widths vary depending on weapons and training requirements. Establish lane width as necessary to safely support intended training.

3-6.4 Range Length.

Locate target lines as necessary to accommodate intended weapons and training.

3-7 GEOMETRY FOR ARMY RANGES.

Refer to TC 25-8 and the RDG for standard Army range layouts.

3-8 RANGE COMPONENTS.

Locate and design components to avoid direct fire and the creation of potential ricochet hazards.

3-8.1 Drainage.

Design positive grading to direct runoff away from the firing lines and prevent flooding at the target line(s) and access roads. Avoid using drainage structures on the range surface when possible. When the length of the slope or natural terrain require using drains between target lines and firing lines, trench drains or subsurface gravel drains should be located on the forward edge of the impact berm or bullet trap. Design inlets so that no hard-flat surface will be exposed to shooters and provide enough protection to account for heavy bullet impacts and erosion.

3-8.2 Floor Surface.

Design the surface to be smooth and graded to drain away from targets. Side to side grading should be minimal except on ranges where defilade or obstructions are desired for training. Transverse firing line grading should match target line transverse grading. Allow enough fore and aft distance to support the type of training conducted. Clearly mark firing lanes on the surface to match the targets. Depending on the number of personnel to be supported, the following surfaces may be considered at the firing line:

- Ground firmly compacted with mown grasses.
- Sand or fine gravel, with shooting mats for prone shooting.
- Wood decking of enough thickness and supporting members to avoid deck movement.
- Concrete pad topped with cushioning material.

3-8.3 Benches.

Continuous benches or individual trays may be provided to hold ammunition and weapons. Place trays to allow safe weapons handling.

3-8.4 Bleachers.

Bleachers and covered shelters may be provided outside the SDZ behind the firing line for training and briefings.

3-8.5 Obstacles.

Mock-up roofs, windows, doors, and other training structures may be provided at the firing line to meet training requirements.

3-8.6 Range Safety Officer Position.

Where possible, provide the Range Safety Officer (RSO) position an unrestricted view of all firing lines and target lines from their control position.

\1 When outdoor range temperatures exceed 86 F (30 C) implement occupational safety procedure identified within the heat injury prevention plan. These measures may include drink water supply, increased break time, cooled or shaded rest area, and heat stress monitoring. See your Service's occupational safety office for detailed guidance and monitor your local Heat Stress Flag Status.

Note: 86F (30 C) threshold is taken from NIOSH Figure 8-2 and falls within the Lower risk level (Table C-1) within NIOSH Occupational Exposure to Heat and Hot Environments publication. **/1/**

3-8.7 Towers.

Tower requirements are service and training dependent. Elevated range towers may be necessary to provide proper visibility for the RSO.

3-8.8 Overhead Cover.

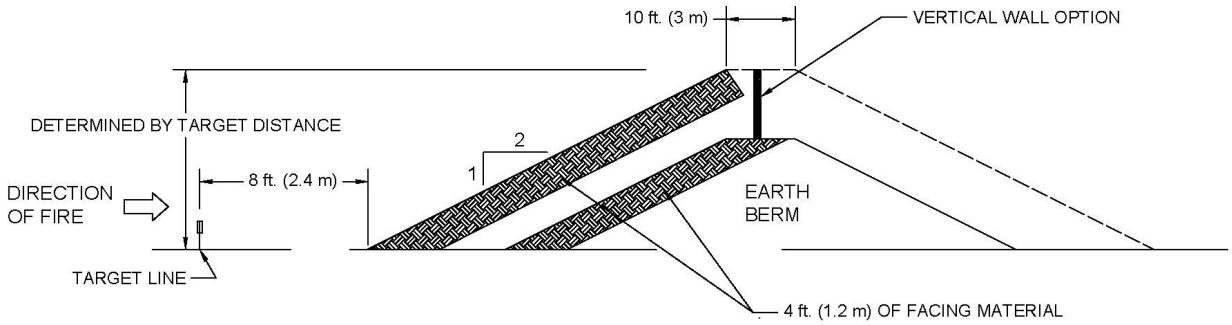
Overhead cover may be provided but is not required nor recommended in most cases. While it can provide some protection from direct sun and the elements, covering the firing line can also increase noise levels below and interfere with air movement needed to remove airborne contaminants away from shooters. When provided, design to reduce noise reflected down to the firing line and to minimize interruption of natural air movement.

3-8.9 Lateral Limit Markers.

Lateral limit markers indicate direction of fire limitations from the outmost firing and target positions. The right lateral limit is found by taking the line of sight from the right firing position at the most uprange firing line to the right most target downrange, and similarly for the left. For Army ranges, TC 25-8 and the RDG along with installation SOPs define the type, size and location of limit markers.

3-9 IMPACT BERMS.

Impact berms are required for Navy and Air Force ranges that are generally flat, fire in one direction, and have target distances of 200 yds. (182 m) or less. Impact berms:



- Capture projectiles where they can be collected and removed more efficiently compared to ranges without impact berms.
- Significantly reduce the number of projectiles spreading out and landing downrange in the SDZ.
- Will not capture all projectiles because ground skips and ricochets will continue downrange.
- Will not reduce the length of the SDZ since the controlling round is at such an angle that its trajectory is well above the impact berm.

3-9.1 Geometry.

When required, design in accordance with Figure 3-1 and as follows:

- Slope: A slope of 2H:1V is recommended. A steeper slope of 1.5:1V may be used if a stable berm can be constructed that also allows future sifting of the soil.
- Width: Provide a total berm width equal to the firing line width plus the additional width necessary to cover a 5-degree dispersion angle from all firing positions.
- Top of Berm: Minimum 10 ft. (3 m) horizontal top on the berm.
- Toe of Berm: A minimum of 8 ft. (2.4 m) past the last target line.
- Minimum Height: 16 ft. (5 m) above the highest grade at the last downrange target line for ranges with target distances of 50 yd. (46 m) or less and 26 ft. (8 m) for ranges with target distances of 100 yd. (91 m) and greater. For ranges with target distances between 50 yd. (46 m) and 100 yd. (91 m), use a height that is prorated between the 50-yd. (46m) and 100-yd. (91 m) berm heights.
- Wall Option: A vertical wall may be provided on the top of the berm to reduce the berm height and footprint. The earth portion must be a minimum of 16 ft. (5 m). As a minimum, the wall should be solid 8 in. (203 mm) thick concrete. The foundation must have a minimum 4 ft. (1.2 m) of earth cover on shooting side of the berm. The direct line of fire from the prone position through the target point must impact the earth portion of the berm 3 ft. (1 m) below the exposed wall.
- See Butt Target Systems paragraphs for minimum berm height and toe of berm distance from target line when using that system.

Figure 3-1 Impact Berm

3-9.2 Berm Material.

Specify berm material in the design that will achieve and sustain a proper slope, promote vegetation growth, reduce the chance of ricochets, and allow for sifting to remove projectiles. Require the upper 4 ft. (1.2 m) of facing material on the impact side to be free from rocks and debris no greater than a No. 4 sieve – equivalent to 0.187 in. (4.76 mm) diameter mesh – that will not clog screens when sifting. A high clay content will help achieve a more stable slope, but too much clay in the upper layer will make it very difficult to sift and remove spent rounds in the future. Therefore, the facing material must not have more than 40% passing the No. 200 sieve.

3-9.3 Berm Construction.

Construct the berm in compacted horizontal lifts. Do not allow compaction up the slope of the berm face. Use benching and keying techniques to enhance slope stability when resurfacing or tying into an existing berm.

3-10 TARGET SYSTEMS.

The type of target system used will influence significant portions of the design. Choose systems based on the type of training anticipated. See individual service policy for procuring range target system equipment. A variety of target systems are available and new systems are under constant development. Current target systems include, but not limited to:

- Paper Targets on Wooden Frames: Paper targets can be mounted on simple wooden or other non-ricochet producing stands at the target line. They are typically used for 27.3 yd. (25 m) target distances or less because the time needed to walk downrange and score the targets.
- Butt Target Systems: Butt systems use paper targets secured to cardboard or plywood frames that are raised, lowered, and scored by personnel located downrange behind a protective berm. These systems are simple, reliable, and allow the shooter to remain at the firing line while

the targets are scored but are labor intensive because a downrange scorer is required for every shooter.

- LOMAH (Location of Miss And Hit) Targets: A computerized target system with sensors at the target end that detect the path of the projectile though the target and provide feedback to monitors at the firing line. These are generally very accurate but expensive and require significant maintenance to maintain calibration.
- Pop-Up Targets and Stationary Infantry Targets (SIT): These targets are raised and lowered remotely and can be either electric or pneumatic.
- Steel Targets and Knockdown Targets: Steel targets are typically used when accurate scoring within the target is not needed, only a hit or miss. Steel targets provide audible feedback and are designed to go down or spin when struck. Knockdown targets fall when struck. Knockdown targets can be steel but other versions are available. Steel targets and knockdown targets can be reset pneumatically, electrically, or by gravity. Check with service safety requirements when considering steel targets as they will impact target design, placement, and safe target distances.
- Turning Targets: These targets rotate on a vertical axis to present alternating target face and edge to initiate and cease firing. They can be designed with a friend face on one side and a foe on the back for shoot and no-shoot drills. Turning mechanism can be pneumatic or electric.
- Running Man and Moving Infantry Targets (MIT): Targets that move laterally or randomly on a track. Targets can present personnel and vehicle silhouette including armored vehicles and tanks. These targets are typically provided to supplement other target systems.
- Stationary and Moving Armor Targets: Targets that simulate a tank or other vehicle for live fire training and qualification programs.
- Mobile and Robotic Targets: A variety of targets are available that move on remote controlled vehicles.

NOTE: When using moving targets, it is critical to incorporate all shooting positions and angles when developing the SDZ.

3-10.1 Target Systems for Army Ranges.

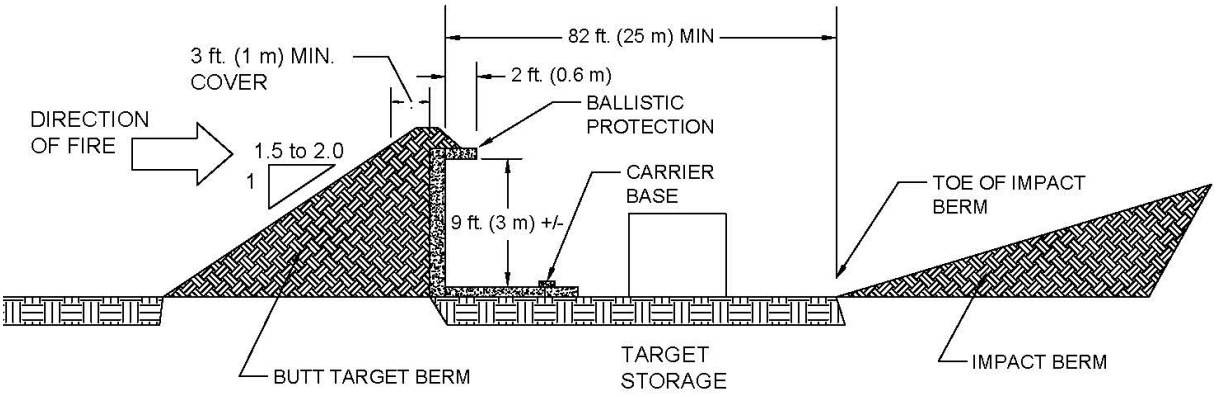
For Army ranges, AR 350-19, TC 25-8, and the RDG define target types, control systems, interface, emplacements, protection, and procurement processes.

3-10.2 Target Line Grading and Protection.

Match grading at target line bases with firing lines when possible. Protect target support bases from direct fire by:

- Providing a target berm on the firing side.
- Burying below ground.
- Providing a protective wall designed to stop rounds but reduce ricochet potential.

3-10.3 Target Supports and Berms.



Target holders and bases should be designed to prevent ricochets and splatter. Earth berms can be placed in front of targets to protect target base and should be constructed from the same material as the impact berm.

3-10.4 Butt Target System.

Butt target systems allow manual scoring of targets by personnel downrange behind the target line and protected by a berm. Design in accordance with Figure 3-2 and as follows:

- Design butt target berm with a slope that is maintainable, typically 1.5 to 2.0H:1V and 3.0 to 4.0H:1V where erosion is a major issue.
- Provide an impact berm behind the target berm with a minimum height of 26 ft. (8 m) above the carrier base elevation.
- Toe of impact berm a minimum of 82 ft. (25 m) from the butt wall.
- A target storage facility protected from direct fire may be included between the butt system and the impact berm. Top of structure must be below all direct lines of fire and the top elevation of the ballistic protection in the pit.
- For Army Ranges, use the Known Distance (KD) Range section of TC 25-8 and the RDG for the design and construction details for this type of target system.
- For pit option, see the RDG.
- For USMC, meet the requirements of MCO 3570.1.

Figure 3-2 Butt Target System

3-11 PARALLEL RANGES.

When parallel ranges have SDZs that cover the firing line of the adjacent range, the ranges may be used concurrently when side containment is provided as follows:

- Earth Berm: Require an inside slope of 1V:1.5H or flatter with a minimum horizontal 6 ft. top width. Provide same material and compaction as required for impact berms.
- Concrete Wall: Require a minimum 8 in. (203 mm) thick concrete wall with a smooth, flat surface free of irregularities, form ties, and protrusions.
- Shock Absorbing Concrete (SACON): Design based on type of weapons and ammunition used.
- Wood and Gravel Walls: Timber and gravel filled wooden walls on new ranges are not recommended because of maintenance and integrity issues.
- Height: Require a minimum height of 10 ft. (3 m) above the highest elevation on either side where personnel could potentially be standing while either range is in use.
- Army ranges may require an SDZ deviation to allow concurrent use.

3-12 MACHINE GUN TUBE RANGE.

Training on machine guns up to 7.62 mm caliber may be provided using a 10-meter tube range. See Figures 3-3 and 3-4. These ranges incorporate range tubes that function as baffles to reduce the size and shape of the SDZ. Army ranges of this type require the same approval as other baffled ranges. Tube ranges are not suitable for:

- Machine guns over 7.62 mm caliber.

- Navy OPNAV 3591 machine gun training since they do not support the training requirements for traverse firing.

3-12.1 Surface Danger Zone.

The machine gun tube SDZ for all ammunition types less than 7.62 mm is 2296 ft (700 m) and the VDZ for all ammunition types less than 7.62 mm is 1640 ft (500 m). The reduction in the SDZ for 7.62 mm and greater ammunition will be determined by the Government. Army ranges require a deviation IAW AR 385-63.

3-12.2 Machine Gun Tubes.

For 10-meter machine gun tube ranges use concrete pipe with a minimum length of 24 ft. (7.3 m) and either round with a minimum 5 ft. (1.52 m) inside diameter or square with a minimum 5 ft. (1.52 m) inside dimension. Provide a reinforced concrete slab the length of the tubes to maintain joint integrity. The tubes may be constructed of sectional pieces if the spigot end of the bell spigot joint is pointed downrange. Tubes may be made of ASTM C75, Class V reinforced concrete pipe (RCP) requirements, or may be steel pipe of suitable thickness fabricated from rolled plates. The interior of the tubes must have a smooth continuous surface. Repair any lifting lugs or holes so the tube interior is smooth and does not produce erratic ricochets.

3-12.3 Drainage.

Slope the tubes approximately 6 in. (150 mm) towards the target line. Firing positions must be at least 12 ft. (3.7 m) apart, measured center-to-center. The end of the tube toward the shooter should touch the firing line.

3-12.4 Firing Platform.

Ensure that the firing tube placement and the firing platform height will place the muzzle of the machine gun at the approximate center of the tube height and at least 6 in. (150 mm) inside the tube. To achieve this, the platform may need to extend inside the tube approximately 3 in. (76 mm) depending on the tripod and weapon dimensions.

3-12.5 Berm Backstops.

For berm backstops, locate the berm no more than 150 ft. (45.7 m) from the firing line to the centerline of the berm. The minimum height of the backstop is established by determining where the highest point that a bullet could exit the target end of the tube and impact the berm. This line must intersect the berm no less than 6.5 ft. (2 m) from the top. Use same material as required for impact berms.

3-12.5.1 Optional Deflector Plate.

Locate the deflector plate at least 2 ft. (0.6 m) above the highest bullet impact point on the berm. The deflector plate may be either angled or vertical which will influence the reduction in the SDZ.

3-12.5.2 Optional Steel Traps.

Locate the trap at least 50 ft. (15m) away from the firing line. The line drawn from the firing point to the highest point that a bullet could exit the target end of the tube must intersect the top plate of the trap not less than 12 in. (300 mm) from the top, measured along the slope of the trap.

3-12.6 Noise.

Engineering solutions to reduce the noise levels from tube ranges are limited and may consist of sand bags along the bottom of the tube. Cement-based acoustical treatment may also be used. Additional sound attenuating materials can also be added to the interior surfaces of square tubes. Appropriate operational mitigation must be established to reduce the high impact noise exposure. For Air Force ranges, the impact of hazardous noise levels for tube ranges must be evaluated by the local Bioenvironmental Engineering (BE) and Civil Engineering (CE) offices.

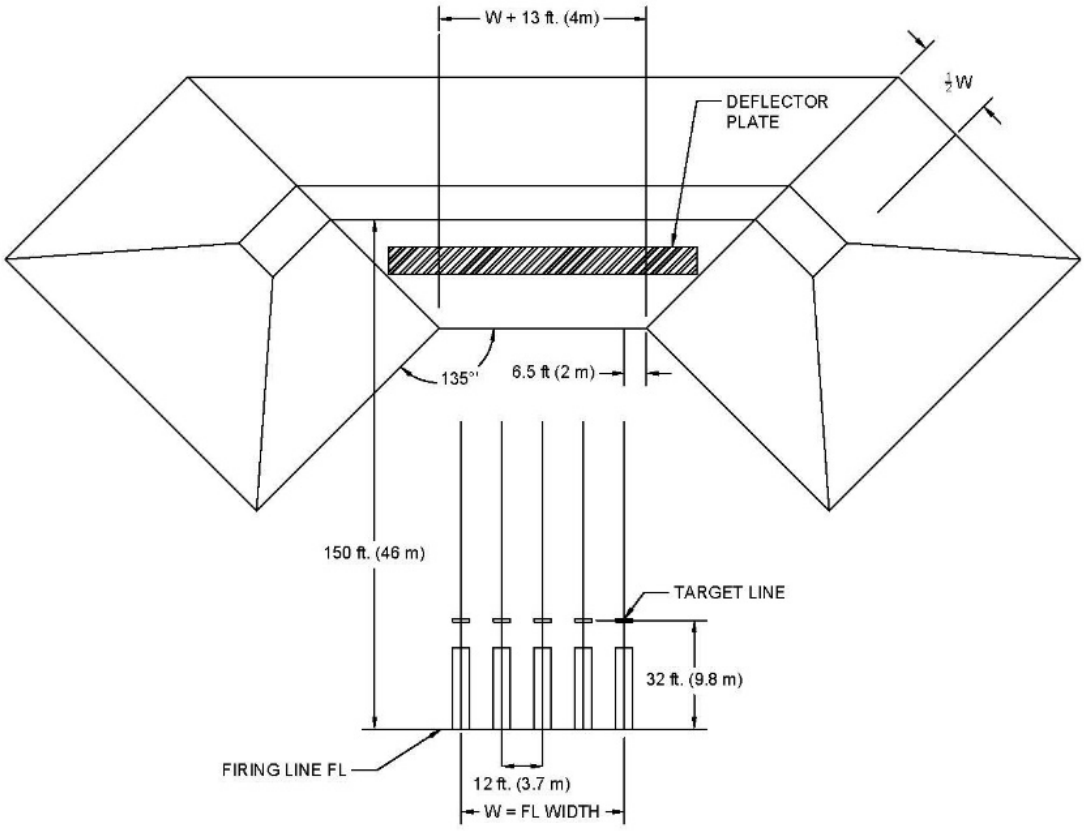

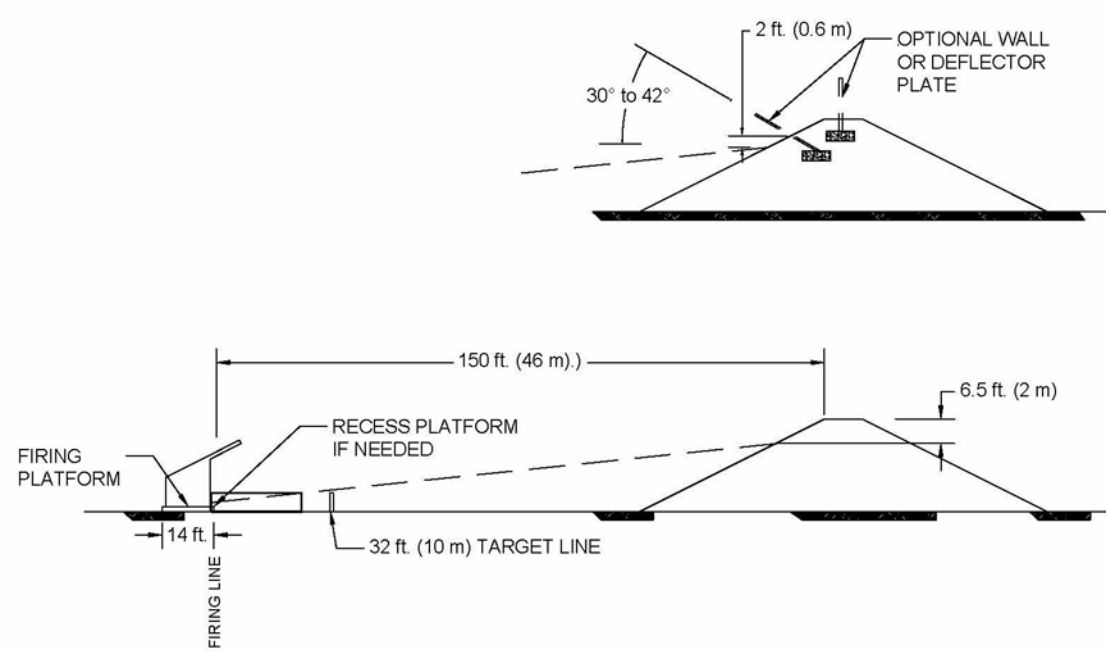

Figure 3-4 Machine Gun 10-Meter Tube Range Section

This Page Intentionally Left Blank

CHAPTER 4 INDOOR RANGES

4-1 GENERAL.

Indoor ranges have open bays with shooting generally straight downrange into a bullet trap. Ballistic containment is provided by ballistic side walls, overhead baffles, and a bullet trap. Indoor ranges can be built using conventional or modular construction methods. A push-pull ventilation system supplies air from behind the firing line and exhausts at the trap end to move airborne contaminants downrange and away from personnel inside the range. Design and construct Army and Marine Corp indoor ranges IAW applicable portions of this UFC and the design and safety requirements found in DA Pam 385-63; the DA PAM controls in case of conflict.

4-1.1 Coverage.

The ballistic containment criteria in this chapter is intended for indoor ranges that support weapons and ammunition with energy up to 2,500 foot-pounds (3,390 Newton-meters) including handguns, 5.56 mm rifles, and 7.62 mm rifles. It does not support:

- Tracers, explosives or incendiary rounds.
- Armor Piercing (AP) rounds.
- 5.56 mm or 7.62 mm Enhanced Performance Rounds (EPR), (M855A1 or M80A1) **\1** may be used on granular rubber bullet trap or steel bullet traps upgraded and specifically certified by the manufacture for these more powerful EPRs. **/1/**

Design the range systems for the specific, worst-case rounds for these or other higher-powered weapons. The ballistic containment system includes baffles, floors, walls, splatter protection, and bullet trap.

4-1.2 Range Areas.

An indoor range facility can be divided into three functional areas:

- The training area between the rear uprange wall and the bullet trap where live fire occurs. The training area requires a ballistic envelope to contain rounds within the facility.
- The direct support area that includes the range safety officer’s office, entrance vestibules, storage areas immediately off the training area, and the area behind the bullet trap.
- The indirect support area and all other spaces including administrative, restrooms, classrooms, hallways, and other storage areas.

4-2 TRAINING AREA.

Define training requirements, ammunition, target distances, and maintenance issues prior to developing a floor plan. For ranges approaching 100 ft. (30.5 m) width and wider, the cost and size of structural components can increase significantly and should be taken into consideration when determining number of lanes and range width. Consider multiple bays to provide flexibility and reduce structural loads.

- Navy: The Navy standard qualification range has an 82 ft. (25 m) target distance with 4 ft. (1.2 m) lane widths. Note that while some Navy training only requires a 25-yard target distances, a 25-meter range provides additional capability and safety. For Naval Special Warfare indoor ranges, the layout is not standard and will vary depending on type of training supported.
- Air Force: Use Air Force Facility Criteria FC 4-179-03 for planning and layout of indoor ranges along with general requirements provided in Chapter 1. This Air Force FC provides general guidance on lanes and detailed planning requirements for the indirect support areas.
- USMC: Typical indoor ranges have either 82 ft. (25 m) or 164 ft. (50 m) target distances.
- Army: Base layout on training and installation specific requirements.

4-3 DIRECT SUPPORT AREA.

4-3.1 Range Control Booth.

4-3.1.1 Ventilation, Layout, and Sound Attenuation.

Include a ventilation system independent of the training area range ventilation system and a 2 ft. (0.8 m) wide, full-length work counter at the base of the window. Locate all range controls and utility panels in this area. Locate lighting and communications controls to allow adjustments while maintaining clear visibility downrange. Provide sound attenuation to allow personnel in the booth during live fire without the need of hearing protection as described by the noise paragraphs in this chapter.

4-3.1.2 Visibility.

Design range control booth to provide full line-of-sight visibility from a center seated position 4 ft. (1.2 m) behind a 4 ft. (1.2 m) high window to 4 ft. (1.2 m) behind the firing line on both sides and extending downrange to the target area. See Figure 4-1. Coordinate window level with that of the ventilation supply diffuser so the downrange view is not blocked by the diffuser when standing. Windows and doors within the booth must not restrict or distort the view downrange. Closed-circuit television monitors may be used to enhance, but will not replace, this requirement. Provide windows with views into the hallway behind and vestibules to the sides that allow monitoring of movement in and out of the training area. Use sliding closures or other method on the windows into

hallways and vestibules that can be used to completely block light from coming into the range control booth during low light conditions. For Air Force ranges, raise floor in booth a minimum 2 ft. (0.6 m) minimum above the range floor to promote visibility downrange and to all range entry points.

4-3.2 Airlock Vestibules.

Entrance vestibules with doors at either end are required to allow movement in and out of the range without disturbing the air balance of the range. A minimum of one vestibule for ranges with seven lanes or less, and two vestibules for ranges with more than seven lanes is required. Place vestibules adjacent to the Range Control Booth with windows to allow monitoring of movement from the booth. All doors into the training area must swing outward from range to help seal doors under negative pressure. Seal around doors and place sweeps at bottom to provide an airtight closure.

4-3.3 Vacuum Storage.

Include a storage area with direct access to the training area for portable High Efficiency Particulate Air (HEPA) vacuum and equipment storage.

4-3.4 Brass Storage.

A 55-gallon drum may be placed next to side wall behind firing line for brass storage immediately after collection.

4-4 TRAINING AND DIRECT SUPPORT AREA LAYOUT.

The width of the range is determined by the number of lanes, width of lanes, and the space provided against each side wall. The length of the range is determined by the distance behind the firing line, the target distance, the depth of the bullet trap, and the space behind the bullet trap. The height of the range is determined by the clear height between floor and bottom of the ceiling baffles, the ceiling baffle height, and the distance above the baffles needed for structural and mechanical systems. Make all surfaces downrange in direct line of fire non-reflective when lasers are allowed in training.

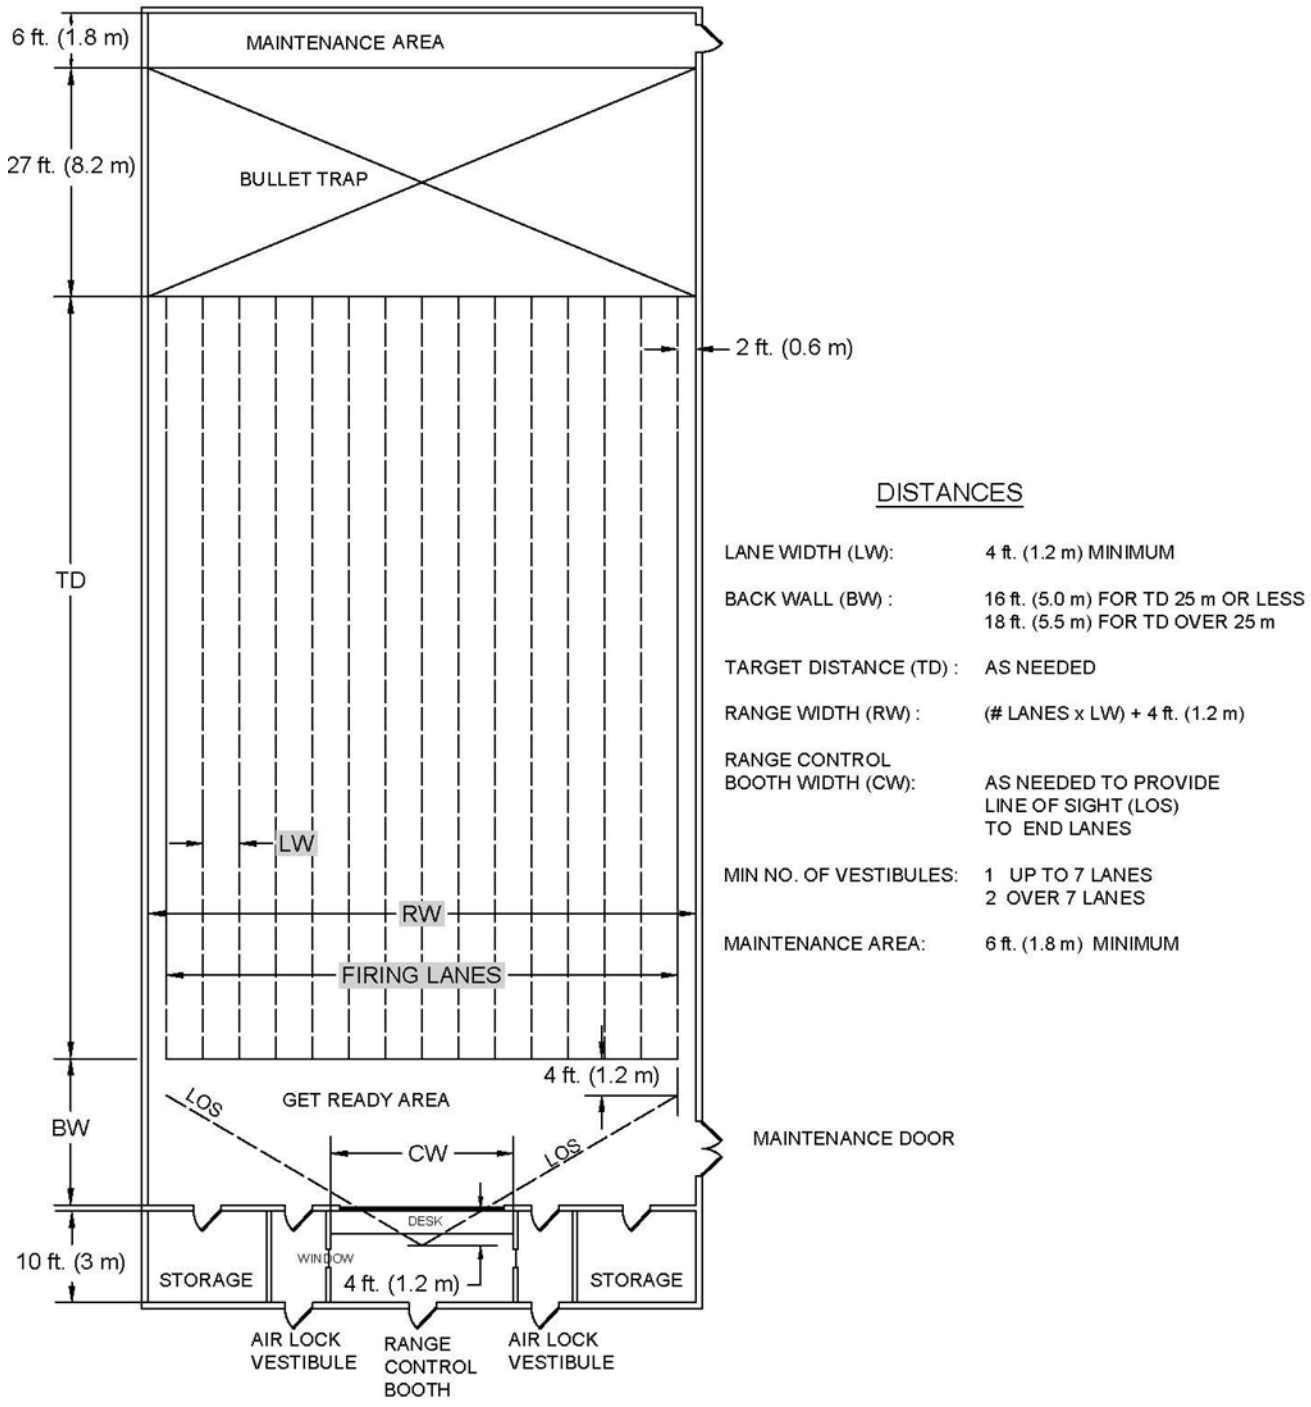
Use Figures 4-1, 4-2, and the following minimum distances:

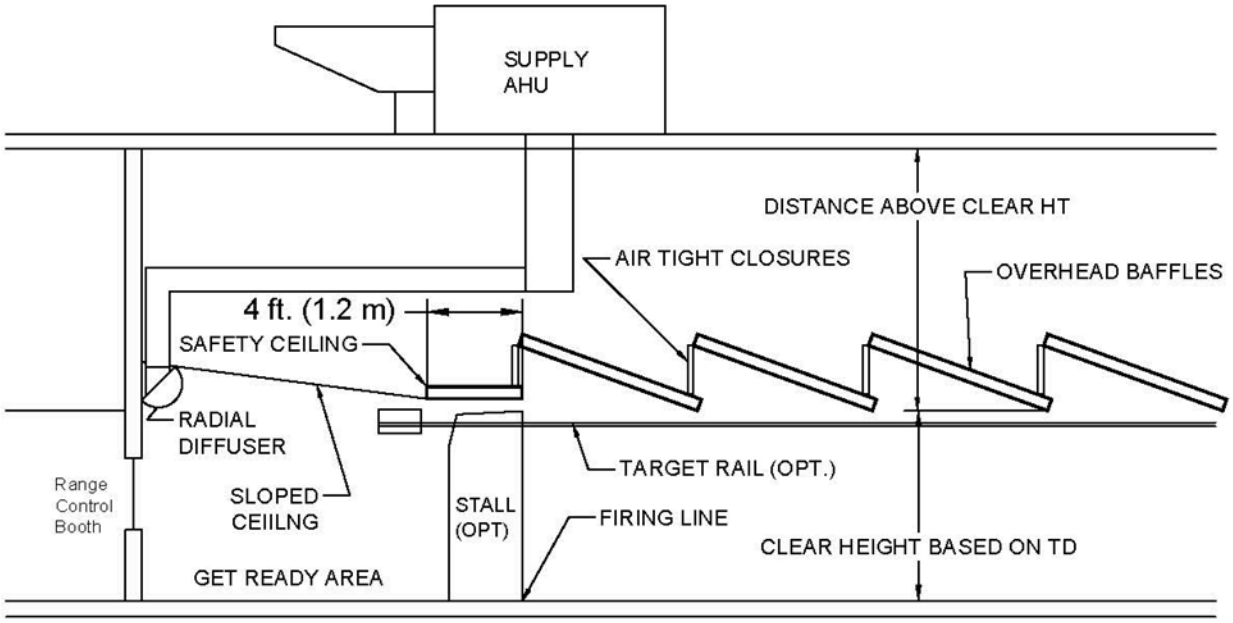
- Range Control Booth: 10 ft. (3 m) front to back.
- Get Ready Area: Table 4-1.
- Target Distance: As required for training. Do not extend target system into the trap.
- Bullet trap: Approximately 27 ft. (8.2 m) – coordinate with trap manufacturer.
- Maintenance Area: Minimum 6 ft. (1.8 m) behind bullet trap. Verify there is enough space in maintenance area for all trap components,

compressors, and other hardware. This is area must not be used for storage.

- Clear Height: Table 4-1 for minimum distance. May need higher ceilings if vehicles are used in training.
- Distance between top of baffles and bottom of roof: As needed, including space for structural components and ventilation ductwork.
- Distance between edge lanes and side walls: Minimum 2 ft. (0.6 m). This distance is needed to help achieve proper airflow and prevent shooting near side walls.
- Lane Width: Minimum 4 ft. (1.2 m). Service and training requirements may dictate wider lanes.
- Avoid interior columns when possible. If provided, include a 2 ft. (0.6 m) buffer between column and lanes.
- Safety Ceiling: Extend ballistic coverage to 4 ft. (1.2 m) behind firing line.

Figure 4-1 Standard Range Layout





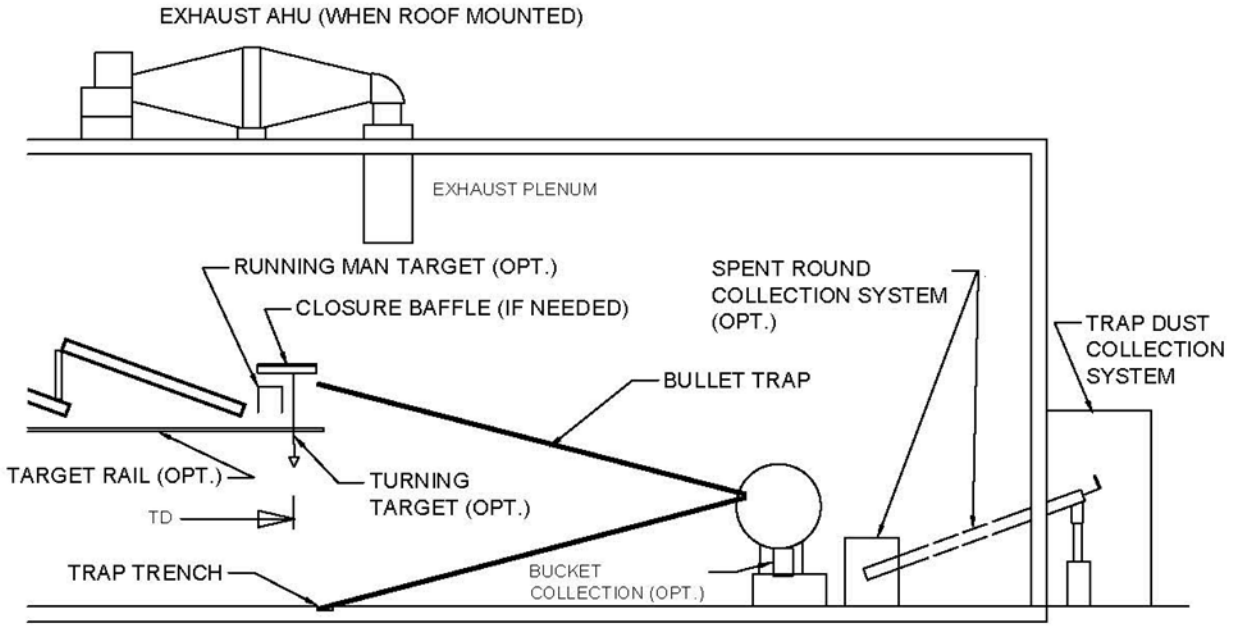


Figure 4-2 Standard Range Section.

UPRANGE

DOWNRANGE

Table 4-1 Range Heights and Get Ready Area Distances.

Target Distance (TD)	Clear Vertical Height	Get Ready Area (Backwall to FL)
Up to 82 ft. (25 m).	8 ft. (2.4 m)	16 ft. (5 m)
Over 82 ft. (25 m) up to 165 ft. (50 m).	10 ft. (3 m)	18 ft. (5.5 m)
From 165 ft. (50 m) to 328 ft. (100 m)	12 ft. (3.7 m)	18 ft. (5.5 m)

4-5 INDIRECT SUPPORT AREAS.

4-5.1 Required Indirect Support Area.

The following areas are required:

- Administrative Area: This area contains offices for the range safety officer, instructors, and maintenance personnel along with file and shelf storage for operations data and maintenance records.
- Restrooms, Shower, and Locker Room Areas: Size restrooms based on occupancy and range use. Size shower and locker based on range staff.
- Laundry: For range laundry use only.
- General Storage: Provide adequate storage for targets, filters, tools, and maintenance equipment.
- Maintenance and Storage area.

4-5.2 Other Indirect Support Areas.

The following areas may be necessary:

- Brass sorting: Include table with raised perimeter and holes to collection buckets or drums underneath.
- Classrooms: This includes space to conduct classroom training prior to live-fire and after-action debriefings.
- Weapons Cleaning Area: This space accommodates workbenches, degreasing tanks, and spray hoods. Exhaust hoods and vapor proof electrical fixtures may be required. Provide a lavatory with potable water and eyewash in the immediate area.
- Arms and Ammunition Storage: **\1** Comply with DODM5100.76, Physical Security of Sensitive Conventional Arms, Ammunition, & Explosives

(AA&E) and any Service supplements to this DoD manual and **/1/** UFC 4-215-01 Armories and Arms Rooms. When provided, include an issue and clearing area adjacent to the weapons storage and cleaning area.

- Break Room: Room for meals and breaks with space for refrigerator, sink, countertops, microwaves, coffee machines, table, and chairs. Provide signage that prohibits food inside the training area.
- Weapons Simulator Room: Design to accommodate anticipated system. These rooms may require raised flooring, compressor area, darkened or no windows, and a small control room. Signs must clearly mark room as simulation weapons only, with no lethal ammunition allowed.

4-6 FIRE PROTECTION.

The training area and trap area do not require a sprinkler system. Coordinate with the DFPE early in the design process for detailed requirements for the rest of the building. Provide 2-hour fire rated construction separating the training and direct support areas from indirect support areas.

4-7 COLLECTION, TEMPORARY STORAGE, AND DISPOSAL.

Design for the collection, storage, and disposal of:

- Brass, typically recycled.
- Supply filters, non-contaminated.
- Exhaust filters, contaminated after use.
- Filters from the dust collection system, contaminated after use.
- Dust captured in the dust collection system.
- Vacuum waste, contaminated.
- Trap collection waste, contaminated.
- Projectiles captured in trap collection system.

Note: Contaminate refers to material with lead, copper, and other compounds typically at levels that classify them as hazardous waste for storage and disposal purposes.

4-8 STANDARD INDOOR RANGE FEATURES.

Design a ballistically contained structure that:

- Contains all shots from each intended firing location, at all respective targets, for all weapons and calibers based on the intended training in the facility.

- Provides airtight connections between walls and roof to prevent air leakage into the range that can interfere with the ventilation system's negative pressure.
- Seals all utility connections leading into the range.
- Provides proper detailing and door hardware for an airtight closure.
- Provides a maintenance double door behind the firing line.
- Provides at least one maintenance double door in the area behind the bullet trap. Two double maintenance doors, one on each side, may be necessary to provide access to all heavy items and equipment.

4-9 MULTIPLE BAYS.

To increase flexibility and reduce spans, ranges may be divided into separate bays with structural walls extending the length of the range from floor to roof that prevent air movement between bays. Ranges that have a partial dividing wall or an interior row of columns are not multiple bay ranges. Design each bay to operate independently from adjacent bays with separate and independent:

- Ventilation systems and controls.
- Bullet traps and trap related equipment.
- Target systems.
- Range control booths.

4-10 CEILING, WALLS, AND DOORS.

Design walls to reduce noise transmission to adjacent occupied spaces and to withstand negative and positive pressures that would be encountered should the ventilation supply or exhaust fans fail. Walls must provide an airtight enclosure to maintain negative pressure inside the range as required for range ventilation. Seal any penetrations in wall including ductwork and utility penetrations.

4-10.1 Uprange Ceiling and Wall Behind Firing Line.

Slope suspended ceiling from back wall to edge of safety ceiling behind firing line to provide a gradual transition for supply air movement to firing line. Place removable suspended ceiling panels along the width of the back wall under ventilation balancing dampers for maintenance access.

4-10.2 Ballistic Side and Downrange Walls.

Make side walls and the downrange wall behind the bullet trap a minimum of:

- Concrete: 8 in. (203 mm) thick using either cast in place, tilt up, or precast construction. Structural design and internal thermal insulation may dictate

thicker walls. If internal cavity is provided, the interior section must meet the minimum thickness requirement. Walls must be smooth and flat with no protrusions, indentions, cavities, exposed steel, or any other feature presenting a ricochet hazard.

- Steel: Minimum 0.375 in. (9.5 mm) AR500 steel plate.
- Provide splatter protection on steel and concrete up to 8 ft. (2.4 m) above the floor and a minimum of 16.4 ft (5 m) down range of all firing positions, except do not place any splatter protection within 10 ft. (3 m) of the bullet trap. This is to allow inspection of the wall where it is most susceptible to bullet strikes.

4-10.3 Wall Joints.

Provide complete ballistic integrity across joints. For side walls, this includes joints from finished floor up to the highest point of the ceiling baffles. For the downrange wall behind bullet trap, this includes up to 12 ft. (3 m) above finished floor. Ballistic integrity can be accomplished using keyed construction joints or by placing 0.375 in. (9.53 mm) thick AR500 steel plate over the joint. When used, design plate to protect the joint and reduce chance of ricochets by:

- Flush mounting plate to wall.
- Placing a 45-degree bevel on the leading edge of the plate that faces the shooter, with the plate fitted securely to the wall with no gaps over 0.0625 in. (1.6 mm) between plate and wall.

4-10.4 Downrange Doors.

Avoid doors between the firing line and bullet trap, but they may be necessary on large ranges to meet Fire and Safety codes. When placed downrange past the firing line, doors and door hardware must meet UL 752 Level 8 protection standard. This includes doors on back wall behind the trap so that rounds cannot escape during a trap failure. Doors behind the bullet trap that are located on the side walls are not required to meet this UL level. Use locking hardware, panic hardware, or magnetic door locks to ensure personnel do not inadvertently enter during live fire events. For doors on the side wall between the firing line and bullet trap, a wall baffle must be placed just uprange of door extending from the floor to the height of the door to reduce the chance of an errant shot striking the door hardware.

4-10.5 Maintenance and Vehicle Entrance.

For each bay, include a 6 ft. (1.8 m) wide maintenance double door uprange at least 4 ft. (1.2 m) behind the firing line. A larger door may be required if vehicles will be used in training. These doors are not operated during training and therefore do not require a double airlock vestibule.

4-11 FLOORS.

Concrete floors must be level with a smooth finish, without any protrusions or irregularities.

- Seal all floor joints and design to minimize ricochet potential.
- Locate longitudinal floor joints between firing lanes. Provide backer material when necessary to support sealant.
- Sawed control joints more than 0.25 in (6.3 mm) wide are not permitted.
- Traditional chamfered construction joints are not permitted.
- Surface seal floor with a waterproof sealant to facilitate cleaning.
- Use non-reflective flat or flat satin sealant when range is designed to allow lasers.

Steel floors may be 0.375 in. (9.5 mm) AR500 steel plate with support to prevent sagging.

- Provide a slip-proof coating.
- Do not apply any surface on the flooring that prevents the bullets from reaching the bullet trap or that will entrap firing residue and hinder the cleaning of the range floor.

4-12 RANGE MARKINGS.

Provide permanent range markings as required by the service. Use nonreflective paint when designing for laser use. The following are recommended:

- 4 in. (100 mm) wide red floor stripe across the width of rear uprange firing line.
- 4 in. (100 mm) wide black stripe across the width of the range in front of the trap at the last target line.
- 4 in. (100 mm) wide vertical black stripes up both side walls with critical target distances starting at the floor and extending 4 ft. up the wall. Provide 4 in. (100 mm) letters above this line indicating distance with units in either yards or meters depending on training requirements. For ranges with fixed firing lines and movable targets, the distances must be measured starting at the firing line. For ranges with a fixed target line at the trap end, the distances must be measured from the target line back towards the firing lines.

- Lane markings at the firing line and the last target line are to be coordinated with users on size and type of markings. For Air Force projects see Chapter 2.
- 4 in. (100 mm) wide yellow ready line 8 ft. (2.4 m) behind the firing line.

4-13 TARGET SYSTEMS.

Choose target systems based on the type of training anticipated and scoring accuracy required. The type of target system used will influence the floor plan, baffle design, and range height and must be considered in the design. Polices for procuring range target system equipment vary between services. All target systems must be designed to prevent ricochets and splatter from returning to shooters, with steel and other hard material angled and no blunt edges presented to the firing line. A variety of systems are available. Some options are presented below.

4-13.1 Static Target Stands.

Basic target stands allow for manual placement of target. Stands may be of wood, poly synthetic, steel angled away from line of fire, or other material designed to reduce ricochets.

4-13.2 Overhead Target Rail System.

Overhead monorail target systems have:

- Rigid overhead rails.
- Capability of 180-degree turning targets.
- Capability of moving and stopping target at all target distances.
- AR500 angled steel plate on front of carrier, target clamps, and connections between clamp and carrier designed for anticipated weapons and ammunition.
- Target rails approximately 7.5 ft. (2.3 m) above the finished floor.
- Ability to control single targets from individual lanes.
- Ability to control both single targets individually and all targets collectively from controls in the range control booth.
- Programmable target positions in both yards and meters.
- Programmable parameters including positions, start/stop times, and edge face targets.
- Drive system located behind the firing line using a cable system for moving targets.

Optional:

- Dimmable light illuminating target on target carrier.
- 360-degree target turning.
- Self-driven target carriers with internal motors and drive system.

4-13.3 Running Man Targets.

Running man targets are typically mounted on overhead rails that move targets left and right across the width of the range near the last target line. Running man targets can be either a single target system or a double system that runs two targets in opposite directions at the same time. Coordinate rail location with bullet trap, overhead baffles, other target systems.

4-13.4 Fixed Turning Targets System.

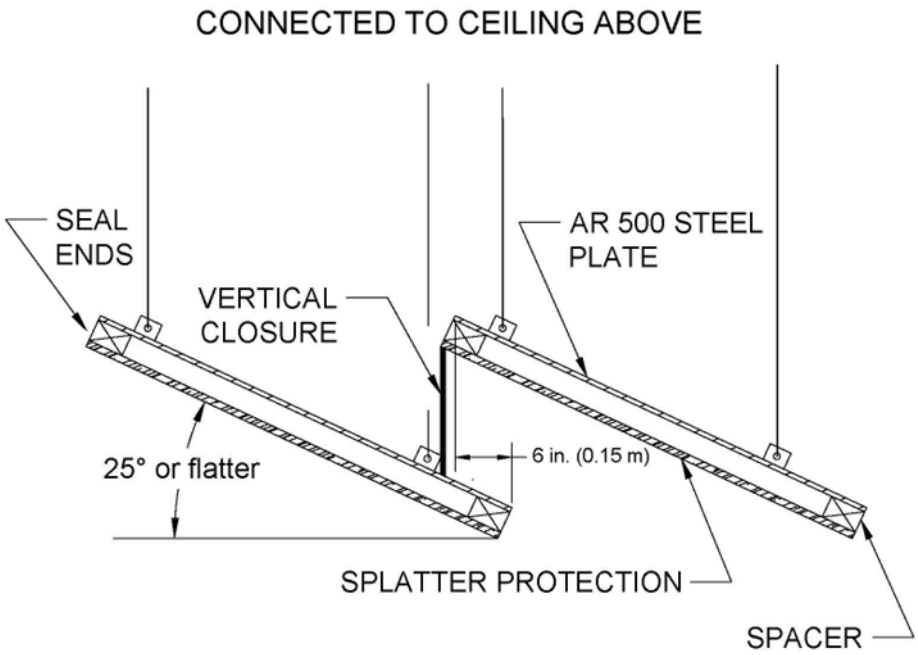
Turning targets are located at the trap end and have a target clamp on a vertical pivoting rod to rotate targets between face and edge. Clamps must hold targets securely but allow one-handed placement and removal of targets. The target clamp and vertical rods should be protected by 0.375 in. (9.5 mm) AR500 steel plate placed at an angle to extend life and help prevent ricochets. The unprotected components of the system must be placed behind overhead baffles to block line of sight from all shooting positions.

4-14 SHOOTING STALLS.

Shooting stalls may be used to provide shooting barriers, separate shooters, mount target controls, block ejecting brass from adjacent lanes, and limit ability of shooters to accidentally shoot sideways. Fold down or swing out tables and barricades may be included. Check individual service policy for requirements.

4-15 BARRIERS AND BARRICADES.

Training may require barriers or barricades and must be addressed in the design. Include storage space when they are not permanently affixed to the building. These may be portable wooden frames or features incorporated into shooting stalls. Other options include swing out barriers that fold flat to a side wall and barriers that can be temporarily attached to the wall and removed for storage when not in use. Check individual service policy for requirements and procurement policy. The following provides geometry for some service specific barrier and barricade requirements:



- Air Force: Position barricades as described in Chapter 2.
- Navy: Standing, low, and window barriers for Practical Weapons Courses in OPNAV 3591.

4-16 OVERHEAD BAFFLES AND SAFETY CEILING.

Design baffle system to provide complete overhead containment within the training area in accordance with Figure 4-3 and the following:

- Minimum 0.375 in. (9.5 mm) AR500 steel plate.
- Maximum 25-degree angle from horizontal.
- Minimum 6 in. (0.15 m) horizontal steel-steel overlap between adjacent baffles.
- Maximum 0.0625 in. (1.6 mm) mm) gap between steel plates for butt joints and 0.125 in (3.2 mm) where backing plate or lap joint is used.
- Non-ballistic vertical closure sections from the lower end of one baffle to the upper end of the next baffle downrange to prevent air from moving between open area below to space above baffles.
- Complete coverage from side to side with no gaps. This can be accomplished by using an AR500 plate connected to the side wall that overlaps with the overhead baffles.
- Provide intermediate support to prevent steel plates from sagging.
- Sealed off baffle section between steel plate and splatter protection to prevent the creation of a plenum that would allow air to move between training area below and ceiling space above. Spacers may be run in either direction provided ends are sealed between steel plates and splatter protection.
- Splatter protection provided on all baffle surfaces a minimum of 16.4 ft (5 m) down range of all firing positions.
- A closure baffle as shown on the downrange section in Figure 4-2 above may be required to complete ballistic protection when a running man target system is used.

Figure 4-3 Overhead Baffles

4-17 BULLET TRAPS.

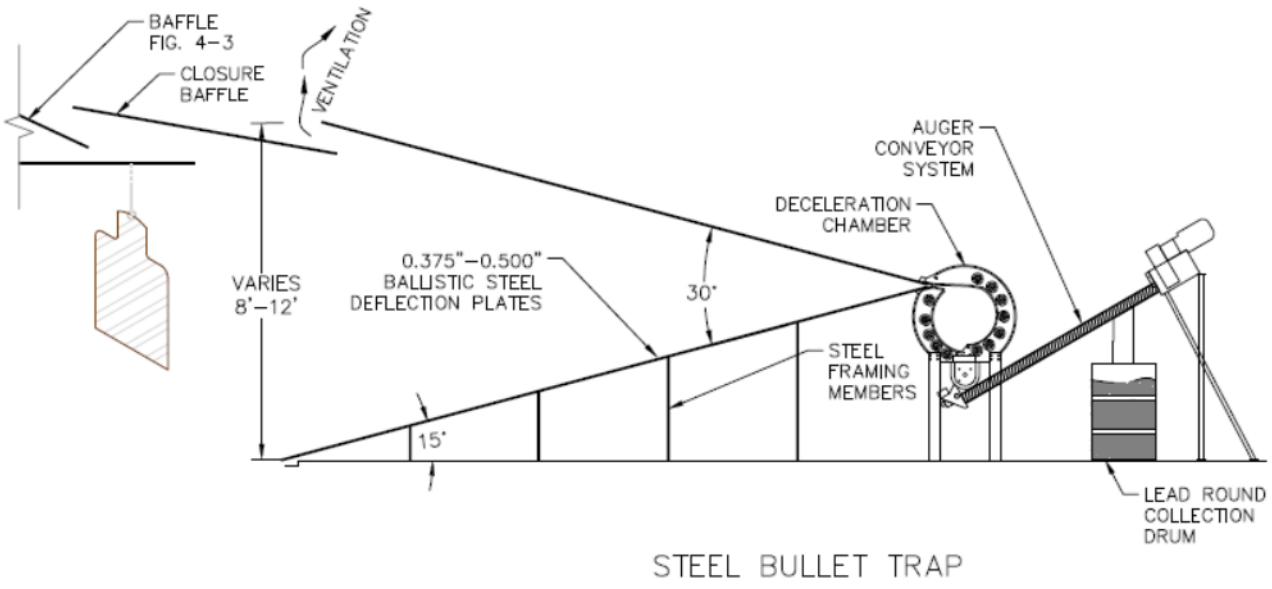
Unless directed otherwise, all new indoor bullet traps must **\1** employ a commercial steel or granular rubber media **/1/** trap. Design the trap for the most powerful round to be used.

\1 A life cycle cost analysis of commonly manufactured bullet trap systems was commissioned by the AF and concluded in 2024. The analysis considered various factors such as installation cost, maintenance cost, benefits related to health, safety, and environmental stewardship, as well as other operational considerations over a projected 25-year period of analysis. The life cycle cost of a granular rubber bullet trap was found to be less than the cost of a steel bullet trap for most applications. The analysis was based on a loading rate of 55,000 rounds per year per lane, but also looked at the effect of fewer or more rounds. The life cycle cost of the steel and rubber traps equalized at approximately 136,000 rounds per year per lane. Above 136,000 rounds the steel trap begins to become a more cost-effective option. Although each bullet trap type depreciates over time, the granular rubber bullet trap system is the most economically viable bullet trap for many situations.
Compared to steel bullet traps, granular rubber traps:

- Take up less space.
- Cost less.
- Capture rounds more intact and thus reduce lead dust at the trap end.
- Can provide some limited reduction in sound reverberation time.

- Eliminates the impact noise of bullet impact against steel plates.
- Rubber traps require range to be shut down during bullet mining procedure whereas steel trap have integral bullet collection systems.
- Require more routine maintenance.
- Will fail if rubber levels are not maintained properly.
- Can ignite if not used and maintained properly.

NOTE: Rubber trap fires have caused significant damage on several DoD indoor ranges, mostly from lack of maintenance and the use of tracers ammunition, which should never be allowed within indoor ranges. Include the reapplication of fire retardant periodically during routine trap mining procedures.



4-17.1 Steel Bullet Trap.

4-17.1.1 Steel Bullet Trap Requirements.

Steel traps must have:

- Minimum 0.375 in. (9.5 mm) thick AR500 ballistic steel plate tested in accordance with ASTM E10-08, meeting MIL-A-46100, and certified as having a minimum Brinell Hardness of 470. Required for all trap components that may be impacted by bullets. A thickness of 0.5 in. (12.7 mm) is recommended to increase the life of the plates.
- Capability to replace individual plates as they become worn or warped. All plates will eventually wear and warp depending on weapons, ammunition, and usage.
- Maximum lower ramp slope of 15 degrees off horizontal.
- Maximum slope of 15 degrees off horizontal for upper ramp plates immediately above the deceleration chamber. The upper ramp is typically hung from the roof.
- Continuous throat across the width of the trap with no vertical connector sections such that a rod placed inside the slot can move unimpeded across the width of the trap.
- Dust collection system to reduce dust at the trap end of the range. Provide forklift access to the dust collection drums.
- Spent round collection system. Provide forklift access to collection drums.

Figure 4-4 Steel Bullet Trap

4-17.1.2 Cantilevered Upper Ramp Support.

On existing ranges where a steel trap is being added, verify the roof can handle the additional load. Where the additional load of the trap cannot be supported, a structural cantilevered arm mounted to the floor behind the trap may be used. The cantilever option reduces roof load but takes up more floor space and increases cost. Account for the extra space required when using a cantilevered arm mount.

4-17.1.3 Dust Collection System.

The trap must include a system to capture and collect airborne contaminants at the deceleration chamber that provides:

- Noise levels below 80 dB when measured 10 ft. (1.2 m) from the system.
- Fans and filters located outside on back or side wall of range.
- Monitoring from within range control booth with indicators that show when system is running, filter status, and when dust collection drums are full.
- The ability to turn system on and off from within range control booth.
- A minimum volumetric flow of 500 cfm (14 m3/min) for every 10 ft. (3 m) of trap.
- Sealed ductwork that prevents the escape of dust.
- HEPA filters on the exhaust.

4-17.1.4 Spent Round Collection System.

Choose either a simple bucket system or mechanical system:

4-17.1.4.1 Bucket System.

Bullets fall from the deceleration chamber into buckets underneath. System must be sealed to contain lead dust and allow for easy removal and replacement with no special tools.

4-17.1.4.2 Mechanical System.

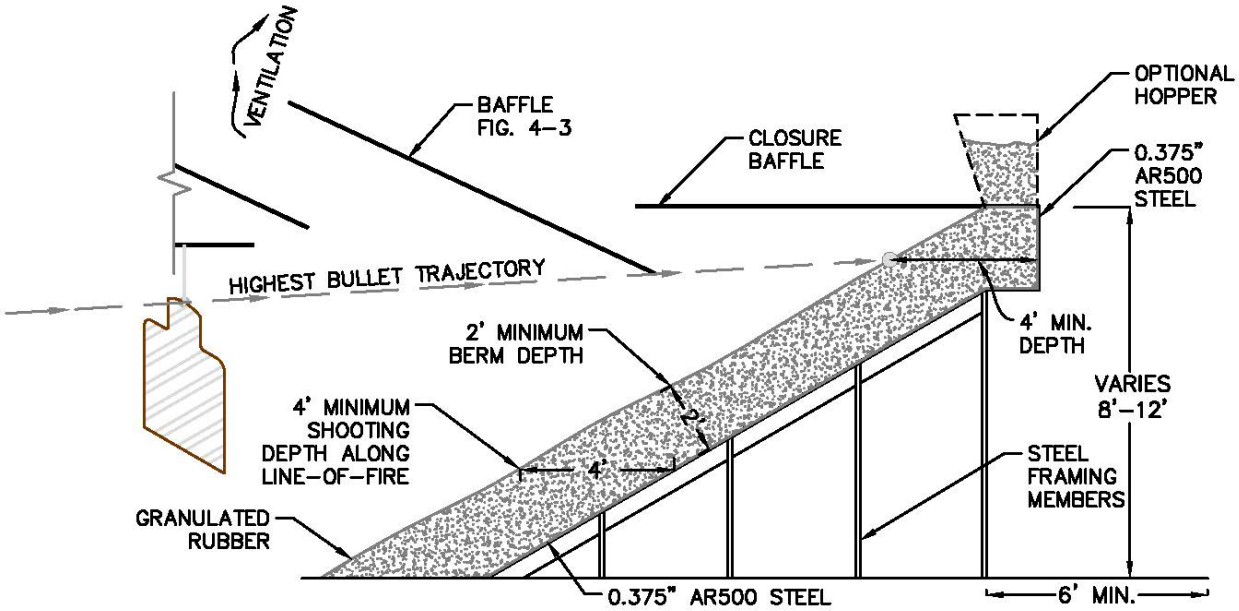
These increase complexity and cost over the bucket system but reduce the labor involved in collecting projectiles. These can be either:

- Auger Bullet Collection Unit: Spent rounds fall from the deceleration chamber into a sealed trough below. An auger pushes the bullets and fragments to one side of the room where another perpendicular inclined auger raises and drops them into a collection drum below.
- Drag Conveyor: Same as auger system except a conveyor belt is used to move spend rounds and fragments to the collection drum.

Include capability to monitor status of mechanical system and to turn system on and off from within the range control booth.

4-17.2 Granular Rubber Bullet Trap.

Do not reduce the range length when a rubber trap is chosen since it will eliminate the option of replacing the rubber trap with a steel trap in the future. Coordinate baffle and trap layout so that any round fired from any firing position will contact either 4 ft. (1.2 m) of rubber or an overhead steel baffle. As with a steel trap the overhead baffles must extend all the way into the trap to prevent any high angle ricochet from bypassing the overhead baffles of the trap backing. Design the trap frame to hold the weight of the trap, rubber, and 120,000 7.62 mm projectiles for every 4 ft. (1.2 m) of trap across the width of the range.



4-17.2.1 Design.

Design the trap to reduce the amount of rubber that spills onto the floor and include:

- Shredded rubber material with average diameter of 0.375 in. (9.6 mm) to 0.875 in. (22 mm).
- Clean chopped rubber that is 99.9 percent free of loose wire or exposed steel, by weight.
- Fire retardant and adhesion promotion treatment.

- Minimum 2 ft. (0.60 m) of rubber as measured perpendicular to the sloping face and a minimum of 4 ft. (1.20 m) of rubber measured horizontally, whichever is greatest.
- Trap base plate must be a minimum or .375 in (9.6 mm) AR500 steel plate.
- Plenum and roof vents above the trap area to collect and release dust, smoke, ammunition residue, and other contaminants.
- Coordinate with the local fire authority for design requirements that help contain smoke in the event of a fire including
- Vertical smoke barrier above the ceiling baffles across the width of the range towards the trap end to limit the movement of smoke up range.
- Fire protection plan showing recommended access to trap in the event of a fire.

Figure 4-5 Granular Rubber Bullet Trap

GRANULAR RUBBER BULLET TRAP

/1/

4-18 COMMUNICATIONS.

Include a loud speaker system between range control booth and range with volume control and capable of producing 110 dBA at the firing line. Locate as to not interfere with supply air flow. Include wall mounted handheld microphones for communication back to the range control booth, with one on each side wall and one on back wall below the range control booth window.

4-19 LIGHTING.

Design lighting system to reduce glare and provide independent lighting zones in accordance with Table 4-2 and:

- Locate downrange lights out of the line of fire. This can be accomplished by placing them behind the vertical section of the overhead baffles.
- Size and locate light and fixtures behind the firing line so they do not interfere with the supply airflow.
- Provide fully dimmable areas with flicker free lighting from 0 to 100 percent intensity levels.
- Locate lighting controls in the range control booth to allow adjustments with clear view of training area. Label controls to allow intuitive operation so that an operator unfamiliar with the system will be able to select and manipulate the controls accurately without any instructions.
- On ranges where training will occur using Night Observation Devices (NODs), all lighting, including emergency lighting, must be able to be turned completely off. Red lighting may be added downrange to assist visibility during low light training.

Table 4-2 Lighting Requirements

LOCATION	**FT CANDLES	TYPE
Range Control Booth.	60	Fully dimmable + dimmable red light.
Vestibules.	40	On/Off with switches in vestibule + range control booth.
Get Ready Area and Uprange Firing Line.	60	Fully dimmable + dimmable red light.
Target Area.	80	Fully dimmable.
Last Target Line.	100	Fully dimmable.
Area Behind Trap.	40	On/off.

** Measured at 4 ft. (1.2 m) above the floor.

4-19.1 Range In Use Lights.

Include a red Range In Use light above and outside vestibule entrances that indicate when range is in use. Light is on when range is operational. Locate switch in range control booth.

4-19.2 Security Training Lights.

Optional flashing lights may be required behind or above the firing line to simulate the flashing lights from security vehicles. Choose location to provide desired effect downrange while minimizing impact on ventilation air movement. Check with local security force for proper color and flashing effects.

4-19.3 Emergency Lighting.

For exit lighting, provide low profile lights oriented with smallest profile pointing downrange to minimize interruption of supply airflow.

4-20 NOISE.

Design range to meet:

- The maximum ambient and live fire noise levels in Table 4-3.
- Reverberation Time 60dB (RT60) less than 1.3 seconds as described in the sound decay rate testing paragraph below.

4-20.1 Noise to Adjacent Land.

Consider all notable sources of noise associated with the training facility when determining its layout. Noise transmitted outside of indoor ranges can be significant and depends on several factors including weapons and ammunition, thickness and material of walls and roof, roof to wall connections, and direction of fire. Air handling and dust collection systems can also produce significant noise. Noise transmitted outside of indoor ranges can be reduced through a combination of strategic layout, acoustic dampening characteristics of construction materials, and construction methods. The location of the range and the adjoining land use will determine the acceptable level of noise transmitted outside of the range.

4-20.2 Noise Inside the Training Area.

The training area design must incorporate acoustic control elements to reduce internal ambient noise levels and reverberation time. To meet these levels, the acoustic design should incorporate strategic layout, construction materials with acoustic dampening characteristics, and intentional construction method types. The seals on doors and windows should be tight to minimize the direct transmission of noise out of the firing range and into other interior rooms or occupied spaces of the facility. Absorptive acoustical surfacing will reduce the noise level in the range. Ambient noise does not

include the impulse noise generated by gunfire but does include other noise sources such as air handling and dust collection systems. Ambient noise levels are generally controlled by preventing the noise from reaching the occupied spaces. Some noise sources can be isolated from the occupied spaces. Walls with designated Sound Transmission Class (STC) ratings can also be used to separate noise generating equipment from occupied spaces. Extending partitions to the ceiling or roof level and sealing air gaps will reduce noise transmission.

Short duration impulse noise peaks created by gunfire will exceed the 85 dBA level and could exceed 160 dBA. Reflective surfaces in a range will reverberate noise during firing, extending the decay time of the noise.

4-20.3 Acoustical Treatment Locations.

Acoustic absorbing materials may be used behind the firing line and on the wall, ceiling, and ceiling baffle surfaces extending down range. Treat the ceiling baffle nearest to the firing line with acoustic absorbing materials as it is the most important ceiling baffle regarding noise levels behind the firing line. Floor areas of the range must remain bare concrete or steel. The floor behind the firing line may be covered with rubber or other acoustic mitigating materials so long as the materials are suitable for floor application and do not impede the removal of ammunition residue. Include the acoustic design calculations in the design analysis.

4-20.4 Acoustic Panels.

Acoustic panels may be installed on walls, ceilings, and baffles. Blown-on acoustic material and carpeting are not permitted due to the difficulty of cleaning accumulated ammunition residue. Acoustic materials must be nonflammable and not impede the vacuum removal of ammunition residue. Do not paint acoustic tiles or surfaces as paint significantly degrades the sound absorbing qualities of the acoustic surfaces. Acoustic panels often serve dual purpose to mitigate sound and provide bullet splatter protection.

4-20.5 Acceptance Testing.

For all new, addition, and modification projects that include modifications to the sound-absorbing materials within the range, acceptance testing must be performed by an independent acoustic specialist whose firm is a member of the National Council of Acoustic Consultants.

4-20.5.1 Sound Decay Rate Testing.

The acoustic design must include mitigation methods and construction materials to reduce the measured Reverberation Time 60dB (RT60) to less than 1.3 seconds in the 250 Hz, 500 Hz, 1 kHz, 2 kHz, and 4 kHz octave bands in accordance with ASTM E2235. Testing must be performed in accordance with ASTM E2235 with noise generating devices placed at the firing line. Aim device parallel with the line of fire when not using omni-directional devices. The contractor must provide certified test results showing that the reverberation time requirements are met.

4-20.5.2 Ambient and Live Fire Noise Level Testing.

The contractor must provide certified test results showing that the ambient and live fire noise levels within the range do not exceed levels shown in Table 4-3.

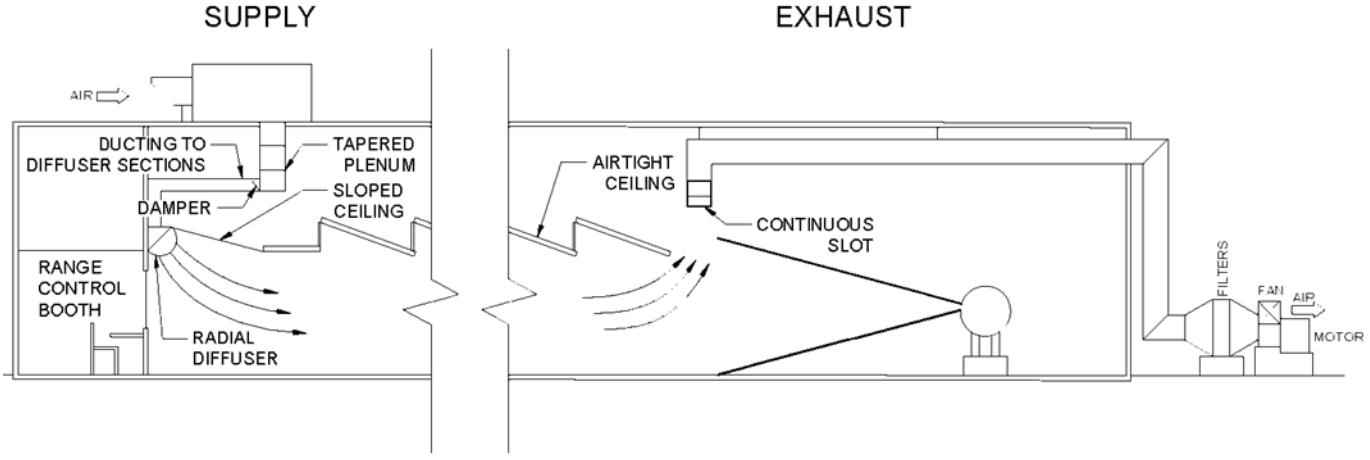
- All Ambient and peak noise level measurements must be taken with all range equipment on, including the air handling and dust collection systems, and no gun fire.
- All live fire noise levels must be taken with all range equipment on and with continuous gunfire from four Government provided shooters firing the maximum caliber design weapon, at full automatic if applicable, and using ball ammunition. Firing must be from the most uprange firing line without using suppressors.

Table 4-3 Maximum Noise Levels

	Maximum Ambient Noise Levels (dBA)	Maximum Live Fire Noise Levels (dBA)
Inside the Firing Range	75	Sound Decay Rate Test
Inside the Range Control Booth	60	85
Offices	45	55
Classrooms	45	55

4-21 RANGE VENTILATION.

In order to provide safe training and working environment, the ventilation system must limit exposure to airborne lead, copper, and other contaminants generated during small arms training. To achieve good air flow across the entire firing line, compliance with the following paragraphs is required. A recommended contracting strategy to help achieve these stringent requirements is provided in Appendix B.



4-21.1 General Ventilation Requirements.

All ventilation system controls must meet the cyber-security requirements found in UFC 4-010-06. The training area ventilation system must be separate and independent from the support and administrative area ventilation system. Design the training-area ventilation system to meet the following:

- An air flow of 75 fpm (23 m/min.) at the firing lines meeting the acceptance standards included later in this section.

- 100 percent outside air with no recirculation.
- A negative pressure inside the range of -0.05 +/- .02 in (1.3 mm +/- 0.5 mm) of water column relative to the non-training areas in the range.
- Paired supply and exhaust units with each exhaust fan interlocked with one corresponding supply fan.
- The preferred location of the supply Air Handling Units (AHUs) is on the roof to reduce the amount of turbulence in the air before it reaches the supply plenums.
- The preferred location of the exhaust AHUs is on the ground to simplify filter changes.
- AHU motors limited to 75 horsepower or less.
- Variable Frequency Drives (VFDs) on all supply and exhaust AHU motors.
- Supply intake vents separated from exhaust outlets by a minimum 30 ft. (9 m).
- Location of exhaust ductwork coordinated with baffle and trap design to protect against direct hit and ricochets.
- Independent local control. Base-wide control systems may connect to the system for monitoring purposes but must not control or alter the system settings.
- Ductwork protection for all ranges within approximately one mile (1.6 km) of salt water bodies. Include a sprayed-on weather and corrosion resistant coating, such as the polyurea coating used to line truck beds, for all ventilation ductwork exposed to the environment. Consider for all other locations where corrosion is a problem. Choose material and thickness based on local conditions and ductwork material.
- See Figure 4-6 for a schematic range ventilation system.

Figure 4-6 Range Ventilation Schematic

4-21.2 Climate Control.

4-21.2.1 Heating.

Provide heat **\1** only in locations where the official DoD engineering weather data (UFC 3-400-02) 99% wet bulb temperature is below **/1/** 50 degrees F (10 degrees C). Specify design heating temperature and heating type. Chose a dry bulb discharge temperature between 65 and 70 degrees F (18 and 21 degrees C) that minimizes temperature differentials between winter and summer temperatures inside the range. Air-to-air heat exchangers may be included in cold climates when cost savings are supported by life cycle analysis.

4-21.2.2 Cooling.

Provide cooling only **\1** in locations where the official DoD engineering weather data (UFC 3-400-02) 1% wet bulb temperature is over 100 degrees F (37.8 degrees C). **/1/** Evaporative cooling may be considered if reduced temperatures do not drive humidity over 65 percent.

\1 When internal range temperatures exceed 86 F (30 C) implement occupational safety procedure identified within the heat injury prevention plan. These measures may include drink water supply, increased break time, cooling/rest area, and heat stress monitoring. See your Service's occupational safety office for detailed guidance and monitor your local Heat Stress Flag Status.

Note: 86F (30 C) threshold is taken from NIOSH Figure 8-2 and falls within the Lower risk level (Table C-1) within NIOSH Occupational Exposure to Heat and Hot Environments publication. **/1/**

4-21.3 Supply Distribution System.

Design system to provide:

- Supply air from the air handling unit through a continuous graduated plenum that is gradually tapered to produce an even pressure along the length of the plenum.
- A single or double duct with an adjustable damper leading from the tapered plenum to each diffuser section.
- Interconnected double wall radial diffuser sections at the top of the back wall above the viewing window, with each section a maximum 5 ft. (1.5 m) long. Design and size diffuser sections to provide enough surface and free area to smoothly transition air as it moves to the firing line. Radial diffusers may be half or quarter round.
- Noise from supply system limited to 70 dBA or less when measured at the most uprange firing line, with no whistling noise coming from the diffusers.

- Single stage Minimum Efficiency Reporting Value (MERV) 8 supply filters as a minimum.
- A supply filter system that prevents filters from being pulled into fan.
- Align dampers within the diffuser sections with lane dividers in order to facilitate testing and balancing.

For high debris areas, provide double stage supply filters consisting of a minimum MERV 8 filter followed by a MERV 13 filter. Take the direction of the prevailing local winds into consideration when selecting location and direction of supply intakes.

4-21.4 Exhaust System.

Design exhaust system to provide:

- An air volume of minimum 110 percent of the rated supply volume of air.
- An exhaust plenum located above and downrange of the trap entrance, with a semi-continuous slot at the intake spanning the entire width of the shooting lanes.
- Minimum exhaust duct velocities of 2000 ft./min (57 m/min).
- Air velocities of 350 to 450 fpm (10 to 13 m/min) across the filter media.
- A two-stage filtration system with a MERV 15 Bag filter no less than 26 in. long (66 cm) followed by a HEPA filter with a 99.95 percent efficiency rating.
- Three-stage HEPA rated racks, leaving one stage empty for future flexibility.
- AHUs sized to provide minimum 5 in. (127 mm) of external static pressure for filter loading over clean required static pressure.
- Factory HEPA rated filter housing for the HEPA filter.
- AHUs and filter housing with a minimum 4 ft. (1.2 m) clearance from all adjacent features.
- Filters capable of being removed and replaced by hand without any special tools or equipment.

4-21.5 Controls.

Incorporate a Direct Digital Control (DDC) system to:

- Initiate supply and exhaust fans at low speeds that ramp up to field adjustable levels as necessary to reach desired negative pressure inside the range.

- Provide gradual adjustments to power and prevent noticeable hunting and modulation of the AHUs.

Note: Values for adjustable parameters must be selected during design and adjusted during balancing as necessary to optimize air movement.

Incorporate the following:

- Two clearly labeled emergency red mushroom cutoff switches wired directly to the supply and exhaust VFDs and the heat enable that manually and safely shut off the entire ventilation system. Locate one switch in the training area behind the firing line and the other inside the range control booth.
- **\1\ /1/**
- A ventilation control panel located in the range control booth with diagnostic screen, an on/off switch, and three condition lights on the panels: Safe to Shoot, Warning, and Do Not Shoot. Locate panel such that all condition lights are easily visible from all positions inside the booth.
- Diagnostic screen that scrolls though all conditions, settings, and status.

Require all controls and logic necessary to produce the following light conditions:

(1) Condition-Green Safe to Shoot light:

- All systems are within operating parameters.

(2) Condition-Yellow Warning light:

- Pressure drop across exhaust pre-filter is past adjustable set point.
- Pressure drop across exhaust HEPA filter is past adjustable set point.
- Pressure drop across supply filters is greater than an adjustable set point.
- Range temperature is outside given adjustable set points.

(3) Condition-Red Do Not Shoot light. If any of these conditions occur, controls will sound alarm and shut down range ventilation system:

- Either supply fan or exhaust fan is off.
- Pressure differential for any of the air filters is outside extreme limits.
- Doors leading into the range from the air lock vestibule remain open for more than a given set point, with an adjustable set point initially set to 5 min.
- Door into trap area is opened.

- Any door leading into the range training area from outside is opened.
- Range pressure is outside the upper limit of zero in. of water and the lower adjustable limit for a given time limit initially set to 2 min.
- Supply static pressure is below adjustable limit.

4-21.6 Acceptance Testing.

Test all new ventilation systems and any system where modification or adjustments have been made that would impact airflow.

4-21.6.1 Controls.

Test all controls for proper operation including fan start up and initiation, emergency cut offs, control panel operation, and all light conditions.

4-21.6.2 Air Flow.

Uprange:

Take measurements at the most uprange firing line in the center of each lane at 1 ft. (0.3 m), 3 ft. (0.9 m), and 5 ft. (1.5 m) off the floor. Test with clean filter first, then block off portions of HEPA filters to simulate a yellow warning condition and retest. Acceptable readings for both scenarios are:

- No single reading under 50 fpm (15 m/min) or over 120 fpm (37 m/min).
- Each lane average between 60 fpm (18 m/min) and 90 fpm (27 m/min).
- Range average between 71 fpm (22 m/min) and 79 fpm (24 m/min).

Downrange:

- With clean filters and measurements taken at the most downrange position nearest bullet trap but no closer than 9 ft. (3 m) from trap, take three measurements at each lane at 5 ft. (1.5 m) off floor.
- Average of three lane readings must be between 50 fpm (15 m/min) and 80 fpm (24 m/min).

Retest as necessary until all acceptance standards are met.

Notes:

These acceptance test standards only apply to new ventilation systems and replacement of existing systems. For existing systems use NEHC TM 6290.99.

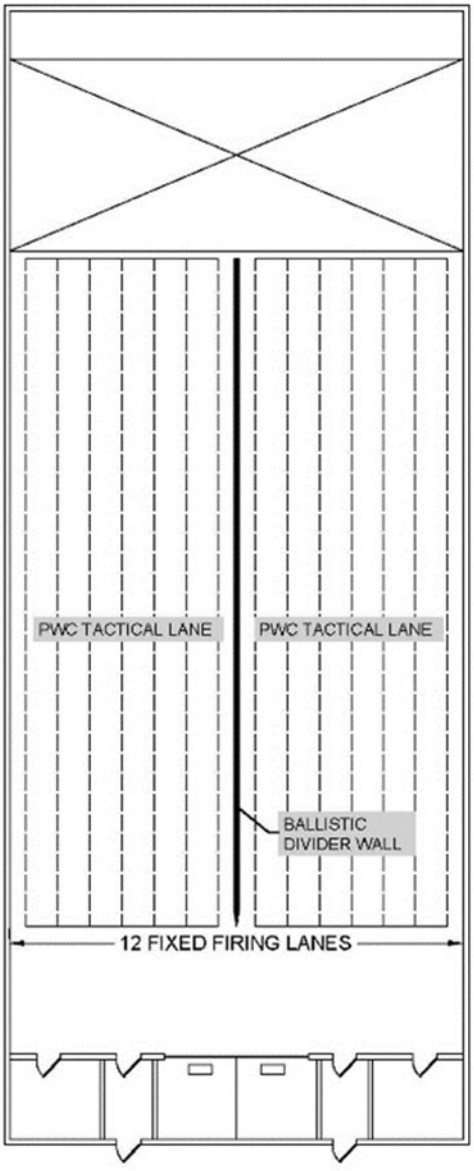
All meters can be unreliable when measuring non-ducted air flow of 50 fpm (15 m/min) and below. When 90 percent of the measurements along one line are acceptable, smoke tests should be used to verify the unacceptable readings. If the smoke tests

show steady air movement downrange at these locations, they should be considered acceptable.

4-22 RANGE OPTIONS.

4-22.1 Relocatable Ranges.

Relocatable ranges constructed of modular sections are designed to be disassembled and relocated using standard overland transportation to alternate locations as the training requirements change or are relocated. To provide this relocatable capability the relocatable modular range must meet all requirements for indoor ranges above with the following exceptions:



- Indirect Support Areas are not required.
- The range control booth may double as the air lock vestibule on small ranges with three or fewer lanes.
- Buffer between end lanes and side wall is not required and distance from back wall to firing line may be reduced to 12 ft. (3.6 m). These modifications are allowed because relocatable ranges can be sealed better than typical indoor ranges and this improves the airflow control.
- The range control booth back to front distance may be reduced to 8 ft. (2.4 m).
- The floor may be 0.375 in. (9.5 mm) AR500 steel plate with support to prevent sagging. Provide a slip-proof coating. Do not apply any surface on the flooring that prevents the bullets from reaching the bullet trap or that will entrap firing residue and hinder the cleaning of the range floor.
- For ranges with defined lanes where no angled shooting is allowed, a more compact steel trap may be used with 0.5 in. (12.7 mm) AR500 steel plates, a vertical throat with replaceable knife edged sides lined up with lanes and rated for the intended ammunition. The range ventilation exhaust may be routed though the trap to function as the dust collection system.
- **\1** When a granulated rubber trap is used, the additional space for a possible future steel trap is not required. **/1/**
- In lieu of concrete, the downrange wall behind the trap may use **\1** 0.375 in. (9.5 mm) **/1/** AR500 steel plate for ballistic containment.

4-22.2 Combination Fixed and Tactical Range.

A range with a ballistic center wall extending from the firing line to the base of the bullet trap can be used to increase flexibility by ballistically dividing the training past the firing line. An example is shown in Figure 4-7 that allows the range to operate as either:

- One 12 lane range with a fixed firing line to accommodate the Navy's OPNAVY 3591 rifle qualification course.
- Two tactical lanes with moving and shooting downrange at the same time to accommodate the Navy's OPNAV 3591 Practical Weapons Courses (PWC).

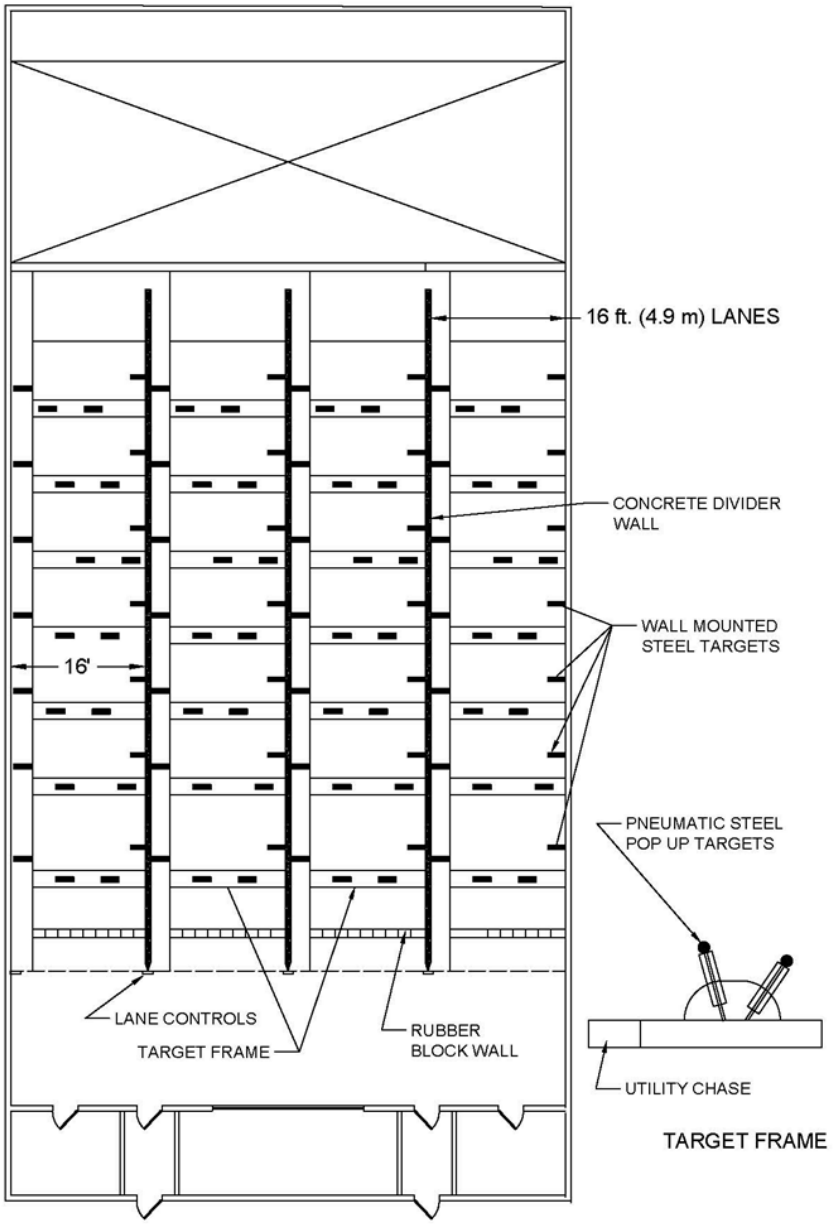


Figure 4-7 Range with Ballistic Divider Walls

4-22.3 Steel Reactive Range.

Advanced training with a knockdown steel target system provides immediate feedback to the shooters. One example is shown in Figure 4-8 but can be varied to meet training and maintenance objectives. This example has 16 ft. (5 m) wide lanes with a series of popup steel head plate targets in each lane. Limit ammunition to frangible rounds or as necessary to prevent rounds and splatter from coming back towards shooter and to minimize damage downrange. Design side walls and lane divider walls for direct hits and splatter where targets are placed near side walls. A control system and hit sensors can be designed to track and score hits. Protect target bases from direct hits.

Figure 4-8 Steel Reactive Range

4-22.4 Wide Angle Shooting.

Ballistic protection can be provided on side walls to allow shooting at angles of 180-degrees (side to side) or more. Downrange protection is provided by a bullet trap. There are several design options for protecting the walls with varying degrees of protection, space, and cost including:

- Placing 0.375 in. (9.5 mm) thick AR500 steel plates with splatter protection to a height of 8 ft. (2.4 m). This is only recommended when all rifle ammunition can be limited to frangible rounds.
- Covering the concrete side walls to a height of 8 ft. (2.4 m) with AR500 steel plate, with another wall in front consisting of a series of angled overlapping AR500 steel similar to a venetian blind trap and covered with splatter protection. The removable plates are sacrificial and should be sized and designed to meet the intended training and allow for easy removal and replacement. This is only recommended when all rifle ammunition can be limited to frangible rounds and rounds that do not have penetrators in the tip.
- Placing an 8 ft. (2.4 m) wall section designed with 0.375 in. (9.5 mm) AR500 steel plate, an approximate 2 ft. (0.6 m) air space, and a 12 in. (300 m) thick ballistic rubber block wall on the exposed shooting side. A wooden support system may be needed to secure the ballistic rubber blocks in place. The space is required to allow inspection of the underlying steel plates.
- Placing bullet traps along the side walls. This provides a high level of protection to the side walls but requires a significant amount of space.

CHAPTER 5 STEEL CLOSE QUARTER FACILITIES

5-1 GENERAL

Close Quarter Combat (CQC) facilities, also known as shoothouses, allow up to 360-degree shooting into ballistic walls. These structures can be built to simulate locations where close quarter combat training may be needed including residential, commercial, industrial, and shipboard environments. CQC facilities may have the following features:

- A full ballistic enclosure that contains all rounds within the facility.
- Ballistic walls with a separate ballistic roof above.
- No ballistic roof. – These are considered outdoor ranges and require a 360-degree SDZ or a waiver.
- Catwalks across the tops of the ballistic panels that allow RSOs to monitor training below.
- Ventilation provided by either a mechanical system, open eaves to encourage natural air movement, ceiling fans, or some combination of these.
- Non-ballistic walls and limited to non-lethal force-force rounds.

5-1.1 Applicability.

This chapter provides criteria for live fire CQC facilities that have steel ballistic walls, a ballistic roof, and limited to:

- Frangible rifle rounds and pistol rounds fired directly into ballistic walls. Note: Frangible rounds produce less airborne contaminants, have reduced ricochet potential, do significantly less damage to steel plates, and greatly reduce the chance of wall failure.
- Ball rounds without tungsten or steel penetrators fired into bullet traps as the primary impact surface, with ballistic walls providing secondary containment.
- Facilities with formal, documented, routine inspections of all ballistic steel plates. All live rounds have the capability to eventually penetrate any ballistic wall and therefore routine inspections are critical.
- Shooting and movement training. These facilities are not intended for multiple shooters firing multiple rounds in one area in a short period of time which can overwhelm the ventilation system.

For Army shoothouses, refer to the information contained in DA Pam 385-63, TC 25-8 and the RDG for training intent, standard shoothouse layouts, design information, instrumentation, support facilities, etc. In the event of conflicting information, these documents take precedence over this UFC for Army shoothouses.

5-1.2 Items Not Addressed.

This Chapter does not apply to CQC facilities and shoothouses where:

- Rounds with tungsten or steel penetrators, such as M855 5.56 mm and M855A1 5.56 mm, are allowed.
- Explosives are used. Explosives requirements are outside the scope of this criteria.
- Shock Absorbing Concrete (SACON) is used for the ballistic walls.

For these facilities follow service provided guidance.

5-1.3 Design.

The design must address:

- Ballistic containment.
- Targetry.
- Fire protection and alarms.
- Lighting.
- Laser use.
- Ventilation to provide a safe training and working environment.
- Maintenance and Storage.
- Noise reduction to the extent possible.

5-2 RANGE AREAS.

A CQC facility can be divided into two different areas:

(1) Live fire area where training occurs.

(2) Support area.

5-2.1 Live Fire Area.

Size area and design ballistic panel layout to support intended training. Careful coordination with trainers is critical to provide a combination of hallways, doors, room sizes, and other training features that maximize training value. Recommend panel layout be approved early in the design phase. Strategically placed movable or swap-out panels may be used to allow significant floor plan changes with minimal effort and panel adjustments. Options include:

- Ballistic panels hung on rollers that slide on a track system above.

- Pivoting panels. As an example, a selected panel that creates a dead end on a hallway in one scenario may be designed to pivot 180 degrees opening that hallway but creating a dead end on an adjacent hallway.
- Swap-out panels designed to allow simple switching between wall and door sections.

When incorporated, design movable and swap-out panels to:

- Maintain ballistic protection between panel, floor, and adjacent panels.
- Allow changes that can be made by two people within a reasonable time with simple hand operated equipment is recommended.

When movable or swap out panels are used, consider requiring mock up panel sections for approval before full scale installation by contractor.

5-2.2 Direct Support Areas.

Design must account for the following:

- Storage for targets, range equipment, and expendables such as splatter protection and spacers.
- Maintenance area for range equipment, targets, and expendables.
- Mechanical and electrical rooms.
- Control space for lights, monitoring, and recording systems.

Restrooms, lockers, and showers may also be provided to support personnel inside the CQC facility.

5-3 EQUIPMENT AND SPECIAL EFFECTS.

Equipment and special effects to enhance training may be incorporated into the design, including:

- Camera systems and two-way Public Address (PA) system throughout.
- Equipment to produce special effects including smoke, lighting, sound, and smells.
- Digital Video Recorder (DVR) systems for recording training and providing after-action review.
- Simulator equipment to project moving targets onto ballistic panels with cameras that can sense and record hit and misses.

5-4 TARGET SYSTEMS.

Target systems may include any of the following:

- Paper targets.
- Overhead rail targets.
- Popup targets.
- Three-dimension (3-D) Targets that are visible when using NODs.

5-5 ALARMS.

Provide audio and visual alarms activated by mushroom switches at key locations on walls and catwalk. Design system to provide the following results when activated:

- Lights and alarms turn on.
- Ventilation system shuts down.
- Special effects, when provided, turn off.
- Magnetic doors, when provided, unlock.

5-6 FIRE PROTECTION.

Each CQC facility is unique and fire protection requirements such as life safety and means of egress, sprinkler systems, fire alarms, and other passive and active systems will vary based on the mission and features of the individual CQC. Therefore, coordinate with the DFPE early in the planning and design process for fire protection requirements.

5-7 LIGHTING AND ILLUMINATION.

Select lighting and illumination based on training goals, requirements, and:

- Include dimmable lighting throughout.
- Locate all lighting above ballistic panels. One option is a grid tracked system just above the panels.
- Include illuminators at key locations on catwalks, exits, and in training area that will not interfere with the light spectrum of Night Vision Devices.

5-8 NOISE.

Design to reduce ambient noise and noise from gunfire to the extent possible. The requirements in Chapter 4 are not feasible and do not apply to the training area. For classrooms and administrative rooms, meet the noise requirements in chapter 4 for these rooms.

5-9 LASERS.

Design for laser use by eliminating all reflective surfaces inside the range. Provide a nonreflecting coating on all surfaces visible from the live fire area including:

- Walls and ceilings.
- Joists and beams.
- Ductwork.
- Door and other hardware.
- Housings for cameras and special effects equipment.
- Exposed piping and utility features.

Exceptions: Any part of any feature where a coating would interfere with its operation including sprinkler heads, lights bulbs, lens, and emergency switches.

5-10 BALLISTIC PROTECTION.

5-10.1 Ballistic Walls.

All wall surfaces subject to live fire must have ballistic panels composed of a minimum 8 ft. (2.4 m) tall and 0.5 in. (13 mm) thick AR525 steel plate with splatter protection covering all surfaces exposed to live fire. Minimize the need for welding and only allow techniques that do not reduce ballistic properties.

5-10.1.1 End Closure.

Design panels with ballistic steel end closures so that there are no panels with open sides or tops for ricochets to escape. This includes all panel tops, doors, and ends of termination panels. Closure must be minimum 0.375 in. (9 mm) AR525 steel plate.

5-10.1.2 Joints.

Provide complete ballistic protection across joints. Where ballistic steel panels cover concrete walls, plates may be bolted to the concrete using concrete anchor fasteners with a flat AR525 steel plate of same thickness as panel covering the joint.

5-10.2 Ballistic Roofs and Decking.

Design the roof to provide weather protection and ballistic containment consisting of either:

- Minimum 3 in. (76 mm) thick concrete.
- 0.375 in. (9.5 mm) thick AR500 Steel Plate.
- Bullet resistant fiberglass panels UL 752 protection level 8.

For multi-story CQC facilities, design deck between floors subject to direct fire on either side with a minimum 4 in. (150 mm) thick concrete, 0.375 in. (9.5 mm) AR500 steel, or ballistic equivalent.

5-10.3 Exterior Openings.

Design exterior openings subject to live fire to prevent rounds from escaping through a combination of:

- Controls and limitations.
- Lockable Level 7 UL 752 ballistic doors.
- Offset ballistic exterior walls covering exits.

5-10.4 Army Shoothouses

- Army shoothouses not designed to support EPR rounds require an exception to standard in accordance with AR 350-19.
- Army shoothouses do not require a ballistic roof; an SDZ deviation may be required.
- The ballistic walls are intended for secondary containment only, bullet traps or hot walls are required behind targets to capture the majority of rounds.
- Bullet traps must be designed for the specific rounds that will be fired in the facility.
- Moveable/sliding covers are an option for covering exterior openings.
- Other materials, as shown in DA Pam 385-63, are allowable for the shoothouse walls.

5-11 CATWALKS.

Catwalks may be included in the design when required to support the training or to provide the range safety officer with visibility and control. Design layout such that all rooms below are observable from positions on the catwalk. Provide stairs to the catwalk outside the ballistic panel enclosure. Where roof overhangs perimeter panels, consider locating the stairs outside the panels but inside the roof line. Retractable vertical ladders may be provided to allow floor access from catwalks above. Ladder should be in the raised position until needed. Catwalks can be supported from above to allow reconfiguration of the panels below in the future.

5-12 VENTILATION.

Consider maintenance and noise to adjacent areas when selecting location of ventilation equipment. Ventilation requirements in Chapter 4 do not apply. Design a mechanical ventilation system to:

- Create air movement within all rooms that clears smoke between training runs.
- Provide each fan with VFD and DDC controls tied to the control room to allow gradual start up and adjustment for obtaining optimal air movement.
- Limit all motors to 75 horsepower or less.
- Minimize noise and vibrations. Provide fans with vibration spring isolation that meet seismic requirements.
- Provide a Noise Criterion (NC) rating of less than 50 on exhaust grills during normal facility operations.
- Roof access to mechanical equipment that meets safety and force protection requirements.

Army ventilation requirements are contained in DA Pam 385-63.

5-12.1 Air Flow Requirements.

Design system to move air and clear smoke from all live fire rooms that meets the following:

- Top to Bottom Systems: A minimum cfm (m/min) to provide a vertical air velocity of 25 fpm (7.2 m/min) in all live fire areas.
- Over the Top and Open Eave Systems: Design system to clear smoke from all rooms within three minutes and all hallways within six minutes. To achieve this, the designer must specify a minimum cfm (m/min) based on the design and account for short circuiting, but as a minimum use 40 air changes per hour (ACH).

Note: A cfm selected based on 20 ACH will theoretically clear smoke within 3 minutes. Smoke will usually take much longer to clear due to short circuiting and inefficiencies.

5-12.2 Design Documents.

Design documents must include:

- Location and cfm for all AHUs.
- VFDs on all supply and exhaust motors.
- Roof penetrations and curb detail for all roof mounted equipment.

- Location and sizing of ductwork. Coordinate with catwalk and structural features.
- Location and sizing of supply and exhaust diffusers and registers.
- Filters location and requirements.
- Acceptance test requirements.

5-12.3 HEPA Filters.

The requirement for HEPA filters on the exhaust will be made on a case-case basis as determined by the responsible local environmental office. When HEPA filters are required, design as follows:

- Locate all exhaust AHUs on the ground.
- Provide two stage filtrations using a MERV 15 Bag filter no less than 26 in. (66 m) long followed by a 99.97 percent HEPA filter.
- Provide 3 stage HEPA rated racks, leaving one stage empty for future flexibility.
- Include 4 in. (100 mm) of external static pressure for filter loading in addition to that required for operating with clean filters.

5-12.4 Contractor Experience.

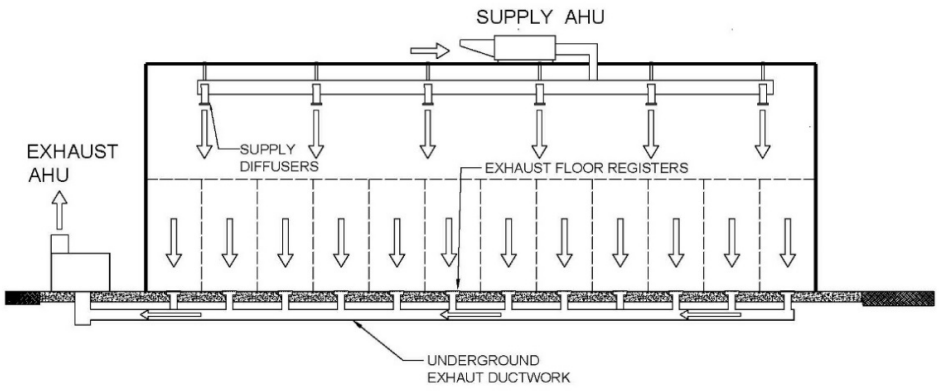
It is highly recommended that a range ventilation contractor, experienced in providing systems with similar requirements, is made responsible for the final design and construction of the ventilation system including controls and balancing. An approach similar to that recommended in Appendix B for indoor ranges can be used.

5-12.5 Acceptance Tests.

Acceptance tests must include the following:

- Air flows at supply and exhaust: Test and balance each supply diffuser and exhaust register against the design air flow. Provide acceptable readings based on system provided.
- Smoke Tests: With the system set in training mode with doors shut and the ventilation system turned on, release smoke into each room using smoke machines capable of filling rooms with smoke. Smoke in all rooms must show movement and signs of clearing and be completely clear within the time specified. Any rooms where smoke is stagnant or fails to clear room completely within time specified constitutes failure requiring the contractor to readjust and modify system until all rooms pass test.

5-13 ENCLOSED CQC FACILITIES.



A concrete structure with a ballistic roof to prevent any round from leaving the facility. Ballistic steel panels with splatter protection must cover all surfaces subject to live fire. Multiple levels may be provided.

5-13.1 Top to Bottom Ventilation System.

Design a mechanical ventilation system that supplies air from the top and exhaust air through floor registers spaced a maximum of 10 ft. (3.0 m) on center. Floor registers must be flush with floor and a maximum of 0.25 in. (6 mm) openings to prevent brass from entering pit. Coordinate floor register layout with panel layout to minimize the number of walls on top of floor registers. See Figure 5-1.

Army ventilation requirements are contained in DA Pam 385-63.

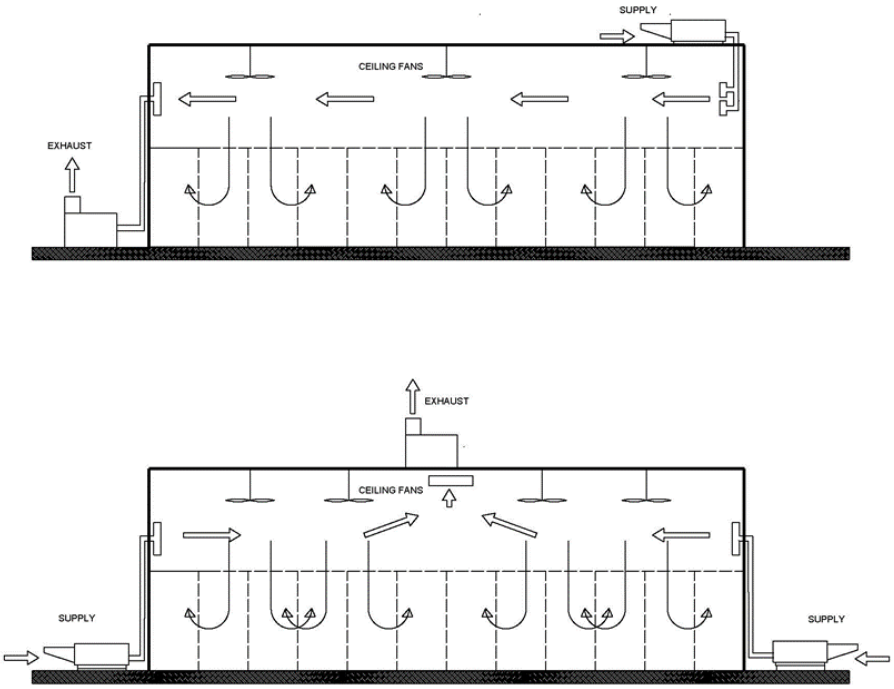


Figure 5-1 Top to Bottom Ventilation System Schematic.

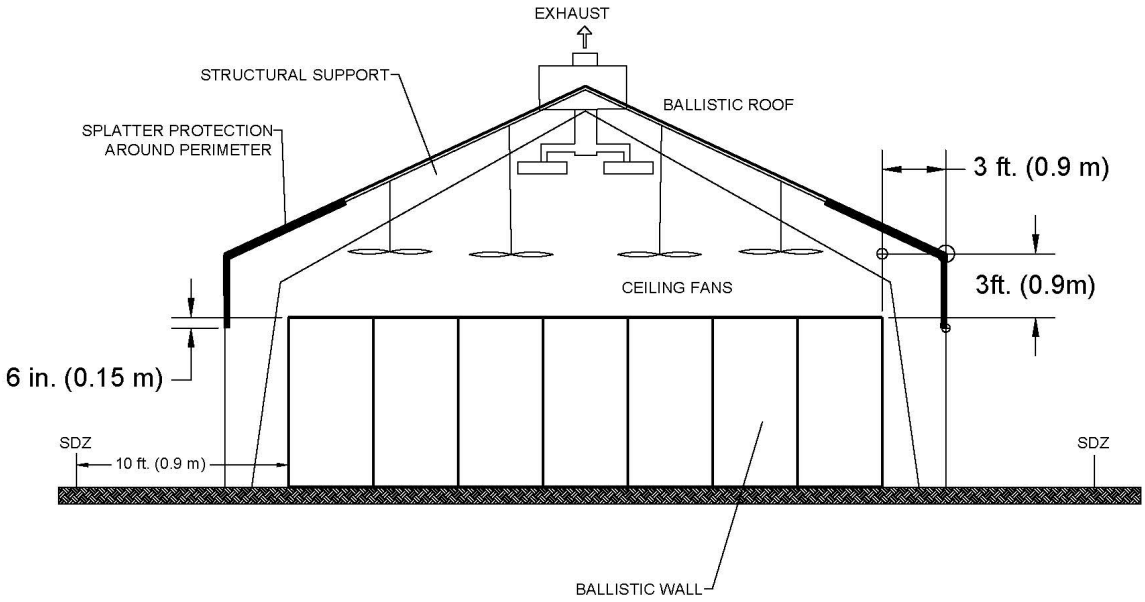
5-13.2 Across-the-Top Ventilation System.

Design a mechanical system that moves air across the top of the panels with supplemental blowers or ceiling fans to push air down into the rooms below. AHUs can be roof or ground mounted. The schematics in Figure 5-2 show options for roof and ground mounted AHUs.

Figure 5-2 Across-The-Top Ventilation System Schematics.

5-14 CQC FACILITIES WITH OPEN EAVES.



This facility has ballistic steel plates connected to a concrete floor, with splatter protection on all shooting sides. A separate roof structure is built over the ballistic walls with structural columns connected to the concrete outside the ballistic walls creating an open eave in between.

5-14.1 Minimum Distances.

As a minimum, provide the following clearances between ballistic roof and walls:

- Minimum 3 ft. (0.9 m) above ballistic walls.
- Minimum 3 ft. (0.9 m) away from ballistic walls.
- Roof sides extend a minimum 0.5 ft. (0.15 m) below height of ballistic walls.
- See Figure 5-3.

Figure 5-3 Ventilation System Supplemented with Natural Airflow

5-14.2 Ventilation.

Design system with open eaves to promote natural air movement supplemented with ceiling fans or blowers and exhaust fans pulling air from above.

Army ventilation requirements are contained in DA Pam 385-63.

This Page Intentionally Left Blank

APPENDIX A BEST PRACTICES

This information is guidance and not requirements. The main purpose is to communicate proven system/facility solutions and lessons learned and may not be the only solution to meet UFC requirements.

A-1 INDOOR RANGE VENTILATION CONTRACTING STRATEGY.

Providing a ventilation system that limits exposure to airborne contaminants is challenging because:

- Range ventilation is a significant portion of the construction cost.
- Performance testing includes measuring airflow velocities at each lane and firing position and comparing them to strict acceptance standards, and this typically comes near the end of the project.
- Meeting the required average airflow velocity across the width of the range is relatively easy, but meeting airflow requirements at each lane and firing position can be very difficult.
- Numerous failures have occurred when inexperienced range ventilation contractors were used.
- When failures occur, it can be difficult to determine whether the problems are related to the design, construction, controls, balancing, or testing. It can be especially difficult when these responsibilities are split between several sub-contractors, which is typically the case.
- The problem persists with both full design and design-build projects.
- Should the system fail to meet the acceptance standards, it may be difficult and time consuming to resolve problems. Significant rework may be required.

Therefore, it is highly recommended that the contract documents only allow range ventilation contractors with proven experience meeting these or similar performance standards and require that this contractor be responsible for the final design, construction, controls, testing, and balancing of the system. In addition:

- Range experience alone should not be considered, it must be experience meeting similar performance requirements since the majority of non-DoD indoor ranges do not use these stringent standards.
- The acceptance testing should be witnessed by experienced government personnel or third parties to verify all tests are performed properly.

A recommended contracting strategy is provided below.

A-1.1 Phase 1 – Requirement Development.

For Design-Build (DB) projects, this is the Request for Proposals (RFP). For Design-Bid-Build (DBB) projects, this is the project design phase.

For DBB and DB projects, include the following in the contract documents:

- Power supply location, and verification that power is sufficient.
- Minimum air flow in cubic feet per minute (cfm) and cubic meters per minute (m3/min.) required for both supply and exhaust systems.
- General location of Air Handling Units (AHU), including whether they are roof or ground mounted. Require stair access to roof when AHUs are located on roof.
- General location of dust collection and spent round collection systems.
- General location of ductwork and diffusers.
- Filter and filter rack requirements.
- Heating requirements.
- Cooling requirements. Cooling is only required in extremely hot climates.
- Ventilation contractor’s experience requirements.
- Design requirements edited for the project, with all options selected or clarified as appropriate.
- Acceptance testing requirements.

For DBB projects, the additional detail below is required to allow coordination with other design disciplines:

- Location of AHUs. Provide estimated weights and electrical loads of all equipment.
- Power connection details.
- Location and general sizing of ductwork, dampers, and radial diffuser in enough detail to allow coordination and avoid conflicts with other design disciplines.
- Exact location of VFDs, control panels, and emergency cutoffs switches.
- Roof penetration and curb details shown for all AHUs and ductwork.
- Section at wall between range control booth and training area showing radial diffuser, ductwork to diffusers, viewing window, suspended ceiling, and structural ceiling.
- Stair access when exhaust AHUs are roof mounted.

Options to be selected and included in the Phase 1 stage:

- Location of supply AHUs: Locate on the roof when possible and centered with symmetrical ductwork leading to the supply diffusers.
- Location of exhaust AHUs: Locate on the ground when possible to allow easy replacement of HEPA filters. When located on the roof, stair access must be provided.

A-1.2 Phase 2 - Ventilation Contractor Requirements.

Make the ventilation contractor responsible for providing the final design, construction, controls, balancing, and final acceptance testing of the range ventilation system. Require that contractor to have completed a minimum of five indoor range ventilation projects with similar design and acceptance testing requirements, including 75 fpm (23 m/min.) air velocity when measured along the entire rear firing line and at least three different heights. During the bidding process the ventilation contractor is encouraged to submit a Request For Information (RFI) if, in their opinion, the Phase 1 design requirements will not result in a system that meets the performance acceptance tests.

Have the ventilation contractor provide:

Prior to starting work:

- Proof of previous experience, including contract documents from each project showing design and acceptance test requirements, along with final acceptance test reports.
- A confirmation that they can provide a system meeting the Phase 1 design and the acceptance testing performance requirements.
- Full design of ventilation system including duct design and supply, exhaust, and filter schedules.

At end of work:

- Prior to acceptance testing, a detailed testing plan for approval with a checklist and step-by-step procedures in a logical sequence.
- Acceptance testing performed in the presence of the Contracting Officer Representative. Provide all materials, equipment, and personnel necessary to perform the tests including smoke generators, air flow meters, communications, plan, and checklist.
- Operations and Maintenance manuals.
- A minimum 8 hours of on-site training covering operations, maintenance, and troubleshooting of the entire range ventilation system.

This Page Intentionally Left Blank

APPENDIX B DOD WEAPONS AND AMMUNITION

A wide variety of small arms weapons and ammunition is used throughout DoD. Some common weapons and ammunition categories are listed below. The Army's Hazard Classification of United States Military Explosives and Munitions is a useful guide that provides detailed information on every DoD approved round including a unique identifier known as the Department of Defense Identification Code (DODIC).

B-1 WEAPONS.

- 12-gauge Shotguns.
- Pistols/handguns: 9 mm and .45 cal.
- Rifles : M4/M16 5.56 mm variants, M14 7.62 mm.
- Crew Served Weapons: M249 5.56 mm and M240 7.62.
- M2 .50 cal. Machine gun.

B-2 CATEGORIES OF SMALL ARMS AMMUNITION.

Most weapons can chamber different types of ammunition with different characteristics. Here are some different types of ammunition and typical uses:

- Short Range Training Ammunition (SRTA): These training rounds much shorter maximum distances than standard rounds allowing them to be used in areas where SDZs prohibit standard ammunition. Some SRTA rounds rely on light plastic projectiles to limit distance and others rely on projectile design to intentionally destabilize the flight path. These rounds are typically lethal and should not be confused with non-lethal training rounds.
- Frangible rounds: These training rounds are designed to disintegrate into tiny particles after impacting steel for minimizing penetration, reducing back splatter, and reducing damage to range components on indoor ranges and Shoothouses. They create more fragment and dust which may increase filter loading. These rounds are lethal and should not be confused with non-lethal training rounds.
- Reduced and zero lead content rounds: Some rounds are completely lead free. Other have small amounts of lead in the primer to prolong shelf life. These rounds can reduce or eliminate the chance of lead exposures and may reduce the costs of disposal of range filters and clean up debris. However, they may contain other potentially harmful compounds and therefore do not lessen range ventilation requirements.
- Non-lethal ammunition: These rounds allow force on force training (participants shoot at each other). They do not imply zero risk and serious injury can occur if not used properly. The DoD versions typically have small amounts of lead in the primer to increase shelf life.

- Rounds with steel penetrators: These rounds have steel penetrators to increase penetration through steel, but generally not to the extent of AP rounds.
- Armor Piercing (AP): These rounds have tungsten tips (or penetrators) to increase penetration through steel. These should not be allowed on indoor ranges, or on outdoor ranges with steel bullet traps or steel targets.
- Tracer rounds: Typically used in belt fed weapons loaded with standard rounds plus a tracer round every fourth or fifth link. Tracer projectiles contain a pyrotechnic making the trajectory visible and enabling the shooter to make aiming corrections. These should not be allowed on indoor ranges and shoothouses.
- Breacher Rounds: Shotgun slug or shot made especially for employment close range into door hinges.
- Multiple Properties: Some rounds have multiple characteristics such as being both lead free and frangible, or SRTA and frangible.

APPENDIX C GLOSSARY

C-1 ACRONYMS

AFCEC	Air Force Civil Engineer Center
AHU	Air Handling Unit
AP	Armor Piercing
AR	Army Regulation
AR	Abrasion Resistance (When used in conjunction with steel plate)
BIA	Bilateral Infrastructure Agreement
BMP	Best Management Practices
CCMCK	Close Combat Mission Capability Kit
CFR	Code of Federal Regulations
CQC	Close Quarter Combat
DA PAM	Department of the Army Pamphlet
dBA	A-weighted decibels
DB	Design Build
DBB	Design-Bid-Build
DDC	Direct Digital Control
DF	Direct Fire
DoD	Department of Defense
DODIC	Department of Defense Identification Code
EOD	Explosive Ordnance Disposal
EPR	Enhanced Performance Round
FAA	Federal Aviation Administration
FL	Firing Line
FLFS	Firing Line Floor Surface

GIS	Geographic Information System
HBW	Hardness Brinell Wolfram (Tungsten)
HE	High Explosive
HEPA	High Efficiency Particulate Air
HNFA	Host Nation Funded Construction Agreements
HQUSACE	Headquarters, U.S. Army Corps of Engineers
KD	Known Distance
LAW	Light Antitank Weapon
LLF	Lower Limit of Fire
LOMAH	Location Of Miss And Hits
LOF	Line of Fire
LOS	Line of Sight
MERV	Minimum Efficiency Reporting Value

SOFA	Status of Forces Agreements
SRTA	Short Range Training Ammunition
STC	Sound Transmission Class
TC	Training Circular
UFC	Unified Facilities Criteria
ULF	Upper Limits of Fire
U.S.	United States
USACE	United States Army Corps of Engineers
UXO	Unexploded Ordnance
VDZ	Vertical Danger Zone
VFD	Variable Frequency Drive

C-2 DEFINITION OF TERMS

Close Quarter Combat (CQC) Facility: A live fire shoothouse that supports short-range training such as room-room clearing.

Crew Served Weapon: Any weapon system that requires a crew of more than one individual to function at optimum efficiency such as a belt fed machine gun.

Direct Fire: Fire delivered to a target within the line-of-sight of the shooter using the target itself as the point of aim.

Distance X: The maximum distance a projectile (to include guided missiles and rockets) will travel when fired or launched at a given quadrant elevation with a given charge or propulsion system.

Double Hearing Protection: Wearing earplugs in combination with noise muffs or noise attenuating helmets. Impulse noise levels can be so high that single hearing protection does not adequately protect hearing.

Dry Fire: Operating a weapon with no ammunition in the chamber. Not all weapons should be dry fired.

Firing Line (FL): The line which consists of firing points or positions, from which weapons systems are fired.

Firing Line Floor Surface (FLFS): The ground surface along the firing line.

Firing Position: The point or location at which a weapon system is placed for firing.

Indirect Fire: Fire delivered to a target when the weapon is not in line of sight with the target.

Line of fire (LOF): An imaginary line drawn from the shooting position to the target.

Live Fire: As used in this UFC, live fire includes use of any potentially lethal ammunition.

Lower Limit of Fire (LLF): An imaginary line consisting of the lowest point on all LOFs combined. This is often taken drawn a prone shooter firing at the lowest target.

Military Operations in Urban Terrain (MOUT) Facility: A mock town or city providing urban warfare training.

Navigable Waterway: Any body of water open to the free movement of marine vessels.

Officer in Charge (OIC): The officer, WO, or Non-Commissioned Officer (NCO) responsible for personnel conducting firing or operations within the training complex.

Partially Contained Range: This range has a covered firing line, side containment, overhead baffles, and a bullet backstop. Direct fire is totally contained by the firing line canopy, side containment, baffles, and bullet trap (no “blue sky” observed from firing positions). Ricochets and splatter are not contained.

Range Safety Officer (RSO): The officer, warrant officer (WO), or noncommissioned officer (NCO) who is the direct representative of the Officer In Charge (OIC) for insuring the adequacy of safety of firing, training operations, and ensuring compliance with laser range safety and local standing operations. Qualifications vary between services.

Reverberation Time 60dB: The time it takes for the sound pressure level to reduce by 60dB, measured after the sound source is abruptly switched off.

Shoothouse: See Close Quarter Combat (CQC) Facility.

Single Hearing Protection: Wearing either earplugs, noise muffs, or noise attenuating helmets.

Small Arms: For this UFC small arms includes all pistols, shotguns, rifles, carbines, submachine guns, light, medium, and heavy machine guns up to and including .50 caliber.

Sound Transmission Class: A rating used to compare the acoustical isolation of different barrier materials or partition constructions.

Surface Danger Zone (SDZ): The ground and airspace designated within the training complex (to include associated safety areas) for vertical and lateral containment of projectiles, fragments, and debris, and components resulting from the firing, launching, or detonation of weapons systems to include explosives and demolition.

Upper Limit of Fire (ULF): An imaginary line consisting of the highest point on all LOFs combined. This is often taken drawn from a standing shooter firing at the highest target.

Vertical Danger Zone (VDZ): For non-contained and partially contained ranges, the VDZ is the volume of airspace above the SDZ between the ground surface and the maximum ordinate of a direct-fired or ricochet round. The height of the VDZ varies with the weapon and ammunition fired. For fully contained ranges, the VDZ is the area between the SDZ and the upper limits of containment.

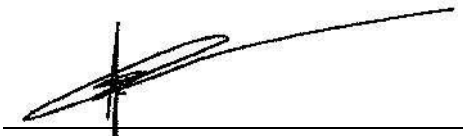
FOREWORD

Facilities Criteria (FC) provide functional requirements (i.e., defined by users and operational needs of a particular facility type) for specific DoD Component(s), and are intended for use with unified technical requirements published in DoD Unified Facilities Criteria (UFC). FC are applicable only to the DoD Component(s) indicated in the title, and do not represent unified DoD requirements. Differences in functional requirements between DoD Components may exist due to differences in policies and operational needs.

All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the most stringent of the FC, the SOFA, the HNFA, and the BIA, as applicable.



Because FC documents are coordinated with unified DoD technical requirements, they form an element of the DoD UFC system applicable to specific facility types. The UFC system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applicable to the Military Departments, Defense Agencies, and the DoD Field Activities. The UFC System also includes technical requirements and functional requirements for specific facility types, both published as UFC documents and FC documents.

FC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing criteria for military construction. HQ U.S. Army Corps of Engineers (HQ USACE), Naval Facilities Engineering Command (NAVFAC), and the Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet site listed below.

FC are effective upon issuance and are distributed only in electronic media from the following source: Whole Building Design Guide web site http://dod.wbdg.org/

Refer to UFC 1-200-01, *General Building Requirements*, for implementation of new issuances on projects.

AUTHORIZED BY:

JOE SCIABICA, SES
Director
Air Force Civil Engineer Center

FACILITIES CRITERIA (FC)

NEW SUMMARY SHEET

Document: FC 4-179-03F, *Air Force Indoor Small Arms Firing Range*.

Superseding: None.

Description: This FC provides guidelines for evaluating, planning, programming, and designing an indoor small arms firing range. The information in this FC applies to the design of all new construction projects, to include additions, alterations, and renovation projects in the continental United States (CONUS) and outside the continental United States (OCONUS). It also applies to the procurement of design-build services for the above-noted projects. Alteration and renovation projects should update existing facilities to meet the guidance and criteria within budgetary constraints.

Reasons for Document: This FC is the initial release to establish requirements for an indoor small arms firing range. It defines the criteria for determining appropriately sized, flexible, cost-optimized, durable, quality-designed facilities on a life cycle basis to support the mission. The plans presented in this FC are concepts only and are primarily intended to communicate functional user and adjacency requirements. A thorough compliance check of all other applicable criteria is required.

Impact: Use of this FC will facilitate and standardize the design of indoor small arms firing ranges throughout the Air Force. It will provide more complete and consistent project requirements and expedite the programming and design of facilities and reduce initial design cost.

Unification Issues: None.

CHAPTER 1 INTRODUCTION

1-1 GENERAL INFORMATION.

1-1.1 Purpose.

This standard facility prototype design criteria was developed to assist Air Force programmers to prepare and validate DD Form 1391 requirements and to assist A-E design professionals with approved project-specific design requirements. It is a source of basic programming and functional information for a small arms firing range. **1**\ This standard is consistent with the Air Force Corporate Facilities Standards (AFCFS) and Unified Facilities Criteria (UFC). This standard, in conjunction with the AFCFS and UFC criteria, defines Air Force expectations for project programming and A-E design decisions. /**1**/

1-1.2 Objective.

The standard facility prototype design program defines consistent facility requirements across the Air Force enterprise to expedite delivery of a facility. This standard was designed in compliance with AFMAN 32-1084. The objective is to deliver appropriately sized, flexible, cost-optimized, durable, quality-designed facilities on a life cycle basis to support the Air Force mission.

1-2 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01*,* which provides applicability of model building codes and government-unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism (AT), security, high-performance and sustainability requirements (comprehensive requirements are detailed in UFC 1-200-02), and safety. **1**\ Use this FC in addition to UFC 4-179-02, UFC 1-200-01, and the UFCs and government criteria referenced therein. /**1**/

1-3 REFERENCES.

Appendix A contains a list of related documents and references to use in conjunction with this FC. In general, use the latest available issuance of the reference.

1-4 INSTRUCTIONS.

1-4.1 Method.

The standard facility prototype was developed by determining personnel counts, allowable room sizes, adjacency diagrams between functional spaces, and overall facility space requirements. The standard facility prototype establishes Air Force criteria for the facility type. **1**\ Use the criteria in conjunction with other departmental publications and UFCs when programming and designing this facility type. /**1**/

Supplement this FC with a thorough review by individual program managers and operations staff.

1-4.2 Standard Facility Prototype Tools.

1\ This standard facility prototype consists of four parts to be used by programmers and A-Es:

1. Facilities criteria for standard prototype (this FC)
2. Interactive programming spreadsheet
3. Facility Building Information Modeling (BIM) drawings
4. UFC 4-179-02 /**1**/

1-4.3 Facilities/Design Criteria.

The FC document consists of three primary components:

1. Notional site
2. Composite facility adjacency diagram(s)/composite floor plan(s)
3. Modules with associated room data sheets

1-4.3.1 Notional Site.

The notional site presents a notional site plan diagram that indicates key site development criteria; it is not a site-specific solution. The information represents the land requirements to construct this facility and includes associated AT standoff distances and parking. Utilization of existing or shared parking is allowable and may reduce the total acreage required for the facility. Adapt the requirements to the specific site and location and comply with the applicable Installation Development Plan (IDP) and Area Development Plan (ADP) for facility siting.

1-4.3.2 Composite Floor Plans.

The composite floor plans are conceptual solutions that illustrate functional user and adjacency requirements. Plan variations may be rotated, flipped, or reversed to fit the actual site. A thorough compliance check of all other applicable criteria is required even when using the conceptual solutions provided in this FC.

1-4.3.3 Modules.

Spaces and rooms that are integrally related with a specific functional connection or operational flow are grouped into a module. Modules and the associated room data sheets identify specific criteria and additional detail for each functional area of the

facility as outlined in the space program sheets in Appendix B. Information is provided in a standard presentation and data sheet format and the required space adjacencies and modules are illustrated in figures.

The resulting shape of the facility assembled from the facility prototype modules must provide construction efficiencies obtained from building proportions and overall configuration. The building footprint shall be organized and well composed. The building design must comply with the installation facility standards (architectural compatibility plan) and the AFCFS. Modules shall not be deconstructed or altered except as indicated in paragraph 1-4.3.4.

1-4.3.4 Module Flexibility/Adjustments.

Utilization of the modules provided is highly recommended to maintain functional relationships, adjacencies, and allowed program areas. Modules contain fixed attributes that are essential to functional requirements. Modules may be rotated, flipped, and reversed to accommodate an overall composition or site issue. When the modules cannot be arranged to produce a constructible floor plan due to site constraints, their proportions may be adjusted to create a constructible plan. Manipulating the module shape must not result in an overall increase in square feet and/or reduce the functionality of any module or the required adjacencies in the composite plan.

Some modules are linked to space requirements that increase or decrease in size based on the personnel count and equipment for a particular mission. In these cases, increase or decrease the size of the module to match the revised scope calculation. This may sometimes require minor adjustments in other adjacent modules so they properly fit together to create a constructible facility floor plan. Spaces must comply with any critical dimensions indicated on module plans. Manipulate as few modules as possible to create a constructible facility. The resulting composite plan must respect the established module’s adjacencies and must not exceed the authorized project scope.

1-4.3.5 Room Data Sheets.

Specific requirements for each room, space, or area are provided on room data sheets that are located following their respective module. Information contained on the data sheets defines the functional and physical requirements for each of the spaces within the facility type.

1-4.4 Programming Spreadsheet(s).

This tool is provided in two formats. A PDF programming sheet is provided in Appendix B primarily as a reference and reflects the baseline standard facility program. The additional interactive programming sheet provides a tool for planners and programmers. It allows the input of authorized personnel positions and special purpose spaces. Updated inputs are automatically calculated and provide new required square footage

for each space and the overall facility size. A link is provided in Appendix B for access to the interactive programming spreadsheet.

1-4.5 Facility Drawings – BIM.

This component of the standard facility prototype tools includes both a PDF version and a Revit version of the modules, and rooms and composite floor and site plans. The spaces, rooms and modules shown reflect the baseline standard facility program spreadsheet in Appendix B. The drawings in this FC are exact copies of the larger BIM drawings and comply with the program scope. The BIM drawings provide a starting point for the digitization of building data and a starting point in the design and construction of a facility. BIM drawings are found at the link provided in Appendix B.

1-4.6 Additions and Alterations.

For additions and alterations to existing facilities, use the adjacencies, sizing/scope, and detailed requirements contained in the site diagrams, module drawings, and room data sheets to the maximum extent possible. The functionality and adjacency of the modules are still valid but may require some manipulation to accommodate the existing structure. Move non-structural walls to the greatest extent possible to open up space in existing facilities to make them more receptive to the placement of the modules. The planner and designer shall determine the most efficient means to balance the placement of modules within existing spaces or as a facility addition.

1-4.7 A-E Design Professionals.

The requirements set forth by this standard are the approved space programming and functional layouts in accordance with AFCFS. The Air Force Security Forces Center (AFSFC) must approve variations to functional and operational issues and deviations from core requirements.

CHAPTER 2 SITE AND OVERALL ADJACENCY

2-1 GENERAL FACILITY OVERVIEW.

The indoor small arms range that houses space to fire and train on weapons use is typically a one-story structure that works best as a standalone facility. All Air Force recruits and active personnel must have weapons training, both initial and ongoing certification. This facility provides a safe space to fire live rounds, train on weapon assembly, and clean and maintain weapons. It consists of a large, enclosed space for firing live rounds, student classrooms, weapons cleaning, weapons storage, administration area, and support spaces. Consult the AFCFS to determine overall quality standards for the facility type. This standard facility prototype is considered as a Group II or III hierarchy based on its actual location on the installation.

2-2 FACILITY USERS/OCCUPANTS.

The facility users are as follows:

- Able-bodied active duty, National Guard, and Reserve military personnel
- Able-bodied DOD civilians, contractors, and others as authorized
- Non-range, common areas shall be ABA compliant

2-3 SIZE DETERMINANTS.

1*\ The indoor small arms firing range size is generally driven by the installation's training requirement and mission. The 21-lane facility has been designated as standard. See paragraph B-1 for the range size requirements calculator tool. /1**/

2-3.1 Indoor Small Arms Firing Range Size.

Indoor small arms firing range sizes vary from 14-lane up to 56-lane facilities. For the purpose of this planning document, the minimum to maximum sizes were analyzed:

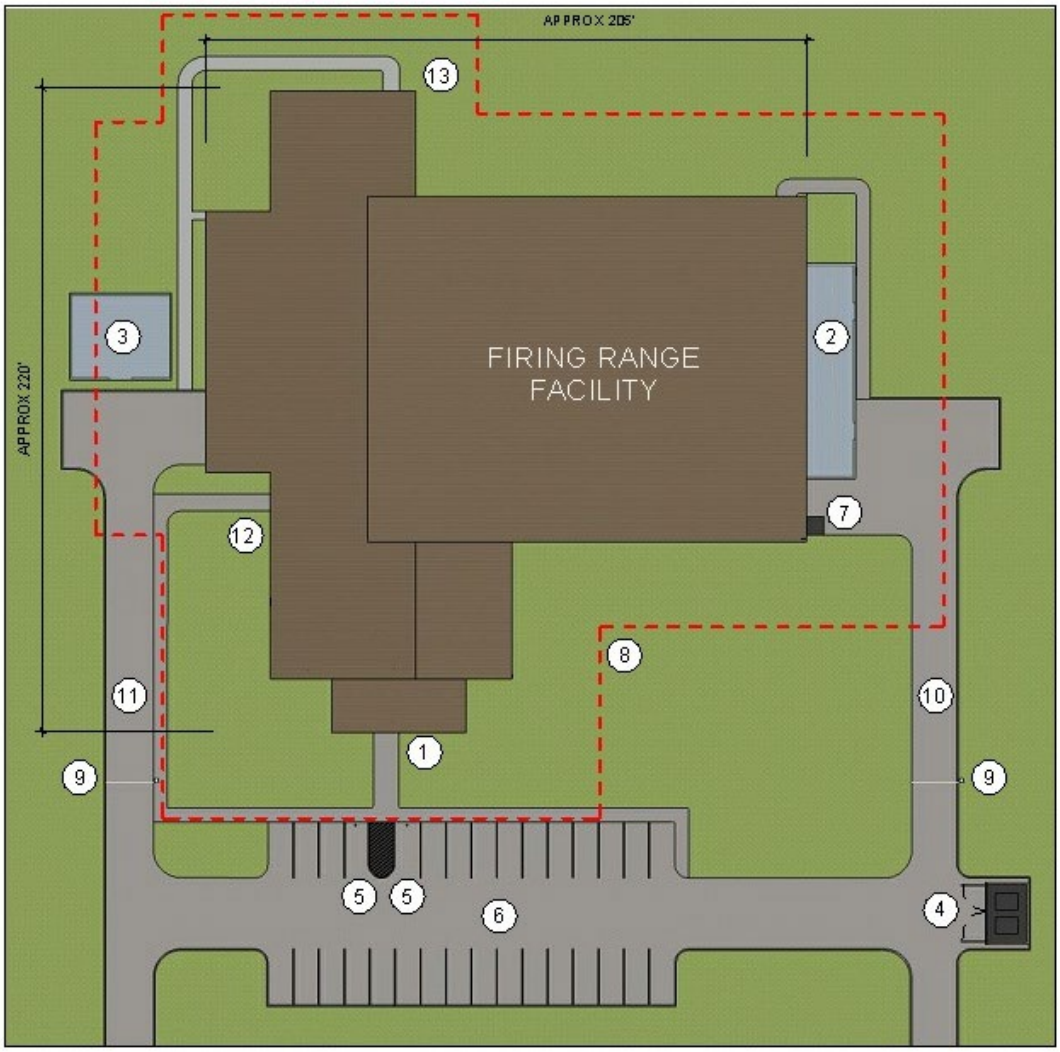
- Small, 14 lanes
- Standard, 21 lanes
- Large, 28 to 56 lanes (in increments of 7)

2-4 OPERATIONAL ASPECTS.

The hours of operation are driven by user and mission requirements.

2-5 NOTIONAL SITE.

The site diagram represents a notional layout to reflect site development requirements/criteria only. It is not an actual site design. Siting must comply with the IDP and ADP.



2-6 LOCATION DETERMINANTS (SITE SELECTION) OR SITE LOCATION AND ORIENTATION.

Several factors determine the most appropriate and cost-effective location for an indoor small arms firing range. The availability and capacity of required utilities and the mass/scale of the facility relative to adjacent structures and noise issues shall be analyzed.

2-6.1 Access.

The indoor small arms firing range's ideal location is in the vicinity of the main Security Forces Squadron facility. Locate the facility with main road access and away from any active pedestrian or populated areas. Provide parking and access drives as close to the facility as possible while complying with AT requirements in UFC 4-010-01. Separate service drives from privately owned vehicle (POV) parking.

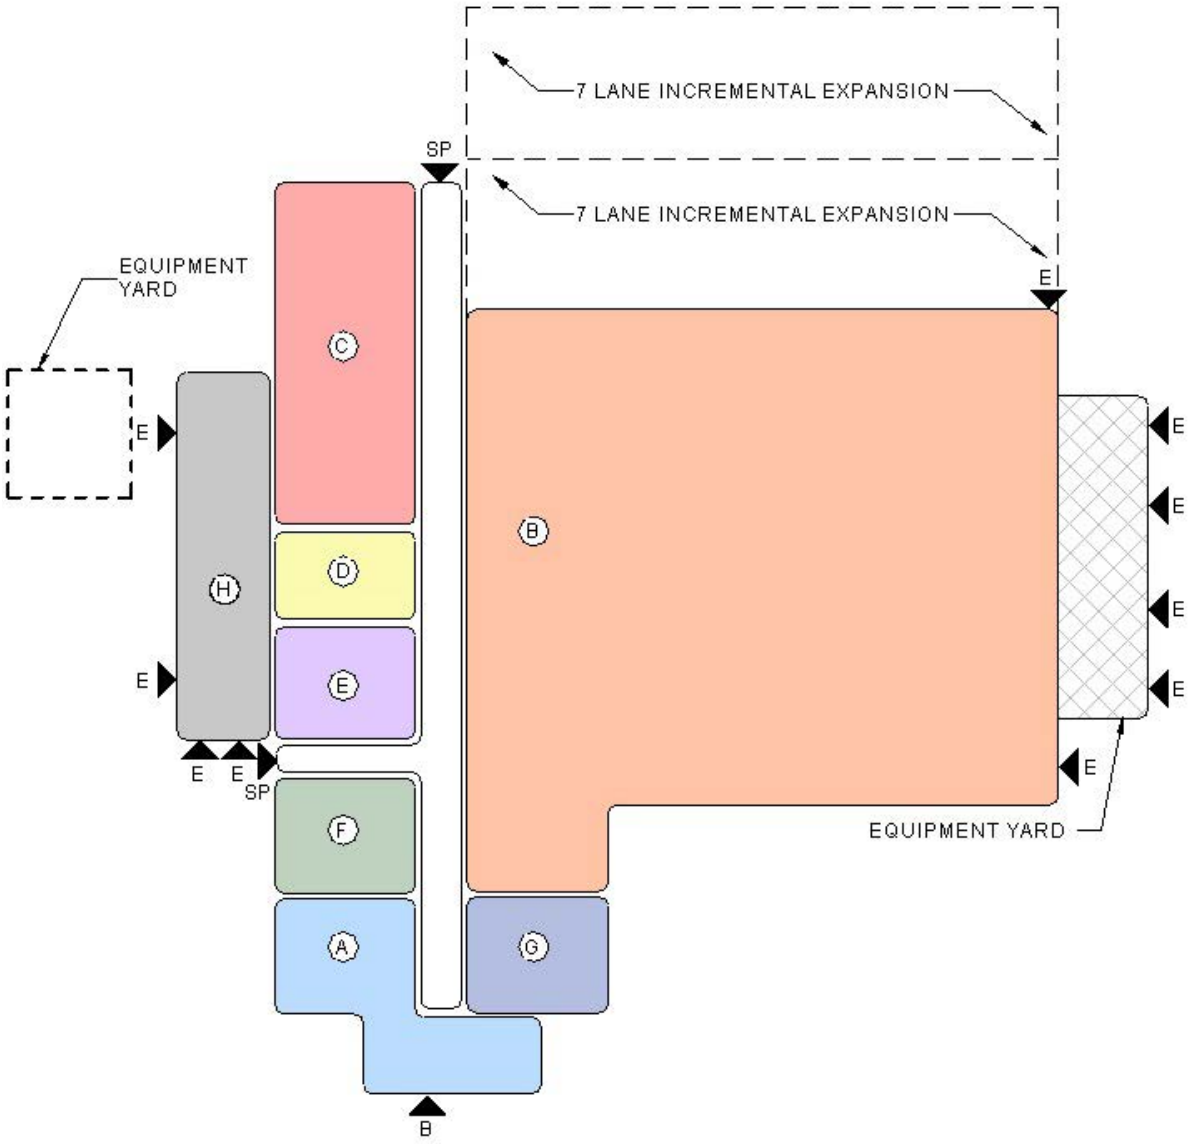
10	SERVICE DRIVE – MECHANICAL EQUIPMENT AND BULLET CONTAINMENT ACCESS
11	SERVICE DRIVE – HVAC AND DELIVERY ACCESS

12	SECONDARY/SERVICE ENTRANCE
13	SECONDARY MEANS OF EGRESS

2-7 COMPOSITE FACILITY ADJACENCY.



The space program for the indoor small arms firing range facilities is developed based upon the annual small arms qualification training requirements and authorized manning of the base, as well as historical data from the Air Force Security Forces Center (AFSFC).

The space program developed through the base planning team generally represents the maximum space allowed. The final space program for a new indoor small arms firing range will need to be carefully determined by installation representatives and the criteria in this FC. Additional information is found in Appendix B.

The required space adjacencies are illustrated in Figure 2-2. All program spaces are assigned a module designator. Spaces that must be located next to each other or share an important operational flow are grouped into one module with the intent that the module will remain intact during final design (although it may slightly change shape).

Composite plans represent conceptual solutions for indoor small arms range project requirements. These composite facility plans convey an AFSFC-approved solution. The building shape may be adjusted in response to site requirements or unusual or specific installation issues if approved in accordance with the procedures in Chapter I. See Appendix B for conceptual facility floor plans. Three concept plans and the related BIM drawings are included in Appendix B.

Ceiling Height		9'-0" minimum
Windows		Daylighting requirements per UFC 1-200-02
Doors	**Type**	Hollow metal
	Security/ Hardware	Keyed lock set
	View Panels/ Kick-Plates	Kick-plates
Finishes	**Walls**	Gypsum board with chair rails, paint
	Floor	Sealed/stained concrete or carpet tile
	Base	Vinyl/rubber or tile
	Ceiling	Acoustical ceiling tile
Plumbing		N/A
HVAC		Air conditioned and heated
Fire Protection		Automatic sprinkler system (see UFC 3-600-01)
Power		120V convenience quad outlets at each work station; copier and other office equipment; charging station
Lighting		Fluorescent or LED (50 fc) lighting; ceiling-mounted occupancy sensor and daylighting sensor
Communication	**Tele.**	One outlet at each work station
	Data	One outlet at each work station
	CCTV	N/A
	CATV	N/A
	Security	N/A
Acoustical		Minimum STC rating of 42. **\1** See UFC 4-179-02 for acoustic sound levels. **/1/**
Furnishings, Equipment, and Casework		Desks with chairs (one per instructor); 2 guest chairs; computer (one per instructor); copier with table; radio charging station with table
Special Requirements		Open office to expand with range size; one instructor for each seven students; Open office area based upon 80 square feet per instructor with additional 20 square feet for admin support

Figure 3-7 Queuing Room Data Sheet

Description/Usage		Queuing area for range students awaiting instruction; includes seating (size based upon range capacity) and display area.
Ceiling Height		9’-0” minimum
Windows		Daylighting requirements per UFC 1-200-02
Doors	**Type**	Pair 3’-0” x 7’-0” anodized aluminum door and frames with sidelights; optional 3’-0” x 7’-0” aluminum door with removable sidelights
	Security/ Hardware	Keyed lock set (minimum); possible access control
	View Panels/ Kick-Plates	Sidelights
Finishes	**Walls**	Impact-resistant gypsum board, paint
	Floor	Sealed/stained concrete or tile
	Base	Rubber/vinyl or tile
	Ceiling	Open to structure or acoustical ceiling tile
Plumbing		Electric water cooler
HVAC		Air conditioned and heated
Fire Protection		Automatic sprinkler system (see UFC 3-600-01)
Power		120V convenience outlets/wall-mounted TV; display case
Lighting		Fluorescent or LED lighting (15 fc) with ceiling-mounted occupancy sensor
Communication	**Tele.**	One public-use wall phone
	Data	Base-specific Wi-Fi
	CCTV	N/A
	CATV	Base-specific
	Security	N/A
Acoustical		Minimum STC rating of 42
Furnishings, Equipment, and Casework		Display case; chairs (number based upon range capacity, minimum one chair per lane); wall-mounted TV; end tables
Special Requirements		Queuing area changes with range size, based upon total number of firing lanes at 20 square feet per student including area for circulation. Additional square feet for entry vestibule; provide walk-off mat.

3-3 MODULE B: ARMS RANGE – 21 LANES.

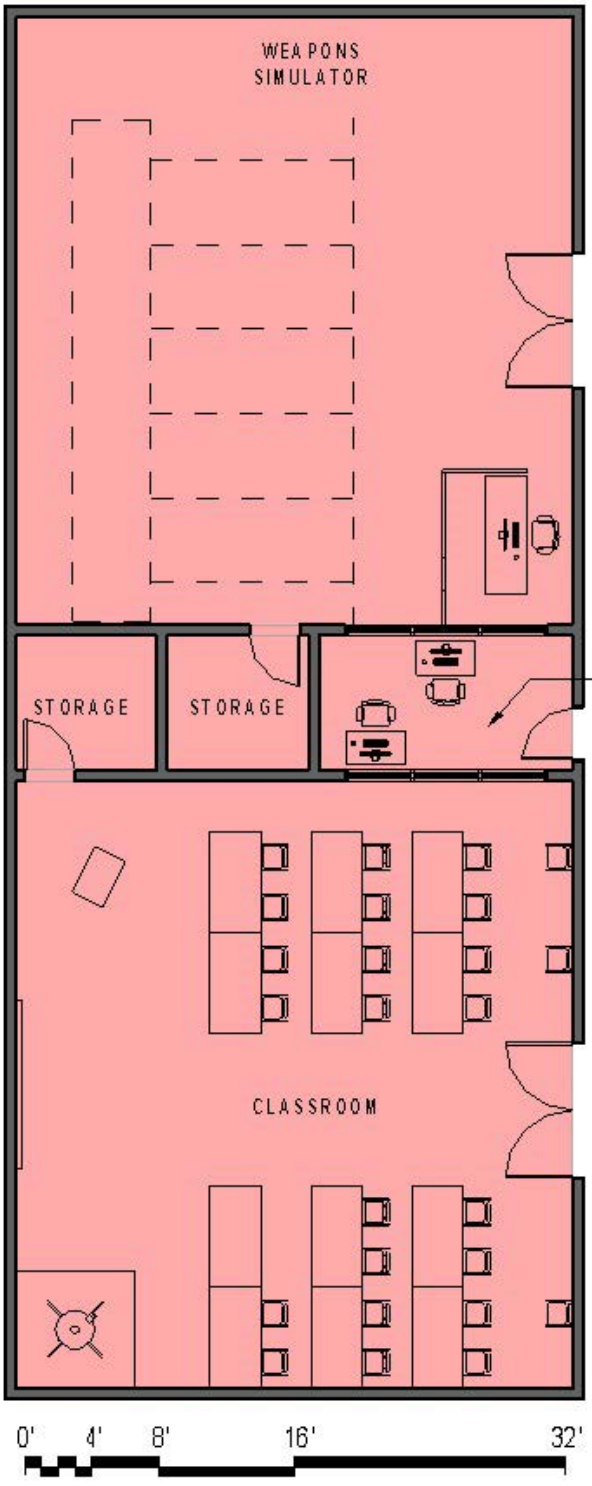
Figure 3-8 Floor Plan and Axonometric

MODULE B – ARMS RANGE ROOM SCHEDULE	
ROOM NAME	**AREA**
ARMS RANGE	**See Appendix-B Programming Worksheets**
CONTROL BOOTH	
RANGE SUPPLIES	

Figure 3-9 Arms Range Data Sheet

Description/Usage		Indoor arms range for weapons training with control room. Allows firing from standing, kneeling, prone, and barricade positions. **\1** Fourteen (14) 5-foot-wide lanes minimum, expandable to 56 lanes maximum; automatic target retrieving system adjustable; bullet trap with deceleration chamber and dust and solids collection. **/1/**
Ceiling Height		**\1** Ceiling height varies based on target distance. See UFC 4-179-02, Table 4-1. For ranges that require vehicle access, use a 12-foot ceiling height. **/1/**
Windows		N/A
Doors	**Type**	Acoustical hollow metal doors, two pair 3'-0" x 7'-0"
	Security/ Hardware	Keyed lockset or cipher system
	View Panels/ Kick-Plates	Kick-plates on all doors
Finishes	**Walls**	**\1** Armor plate or cast-in-place concrete (unpainted) with acoustical panels **/1/**
	Floor	**\1** Sealed concrete or armor plate **/1/**
	Base	N/A
	Ceiling	Steel baffles with acoustical panels
Plumbing		N/A
HVAC		Laminar airflow 75 fpm; see para. 4-5.2
Fire Protection		Visual strobes and mass notification. No sprinkler system.
Power		Specific for target retrieval and bullet collection systems
Lighting		Special lighting (controlled by control room); target controls
Communication	**Tele.**	One outlet in control room
	Data	One outlet in control room; one outlet near bullet collection
	CCTV	N/A
	CATV	N/A
	Security	None
Acoustical		**\1** Provide acoustical panels at perimeter walls and baffles in sufficient quantity to meet the noise reduction criteria of UFC 4-179-02 **/1/**
Furnishings, Equipment, and Casework		**\1** Preparation area with wall-mounted benches and tables; control room with range control system; barricades; bullet trap system; acoustical panels; automatic target retrieval system (non-RPIE). **/1/** See BIM drawings for additional information.
Special Requirements		**\1** Refer to UFC 4-179-02 for small arms range requirements **/1/**

Figure 3-10 Control Booth Room Data Sheet



Description/Usage		Area for control of range operations.
Ceiling Height		**\1** N/A **/1/**
Windows		**\1** Full range visibility acoustic **/1/**
Doors	**Type**	**\1** Acoustic metal doors and frames **/1/**
	Security/ Hardware	Keyed lockset
	View Panels/ Kick-Plates	Kick-plates on all doors
Finishes	**Walls**	**\1** Acoustic walls and windows **/1/**
	Floor	**\1** Sealed concrete with 2-foot raised floor **/1/**
	Base	N/A
	Ceiling	Acoustic ceiling tile
Plumbing		N/A
HVAC		Air conditioned and heated w/separate unit; see para. 4-5.2 (maintain positive air pressure)
Fire Protection		**\1** Visual strobes and mass notification. No sprinkler system **/1/**
Power		120V power strip(s) for controls
Lighting		Fluorescent or LED (15 fc) light fixtures with wall-mounted dimming control
Communication	**Tele.**	One outlet
	Data	One outlet connected to base LAN
	Control	Control panel for lights, target retrieval, and bullet collector
	PA	Speakers throughout facility
Acoustical		**\1** See UFC 4-179-02 **/1/**
Furnishings, Equipment, and Casework		Countertop and two workstations
Special Requirements		Locate adjacent to arms range with direct access to corridor

Figure 3-11 Range Supplies Data Sheet

Description/Usage		Area for storage of targets and other range-required supplies; secure tool storage.
Ceiling Height		**1*\ 8’-0” minimum */1**
Windows		N/A
Doors	**Type**	Hollow metal, pair 3’-0” x 7’-0”

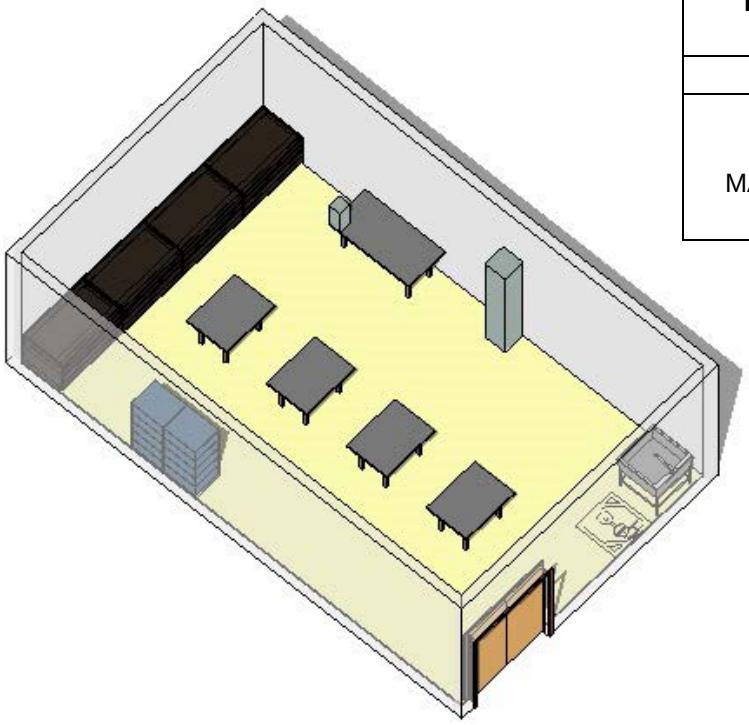
Furnishings, Equipment, and Casework		Commercially purchased projection-based simulator system; desk with chair; computer; simulator instructor booth
Special Requirements		Simulator module is preferred module; module can be deleted based upon specific base installation requirements and budgeted facilities

3-5 MODULE D: MAINTENANCE.

Figure 3-17 Floor Plan and Axonometric

MODULE D – MAINTENANCE ROOM SCHEDULE	
ROOM NAME	**AREA**
WEAPONS MAINTENANCE SHOP	**See Appendix-B Programming Worksheets**



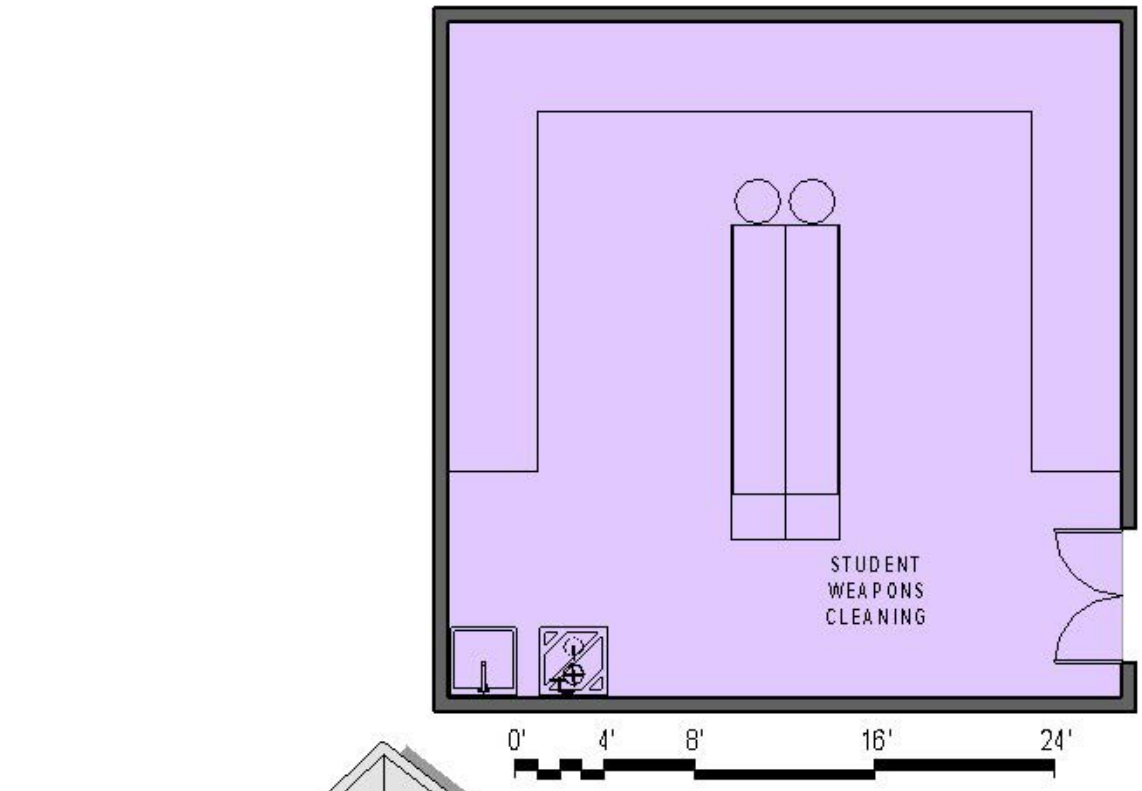


Figure 3-18 Weapons Maintenance Shop Data Sheet

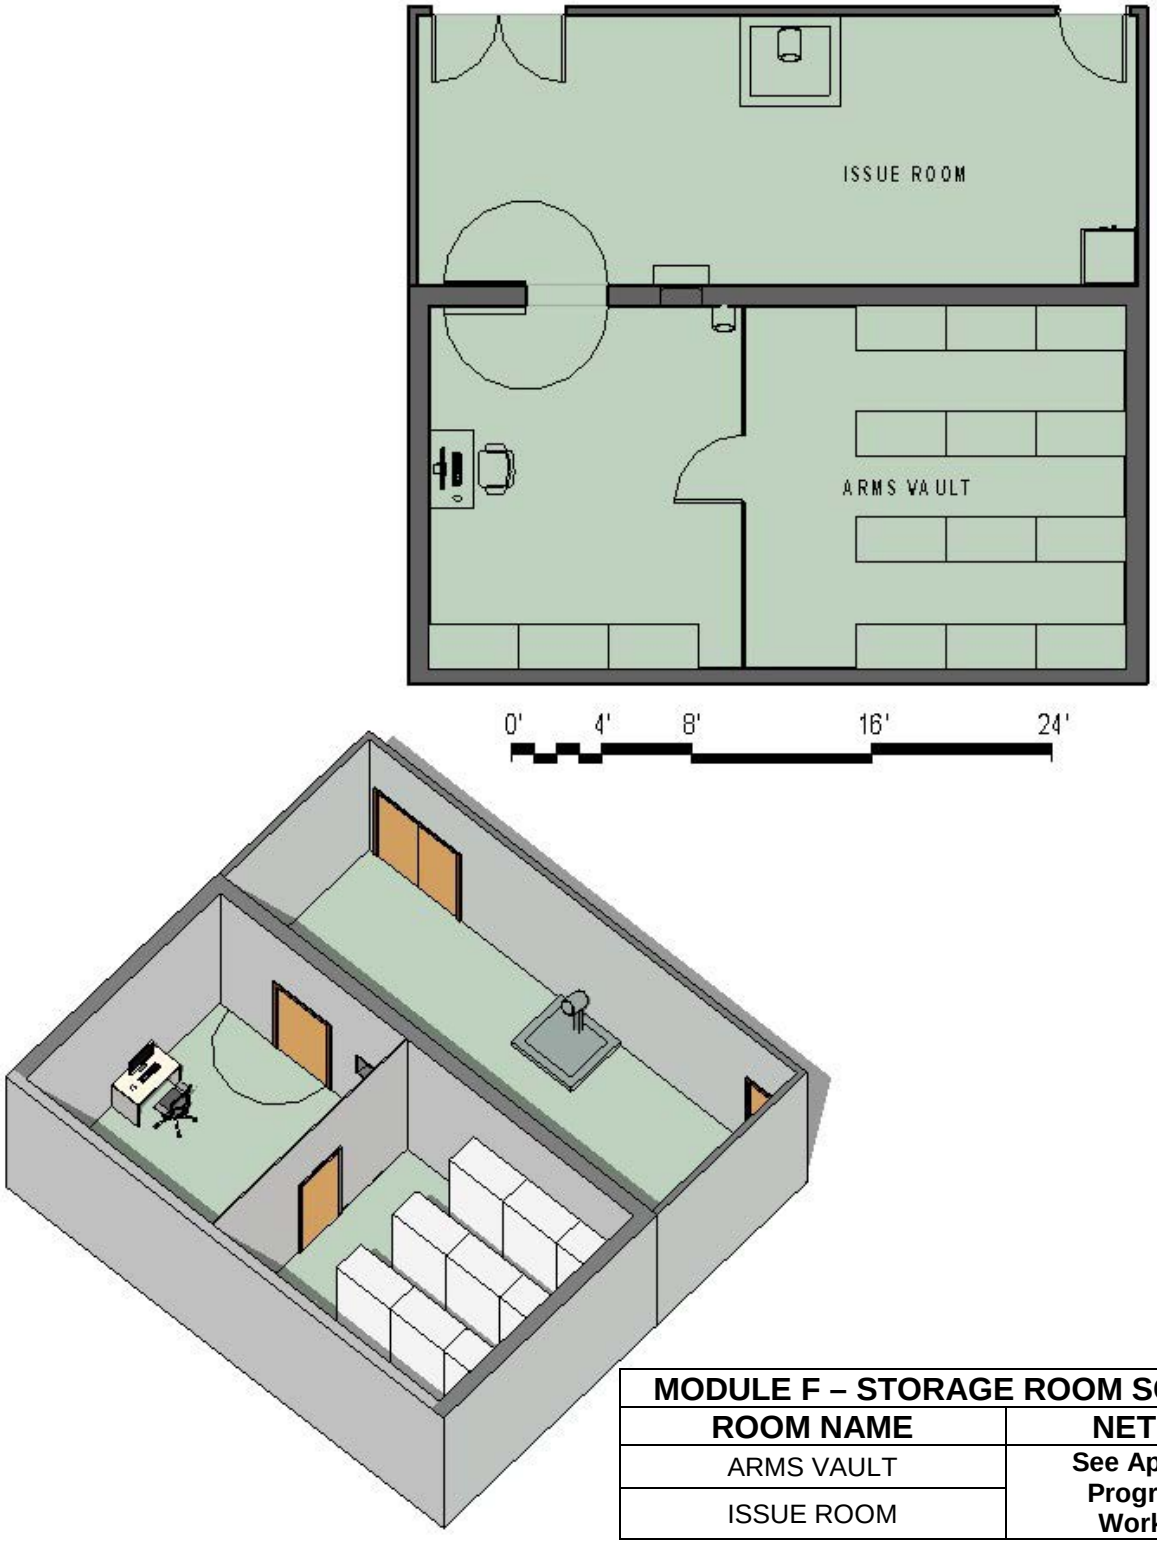
Description/Usage		Space to restore/maintain weapons to serviceable condition. Primarily for instructor use.
Ceiling Height		9’-0” minimum
Windows		N/A
Doors	**Type**	Hollow metal, pair 3’-0” x 7’-0”
	Security/ Hardware	Keyed lock set
	View Panels/ Kick-Plates	Kick-plates
Finishes	**Walls**	CMU, paint
	Floor	Sealed concrete
	Base	Vinyl
	Ceiling	Open to structure
Plumbing		Connections for shop sink and emergency eyewash
HVAC		Air conditioned and heated w/exhaust ventilation for chemicals
Fire Protection		Automatic sprinkler system (see UFC 3-600-01)
Power		120V convenience outlets around room and at work spaces; provide power to workbenches and grinding wheel stand
Lighting		Fluorescent or LED lighting fixtures (50 fc) with wall-mounted occupancy sensor; task lighting at repair stations
Communication	**Tele.**	One outlet
	Data	One outlet
	CCTV	N/A
	CATV	N/A
	Security	N/A
Acoustical		Minimum STC rating of 50
Furnishings, Equipment, and Casework		Lockable parts storage cabinets; stainless steel workbenches; grinding wheel with stand; shop sink; table with vise; flammable storage cabinets; emergency eyewash
Special Requirements		Expandable with range; provide one workbench per instructor;

3-6 MODULE E: CLEANING.

Figure 3-19 Floor Plan and Axonometric



MODULE E – CLEANING ROOM SCHEDULE	
ROOM NAME	**AREA**
STUDENT WEAPONS CLEANING	**See Appendix-B Programming Worksheets**

Figure 3-20 Student Weapons Cleaning Data Sheet

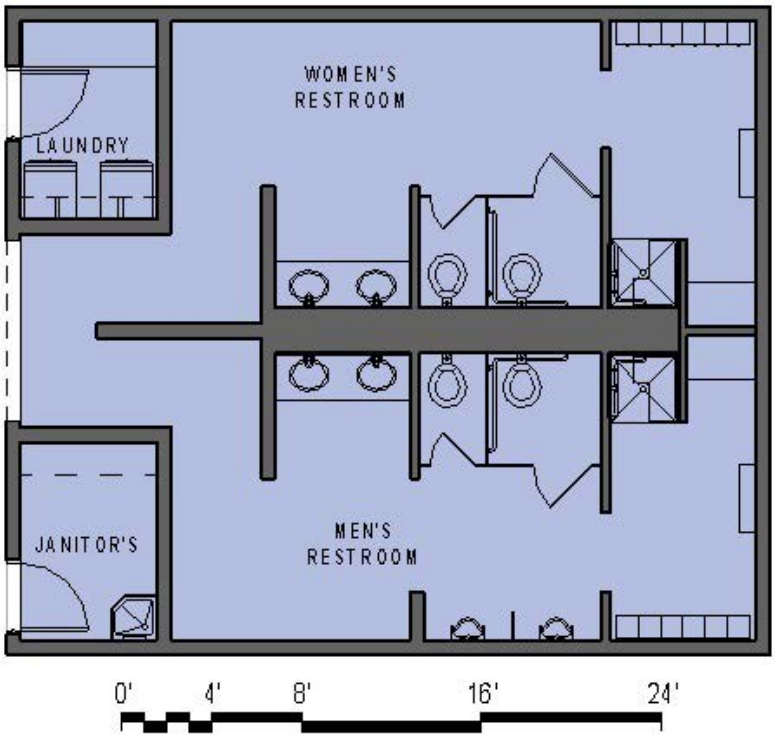
Description/Usage		Space for instructor-supervised weapons cleaning procedures performed by students.
Ceiling Height		9’-0” minimum
Windows		N/A
Doors	**Type**	Hollow metal, pair 3’-0” x 7’-0”
	Security/ Hardware	Keyed lock set
	View Panels/ Kick-Plates	Kick-plates
Finishes	**Walls**	CMU/impact-resistant gypsum board, paint
	Floor	Sealed concrete
	Base	Vinyl
	Ceiling	Acoustical ceiling tile
Plumbing		Connections for shop sink and emergency eyewash
HVAC		Air conditioned and heated w/exhaust ventilation
Fire Protection		Automatic sprinkler system (see UFC 3-600-01)
Power		120V convenience outlets at all tables
Lighting		Fluorescent or LED lighting fixtures (50 fc) with ceiling-mounted occupancy sensors; task lighting at cleaning stations
Communication	**Tele.**	One outlet
	Data	One outlet
	CCTV	N/A
	CATV	N/A
	Security	N/A
Acoustical		Minimum STC rating of 50
Furnishings, Equipment, and Casework		Continuous stainless steel U-shaped perimeter table (standing height); lockable storage cabinets; shop sink; emergency eyewash; flammable storage cabinets; hazardous waste receptacles
Special Requirements		Expandable with range; verify egress requirements for larger facilities

3-7 MODULE F: STORAGE.

Figure 3-21 Floor Plan and Axonometric

MODULE F – STORAGE ROOM SCHEDULE	
ROOM NAME	**NET AREA**
ARMS VAULT	**See Appendix-B Programming Worksheets**
ISSUE ROOM	

Figure 3-22 Arms Vault Data Sheet



Description/Usage		Weapons and ammunition storage and distribution. Vault constructed area to provide secure storage of arms and ammunition; secure storage of ammunition separate from arms; issue window.
Ceiling Height		9'-0" minimum
Windows		N/A
Doors	**Type**	GSA-approved Class V vault door
	Security/ Hardware	N/A
	View Panels/ Kick-Plates	N/A
Finishes	**Walls**	Concrete/CMU, paint
	Floor	Sealed concrete
	Base	Vinyl
	Ceiling	Concrete
Plumbing		N/A
HVAC		Air conditioned and heated (maintain RH < 65%)
Fire Protection		Automatic sprinkler system (see UFC 3-600-01)
Power		120V outlets at all workstations
Lighting		Fluorescent or LED (30 fc)
Communication	**Tele.**	One outlet at workstation
	Data	One outlet at workstation
	CCTV	N/A
	CATV	N/A
	Security	Access control and door switch monitoring
Acoustical		N/A
Furnishings, Equipment, and Casework		Clearing barrel; issue window; GSA-approved Class V vault door; wire mesh partition for ammunition storage; desk and chair; computer; arms rack (number determined by location requirements)
Special Requirements		Day gate optional based upon specific base installation; expandable with range

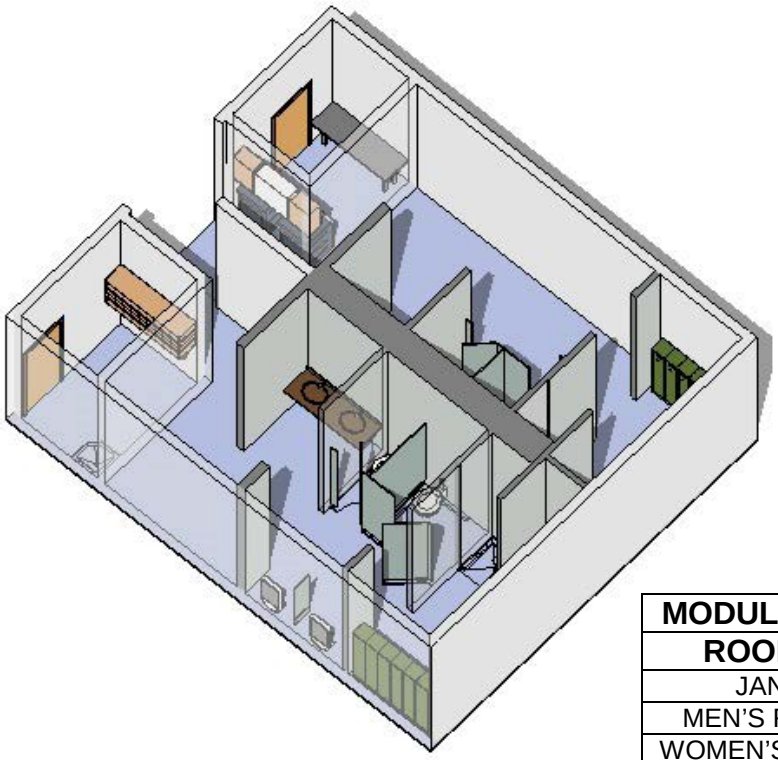


Figure 3-23 Issue Room Data Sheet

Description/Usage		Area for students to obtain and safely clear arms.
Ceiling Height		9’-0” minimum
Windows		N/A
Doors	**Type**	Hollow metal
	Security/ Hardware	Keyed lock set
	View Panels/ Kick-Plates	Kick-plates
Finishes	**Walls**	**\1** Wall behind clearing barrel must be UL-rated for maximum weapon. **/1/** CMU/impact-resistant gypsum board, paint.
	Floor	Sealed concrete
	Base	Vinyl
	Ceiling	Acoustical ceiling tile
Plumbing		N/A
HVAC		Year-round temperature control
Fire Protection		Automatic sprinkler system (see UFC 3-600-01)
Power		One outlet near window
Lighting		Fluorescent or LED lighting fixtures (20 fc) with ceiling-mounted occupancy sensor
Communication	**Tele.**	N/A
	Data	N/A
	CCTV	N/A
	CATV	N/A
	Security	Intrusion detection system (IDS)
Acoustical		N/A
Furnishings, Equipment, and Casework		GSA-approved two-drawer safe; clearing barrel (design per AFMAN 31-229)
Special Requirements		Maintain 12’-0” clear depth of room; expandable with arms vault

3-8 MODULE G: UTILITY.

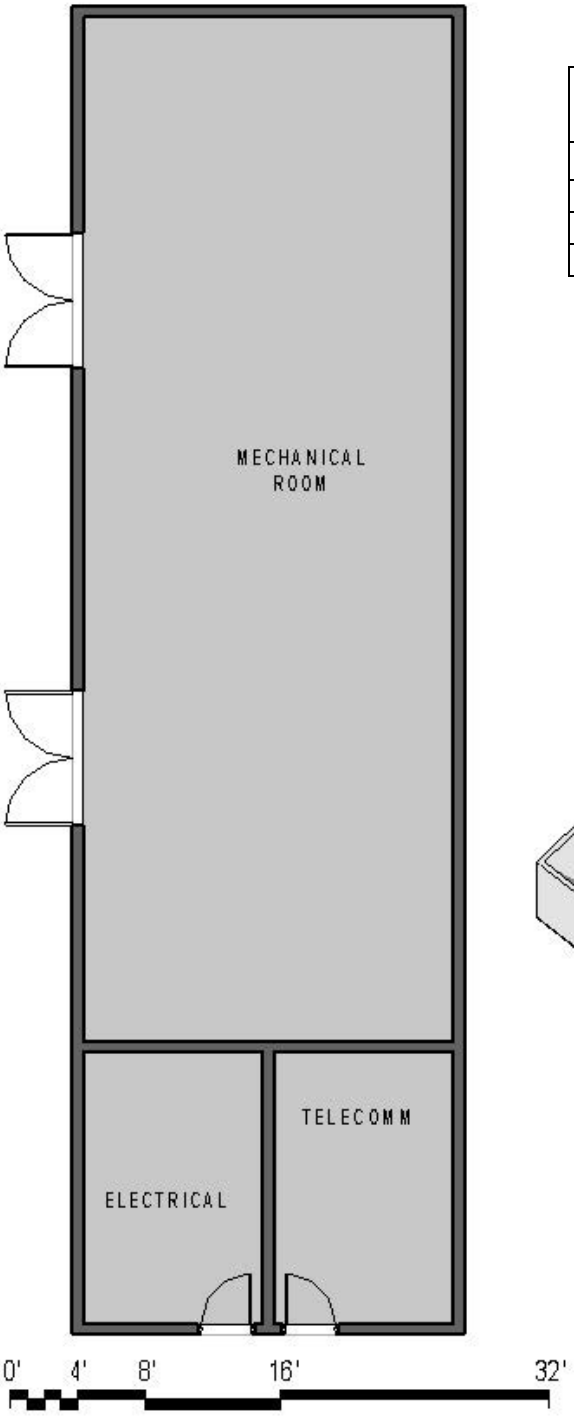
Figure 3-24 Floor Plan and Axonometric

MODULE G – UTILITY ROOM SCHEDULE	
ROOM NAME	**AREA**
JANITOR'S	**See Appendix-B Programming Worksheets**
MEN'S RESTROOM	
WOMEN'S RESTROOM	
LAUNDRY ROOM	

Figure 3-25 Janitor's Closet Data Sheet

Description/Usage		Storage for cleaning supplies.
Ceiling Height		9'-0" minimum
Windows		N/A
Doors	**Type**	Hollow metal, 3'-0" x 7'-0"
	Security/ Hardware	Keyed lock set
	View Panels/ Kick-Plates	Kick-plate
Finishes	**Walls**	Moisture-resistant gypsum board; cement board at wet walls, paint
	Floor	Sealed concrete
	Base	Vinyl
	Ceiling	Moisture-resistant gypsum board
Plumbing		Connection for utility sink, floor drain
HVAC		Exhausted (provide fresh make-up air)
Fire Protection		Automatic sprinkler system (see UFC 3-600-01)
Power		None
Lighting		Fluorescent or LED lighting fixtures (5 fc) with ceiling-mounted occupancy sensors
Communication	**Tele.**	N/A
	Data	N/A
	CCTV	N/A
	CATV	N/A
	Security	N/A
Acoustical		N/A
Furnishings, Equipment, and Casework		Stainless-steel shelving with integrated mop holders; floor-mounted utility sink
Special Requirements		None

Figure 3-26 Restroom/Locker Room Data Sheet



Description/Usage		Restroom facilities for students and instructors; locker/shower room facilities for instructors to remove potential lead contamination.
Ceiling Height		9'-0" minimum
Windows		N/A
Doors	**Type**	Hollow metal, if utilized
	Security/ Hardware	N/A
	View Panels/ Kick-Plates	N/A
Finishes	**Walls**	Moisture-resistant gypsum board; cement board at wet walls; tile at wet areas near fixtures or tile wainscot
	Floor	Tile
	Base	Tile
	Ceiling	Moisture-resistant gypsum board
Plumbing		Connections for lavatories, water closets, urinals, showers; floor drain
HVAC		Year-round temperature control, humidity control, exhaust at showers
Fire Protection		Automatic sprinkler system (see UFC 3-600-01)
Power		Outlet for hand dryer and hair dryer in locker area
Lighting		Fluorescent or LED lighting fixtures (10 fc) with ceiling-mounted occupancy sensors; moisture-resistant
Communication	**Tele.**	N/A
	Data	N/A
	CCTV	N/A
	CATV	N/A
	Security	N/A
Acoustical		N/A
Furnishings, Equipment, and Casework		Vanities with lavatories; urinals; toilet partitions with water closets; urinal partitions; toilet and shower accessories; accessible and standard benches; accessible showers; lockers; mirrors at lavatories and shower areas
Special Requirements		70/30 male to female ratio typical (verify with location requirements) plumbing fixture count per UFC 3-420-01; Provide lockers per location requirements

Figure 3-27 Laundry Room Data Sheet

Description/Usage		Laundry facilities for instructors to remove lead contamination.
Ceiling Height		9’-0” minimum
Windows		N/A
Doors	**Type**	Hollow metal, 3’-0” x 7’-0”
	Security/ Hardware	Standard
	View Panels/ Kick-Plates	Kick-plate
Finishes	**Walls**	Moisture-resistant gypsum board, paint
	Floor	Sealed concrete
	Base	Vinyl
	Ceiling	Moisture-resistant gypsum board
Plumbing		Connection for washer
HVAC		Vent dryer and exhaust room air (provide fresh make-up air)
Fire Protection		Automatic sprinkler system (see UFC 3-600-01)
Power		Connection for washer and dryer
Lighting		Fluorescent or LED lighting fixtures (10 fc) with ceiling-mounted occupancy sensors
Communication	**Tele.**	N/A
	Data	N/A
	CCTV	N/A
	CATV	N/A
	Security	N/A
Acoustical		Minimum STC rating of 50
Furnishings, Equipment, and Casework		Washer; dryer; 2’-0” x 4’-0” stainless-steel layout table
Special Requirements		None

3-9 MODULE H: BUILDING SUPPORT.

Figure 3-28 Floor Plan and Axonometric

MODULE H – BUILDING SUPPORT ROOM SCHEDULE	
ROOM NAME	**NET AREA**
ELECTRICAL	**See Appendix-B Programming Worksheets**
MECHANICAL ROOM	
TELECOMM	

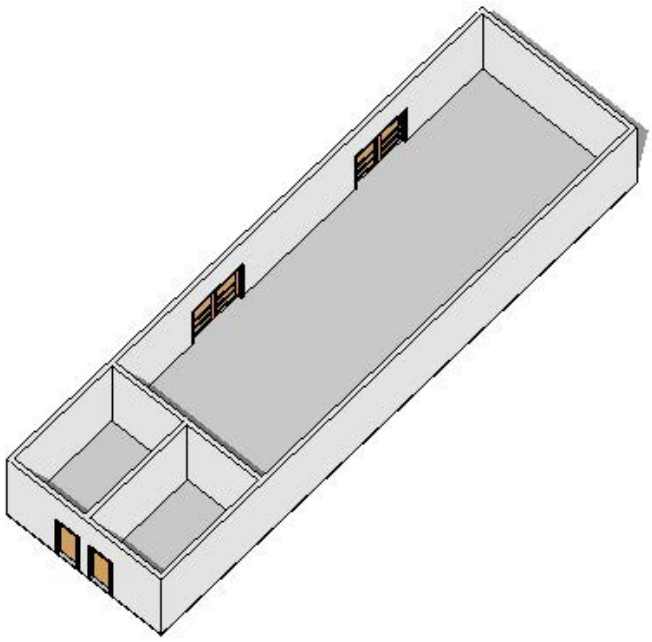


Figure 3-29 Building Support Data Sheet

Description/Usage		Space for mechanical, electrical, and telecommunications systems.
Ceiling Height		9’-0” minimum
Windows		N/A
Doors	**Type**	Hollow metal
	Security/ Hardware	Keyed lock set
	View Panels/ Kick-Plates	Kick-plate
Finishes	**Walls**	Gypsum board/CMU
	Floor	Sealed concrete
	Base	Vinyl
	Ceiling	Open to structure
Plumbing		Floor drains, water connections; compressed air
HVAC		Ventilated w/fresh air (provide conditioned air for telecom rm)
Fire Protection		Automatic sprinkler system (see UFC 3-600-01)
Power		120V outlet on each wall; circuit connections to specific equipment
Lighting		Fluorescent or LED fixtures (10 fc)
Communication	**Tele.**	One outlet; service entrance to main room rack
	Data	One outlet
	CCTV	N/A
	CATV	N/A
	Security	N/A
Acoustical		Minimum STC rating of 50 at mechanical room walls
Furnishings, Equipment, and Casework		Mechanical, electrical and telecommunication equipment
Special Requirements		Design each system per appropriate UFC document

CHAPTER 4 TECHNICAL CRITERIA

4-1 GENERAL.

1\ Comply with UFC 1-200-01, which provides the applicability of model building codes and government-unique criteria for typical design disciplines and building systems, as well as for accessibility, AT, security, high-performance and sustainability requirements, and safety. /**1**/ Use this FC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein. **1**\ Use UFC 4-179-02 for specific indoor small arms firing range requirements. /**1**/

4-2 STRUCTURE.

4-2.1 Foundation.

The foundation design and type is site specific and must be designed based on geotechnical recommendations provided by a licensed geotechnical engineer knowledgeable of the local conditions.

4-2.2 Superstructure.

1\ The range may be constructed using modular or conventional construction methods. /**1**/ Provide clear spans for the firing range and target systems. Use pre-engineered components for superstructure framing, where feasible. The superstructure must support the bullet deflector plates/baffle system and other equipment (e.g., bullet trap). Camber the roof framing for the firing range to remain flat under super-imposed dead loads.

1\ Provide hardened ceilings and walls for the arms/ammunition storage rooms. /**1**/

A perimeter steel structure to support the roof framing and CMU or concrete walls may be used for ease of construction and local parameters. **1**\ CMU is no longer allowed for ballistic containment. /**1**/

The framing for the roof structure of the firing range may be one of the following two options:

- Roof joists spanning the full distance from the front to the back of the range with no intermediate supports. Do not span side to side because it limits expansion.

- Along the firing line (barricade) there may be steel columns (dividing the lanes) supporting steel girders spanning the width of the firing range. This line of girders could support open web bar joists spanning from the girder to the front wall (about 25 feet [7.6 meters]) on one side and to the back wall (about 115 feet [35 meters]) on the other side.

4-3 EXTERIOR DESIGN.

In general, the building's image, theme, and fixtures must be consistent with the programs offered and the architecture established on base. Reflect the local geographical and cultural environment in the design and comply with AFCFS and installation architectural standards. Provide a visually attractive, safe, and welcoming appearance. Consider grouping high bay spaces together. Do not allow the building massing to dominate or overwhelm surrounding structures.

4-3.1 Entrances/Exits.

Entries into the firing range must be limited and secured for safety. Entries to the range are not to be provided downrange of the firing line. Provide warning lights to signal that live rounds are being fired within the range.

4-3.2 Doors and Windows.

Limit windows to the queuing room, classroom, administrative areas, break room, and corridor. Use aluminum or hollow metal frames and doors. Mitigate glare and direct sunlight in activity spaces.

4-4 INTERIOR DESIGN.

4-4.1 Interior Construction.

Personnel will be handling weapons that bump against walls and trim. Provide durable, low-maintenance construction materials and do not use hollow-core wood doors. All interior glass must be tempered safety glass and mirrors must be made of break-resistant materials.

Provide counters, casework, and cabinets of high-quality and durable construction. Provide countertops of solid surface/solid composite plastics only or stainless steel.

4-4.2 Finishes.

Provide finishes that are compatible with the intended uses and are highly durable and low maintenance. They must meet the requirements listed in NFPA 101. **1*\ Also coordinate the interior design with the Air Force Interior Design Standards, major command and installation design standards, and UFGS 09 68 00. /**1**/ Personnel with weapons and ammunition often bump and scrape walls, so provide heavy-duty, durable finishes.

Provide acoustical treatment to minimize sound reverberations and intensity within the indoor small arms firing range.

4-4.3 Window Treatments.

Include window treatments (shading systems) as an integral part of the construction contract in administrative areas. Dual fabric solar roller shade systems with manual roll chain operation are recommended. Analyze solar conditions when selecting a window treatment. Window treatments must provide full coverage to reduce light leakage. Any window treatment must be flame-resistant and commercial quality.

4-5 SERVICES.

4-5.1 Plumbing.

Design domestic hot and cold water, sanitary and storm drainage, compressed air, propane, fuel oil, or natural gas systems to meet the requirements of UFC 3-420-01 and local installation standards.

The weapons maintenance and student weapons cleaning rooms shall each require emergency eyewash. Compressed air shall be provided in the student weapons cleaning room.

4-5.2 Heating, Ventilating, and Air Conditioning (HVAC).

1*\ Design the HVAC system to meet the requirements of UFC 3-410-01 and UFC 4-179-02. /1**/

The air supply system for the firing range must ensure a safe environment for participants by delivering air at the firing line and exhausting air at the target end. **1*\ Air must travel in a laminar fashion at 71 to 79 fpm across the firing line to prevent powder residue from settling. Provide uniform, unidirectional laminar airflow across the firing line by installing a perforated air distribution radial plenum along the rear wall. See UFC 4-179-02 for heating and cooling criteria. Exhaust air must be provided at the end of the indoor small arms firing range at the bullet trap and must maintain 0.05 inch of water negative pressure on the range. /**1**/ Exhaust fan controls must be interlocked with the supply fan to ensure simultaneous operation. Re-circulation of range air is not permitted and exhaust air discharge from the range and bullet trap shall meet local, state, and federal requirements. The range control booth shall maintain positive pressure relative to the indoor small arms firing range.

The HVAC system for the weapons cleaning area, ammunition storage area, and weapons maintenance area must be designed for safe operations with chemicals and munitions. Provide exhaust ventilation for the weapons maintenance shop, range supplies, student weapons cleaning room, laundry, janitor closet, and restrooms. Exhaust makeup air may be transferred from adjacent spaces (not from firing range), provided adequate ventilation is supplied to prevent negative air pressure in relation to the outside. Provide occupancy sensors to control all exhaust fans. Weapons and ammunition storage areas must maintain relative humidity below 65 percent.

4-5.3 Fire Protection and Life Safety.

Refer to UFC 1-200-01 to determine the applicable design codes and standards for all building and life safety features for the facility. UFC 1-200-01 references UFC 3-600-01 and will be utilized to determine the passive fire protection features of the facility, such as building height and area, construction type, egress limitations, etc., as well as the active fire protection features of the facility, including fire detection, fire alarm, fire suppression, etc.

1\ UFC 4-179-02 provides specific DoD design and construction criteria for small arms ranges and shall take precedence over all other design standards where conflicts exist for fire protection requirements. /**1**/

4-5.4 Electrical.

1\ Provide electric service and distribution equipment, wiring receptacles and grounding, interior and exterior lighting and control, emergency lighting, telephone, communication systems, fire alarm, other health and safety alarms, and intrusion systems in accordance with NFPA 70, UFC 3-520-01, UFC 4-179-02, and installation design requirements. /**1**/

See the latest edition of *Electric Current Abroad* to determine voltages and cycles in overseas locations. Service grounding system and all wiring methods must meet current NFPA 70 requirements. All service equipment must be Underwriters Laboratories (UL) listed. Alternately, published proof from an approved independent testing laboratory may be provided.

4-5.4.1 Lighting.

1\ Provide lighting and control systems throughout the facility in accordance with UFC 3-530-01 and UFC 4-179-02. /**1**/ Pay particular attention to issues such as glare, heat generation, and impact protection for the fixtures in the indoor small arms firing range. Provide a control system to highlight target lines at the 3, 7, 10, 15, and 25 meter lines and to simulate night or daylight.

Provide a flashing light system to simulate a police car light bar. Provide “range in use” warning lights.

4-5.4.2 Communications and Data.

Telephone and data outlets may be independent of each other or combined into a single junction box. Also consider wireless audio, video, and data installations to add flexibility. If the hard-wired connections can be combined into a single junction box then the cover plate to that junction box must allow for multiple connections. In some unique situations, the CATV/internal video connection can also be combined into a single junction box with the appropriate cover plate.

Identify the technical design requirements for the CCTV system with the base user and AFSFC.

4-5.4.3 Alarm Systems.

Provisions for alarm systems must be identified during the planning/programming process. Provide an alarm system to warn personnel that live fire is in progress and/or if any downrange doors are open. Provide an intrusion detection alarm system to protect vault arms and ammunition.

4-6 SITE DESIGN AND ORGANIZATION.

4-6.1 Parking and Access Drives.

Provide parking for both staff and patrons with the appropriate access drives. Consider bicycle racks near the facility entrance in a secure location. **1**\ For landscaping and site pavements refer to UFC 4-010-01, paragraph 3-3, for the unobstructed space requirement around the facility. /**1**/

4-6.2 Service Drive.

The size of required service vehicles should be verified by the designer prior to planning the service access areas. Provide a back-up spur for dead-end and service drives that exceed 100 feet (30 meters) in length for receiving area, garbage dumpster/storage (indoor or outdoor), mechanical room, and service entry, if one is designated. Provide a service vehicle apron and consolidate service access when possible.

4-6.3 General Site Lighting.

1\ Provide exterior “range in use” flashing red indicator lighting as required by UFC 4-179-02. /**1**/

4-7 BARRIER-FREE DESIGN REQUIREMENTS.

Refer to UFC 1-200-01 for barrier-free design requirements.

Indoor small arms firing range activities will be for able-bodied personnel only. Visitors with physical disabilities will be allowed as observers but not participants.

4-8 ANTITERRORISM.

Refer to UFC 4-020-01 for AT requirements. The firing range portion of the building may be classified as low occupancy due to the personnel density of more than 430 SF/PN, which would exempt the firing range from all UFC 4-010-01 provisions.

4-9 SUSTAINABLE DESIGN.

Comply with the requirements of UFC 1-200-02, *High Performance and Sustainable Building Requirements* and achieve green building certification in accordance with the current AF Sustainable Design and Development memo.

APPENDIX B BEST PRACTICES

\1\

B-1 U.S. AIR FORCE RANGE SIZE REQUIREMENTS CALCULATOR.

The Range Size Requirements Calculator is used to determine the number of lanes required based on the historic training load and as adjusted for future growth or draw-down expectations. The spreadsheet can be found on the Whole Building Design Guide website: http://www.wbdg.org/references/pa_dod_sps.php

Figure B-1 Range Size Requirements Calculator

STEP 1--Annual Training Requirement						
Historical AF Training requirement		Rifle Qual	Pistol Qual	Shotgun Qual	Other Qual (i.e. MP5	Yr Total
	Current FY -1	1233	455	28	14	1730
	Current FY -2	1337	335	32	32	1736
	Current FY -3	1298	438	14	28	1778
	3 Yr Average					1748
Mission Changes: list, and add/subtract the number of personnel projected to require annual training (+ or -)						0
Total Design Training Requirement (DTR)						**1748**

STEP 2--Total Training Days Requirement		
Available Training Days	365	Days
Weekends (104), Holidays (10)	-114	Days
SF Core Trng	-27	Days
CA Core Trng	-12	Days
MAJCOM, Wing Down days	-4	Days
Non-Main Range Weapons Trng (i.e. M203, M249, M240, MK19, etc.)	-9	Days
Range Maintenance (1 day dedicated per month, does not include range rehab/project)	-12	Days
Weapons Maintenance (1 day dedicated per month)	-12	Days
Annual Weapons Inspections	-10	Days
List additional requirement/ # of days (do not include pro-fire or sustainment) (AFSFC must validat	0	Days
Total Training Days Available (TDA)	**165**	Days

STEP 3--Lane Requirement		
Range Lane Requirement DTR/TDA	10.59	Lanes
Greatest multiple of 7 lanes to satisfy the range lane requirement	**14**	Lanes

STEP 4--Manpower Consideration	
Manpower Authorization--as reflected on the UMD	
Officer-in-charge (if applicable)	0
Non-commisioned Officer-in-Charge (SEI 312 or 3P051B)	1
CA Instructors (3P051B or 3P031B)	3
Total Manpower Authorized	**4**

STEP 5--AFCEC and AFSFC Consideration (i.e. number of ranges, range type, and mission set)

B-2 U.S. AIR FORCE INDOOR RANGE INTERACTIVE PROGRAMMING SPREADSHEET.

The Interactive Programming Spreadsheet assists programmers to determine the size of the direct and indirect support component of the range based on the training load requirement, as described in paragraph B-1. The Interactive Programming Worksheet can be found on the Whole Building Design Guide website: http://www.wbdg.org/references/pa_dod_sps.php

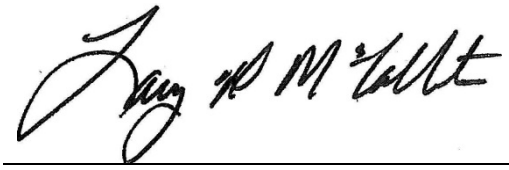
Change No.	Date	Location
1	November 2017	See UFC Summary Sheet
2	May 11, 2020	See UFC Summary Sheet
3	April 20, 2021	See UFC Summary Sheet

This UFC supersedes UFC 4-211-01N dated 25 October 2004 with Change 3, dated 16 December 2009.

FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.



UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://dod.wbdg.org/.

Refer to UFC 1-200-01, *DoD Building Code (General Building Requirements)*, for implementation of new issuances on projects.

UNIFIED FACILITIES CRITERIA (UFC)
NEW DOCUMENT SUMMARY SHEET

Document: UFC 4-211-01, *Aircraft Maintenance Hangars*

Superseding: UFC 4-211-01N, *Aircraft Maintenance Hangars*: Type I, Type II and Type III dated 25 October 2004 with Change 3 dated 16 December 2009, NAVFAC Interim Technical Guidance (ITG 2010-01) - *Maintenance Hangar Design and Planning Guidance for F35B or C*, and Engineering Technical Letter (ETL) 02-15: *Fire Protection Engineering Criteria New Aircraft Facilities*, 3 December 2002.

Description: This UFC provides criteria for planning and design of Aircraft Maintenance Hangars for the aircraft of the combined DoD United States Armed Forces.

Reasons for Document: This is a new Joint Service document. This new document represents another step in the Joint Services effort to bring uniformity to the planning, design and construction of military facilities. The UFC was developed to provide design requirements to accomplish the following:

- Assist planners in understanding the facility requirements to ensure accurate space programs budgets.
- Provide architects, engineers, and construction surveillance personnel with essential, minimum (min) requirements for the design and construction of Aircraft Maintenance Hangars.
- Clarify the operational intent of the facility design.

Impact: The following will result from the publication of this UFC:

- This UFC creates a single source for common DoD Aircraft Maintenance Hangar criteria and an accurate reference to individual Service-specific documents.
- This UFC facilitates updates and revisions and promotes agreement and uniformity of design and construction between the Services.

Unification Issues: Non-unified content is mainly a result of operational differences among the Services and is addressed in the Service-specific chapters including:

- The Navy included Functional Data Sheets (FDS) in this UFC. The Army keeps their Room Data Sheets with the Army Standard and the Air Force keeps these specific requirements with their Dynamic Prototypes.
- The Army and Navy perform fuel cell operations in the Aircraft Maintenance Bay per operational guidelines. The Air Force has specific construction criteria for the design of fuel cell maintenance hangars.

- Service differences in various subjects are noted in this UFC:
  - Aircraft Clearance Tables
  - Design of the Aircraft Maintenance Bay slab on ground
  - Ordnance grounding
  - Fire suppression and detection
  - High intensity overhead radiant heaters in the Aircraft Maintenance Bay
  - Aircraft power distribution servicing aircraft
  - Aircraft Maintenance Bay floor finish options

\1\ Reasons for Document Change 1:

Revised paragraphs 3-4.2 Ground Floors, 3-4.2.3.1Aircraft Maintenance Bay - Slab on Ground Design, and 7-4.1Aircraft Maintenance Bay - Slab on Ground Loading.

Previously, the UFC did not allow for slab on ground variable thickness in the hangar bay for areas not subject to aircraft loading. Generally, the reasoning was that the hangar bay may experience different aircraft during its lifespan due to change in mission or during special circumstances such as airshows or storms where aircraft may be "dense packed" into every available slab space or just to maintain future flexibility of use. However, it was recognized that this could result in substantial savings in a very large hangar bay. The governing rationale to revise was to continue to prohibit variable thickness in multiple aircraft hangar bays since these hangars generally house smaller aircraft and are less likely to maintain dedicated aircraft parking locations in perpetuity, but to allow slab thickness variation for single aircraft hangar bays where a very large aircraft dedicated to one single parking spot was envisioned. In any case, the designer should validate the requirements with the user. For standard hangars, such as Navy Type I, II, III, and IV, this is prohibited since the intention for these is to maintain hangar bay flexibility in accommodating multiple aircraft platforms or repurposing the hangar.

Revised paragraph 5-6.7.4 Existing Water Only Delue Systems.

Paragraph revised due to error in intent.

Deleted old bullet under paragraph 3-5.8.2.1 Preconditioned Air Systems relating to portable units being used for backup since later paragraph describes two units tied together with manifold for redundancy. /1/

\2\ Reasons for Document Change 2:

Revised paragraphs:

- General
  - Incorporated Navy FY 19-01 ITG and other F-35 cooling air system lessons learned in 3-5.8 Process Systems and 4-2.2 Mechanical Systems.
  - Upgraded compressed air hangar bay and shop requirements to reflect new equipment needs of cabin pressure testing and fuel cell evacuators.
  - Removed AFFF specific fire protection requirements
  - Other general fire protection system changes
  - Additional references added for battery maintenance shops
- Chapter 1
  - 1-4 Scope of Facility revised to clarify applicability to all aircraft hangars.
- Chapter 2
  - 2-1.6 Solar Glare Hazard Analysis revised.
  - Paragraph 2-2.1.3 Heavy Maintenance Shops revised.
- Chapter 3
  - Figures 3-1, 3-1-1, 3-1-2, 3-1-3 revised.
  - Revised typographical errors in column labels.
  - 3-3.4.1.1 Aircraft Maintenance Bay and 3-3.4.1.3 Heavy Maintenance Shops revised to generalize light-colored floor coatings
  - Paragraph 3-5.3.1.7 Specialized or Localized Exhaust revised.
  - 3-5.8.1Compressed Air, Table 7-4: Hangar Bay (OH), and Table 7-19: Hangar Bay (OH) (F-35 Only) revised to include minimum requirements
  - Paragraph 3-7.1 Hazardous (Classified) Locations revised.
  - 3-7.4 Renewable Energy Sources
  - 3-7.13 \2\ Aerospace Ground Equipment (AGE) Electrical Power Provisions added for safety.
  - Revised paragraph 3-10 Hangar Doors for reference to structural prohibition on vertical lift fabric doors in high wind areas.
  - 3-10.1.3 Catwalk revised to emphasize importance and need.

- 3-11.3.1Trench Design revised to emphasize ductile iron trench covers
- Fire Protection
    - ◊ Removed AFFF specific requirements
    - ◊ Clarified fire protection requirements variation between services.
    - ◊ Updated separation drawing and section details.
    - ◊ Unified pump redundancy requirements between services.
    - ◊ Updated positioning of high-expansion generators in relation to helicopters.
    - ◊ Clarified allowable location for fire protection system controls.
    - ◊ Added additional guidance on zoned systems
    - ◊ Revised guidance on testing of optical detectors.
    - ◊ Added clarifying note on electrical classified locations.
    - ◊ 3-6.4 Fire Water Supply AFFF deleted and replaced with Low Level Water only
    - ◊ 3-6.8.1 Fire Suppression Pipe Labeling AFFF bullet for label deleted.
    - ◊ 3-6.8.2 Fire Suppression Drainage AFFF deleted.
    - ◊ 3-6.9 \2\ Foam/Water or Water Only Flow Control Valves Paragraph title change to include Water Only flow control valves and deleted last sentence regarding AFFF.
    - ◊ 3-6.10 Foam/Water Proportioning System 3rd bullet modified to replace “AFFF” with “concentrate”.
    - ◊ 3-6.11.2 \2\ Deleted **Paragraph retained to avoid numbering issues for references. /2/** paragraph deleted regarding AFFF.
    - ◊ 3-6.12 \2\ Foam/Water Solution and Low Level Water Only Piping /2/ Edited to include Low Level Water systems.
    - ◊ 3-6.12.1 \2\ Low Level Water Only Piping AFFF replaced with Low Level Water
    - ◊ 3-6.16 \2\ Low Level Water Trench Nozzle System and 3-6.16.1 Low Level Water System Performance AFFF/foam replaced with Low Level Water.

- ◊ 3-6.18 Hydraulic Calculations AFFF/foam replaced with Low Level Water.
- ◊ 3-6.19.1 \2\ Fire Alarm Control Unit/Autonomous Control Unit (FACU/ACU) through 3-6.19.2.3 Foam/Water, Low Level Water Only, and Preaction Supervised Solenoid Disconnect AFFF/foam replaced with Low Level Water.
- ◊ 3-6.19.5.1 \2\ Conduit and Enclosure Installation within the Hangar Bay through Figure 3-10: Start Foam System Signage AFFF/foam replaced with Low Level Water.
- ◊ Revised and added: Figure 3-10: Start Foam System Signage, Figure 3-11: Stop Low Level System Signage, Figure 3-12: Stop Foam System Signage, Figure 3-13: Stop Low Level System Signage

- Chapter 4
  - o 4-2.2 Mechanical Systems \2\ revised.
- Chapter 5
  - o 5-3.2 Aircraft Maintenance Bay Striping Requirements and Figure 5-1 Notes revised allowing matching of center line from outside.
  - o 5-1.2\2\ US Air Force Standard Designs for Aircraft Maintenance Hangars
  - o 5-12.3.4 Fuel Foam/Cell Repair Room
  - o 5-12.5.3 Washing Facilities
  - 0 5-12.7.1Hazardous (Classified) Locations
  - o 5-14 Facilities for Unfueled Aircraft to 5-15 Hangars for Fuel Servicing added.
  - o General Fire Protection
    - ◊ Clarified requirements for fire protection releasing controls.
    - ◊ Clarified requirements for fire protection optical detectors.
    - ◊ Clarified requirements for auxiliary notification devices.
    - ◊ Clarified requirements for HAS/PAS electrical classified locations.
    - ◊ Deleted requirements of HAS/PAS AFFF systems.
    - ◊ Added modernization requirements for existing high-expansion foam protected hangars.

- ◊ Added modernization requirements for existing unprotected hangars.
- ◊ Revised drain requirements to unify with NAVY and support F-35 cooling requirements.
- ◊ Added requirements for unfueled aircraft hangars at Air Logistics Centers and at government owned contractor operated plants.
- ◊ Added guidance for aircraft fuel servicing in hangars.

- Chapter 6
  - 6-1 INTRODUCTION Clarified Army UAS hangar applicability.
  - 6-1.1 US Army Aircraft Maintenance Strategy revised.
  - 6-3.1.2 UAS Aircraft revised.
  - Figure 6-1: Typical Maintenance Bay Configuration andFigure 6-2 Maintenance Bay Pavement Markings revised.
  - 6-4.1.1\2\ UAS Hangars – Group 3 and Group 4 /2/clarified for Group 3 and Group 4
  - 6-5.1 Heating revised
  - 6-5.3 Plumbing revised
  - 6-6.2 Fire Pumps Revised
  - 6-11.1.2 Location and Spacing
- Chapter 7
  - Table 7-1: \3\ Standard Hangar Bay Module Dimensions and Crane Capacities* Type I F-35B (USMC) width revised for Iintermediate Maintenance Program (IMP) maintenance and renamed to Navy and USMC Type I vs. F-35B and F-35C.
  - 7-2.4 \2\ Low Level System Containment to 7-11.1.6 \2\ Low Level Discharge Devices AFFF term removed generally
  - 7-7.3 Power Service Points bullet added for Triton hangar GSE
  - 7-3.2 Aircraft Maintenance Bay Striping Requirements and Figure 7-1 Notes revised allowing matching of center line from outside.
  - 7-14.5 Functional Data Sheets “cfm” changed to “scfm” throughout.
- Appendix
  - APPENDIX B: GLOSSARY SCFM added
  - C-6.5 \2\ Trench Drain Location to C-6.6 Alternate Foam/Water Discharge Notification AFFF term deleted.

/2/

\3\ Reasons for Document Change 3:

- Chapter 1
  - 1-5 Commentary added to this document per UFC 1-300-01.
- Chapter 3
  - 2-1.7 and 2-1.7.1 added for lighting impacts.
  - 3-3.2.3 revised.
  - Figure 3-4 revised.
  - 3-5.1 and 3-5.2 revised.
  - 3-5.8.2.6 and 3-5.8.2.7 revised.
  - 3-6.3.2 revised.
  - 3-6.17.2 revised.
  - 3-6.19.2.4 Optical Flame Detection Inhibit Switch clarified.
  - 3-6.19.4 revised.
  - 3-7.6.1 Typo corrected.
  - 3-6.10 bullet added.
  - 3-6.17.3 revised.
  - 3-7.1 revised.
  - 3-7.5.2 revised.
  - 3-7.14 added.
  - 3-9.3 revised.
  - 3-10.1.1 revised.
  - 3-10.2 revised.
  - Table 3-3 title and notes revised.
- Chapter 4
  - Title Change and 4-1 Title revised.

- 4-2.2 Mechanical requirements modified.

- Chapter 5
  - Table 5-1 title and table revised.
  - 5-2.2 reviesed.
  - 5-6.1 revised.
  - 5-6.5 revised.
  - 5-6.6 through 5-6.7.9 relocated to 5-15, 5-16, 5-17 and revised.
  - 5-11.1 revised.
  - 5-12.7.1 revised.
  - 5-12.6.2 revised.
  - 5-15, 5-16, 5-17 relocated and revised from 5-6.6 through 5-6.7.9.
- Chapter 6
  - 6-1.3 Applicability added.
  - 6-6.3.1 revised.
  - 6-6.6 revised.
  - 6-6.7 revised.
  - Table 6-1 Title and notes revised.
- Chapter 7
  - 7-3.1.3 corrected
  - 7-3.1.5 revised.
  - 7-9 and 7-9.3 revised to clarify Navy crane hazardous environment.
  - Table 7-1 revised. Table 7-2 Title and notes revised.
  - 7-7.5 revised.
- Appendix
  - C-7.4 Hazardous (Classified) Locations added. /3/

CHAPTER 1 INTRODUCTION

1-1 PURPOSE AND SCOPE

This UFC provides requirements for Aircraft Maintenance Hangars. This UFC is not intended as a substitution for thorough review during design by individual Program Managers and Operations Staff in the appropriate Service.

This UFC is organized with general requirements and Service-specific requirements. Apply Chapters 1, 2, 3, 4 and Appendices to all Services. Additionally, apply Chapters 5, 6, and 7 to Air Force, Army, and Navy respectively for Service-specific requirements.

1-1.1 Applicability

The information in this UFC applies to the design of all new construction projects, to include additions, alterations, and renovation projects within the United States and its territories and possessions and outside of the United States and its territories and possessions.

1-1.2 References

APPENDIX A: REFERENCES contains a list of references used in this UFC.

1-2 USERS OF THIS UFC

This UFC is intended as a source of basic architectural and engineering information for all individuals involved in the planning, design and construction of Aircraft Maintenance Hangars.

Specific users of the UFC include the following:

1-2.1 Architects and Engineers

Architects and Engineers (A/E) who will provide design services under the direction of the individual Service design agencies.

1-2.2 Planning Personnel

Planning personnel will use this UFC for programming new or replacement facilities, pre-design planning, or assessing the extent of improvements required in an existing Aircraft Maintenance Hangar in order to achieve the standard established herein.

1-2.3 Additional Users

Additional users may include entities for operational or other purposes. The respective users should refer to this UFC from their own policy documents as appropriate and may include:

- Headquarters Staff and Field Operating Agencies,

- Major Command (MAJCOM) Staff/Regions,
- Base, Installation and Garrison Commanders,
- Installation Facilities Management,
- Installation Technical Proponents.

1-3 GENERAL BUILDING REQUIREMENTS

Comply with UFC 1-200-01. UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and government criteria referenced therein.

1-3.1 Facility Requirements Document (FRD)

The airframe manufacturer's FRD or equivalent document is an integral requirement of hangar design that contains additional airframe specific facilities requirements that must be considered and satisfied in addition to this UFC.

FRDs are typically authored by the airframe manufacturer and contain many specific details, are often quite voluminous and difficult to obtain. The FRD may have additional technical facility requirements, special spaces, special clearances, special maintenance procedures, systems, data or other items that may impact the hangar design. This UFC is not a substitute for the FRD of the design airframe(s) being hangared.

1-4 SCOPE OF FACILITY

This UFC specifies requirements for aircraft hangars that support all types of fixed wing, rotary wing, and hybrid aircraft of the Army, Air Force, Navy, Marine Corps, and Reserves. The UFC additionally applies to hangars for select Unmanned Aircraft Systems (UAS)/Remotely Piloted Aircraft (RPA).

\2\ This UFC applies to all aircraft hangars including maintenance hangars and also to other specialized hangar types. Additional study is required to identify unique requirements, functional areas or systems based on mission or aircraft. /2/ Some specialized hangars include but are not limited to depot, transient, special operations, research, fuel-cell maintenance, and prototype hangars. For aircraft corrosion control and paint facility hangar design requirements, refer to UFC 4-211-02 and this UFC where incorporated by specific reference. Maintenance hangars support ongoing day to day functions of the aviation squadron, wing or brigade and facilitate routine, preventative, basic aircraft upkeep to sustain aircraft operations. Maintenance activities are generally short-term and minor in nature compared to those that might be performed in more intensive intermediate maintenance level or depot-level hangars that facilitate extensive breakdown and rebuilding of components. Maintenance hangars are typically characterized by large obstruction-free hangar bays surrounded by various configurations of supporting trade shop and administrative spaces. Extra value has been placed on facility safety, continuity of mission operations, flexibility, maximizing

hangar bay utilization, and minimizing life-cycle costs of materials and systems. For these reasons, the UFC limits options on certain requirements, ranging from structural systems and hangar doors, to proven systems for the expected large-scale aircraft and operations common in military maintenance hangars. Exemptions to certain requirements may be submitted for consideration where supported and warranted by the mission requirements. \2\ See Mil-STD 3007G. /2/

1-4.1 Service Specific Information

Refer to Chapters 5, 6, and 7 for Air Force, Army, and Navy, respectively, for Service-specific information.

\3\

1-5 COMMENTARY

Limited commentary has been added to the chapters. Section designations for such **commentary are preceded by a "[C]" and the commentary narrative is highlighted with** light gray. Below is an example:

[C] 1-2.3 EXAMPLE TEXT

This is an example of how commentary appears in this document.

/3/

This Page Intentionally Left Blank

CHAPTER 2 PLANNING AND LAYOUT

2-1 SITE ISSUES

Coordinate the design and construction of Aircraft Maintenance Hangars adjacent to an airfield with airfield operations, civil engineering master planning, existing Air Traffic control Tower site lines, and the Federal Aviation Administration (FAA) (when applicable) to confirm the new facility will not conflict with airspace, ground operations or required unobstructed clearances. Review safety and security prior to commencement of design or construction. Refer to UFC 3-260-01 for further requirements.

2-1.1 Airport Operations Area (AOA) Safety

The planning and design of an Aircraft Maintenance Hangar will emphasize AOA safety. AOA safety includes unobstructed airspace and safe and efficient ground movements per UFC 3-260-01.

The Airport Operations Area is any area of an airport, installation, or station used or intended to be used for the landing, takeoff or surface maneuvering of aircraft. The AOA includes such paved areas or unpaved areas that are used or intended to be used for the unobstructed movement of aircraft in addition to its associated runway, taxiway or aprons.

2-1.2 Construction Phasing Plan

Prior to Construction, provide notification of construction by issuing notices as required by Federal Aviation Administration Advisory Circular (FAAAC) 150/5200-28, latest edition. Include a construction phasing plan in the contract documents. The purpose of a phasing plan is to establish guidelines and constraints for the contractor to follow during construction. Submit the construction phasing plan for coordination and review at the concept stage and all design stages. Coordinate the plan with airfield management, airfield operations, communications, ground and flight safety, environmental, emergency services, security forces, and logistics. Include the extent of fencing required to keep personnel out of the construction area and to keep Foreign Object Damage (FOD) off the airfield. Include crane restrictions, required FAA permits, flight line access requirements for personnel and equipment, hours of operations within the AOA, haul routes for materials (especially concrete trucks), stockpile locations, details for closing portions of the airfield, and airfield barricades. Refer to UFC 3-260-01 ABBREVIATIONS Section 14 for further guidance on phasing and operational safety plans.

2-1.3 Safety Clearances

Apply all horizontal and vertical operational safety clearances to Aircraft Maintenance Hangars that dictate the general arrangement and sizing of hangars and their relationship to airfield and airside facilities. There are, however, general considerations that apply in most cases, such as:

- Adherence to required unobstructed clear zones

- Adherence to standards in support of safety in aircraft operations
- Non-interference with line of sight or other operational restrictions
- Use of existing facilities
- Flexibility in being able to accommodate changes in aircraft types or missions
- Efficiency in ground access
- Priority accorded aeronautical activities where available land is limited
- Security
- DoD and Military Service-level explosive safety quantity distances when applicable

2-1.4 Airport Operations Area Security

Regulatory requirements for security of assets can have a significant impact on the planning and layout associated with aircraft, as well as the aircraft themselves, requiring varying types and levels of protection. Operational security of the airfield is also a consideration. Collocate maintenance buildings to inhibit or prevent unauthorized access and enhance facility and airfield security.

2-1.5 Integration of Security Measures

Integrate protective features such as barriers, fences, lighting, access control, intrusion detection, and assessment into the site and facility planning and design process to minimize problems with aircraft operations and safety requirements. Include the protective measures in the design, based on risk and threat analyses, with an appropriate level of protection, and comply with security-related requirements.

2-1.6 Solar Glare Hazard Analysis

If any new photovoltaic and glass-enclosed solar-hot water systems are proposed, provide solar glare hazard analysis as required by FAA policy. Refer to Interim Policy, FAA Review of Solar Energy System Projects on Federally Obligated Airports. FAA policy on Glint/Glare Impacts on DoD Aviation Operations requires Glint/Glare analysis of photovoltaic and glass-enclosed solar-hot water systems that are on military airfields and within 2 miles of military airfield control towers, active runways thresholds, and helicopter landing zones. FAA policy requires the use of FAA's Solar Glare Hazard Analysis Tool (SGHAT) for Glint/Glare analysis found on website: https://share.sandia.gov/phlux. This analysis is required for eliminating the potential for ocular impact to pilots and/or air traffic control facilities due to glare from solar photovoltaic (PV) and solar hot water (SHW) systems on airports.

To prevent mirror-like reflections from building surfaces to aircraft in flight, provide roofs and other external surfaces with a specular reflectance compatible with the location of the building on the airfield. If the building is located so that glare is an operational hazard, provide surfaces of the building with a light reflectance of not more than 10,

measured at an angle of 85 degrees in accordance with American Society of Testing and Materials (ASTM) D523, *Specular Gloss* at critical surfaces of the building.

\2\ Solar PC or SHW systems should not block, reflect, or disrupt NAVAIDS, and other equipment required for safe aviation operations. Designer must coordinate with appropriate authorities to insure no impact to NAVAIDS system operations./2/

2-1.6.1 Airfield Manager Approval for Solar Energy System Projects

Provide the results of the SGHAT to the Airfield Manager for evaluation of any possible adverse effects to the airfield daily operations prior to approving new photovoltaic and glass-enclosed solar-hot water systems on the military airport.

\3\

2-1.7 Nightime Light Hazard Analysis

Nighttime light pollution impacts both airfield operations and flight operations when Night Vision Goggles are in use. Minimize operational hazards due to nighttime light pollution emanating from both interior and exterior of facility by minimizing and orienting glazed openings and exterior lighting fixtures. Provide cutoff shielding on exterior lighting fixtures. Consider impacts from any major interior light sources such as hangar bay lights with open hangar door or through translucent panels of fabric hangar doors. During conceptual design, perform computer rendering lighting studies from point of view of Control Tower and Ground Control stations to ensure no hazards exist.

2-1.7.1 Airfield Manager Approval

During review of the concept phase submission, provide the results of the nighttime light hazard analysis to the Airfield Manager for evaluation of any possible adverse effects to airfield operations. Obtain approval of Airfield Manager prior to executing projects on the military airport or heliport. Resubmit and obtain approval of Airfield Manager of any proposed design modifications that deviate from previous approved solution.

/3/

2-2 FACILITY FUNCTIONS AND ADJACENCIES

Maintenance hangars are required to provide weather-protected shelter for the servicing and repair of aircraft at the organizational level.

2-2.1 Ground Level

The following spaces are typically provided on the ground level of a two story hangar. Locate these rooms with consideration of the access requirements described in each Paragraph, regardless of the number of levels in the hangar.

2-2.1.1 Aircraft Maintenance Bay

Aircraft Maintenance Bays are sized to accommodate aircraft as well as the maintenance activities around the aircraft. The Aircraft Maintenance Bays require direct access to a component of the flight line, preferably a peripheral taxi or tow-way.

2-2.1.2 Maintenance Administration

Maintenance administration spaces include maintenance control, quality control, rooms to access maintenance records and manuals on computers, as well as office space for manufacturers' representative personnel. Most of these spaces need direct or nearly direct access to the Aircraft Maintenance Bay.

2-2.1.3 Heavy Maintenance Shops

These industrial spaces house shops for maintaining large heavy parts and equipment such as engines, sheet metal and composites. All of these spaces require direct or nearly direct access to the Aircraft Maintenance Bay. Provide an overhead door or a pair of personnel doors to the Aircraft Maintenance Bay for movement of large equipment. \2\ If a battery maintenance shop is required, see UFC 3-520-05 for additional requirements. Lithium-Ion battery maintenance requires significant space and mechanical systems. /2/

2-2.1.4 Light Maintenance Shops

These spaces house shops for maintaining parts from the aircraft such as electronics, avionics, or weapons systems. Direct access to the Aircraft Maintenance Bay is preferred but not required because these parts are more portable than those in the heavy maintenance shops.

2-2.1.5 Storage

Ground level storage includes spaces for storing and issuing parts and tools for the maintenance of the aircraft. Direct access to both the Aircraft Maintenance Bay and to the exterior are preferred, but direct access to the exterior is more important to allow for deliveries.

2-2.1.6 Personnel Support

Break rooms, restrooms, showers and locker rooms should be located to support ground level personnel.

2-2.1.7 Building Support

Building support spaces includes areas used for maintaining the building and areas that house building utilities. Facility maintenance rooms have a low priority for adjacency, but they are typically located near the utility rooms. Utility spaces include mechanical rooms, compressor rooms, electrical rooms, communication rooms, fire protection rooms, and janitor closets. Provide major utility rooms with direct exterior access and locate them close to exterior equipment related to the space. Communication rooms

typically require interior access. Provide separate general, secure and unit-managed communications rooms. Confirm access with the installation. Account for equipment and access space for maintaining equipment in Utility space sizing. Consider user access for user-owned and operated equipment such as a compressor that may be in a shared utility room. Mechanical rooms in hangars are typically larger than in other types of buildings because they often contain equipment supporting maintenance operations, such as air compressors. Fire Protection Rooms in hangars are typically larger than in other types of buildings due to foam systems required to protect Aircraft Maintenance Bays. Provide a janitor closet near the restrooms.

2-2.2 Upper Level

The following spaces are typically provided on the upper level of a two story hangar. Locate these rooms with consideration of the access requirements described in each Paragraph, regardless of the number of levels in the hangar.

2-2.2.1 Operational Administration

Unit administration offices, conference rooms and training rooms may be remote from the Aircraft Maintenance Bay and are typically located on the upper level. Spaces in this category are often grouped based on the level of security required for the use.

2-2.2.2 Personnel Support

Break rooms, restrooms, locker rooms should be located to support upper level personnel.

2-2.2.3 Building Support

These spaces are often satellite rooms associated with ground level mechanical, electrical and communication rooms. Provide a janitor closet near the restrooms.

2-2.3 Secure Spaces

Many hangars require some level of physical security for the protection of assets such as classified materials, Sensitive Compartmented Information (SCI) or Special Access Program (SAP) information. The requirements for the protection of assets is defined in DoD and Service regulatory guidance or policy. The security requirements must be coordinated with the supported command and their security representatives to ensure the configuration will meet their operational (compartmented) and the regulatory and policy based security requirements. When a hangar has more than one secure space, serious consideration should be given to consolidate multiple secure spaces. Any consolidation will reduce the initial and sustainment cost for infrastructure, electronic security systems and the associated accrediting requirements. When required, integrate the physical security protective measures into the site, building, room(s), or area(s) as applicable.

2-3 MINIMUM AIRCRAFT MAINTENANCE BAY CLEARANCES

Provide the minimum required clearances between the aircraft and adjacent horizontal obstructions, vertical obstructions, and other aircraft in designing the Aircraft Maintenance Bay as indicated in Table 2-1: Minimum Aircraft Maintenance Bay Clearances and Figure 2-1: Minimum Aircraft Maintenance Bay Clearances, Figure 2-2: Alternate Corner Configuration, Figure 2-3: Vertical Hangar Clearances, Figure 2-4: Vertical Hangar Clearances with Sloped Roofs. These clearances are essential to ensure aircraft are protected from structural damage as they are moving in and out of the hangar and to allow personnel and equipment to safely and efficiently maneuver around the aircraft during aircraft maintenance activities.

2-3.1 Horizontal Obstructions

The nearest horizontal fixed obstructions include but are not limited to the inside face of the wall, faces and jambs of hangar doors, structural columns or bracing, bollards, liner panels, mechanical equipment or ductwork, plumbing equipment, valves and pipes, electrical equipment such as power transformers or other permanent physical items. Fixed obstructions do not include furniture, tables, desks, benches, cabinets, tools, parts, carts or other movable objects. Clearances from rotary blade aircraft are from rotor blade arcs, except where specifically noted otherwise in Table 2-1: Minimum Aircraft Maintenance Bay Clearances.

2-3.2 Vertical Obstructions

The nearest fixed or mobile overhead obstructions include but are not limited to structure, draft curtains, mechanical, electrical, and plumbing equipment such as lighting, fans, heaters, ductwork, and fire protection systems, crane rails and crane bridges. Crane hoists and hooks are excluded if they can be maneuvered around tall parts of the aircraft and can be stored out of the way during aircraft movement.

2-3.3 Additional Clearances

Specific airframe or Service requirements may increase the minimum clearances required by Table 2-1: Minimum Aircraft Maintenance Bay Clearances to allow performance of certain maintenance operations. Coordinate with the maintenance unit staff to determine if additional space is required to maintain the aircraft. Provide additional clearances where required by an approved document such as the design aircraft's Facility Requirements Document (FRD) or a Service-specific standard design, defined Service hangar type, or other approved criteria. For example, the FRD may require additional space aft of the aircraft to remove the engine, or additional space above an aircraft to provide the crane hook height to perform maintenance operations such as pulling the rotor shaft out of a helicopter or maintaining the radar dome on an Airborne Warning and Control System (AWACS) aircraft. Jacking the design aircraft will reduce the overhead clearance below requirements in this UFC. Confirm jacking the design aircraft in the parking position does not require additional height to avoid conflict with an overhead obstruction. Minimum hook height is to the saddle of the hook.

Maximize the unobstructed space in Aircraft Maintenance Bays where designs allow for exceeding the minimum clearances determined from this section. Exceeding minimum requirements for bay widths and depths, door heights, clear heights or crane hook heights may provide the flexibility to accommodate a future aircraft type or a revised aircraft parking layout without violating required clearances. For example, if for some good reason the structure of an Aircraft Maintenance Bay roof is higher than necessary to meet the minimum vertical clearance requirements, locate MEP systems and cranes as high as possible rather than dropping them to the minimum clear height allowed.

2-3.4 Alternate Corner Configuration

The concept indicated in Figure 2-2: Alternate Corner Configuration is acceptable for Aircraft Maintenance Hangars of any size where it may be desirable to re-distribute large corner areas. The clearances indicated by Table 2-1: Minimum Aircraft Maintenance Bay Clearances apply to all hangars, even if using the alternate corner configuration. Where used in hangars with multiple aircraft parking positions the alternate corner configuration is only acceptable at the end bays. Do not reduce the square footage of the Aircraft Maintenance Bay. Distribute the area gained by the corner configuration within the Aircraft Maintenance Bay.

This UFC allows encroaching on the space in front of the wings of aircraft with walls and other fixed obstructions. However, it is the designer's responsibility to confirm operational clearance requirements around the aircraft if introducing obstructions in front of the wings of aircraft. Consult the users for any specific airframe or Service requirements that limit the location of an alternative sidewall configuration. Provide additional clearances where required by an approved document such as the design aircraft's Facility Requirements Document (FRD) or a Service-specific standard design, defined Service hangar type, or other approved criteria. For example, the FRD may require additional space in front of the wing of the aircraft to remove a wing-mounted engine. Allow for alternate aircraft layouts that could be used in the future such as tail-in parking. If future flexibility is a guiding concern, do not locate core spaces such as elevators, utility rooms, restrooms or showers in the high bay space. Refer to Appendix C-3.2: Considerations for Large Aircraft Maintenance Bays.

Table 2-1: Minimum Aircraft Maintenance Bay Clearances

	H	HOOK HEIGHT (SADDLE OF HOOK)	Army: Per Std Design Air Force: Per FRD		Refer to Table 7-1				1, 7, 9

Notes:

1. Refer to 2-3: Minimum Aircraft Maintenance Bay Clearances.

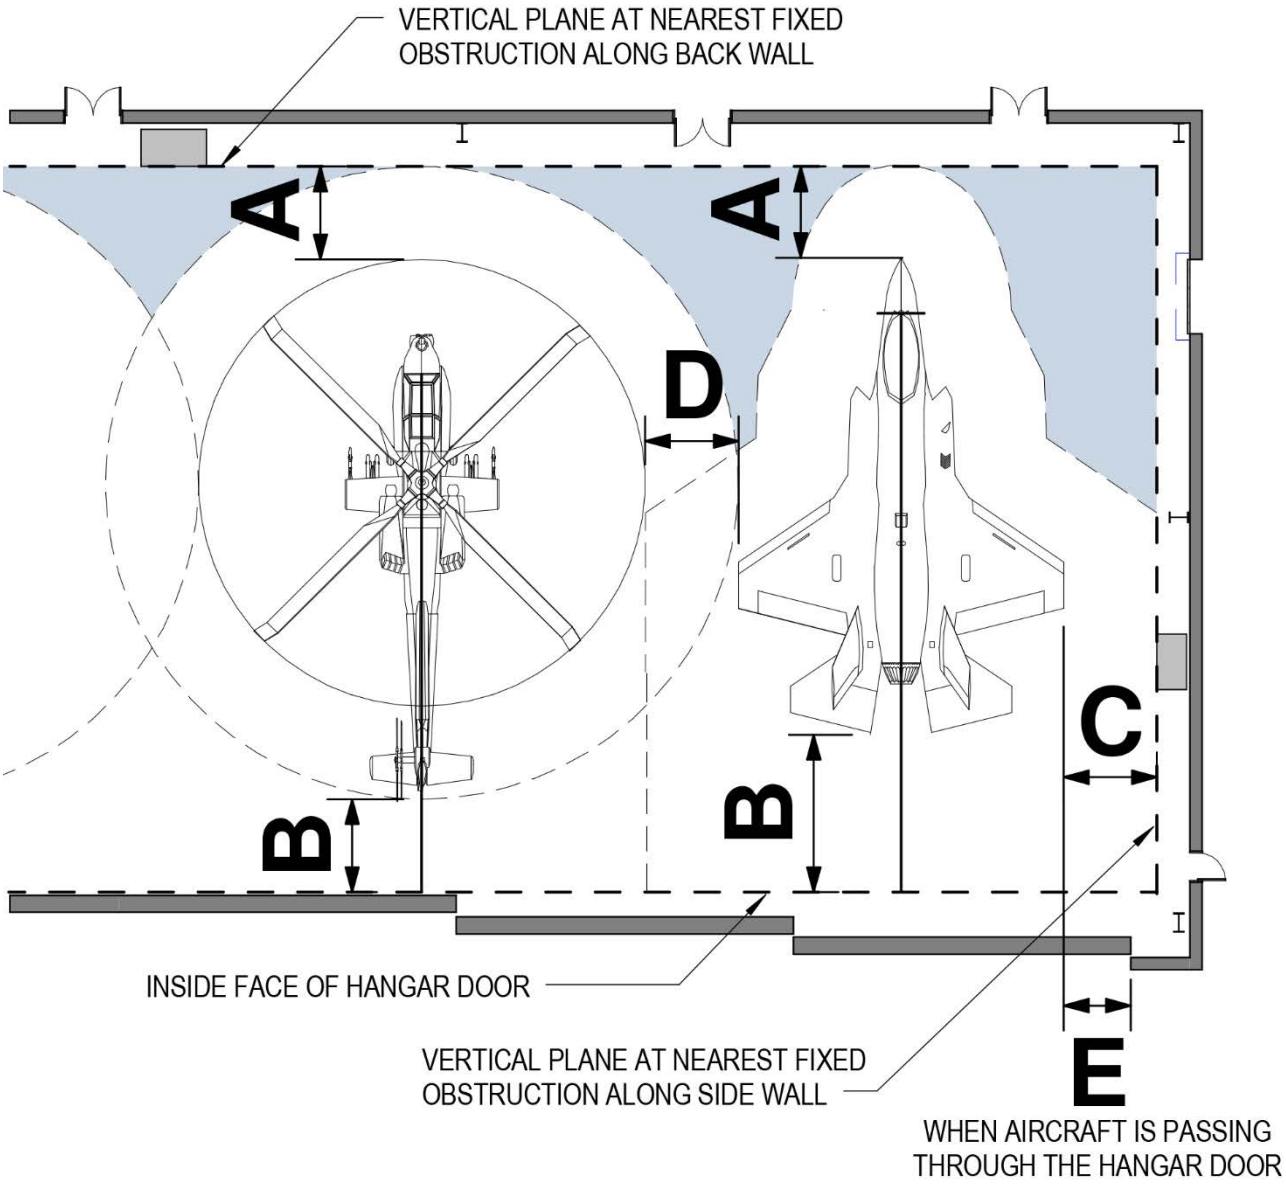
2. Refer to Figure 2-1: Minimum Aircraft Maintenance Bay Clearances.

3. Minimum clearances A and C are to a vertical plane at the face of the fixed obstruction that extends furthest toward the aircraft.

4. The minimum clearance from the aircraft to the hangar door is to a vertical plane at the interior face of the innermost panel of a sliding door, or to the interior face of a vertical lift door panel or mullion. Fixed columns along the hangar door separating bays are considered hangar door jambs for the purpose of determining clearances.

5. Minimum clearance between aircraft is from any part of the aircraft. Depending on the hangar configuration, the minimum clearance between aircraft is wingtip to wingtip, nose to nose, tail to tail, nose to tail, or rotor blade arc to rotor blade arc. Do not assume wingtips or rotor blades are folded. Do not determine minimum clearances between aircraft based on specific stationary rotor blade positions.

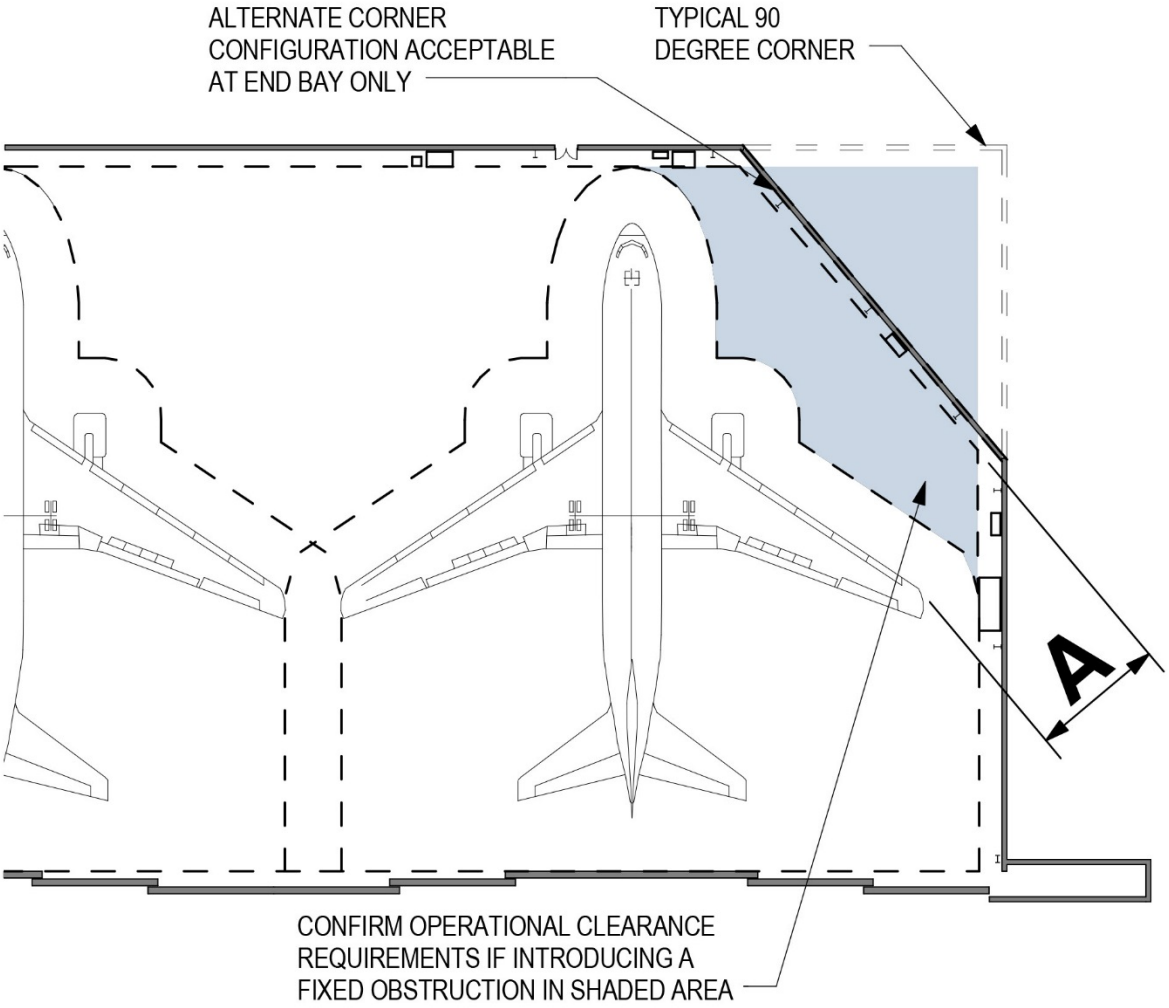
6. Minimum horizontal clearances at hangar door jambs are from wingtip or rotor blade to the edge of the clear width of the hangar door opening as the aircraft passes through the door opening. Rotor blades are assumed to be fixed in the narrowest configuration possible when entering and leaving the hangar. Do not assume wingtips or rotor blades are folded. Fixed columns along the hangar door separating bays are considered hangar door jambs for the purpose of determining clearances.



7. Refer to Figure 2-3: Vertical Hangar Clearances and Figure 2-4: Vertical Hangar Clearances with Sloped Roofs.

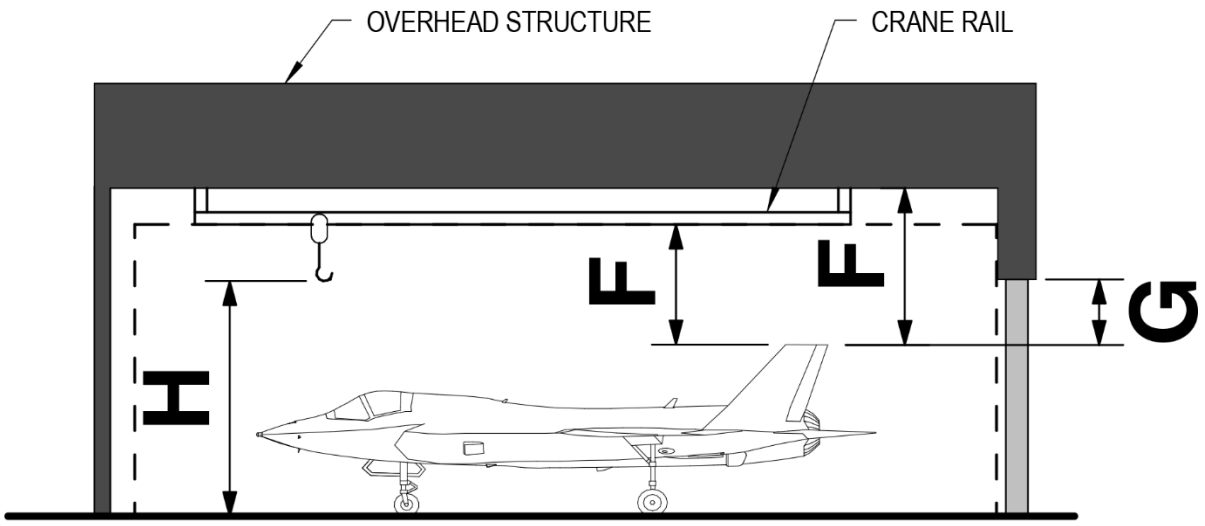
8. Minimum vertical clearances are from the top of the aircraft to the bottom of the nearest fixed or mobile overhead obstruction.

9. Minimum Hook height is to the saddle of the hook.



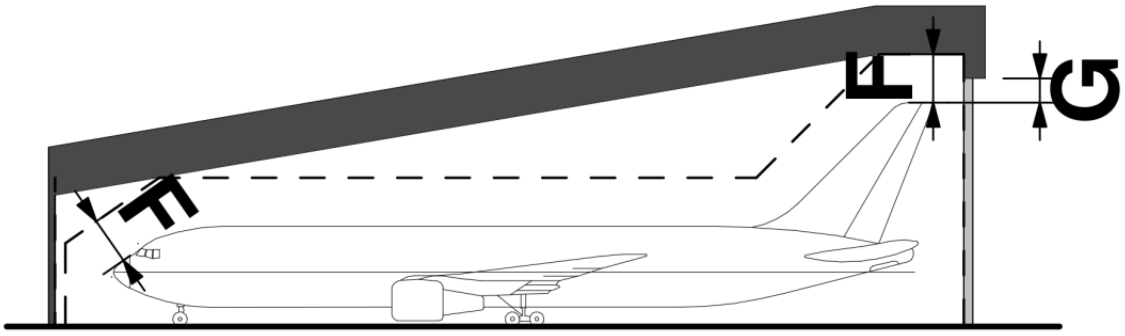
10. Refer to 7-3.1: Types of Hangars.

Figure 2-1: Minimum Aircraft Maintenance Bay Clearances



Note: Refer to Table 2-1: Minimum Aircraft Maintenance Bay Clearances for dimensions A, B, C, D and E.

Figure 2-2: Alternate Corner Configuration

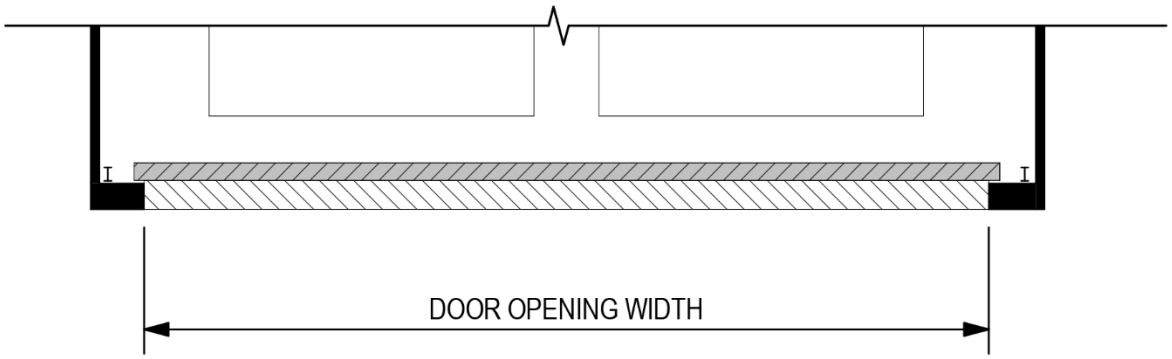


Note: Refer to 2-3.4: Alternate Corner Configuration and Table 2-1: Minimum Aircraft Maintenance Bay Clearances for dimension A.

Figure 2-3: Vertical Hangar Clearances

Note: Refer to Table 2-1: Minimum Aircraft Maintenance Bay Clearances for dimensions F, G, and H.

Figure 2-4: Vertical Hangar Clearances with Sloped Roofs



Note: Refer to Table 2-1: Minimum Aircraft Maintenance Bay Clearances for dimensions F and G.

2-4 NET TO GROSS AREA IN AIRCRAFT MAINTENANCE HANGARS

Planning personnel are encouraged to allow sufficient net-to-gross area for specific spaces in Aircraft Maintenance Hangars. Aircraft Maintenance Bays require additional square footage outside of the safety lane where structure and other utilities create obstructions which cannot be specifically accounted for in paragraph 2-3: Minimum Aircraft Maintenance Bay Clearances. Hangars require large mechanical rooms to accommodate equipment such as air compressors. Hangar fire protection rooms are larger than in typical buildings due to the foam suppression system required for the Aircraft Maintenance Bay. Select Hangar doors based on the pros and cons of the different types of doors and by the users/installation preferences.

The area required for different types of hangar doors varies, but is not intended to govern the decision of the type of hangar door to use. Calculate the area inside the exterior face of hangar doors in the closed position at 100% square footage. Calculate the area inside the exterior face of door pockets at 100% square footage. Enclose all door pockets. Do not include the area under the roof, outside of the hangar doors. Refer to Figure 2-5: Space Requirements for Vertical Lift Fabric Doors and Figure 2-6: Space Requirements for Sliding Steel Hangar Doors for clarification on calculating gross square footage of different hangar doors.

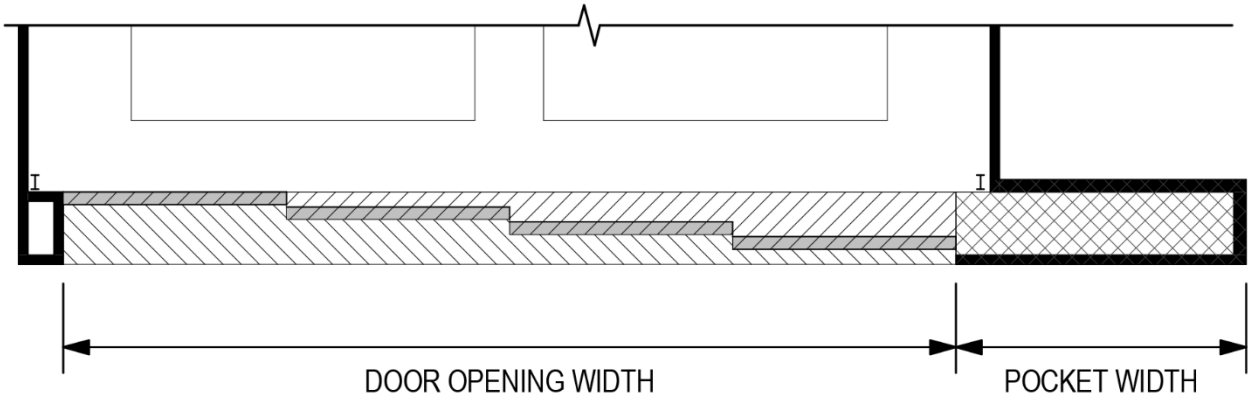


Figure 2-5: Space Requirements for Vertical Lift Fabric Doors

Count the area inside the exterior face of the door as 100% square feet

Do not count the area under roof and outside the exterior face of the door

Figure 2-6: Space Requirements for Sliding Steel Hangar Doors

Count the area inside the exterior face of the door as 100% Square Footage (SF)

Do not count the area under roof and outside the exterior face of the door

Count the area inside the exterior face of a door pocket as 100% SF

2-5 ACCESSIBILITY

It is the goal of the DoD to make its facilities accessible to persons with disabilities. In accordance with UFC 1-200-01, follow the Architectural Barriers Act (ABA) Accessibility Standard for Department of Defense Facilities.

2-6 SUSTAINABLE DESIGN

Design Aircraft Maintenance Hangars per the requirements of UFC 1-200-02. Refer to Appendix C - Best Practices for discussion on sustainability strategies applicable to Aircraft Maintenance Hangars.

2-7 HAZARDOUS MATERIALS

2-7.1 Background Information

The DoD, including the Department of the Navy, operates facilities which routinely utilize, or have utilized in the past, hazardous materials and chemicals that contain lead, cadmium and chromium, and other heavy metals. Operations and activities which can create an unsafe condition with regards to worker protection, include (but are not limited to): manual demolition, scraping, grinding, heat-gun applications, power tooling with dust collection, application of corrosion control materials, spray paint with lead/chromium (VI)/Cadmium-based paints, burning, power tooling without dust

collection, rivet busting, cleanup activities with dry abrasives, movement/removal of enclosures, abrasive blasting, welding, cutting and burning on steel structures. When these operations occur, there are hazards associated with the generation of dust, debris and fumes. The hazards and the controls required are dependent on the materials used. Additionally, these operations, and utilization of these hazardous materials and chemicals, are found in aviation facilities.

2-7.2 Facility Design Requirements

Comply with the Occupational Safety and Health Act (OSHA), American Conference of Governmental Industrial Hygienist (ACGIH), and DoD regulations and guidelines for facilities that will operate, or will continue to operate, utilizing hazardous materials and/or chemicals. The requirements found in the OSHA regulations and the DoD Instructions and Directives may affect facility design requirements, which may include (but are not limited to): separate toilets and washing/bathing areas for workers who are exposed to the hazard, change rooms, decontamination areas, break rooms, clothes washing facilities, areas for controlled disposal of contaminated waste and work clothes, both local and general high-efficiency particulate air (HEPA) ventilation systems and filters, eyewash stations and deluge showers. Areas of facilities utilizing these hazardous materials and/or chemicals must be designated as regulated areas whenever exposure can be expected to be in excess of the permissible exposure limit(s), and must be demarcated from the rest of the workplace in a manner that adequately establishes and alerts building occupants of the boundaries of the regulated area. Design facilities in a manner to allow the OSHA required air sampling and monitoring that are required for the specific hazardous material in use. Design facilities to control these hazards below the standards set in the stated regulations. Refer to Appendix D, Questionnaire, for a list of questions the planner and designer should ask the operators regarding their aircraft maintenance operations and activities.

Additionally, the DoD Instruction 6055.01, Appendix 4 lists additional requirements for facilities which involve operations generating airborne dust, mist, debris, or aerosols containing lead, chromium (VI), or cadmium. These requirements include (but are not limited to): containment processes and methods to monitor effectiveness of housekeeping procedures, decontamination procedures, and engineering controls tailored to each facility.

This Page Intentionally Left Blank

CHAPTER 3 GENERAL HANGAR REQUIREMENTS

3-1 INTRODUCTION

Typical systems utilized in Aircraft Maintenance Hangars are described below. Refer to Chapters 5, 6, and 7 for Air Force, Army, and Navy specific applicability and exceptions to Chapter 3. Specific rooms where these systems are used are indicated later in this UFC.

3-2 CIVIL

3-2.1 Siting

3-2.1.1 General

When siting the hangar, place emphasis on operation, function, energy efficiency, safety, and Fire Department and Emergency vehicle access. Provide efficient access to the flight line. Other factors to consider include topography, vegetative cover, existing construction, weather elements, wind direction, soil conditions, flood hazards, natural and man-made obstructions, adjacent land use, availability of usable airspace, accessibility of utilities, taxiway and runway clearances, existing Control Tower sight lines, and future expansion capability. When siting the Hangar, give careful consideration to vehicular parking, pedestrian access, and traffic flow. Follow UFC 3-260-01 and UFC 1-200-01.

3-2.1.2 Airfield Clearance Criteria

Site hangars in accordance with the airfield clearance requirements in UFC 3-260-01.

3-2.1.2.1 Restrictions

Land use restrictions dealing with runway clearances, helipad planning, aircraft noise, and use of airspace are to be applied to the site location with UFC 3-260-01 and UFC 2-100-01.

3-2.1.2.2 Construction in Floodplains or on Wetlands

Avoid siting and construction of facilities in wetlands and floodplains. If this cannot be avoided, design and site the facility in accordance with UFC 1-200-01 and UFC 3-201-01.

3-2.1.2.3 Soil and Groundwater Conditions

Complete the geotechnical design in accordance with UFC 3-220-01.

3-2.2 Vehicular and Pedestrian Circulation

3-2.2.1 Street System

Coordinate design of the parking lot and street system with the overall traffic circulation plans for the installation as well as the adjacent road system. Provide convenient and safe vehicular access and circulation for essential services, such as deliveries, trash and garbage collection, fire protection, and maintenance and repair. Minimize through traffic routes adjacent or near the Hangar and Pedestrian routes. Design items such as site access and drives, tactical vehicle access, parking lots, fire truck access, and accessible parking in accordance with applicable criteria set forth in the Unified Facilities Criteria (UFC). Design pavement in accordance with UFC 3-250-01FA.

3-2.2.2 Pedestrian Sidewalks/Circulation

Design sidewalks to provide convenient and safe pedestrian access and necessary circulation. Provide an accessible route in accordance with the ABA Accessibility Standards. Coordinate pedestrian access routes into vehicular traffic to minimize crossing to provide safe ingress/egress for personnel. Design pavement in accordance with UFC 3-250-01FA.

3-2.3 Airfield Pavements

3-2.3.1 Airfield Pavements Design

Design geometry of airfield pavements, including hangar access aprons, in accordance with UFC 3-260-01 and UFC 3-260-02. Refer to 3-11.2: Existing Apron Slope for additional requirements. All exterior pavements required to support aircraft loadings are to be considered airfield pavements. Design all interior hangar slabs that support aircraft loadings per Structural Section - Aircraft Maintenance Bay Slab on Ground in this UFC.

Consider flexibility of the pavement sections to accommodate a wide variety of aircrafts, if possible, to accommodate potential aircraft and mission changes.

3-2.3.2 Airfield Pavement Markings

Refer to Chapters 5, 6, and 7 for Service-specific airfield pavement marking requirements. DoD tenant organizations use Service-specific criteria on the military portions of the airfield to the maximum extent practicable, including UFC 3-260-01 and UFC 3-535-01.

3-2.4 Exterior Utility Services

Design utilities in accordance with the appropriate UFC. Avoid installing utilities under airfield pavements to the maximum extent possible. Obtain written approval for the need of any utilities under the airfield pavement other than those directly supporting the apron or parked aircraft, from NAVFAC Headquarters (HQ) Chief Engineer for Navy projects, United States Army Corp of Engineers (USACE) Transportation Systems Center (TSC) for Army projects, and AFCEC pavements engineer for Air Force projects.

3-2.4.1 Storm Drainage

Design storm drainage around hangars and aircraft movement areas in accordance with UFC 1-200-01, and FAA AC 150/5320-5D. Design the storm drainage system, including gutters, drains, inlets and culverts, to carry the anticipated runoff for the appropriate level design storm event, including runoff from melting snow. Design of aboveground storage of runoff tends to attract birds that are not recommended in the AOA.

3-2.4.2 Sanitary Sewer

Capture oily wastewater contaminants from the hangar bay trench system and hangar sinks and drains, if provided, with oil/water separators, or as directed by the department overseeing environmental policy for the installation.

3-2.4.3 Containment of Fire Suppression Effluent

Consider all local environmental regulations to determine the control, treatment and/or remediation measures for the discharge of fire suppression effluent. Refer to Chapters 5, 6, and 7 for Service-specific containment requirements.

3-3 ARCHITECTURAL

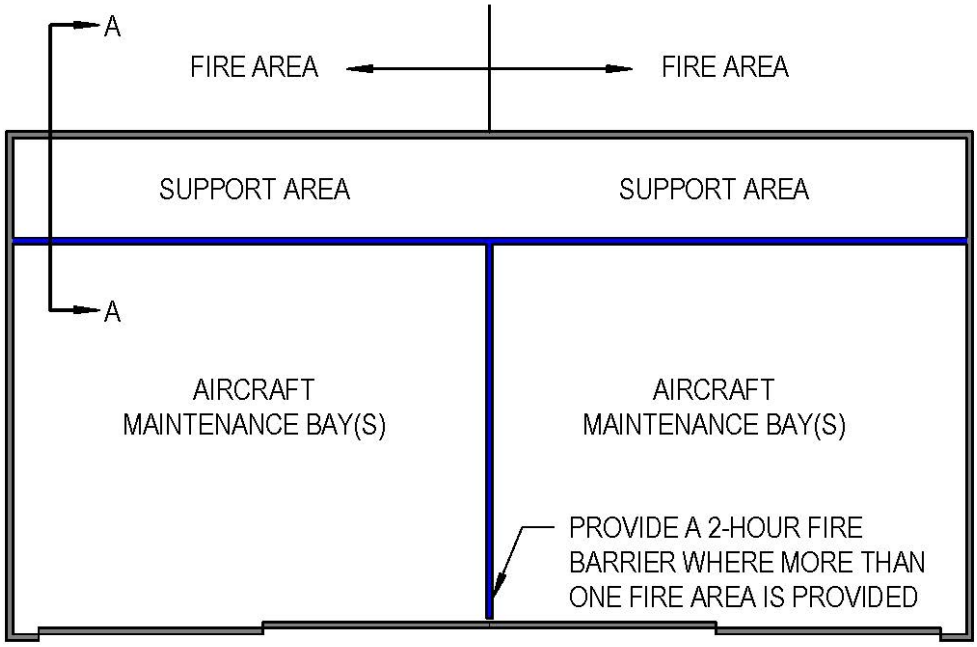
3-3.1 Construction, Life Safety, and Fire Fighter Access

Provide hangar construction, life safety, and fire department access in accordance with UFC 3-600-01 except where additional requirements are added by this UFC. Use National Fire Protection Agency (NFPA) 409 only where explicitly noted. If there is a conflict, this UFC supersedes UFC 3-600-01 and NFPA standards.

3-3.1.1 Construction Type

Where Group I, II, and III hangars as defined by National Fire Protection Agency (NFPA) 409 are provided, they are limited to non-combustible Type I or Type II construction as defined by the International Building Code (IBC). Construct Group IV hangars in accordance with the membrane construction requirements in NFPA 409.

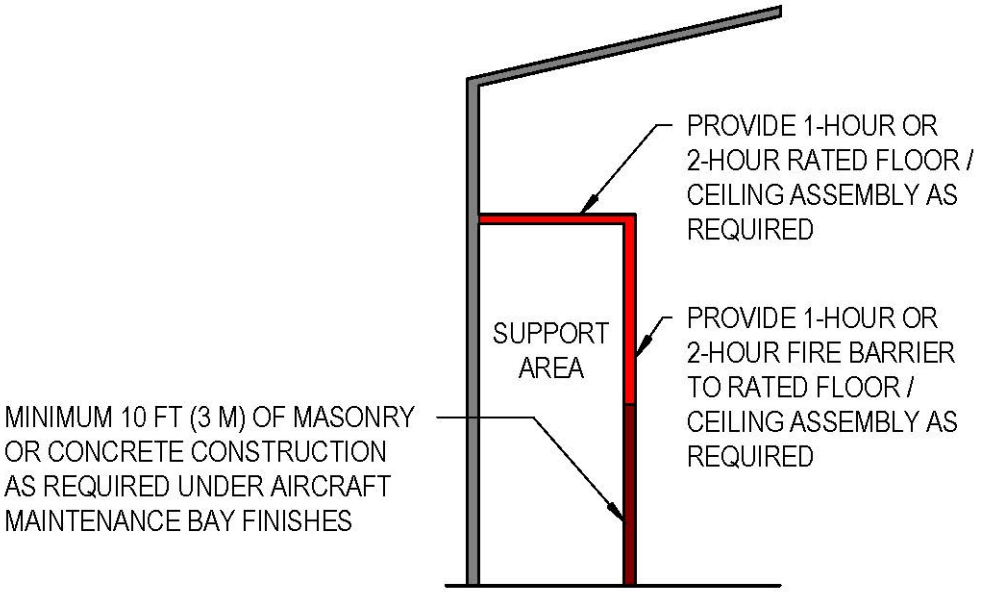
3-3.1.2 Protection of Structural Members



Protection of structural members (columns, beams, trusses, joists) above that established in the type of construction is not required in the hangar bay when protected by an approved fire suppression system in compliance with this UFC.

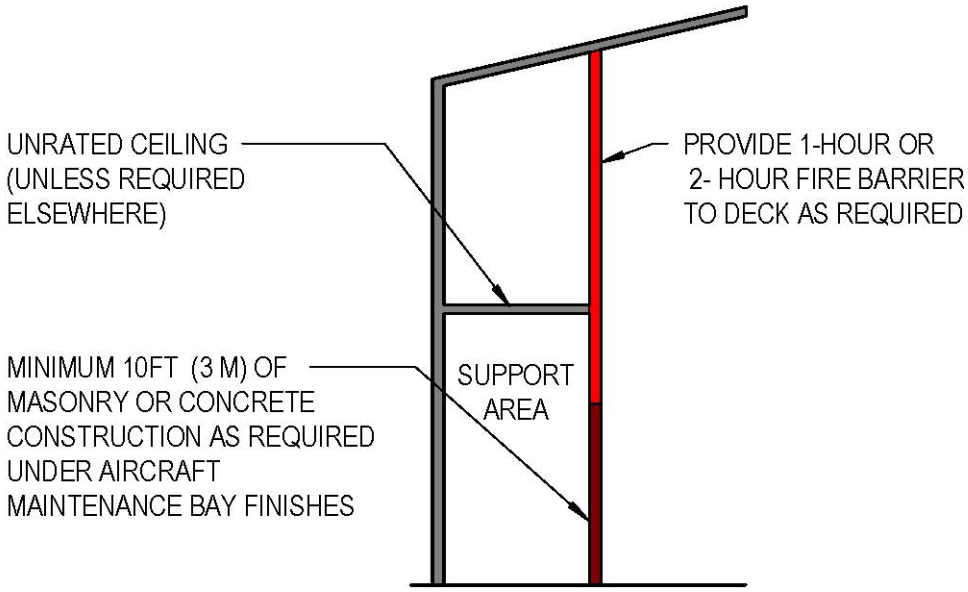
3-3.1.3 Internal Fire Rated Separations

Provide fire rated separations that are Underwriters Laboratory (UL) listed, Factory Mutual (FM) approved, a calculated assembly by a Nationally Recognized Testing Laboratory (NRTL), or an assembly calculated in accordance with IBC. At a minimum, provide the fire rated separations listed below and shown in Figure 3-1: Internal Fire Rated Separations.



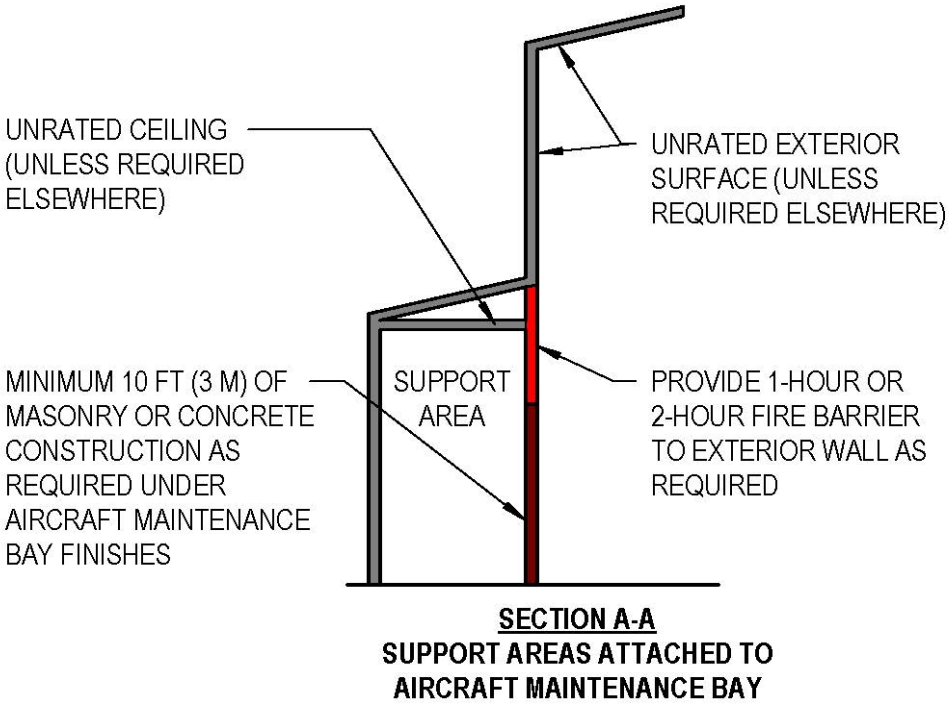
- Provide a 1-hour fire barrier between hangar bay and support areas such as offices, maintenance shops, and storage areas including tools, parts, and tires.
- Provide a 2-hour fire barrier between separate fire areas within the hangar bay.
- Internal fire barriers are not required between adjacent aircraft servicing areas unless required elsewhere in this UFC.
- Protect openings in fire barriers in accordance with NFPA 101, such as doors and windows.
- Protect duct penetrations through fire barriers in accordance with UFC 3-600-01. \2\

Figure 3-1: Internal Fire Rated Separations



HANGAR BUILDING PLAN VIEW

Figure 3-1-1: Internal Fire Rated Separations



SECTION A-A
SUPPORT AREAS WITHIN AIRCRAFT MAINTENANCE BAY

Figure 3-1-2: Internal Fire Rated Separations

SECTION A-A
SUPPORT AREAS SEPARATED FROM AIRCRAFT MAINTENANCE BAY

Figure 3-1-3: Internal Fire Rated Separations

/2/

3-3.1.4 Internal Fire Wall Separations

Where operational aircraft assets are isolated from non-DoD areas, provide 4-hour rated fire walls where these assets are co-located in a building with non-DoD operations that are beyond the control of the DoD users. Minimize penetrations through such firewalls. Protect any necessary door, window, and other penetration in accordance with Factory Mutual Global Property Loss Prevention Data Sheets 1-22, Criteria for Maximum Foreseeable Loss Fire Walls and Space Separation and 1-23, Protection of Openings.

3-3.1.5 Allowable Fire Area

The allowable fire area in the hangar bay is unlimited where a building is constructed in accordance with this UFC. In some instances, more than one fire area may be provided to limit the size of the foam/water system discharge area.

3-3.1.6 Allowable Building Area

The allowable building area is limited to the restrictions of the IBC. Where a building is constructed in accordance with this UFC, modify the restrictions of unlimited area buildings to allow for three stories and Group A-3 occupancies.

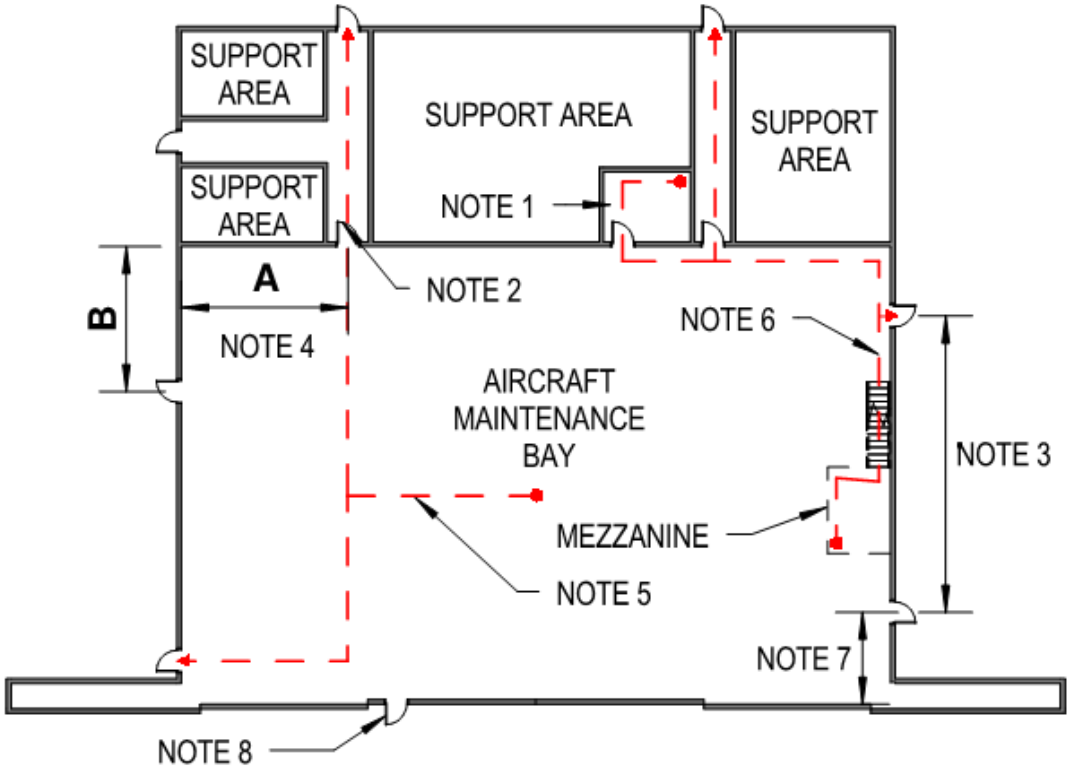
3-3.1.7 Allowable Building Height and Stories

Where the building is constructed in accordance with this UFC, the allowable building height is unlimited. The allowable number of stories is limited to the restrictions of the IBC based on the construction type.

3-3.1.8 Building Clear Space and Fire Separation Distance

Provide clear space around the facility in accordance with NFPA 409. The clear space is permitted to be around a group of buildings, where those buildings are considered a portion of one building on the same lot as defined by IBC.

Provide fire separation distance in accordance with IBC.



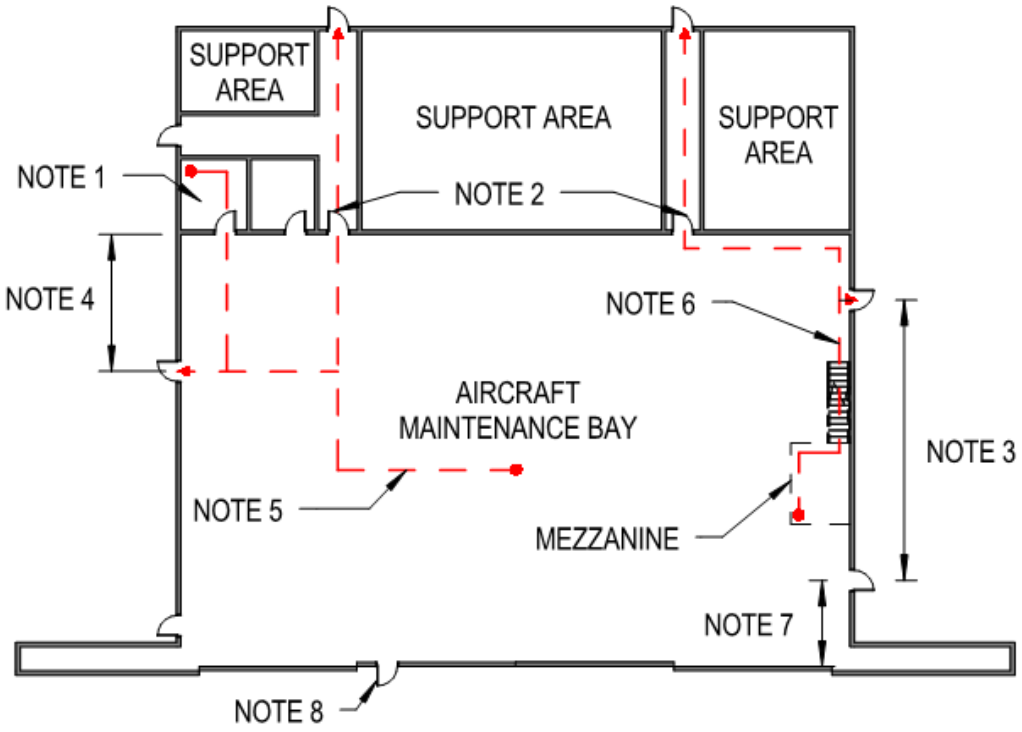
3-3.1.9 Hangar Bay Egress

The requirements of NFPA 101 apply to hangar bay egress, except as modified.

- **For Air Force and Navy**: Provide exits or exit access doors around the entire perimeter of the hangar bay at a maximum spacing of 150 feet (ft.) (45.7 meters (m.)). Unless otherwise noted in this UFC, travel distance limitations do not apply in the hangar bay. Provide each exit access door from the hangar bay, which passes through adjacent building areas, with a continuous unobstructed path to an exit. Travel distance begins at the hangar bay exit access, and is measured along the path of egress travel to the exit. Refer to Figure 3-2: Air Force and Navy Hangar Bay Egress for additional information.
- **For Army:** Provide exits on the exterior walls around the hangar bay egressing directly to the exterior at a maximum spacing of 150 ft. (45.7 m). Locate the first exit on the exterior wall no further than 75 ft. (22.9 m) from the start of the hangar bay exterior wall. Apply the maximum travel distance for General Industrial occupancy as defined by NFPA 101. Refer to Figure 3-3: Army Hangar Bay Egress for additional information.
- Where hangar bay doors exceed 110 ft. (33.5 m), do not provide exits in the hangar bay door to meet the maximum distance limitation between exits. Provide exits within 20 ft. (6.1 m) of each end of the hangar bay door opening.
- Personnel access doors may be provided through the hangar bay door; however these doors are not considered exits for egress.
- Install an egress door in the structure between hangar bay doors, when the structure is greater than 7 ft. (2.1 m) in width. Provide this door regardless of whether the 110 ft. (33.5 m) limitation is exceeded.
- Provide each required exit or exit access door from the hangar bay with panic hardware, and swing the door in the direction of egress travel.

- Support areas are not permitted to have their required egress through the hangar bay with the exception of normally unoccupied rooms less than 100 sq. ft. (9.3 sq. m). This limitation is not inclusive of equipment platforms as defined by IBC.
- Do not exceed a travel distance of 75 ft. (22.9 m) from the most remote location on the mezzanine to an exit or exit access. Equipment platforms as defined per IBC are not considered mezzanines.

Figure 3-2: Air Force and Navy Hangar Bay Egress



Air Force and Navy Egress Notes:

1. Normally unoccupied rooms less than 100 sq. ft. (9.3 sq. m) may have their sole means of egress through the hangar bay.
2. Travel distance limitations begin at the door from the hangar bay.
3. Except where noted, do not exceed 150 ft. (45.7 m) between exits and exit access doors along the hangar bay perimeter.
4. Do not exceed a cumulative total of 150 ft. (45.7 m) for the distance of A + B.
5. Except where noted, travel distance limitations do not apply within the hangar bay.
6. Do not exceed a travel distance of 75 ft. (22.9 m) from the most remote location on the mezzanine to an exit or exit access.

7. Where the hangar bay door opening exceeds 110 ft. (33.5 m), provide the first exit or exit access within 20 ft. (6.1 m) of the hangar bay door opening.

8. Personnel doors are permitted in the hangar bay door, however they are not considered exits for egress.

Figure 3-3: Army Hangar Bay Egress

Army Egress Notes:

1. Normally unoccupied rooms less than 100 sq. ft. (9.3 sq. m) may have their sole means of egress through the hangar bay.

2. Unless the wall separating the hangar bay from the support area is a horizontal exit as defined by NFPA 101, the distance between exit access doors along this wall is only limited by the travel distance.

3. Except where noted, do not exceed 150 ft. (45.7 m) between exits in the hangar bay exterior wall.

4. Do not exceed 75 ft. (22.9 m) between the start of the hangar bay exterior wall and the first exterior exit along the wall.

5. Travel distance limitations from the hangar bay are applicable until an exit is reached.

6. Do not exceed a travel distance of 75 ft. (22.9 m) from the most remote location on the mezzanine to an exit or exit access.

7. Where hangar bay door exceeds 110 ft. (33.5 m), provide the first exit or exit access within 20 ft. (6.1 m.) of the hangar bay door opening.

8. Personnel doors are permitted in the Aircraft Maintenance Bay door, however they are not considered exits for egress.

3-3.1.10 Draft Curtains

Provide draft curtains in accordance with NFPA 409 and the following requirements. Steel sheeting thinner than 26 gauge (0.455 mm), aluminum, fiberglass reinforced plastic or other plastic materials are not permitted. Fit the curtain tightly against the underside of the roof. Use mineral wool, ceramic fiber or another approved fire stop material to fill steel deck flutes or other gaps through the curtain. Install draft curtains to form rectangular roof pockets. Where structural roof supports extend below the roof or ceiling, install draft curtains on structural roof supports to the extent practical. Construct the bottom edge of the draft curtain at a constant height above and parallel with the finished floor. Draft curtains are not required to extend below the tail height of the aircraft plus the clearance dimension in Table 2-1: Minimum Aircraft Maintenance Bay Clearances.

Provide draft curtains such that d_{min} is the greater of:

- $d_{min} = H_{max}/8$, or
- d_{min} = 4 ft. (1220 mm), and the draft curtain extends at least 1 ft. (305 mm) below H_{min}.

Where:

- d_{min} = Minimum depth of the draft curtain measured down from H_{max} (ft., m).
- H_{max} = Maximum roof height AFF where the draft curtain is installed (ft., m).
- H_{min} = Minimum roof height AFF where the draft curtain is installed (ft., m).

3-3.1.11 Exterior Firefighting Accessibility

Provide suitable exterior fire apparatus access on at least two complete sides of the building. Fire apparatus access is permitted to be around a group of buildings, where those buildings are considered a portion of one building on the same lot as defined by IBC.

Suitable access surfaces include ramps, aircraft parking aprons, automotive parking areas, fire apparatus access roads, and stabilized landscaped areas. Where automotive parking areas are used for fire department access, provide at least one aisle 20 ft. (6.1 m) wide with an adequate turning radius for fire department apparatus.

3-3.1.12 Interior Firefighting Accessibility

Exit and exit access doors from the hangar bay provide building access into the hangar bay for normal structural firefighting operations.

Provide the ability to operate the hangar bay door under emergency conditions. Refer to 3-7.2: Hangar Bay Door Power for requirements.

3-3.2 Exterior Systems

3-3.2.1 Exterior Materials

UFC 3-101-01 recommends that facilities be designed in harmony with the surrounding architecture, judiciously employing the style and character of architecturally significant facilities in the area. Utilize exterior materials and develop a character befitting the size and nature of Aircraft Maintenance Hangars and their location within a typically industrial area near an airfield. Select a color pallet to harmonize with the surrounding architecture. Consider adjacent historical precedent but not to the extent of unwarranted additional cost to the Government.

Provide exterior materials appropriate for the environment at the project location.

3-3.2.2 Exterior Envelope

Provide an exterior envelope per UFC 3-101-01 Chapter 3 Building Envelope Requirements. Construct walls between semi-heated Aircraft Maintenance Bays and adjacent conditioned spaces per requirements for semi-heated spaces in American Society of Heating, Refrigeration and Air Conditioning Engineers (ASHRAE) 90.1 Building Envelope Requirements Tables. Consult UFC 3-101-01 to confirm envelope air barrier testing requirements for Aircraft Maintenance Bays.

3-3.2.3 Exterior Walls

\3\ Provide masonry or concrete impact resistant construction for a minimum height of 10 ft. (3.0 m) above the finished floor for the interior and exterior face of the entire perimeter of the Aircraft Maintenance Bay, except at hangar doors. /3/ This includes the side/end walls, as well as the back wall which typically separates the Aircraft Maintenance Bay from shops and parts repair rooms. Refer also to 3-3.1: Construction, Life Safety, and Fire Fighter Access for fire rating requirements for walls between the Aircraft Maintenance Bays and other spaces.

3-3.2.4 Roof

Provide a roof system in accordance with UFC 3-110-03, except as modified in this paragraph. Aggregate surfaces and vegetative roofs are not acceptable due to FOD prevention concerns at airfields. Do not slope roof toward airfield unless rainwater will be collected at the roof eave and taken below grade to storm water drain system. Do not direct rainwater above grade to the flight line side of the hangar. Slope roof away from hangar doors and aircraft movement areas. Provide fall prevention and/or fall protection in accordance with UFC 3-110-03. Most hangars do not have mechanical

equipment on the Aircraft Maintenance Bay roofs but there may be other equipment such as antenna platforms. Provide path and fall protection for access to all roof mounted lighting and antenna platforms from interior roof access point. Refer to 2-1.6 Solar Glare Hazard Analysis.

3-3.2.5 Windows

Provide exterior windows, skylights, and doors on inhabited portions of the building per UFC 4-010-01. In addition, provide all interior windows and glazed doors exposed to the Aircraft Maintenance Bay with laminated glass designed in accordance with UFC 4-010-01 for the same blast effects as the most severely loaded exterior glazing system. Provide materials appropriate for the environment at project location and warrant material for expected lifespan of the building without any requirements for special maintenance. Provide insect screens with any operable windows.

3-3.2.6 Exterior Doors and Hardware

Security issues may govern over these minimum requirements.

3-3.2.6.1 Exterior Hangar Doors

Refer to 3-10: Hangar Doors for hangar door requirements. Refer to C-10: HANGAR DOOR for guidance on best practices for hangar door selection and design.

3-3.2.6.2 Exterior Personnel Door and Frames

Exterior aluminum doors are to be wide stile type with minimum 5 inches (127 millimeters (mm)) stiles, top rails, and mid rails, minimum 10 inches (254 mm) bottom rails, 3/16 inch (5 mm) wall thickness, welded corner construction.

Exterior hollow metal doors to be galvanized or galvannealed steel, Level 4 and Physical Performance Level A. Exterior hollow metal frames to be galvanized or galvannealed steel, welded, Level 4. Refer to American National Standards Institute/Steel Door Institute (ANSI/SDI) A250.8.

3-3.2.6.3 Exterior Door Hardware

Provide hardware meeting ANSI/BHMA Grade 1 listed in the certified products directory. Coordinate hardware scheduling requirements with Base Staff. The hardware requirements include:

- Hinges - ANSI/BHMA A156.26.
- Locksets - ANSI/BHMA A156.13 Operational and security Grade 1 Series 1000 mortise locks tested to exceed at least 3 times the number of cycles required for Grade 1.
- Exit Devices - ANSI/BHMA A156.3 tested to exceed at least 3 times the number of cycles required for Grade 1.

- Closers - ANSI/BHMA A156.4 tested to exceed at least 3 times the number of cycles required for Grade 1.
- Overhead Stops - ANSI/BHMA A156.8.
- Protection Plates - ANSI/BHMA A156.6 - Kick Plates J102, Armor Plates J101.
- Thresholds - ANSI/BHMA A156.21.
- Weather-strip, Sweeps, Drip Caps - ANSI/BHMA A156.22.

Provide closers with heavy-duty arms at all exterior doors. Provide closers with integral spring stop arms or provide separate heavy-duty overhead stops. Provide thresholds, head and jamb weather-strip (with astragals at pairs of doors without mullions), sweeps with integral rain drips, and overhead rain drips at exterior doors. Provide kickplates at hollow metal doors with closers, and at storage room doors with or without closers. Armor plates are required at doors anticipated to encounter cart traffic.

3-3.3 Interior Systems

Durability is extremely important when specifying materials for interior construction and finishes. Aircraft Maintenance Hangars are often occupied 24 hours per day, seven days a week and heavy equipment is regularly handled throughout the facility. Provide durable low maintenance finishes in a limited palette with good appearance retention. Incorporate colors, patterns, and textures which successfully mask minor abrasions and day-to-day soiling between cleaning. Provide finishes that are easily repairable if and when necessary. Provide corner guards if using gypsum board in corridors and other high traffic areas. Provide finishes to incorporate LEED criteria, with low and no VOC adhesive and paint finishes, walk off mats for increased indoor air quality, with highest recycled content as is feasible for the project, and other environmentally sensitive features and benefits.

3-3.3.1 Resilient Flooring

At a minimum, provide durable Class I monolithic vinyl tile resilient flooring resistant to stains and scuffing, able to stand up to high foot traffic and requiring minimum maintenance.

3-3.3.2 Interior Partitions

Extend partitions up to the bottom of the floor/roof construction above for the following areas:

- Commanding Officers Office
- Executive Officers Office
- Conference or Briefing Rooms
- Classrooms or Training Rooms
- Rooms or offices with secure communication systems

- Corridors
- Perimeter of toilet and locker room areas
- Offices and operational spaces where privacy issues are of significant concern
- Flight planning
- Maintenance Shops

Refer to 3-3.3.3: Acoustics for additional requirements. Provide a wall base on all walls in spaces with an applied floor finish.

3-3.3.3 Acoustics

Provide acoustics per UFC 3-101-01 unless superseded by other criteria or the STC ratings listed in individual Functional Room Data Sheets as the basis for the sound attenuation design of the partition, door and window assemblies for the facility.

Hangar maintenance bays and maintenance shops can be high noise areas. Prevent sound from the exterior and sound from these and other noisy spaces such as corridors, toilets, elevator, machine rooms, and mechanical rooms from having negative impact on the adjacent spaces.

3-3.3.4 Floors

Provide floors per 3-4.2: Ground Floors.

3-3.3.5 Ceilings

The following spaces may have exposed ceiling structure:

- Hangar Bay
- Maintenance Shops
- Corridors (Ground Level) and Stairs
- Building Support Spaces

Provide finished ceilings in all other spaces. Refer to Finishes. Typical minimum finished ceiling height to be 9 ft. (2.74 m) unless otherwise indicated. Coordinate minimum hook heights for overhead cranes and hoists with MEP and Structural building systems when setting floor to floor and floor to roof heights to ensure a safe working environment for occupants in those spaces.

3-3.3.6 Interior Doors and Hardware

Security issues may govern over these minimum requirements.

3-3.3.6.1 Interior Hollow Metal Doors and Frames

Interior hollow metal doors are to be Level 3 and Physical Performance Level A. Interior hollow metal frames are to be welded Level 3. Interior hollow metal doors between Aircraft Maintenance Bays and shop spaces and other areas subject to high abuse are to be Level 4 and Physical Performance Level A, with Level 4 welded frames. Interior hollow metal doors at administrative areas may be Level 2 and Physical Performance Level B, with Level 3 frames. Refer to ANSI/SDI A250.8. Provide fire resistant assemblies where required to meet fire ratings. Provide fire-rated glazing door vision panels where required in this UFC. Meet ASTM E90 where acoustical door assemblies are specified.

3-3.3.6.2 Interior Wood Doors

Provide Heavy Duty, Type II, Particle Core, PC-5 or PC-7 interior wood doors. Provide fire resistant composite cores where required to meet fire ratings. Provide wood blocking as required to eliminate the use of through bolts for hardware mounting at fire-resistant composite core doors. Provide Premium "A" Grade veneers using Plain Sliced Red Oak as a minimum standard at wood doors. Provide edge veneers to match face veneers. Provide wood doors prefit, beveled, and factory machined for mortise hardware including pilot holes for hinges screws. Refer to WDMA I.S.1-A and AWS Section 9. Provide factory finished wood doors utilizing WDMA finish system TR-6 as a minimum standard. Meet ASTM E90 where acoustical door assemblies are specified.

3-3.3.6.3 Interior Door Hardware

Provide hardware meeting ANSI/BHMA Grade 1 listed in the certified products directory. Coordinate hardware scheduling requirements with Base Staff.

The hardware requirements include:

- Hinges - ANSI/BHMA A156.26 Full mortise continuous aluminum at Level 4 doors.
- Hinges - ANSI/BHMA A156.1 Heavy weight ball bearing type at Level 2 and 3 metal doors and wood doors with closers, overhead stops, or sized larger than 3'0" x 7'0".
- Hinges - ANSI/BHMA A156.1 standard weight ball bearing type at wood doors without closers or overhead stops, sized 3'0" x 7'0" or smaller.
- Locksets - ANSI/BHMA A156.13 operational and security Grade 1 Series 1000 mortise locks tested to exceed at least 3 times the number of cycles required for Grade 1.
- Locksets - ANSI/BHMA A156.2 Grade 1 series 4000 per are allowable at administrative spaces. Locks tested to exceed at least 3 times the number of cycles required for Grade 1.
- Exit Devices - ANSI/BHMA A156.3 tested to exceed at least 3 times the number of cycles required for Grade 1.

- Closers - ANSI/BHMA A156.4 tested to exceed at least 3 times the number of cycles required for Grade 1.
- Protection Plates - ANSI/BHMA A156.6 Kick Plates J102, Armor Plates J101.

Provide exit devices on door at rooms containing explosives (Paraloft, Flight Gear, and Ordnance). Provide kickplates at all doors with closers and at all storage rooms with or without closers. Armor plates are required at doors that are anticipated to encounter cart traffic.

3-3.3.7 Casework

Specify Architectural Woodwork Institute (AWI) Premium or Custom for construction and finishes per AWI Quality Standards Illustrated, Current Edition. Provide veneer panel core casework, cabinet doors and drawer faces. Provide plastic laminate or better finish on all exposed surfaces of the casework must. Provide solid composite plastics countertops, unless otherwise indicated or requested.

3-3.3.8 Signage

Provide signage per UFC 3-120-01, in Aircraft Maintenance Bay to explain operation of significant building features and limiting factors for hangar door operation. For example, locate a sign near the controls of hangar doors explaining proper operation. Similarly, provide signage near the maintenance control office to explain items such as maximum slab loads, jacking loads, use of ventilation system, operation of the fire protection system, and lighting controls. Develop a comprehensive signage package (both interior and exterior) that addresses way-finding and definition of all spaces within the facility. Provide signage to reflect and complement the environment through colors, images and materials used.

3-3.4 Finishes

3-3.4.1 Ground Level

3-3.4.1.1 Aircraft Maintenance Bay

\2\ Slope Aircraft Maintenance Bay floors to prevent liquid spills from flowing into adjacent areas in compliance with NFPA, IBC, and ABA. Provide a reflective light-colored 5-coat fuel resistive resinous flooring with striping of safety lanes, lead-in lines, nose gear stop lines, grounding points, and other safety markings. Floor color coating is typically light gray to reflect and contrast sharply with foreign objects and small parts and enhance visibility of such items. Although light gray is recommended, other colors may be used as local needs dictate as approved by the user. Coordinate colors, striping and grit level with the users. Provide a grit level meeting OSHA slip resistance requirements. /2/

Provide painted masonry, or concrete construction to a minimum of 10 ft. (3.0 m) Above Finished Floor (AFF) around perimeter of Aircraft Maintenance Bays except at hangar door. Refer to 3-3.1: Construction, Life Safety, and Fire Fighter Access for fire rated

separations between the Aircraft Maintenance Bay and other spaces. A wall base is not required in the hangar bay.

3-3.4.1.2 Maintenance Administration

Provide resilient flooring, painted walls, resilient base, and suspended acoustical ceiling systems. Partitions separating administrative spaces may be gypsum board on metal stud construction. Partitions may extend to above the ceiling for similar office types and spaces where noise between offices is not an acoustical issue.

3-3.4.1.3 Heavy Maintenance Shops

\2\ Provide a reflective light-colored, 5-coat fuel resistive resinous flooring system with striping for safety markings. Floor color coating is typically light gray to reflect and contrast sharply with foreign objects and small parts and enhance visibility of such items. Although light gray is recommended, other colors may be used as local needs dictate as approved by the user. Coordinate colors, striping and grit level with the users. Provide painted concrete or masonry walls up to 10 ft. (3.0 m) minimum around perimeter of each shop. Provide painted exposed ceilings. /2/

3-3.4.1.4 Light Maintenance Shops

Provide resilient flooring or 3-coat fuel resistant resinous flooring. Provide painted gypsum board on metal stud walls and suspended acoustical ceiling systems. Provide static dissipative flooring in electronics, avionics, paraloft, flight gear, ordnance shops and other spaces as required by the user.

3-3.4.1.5 Storage

Provide sealed concrete floors, painted masonry or concrete walls, painted exposed ceilings.

3-3.4.1.6 Personnel Support

Provide porcelain tile floors in shower, toilet and locker rooms. Provide painted concrete or masonry partitions around shower, toilet, and locker rooms. Provide full-height or wainscot-height ceramic or porcelain tile at "wet" walls, at a minimum. Provide moisture-resistant gypsum board or moisture-resistant suspended acoustical ceiling system.

In support spaces such as break rooms provide resilient flooring or seamless resinous flooring, painted gypsum board walls and suspended acoustical ceiling system.

3-3.4.1.7 Building Support

Provide sealed concrete floors and painted masonry or concrete walls and unpainted exposed bottom of floor/roof construction above.

3-3.4.1.8 Corridors

Provide flooring equal to the most durable finish provided in the spaces served by the corridor. Provide 5-coat fuel resistive resinous flooring in corridors providing indirect access to heavy maintenance shops. Provide resilient flooring or 3-Coat fuel resistive resinous flooring in corridors serving light maintenance shops. Provide sealed concrete or resilient flooring in corridors serving only personnel and building support spaces. Provide painted concrete, masonry or impact resistant gypsum board walls, resilient base, and suspended acoustical ceiling systems. Provide full-height corner guards at all exterior corners, including columns.

3-3.4.1.9 Stairs

In stairs, provide resilient flooring and stair accessories, painted concrete, masonry or impact resistant gypsum wall board up to a minimum of 8 ft. (2.44 m) above stair level.

3-3.4.2 Upper Level

Finish upper level spaces similar to commercial office spaces.

3-3.4.2.1 Operational Administration

Provide carpet tile, resilient base, painted gypsum board walls and suspended acoustical ceiling systems.

3-3.4.2.2 Personnel Support

Provide porcelain tile floors and painted gypsum board walls. Provide ceramic tile wainscots at toilet, shower, and locker rooms. Provide full-height ceramic tile wall finishes on all walls in showers or similar 'wet' spaces. Provide moisture-resistant gypsum board or moisture-resistant suspended acoustical ceiling system in toilet, shower and locker rooms.

In support spaces such as break rooms provide resilient flooring or seamless resinous flooring, resilient base, painted gypsum board walls and suspended acoustical ceiling system.

3-3.4.2.3 Building Support

Provide sealed concrete floors and painted gypsum board walls and unpainted exposed bottom of floor/roof construction above.

3-3.4.2.4 Corridors

Provide resilient flooring or carpet tile, painted impact resistant gypsum board walls, resilient base and suspended acoustical ceiling systems.

3-3.4.3 Protective Coatings

Paint all non-prefinished items per requirements below.

- Shop coat exposed exterior ferrous metal primary and secondary steel framing per UFGS 09 97 13.27. Coat all other exposed exterior ferrous metal per 09 90 00, Division 5: Exterior Metal, Ferrous and Non-Ferrous Paint Table.
- Shop coat all exposed and non-exposed ferrous metal of hangar doors per UFGS 09 97 13.27.
- Shop coat exposed interior ferrous metal primary and secondary steel framing inside Aircraft Maintenance Bays per UFGS 09 97 13.27. Coat all other exposed interior ferrous metal inside Aircraft Maintenance Bays per UFGS 09 90 00, Division 5: Interior Metal, Ferrous and Non-ferrous Paint Table.
- Coat exposed interior ferrous metal in spaces other than Aircraft Maintenance Bays and Building Support spaces as defined in 3-3.4: Finishes per UFGS 09 90 00, Division 5: Interior Metal, Ferrous and Non-ferrous Paint Table.
- Coat exposed interior ferrous metal in Building Support spaces as defined in 3-3.4: Finishes at a minimum with primer coat only per UFGS 09 90 00, Division 5: Interior Metal, Ferrous and Non-ferrous Paint Table.
- Coat non-exposed interior ferrous metal at a minimum with a primer coat only per UFGS 09 90 00, Division 5: Interior Metal, Ferrous and Non-ferrous Paint Table.
- Coat other interior substrates such as gypsum board, concrete, masonry and wood per UFGS 09 90 00.
- Provide 5-coat fuel resistive resinous flooring at the Aircraft Maintenance Bay and heavy maintenance shops and associated corridors per UFGS 09 67 23.16. Provide striping of safety lanes, lead-in lines, nose gear stop lines, grounding points, emergency eye wash fixtures, fire extinguishers and other safety markings. Coordinate colors, striping and grit level with the users. Provide grit to meet OSHA Requirements for wet floors. Refer to Chapters 5, 6, and 7 for figures showing Service-specific striping requirements. Follow recommendations in UFGS 09 67 23.16 to coordinate with the structural engineer doing the slab design to provide a below slab vapor barrier, and to design the slab to be as low vapor emitting as possible. Do not use spray-on curing compounds. Specify the manufacturer's Moisture Vapor Reducer coating and just don't use it if the concrete test come in at acceptable vapor emissivity rates.
- Provide 3-coat fuel resistive resinous flooring at light maintenance shops and associated corridors per UFGS 09 67 23.15. Provide striping safety markings. Coordinate colors, striping and grit level with the users. Follow recommendations in UFGS 09 67 23.15 to coordinate with the structural engineer doing the slab design to provide a below slab vapor barrier, and to design the slab to be as low vapor emitting as possible. Do not use spray-on curing compounds. Specify the manufacturer's Moisture Vapor

Reducer coating and just don't use it if the concrete test come in at acceptable vapor emissivity rates.

3-3.5 Elevators

Provide an elevator car of size and arrangement to meet ABA Accessibility requirements and to accommodate an ambulance stretcher. Provide elevators in accordance with NAVFAC ITG 2013-01 Elevator Design Guide or superseding Elevator UFC when published.

3-3.6 Bird Intrusion Prevention

Coordinate accepted intrusion prevention measures with environmental office for host facility. Design intrusion prevention systems to not restrict access to building systems. Design all access required as removable panels that can be removed and replaced with the normal means of access and tools used by maintenance personnel.

3-4 STRUCTURAL

Typical structural systems utilized in Aircraft Maintenance Hangars are described below. Refer to Chapters 5, 6, and 7 for Air Force, Army, and Navy specific applicability and exceptions to this section.

Aircraft Hangars are to be assigned Risk Category III unless the Authority Having Jurisdiction approves a different Risk Category based on the following conditions:

- Aircraft Hangars housing aircraft which are not "high value equipment" may be assigned to Risk Category II.
- Aircraft Hangars that house aircraft with a "mission critical" function, which are required to remain operational, may be assigned to Risk Category IV.

3-4.1 Foundations

Foundations are not to utilize the slab on ground to resist lateral forces. Foundations are to be separated from the slab on ground by an isolation joint. Hairpins or tie beams within the slab on ground are not allowed. Tie beams are allowed if they are completely independent of the slab on ground such as when the tie beams are located below the slab on ground.

3-4.2 Ground Floors

Design ground floors for all loadings anticipated to be supported by the floor system. These loads may include aircraft wheel loads, aircraft tug wheel loads, fire truck wheel loads, fork truck wheel loads, jacking loads, wall loads, and point loads. \1\ Confirm with using activity full range of intended aircraft to be housed within the hangar including whether it is to be used for "dense packing" of multiple aircraft in non-standard use during storms or other events. /1/

Design ground floors to be either deep foundation supported reinforced concrete structural slab (slab supported by deep foundations) or concrete slab on ground (slab supported by the subgrade). Design deep foundation supported reinforced concrete structural slabs in accordance with the structural requirements and criteria of UFC 3-301-01. In the Aircraft Maintenance Bay these structural slabs are also to be designed for the aircraft loads stated in this UFC. Design the slab on ground in the three different areas of the Aircraft Maintenance Hangar as follows:

3-4.2.1 Office/Administration Slabs on Ground

Design slab-on-ground systems for the offices and administration spaces of the hangar facility in accordance with the American Concrete Institute ACI 360R. The minimum thickness of the slab-on-ground is to be 5 inches (127 mm).

3-4.2.2 Shops Slabs on Ground

Design slab on ground systems for the shop spaces of the hangar facility in accordance with the American Concrete Institute ACI 360R. Design the slab for all shop equipment loads, fork truck wheel loads and other applicable wheel loads. The finished floor elevation of the shop spaces to be at or above the highest floor elevation of the Aircraft Maintenance Bay. The minimum thickness of the slab on ground is to be 6 inches (152 mm).

3-4.2.3 Aircraft Maintenance Bay Slab on Ground

Design the Aircraft Maintenance Bay slabs on ground for the minimum wheel loads shown in the Service-specific chapters of this UFC. Design in accordance with the procedure described below.

The Aircraft Maintenance Bay floor will be above the exterior grade and the floor slope will project beyond the face of the building to meet the exterior apron grade. Slope the Aircraft Maintenance Bay floor a minimum of 0.5% (1/16" per foot) towards the flight line door or trench drains (when provided). Additional cross-slopes may be necessary to meet other drainage requirements. Do not slope floors more than 1.5% (3/16 inch per foot).

3-4.2.3.1 Aircraft Maintenance Bay - Slab on Ground Design

Determine the concrete slab on ground thickness for the Aircraft Maintenance Bay in accordance with UFC 3-260-02, utilizing a non-reinforced concrete section with the Service-specific minimum loads shown in this UFC. It is acceptable to design and install reinforcing for temperature and/or crack control but the reinforcing cannot be used to decrease the slab on ground thickness from the calculated non-reinforced slab thickness. If point loads other than wheel loads require a thicker slab section, then reinforcing can be utilized in the area of the point load to keep from increasing the slab thickness for the point load. A typical cross-section is shown in

Figure 3-4: Typical Aircraft Maintenance Bay Slab on Ground Cross-Section. Other criteria is as follows.

- Minimum concrete slab on ground thickness will be 8 inches. Increase slab thickness in 1/2" increments.
- Minimum concrete flexural strength will be 550 pounds per square inch (psi) at 90 days.
- Maximum concrete flexural strength will be 650 psi at 90 days.

  \1\
- In hangar bays that allow for multiple aircraft parking positions, provide a uniform slab on ground design throughout the hangar bay. Do not reduce the slab on ground thickness in areas not subject to the design aircraft wheel loads.
- In single aircraft hangar bays that only allow for parking of one aircraft in one position, slab on ground thickness in areas that are not subject to the design aircraft loads may be optimized or reduced in thickness. Before optimizing the slab, using activity should confirm any additional loads including whether hangar is intended to be used for "dense packing" of multiple aircraft in non-standard use during storms or other events. For Navy Standard Hangar Types, variable slab thickness is not permitted per section 7-4.1Aircraft Maintenance Bay - Slab on Ground Loading.
- Where slab is not a uniform design, provide clear markings for special slab areas designated for wheel load paths, jacking, etc.

  /1/
- If welded wire fabric is utilized, it must be provided in flat sheets with a minimum wire size of W4.0.
- Do not use fiber reinforced concrete systems inside the hangar facility without prior approval.

For Navy: Utilize a minimum of 0.05% reinforcing steel in both directions in the aircraft maintenance bay slab on ground.

Figure 3-4: Typical Aircraft Maintenance Bay Slab on Ground Cross-Section

\3

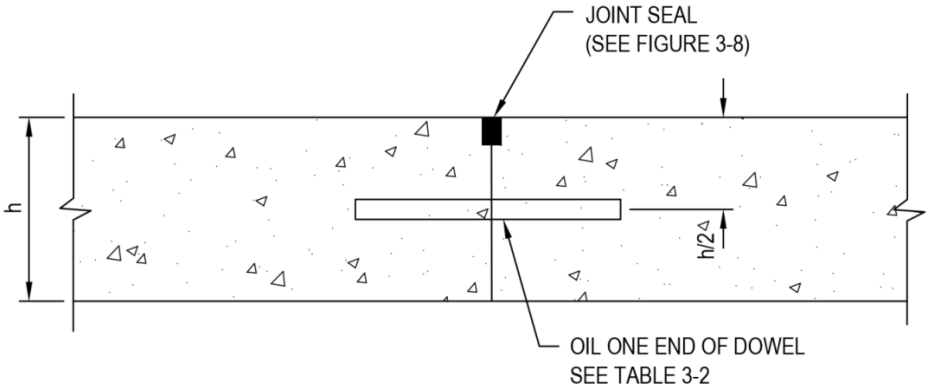
*FUNCTIONS AS A CAPILLARY WATER BARRIER. PUMP OUT EXCESS WATER BEFORE SLAB ON GROUND PLACEMENT.

/3/

3-4.2.3.2 Aircraft Maintenance Bay - Concrete Slab on Ground Joint Spacing

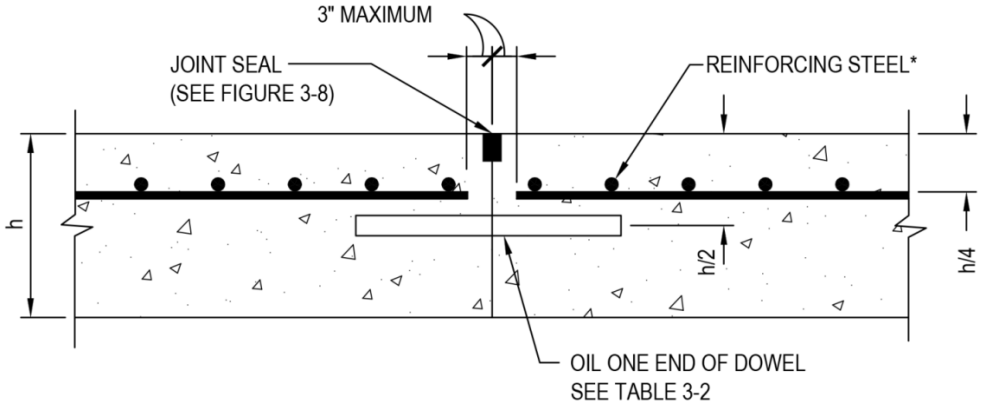
Space the Aircraft Maintenance Bay slab on ground joints in accordance with Table 3-1: Aircraft Maintenance Bay Slab on Ground Joint Spacing. Locate the joints considering the column line spacing while not exceeding the maximums listed in Table 3-1: Aircraft Maintenance Bay Slab on Ground Joint Spacing.

Table 3-1: Aircraft Maintenance Bay Slab on Ground Joint Spacing



SLAB TYPE	CONCRETE THICKNESS* (T) MILLIMETERS (INCHES)	SPACING METERS (FEET)
NONREINFORCED SLAB	205 (8) ≤ T ≤ 230 (9) 230 (9) < T ≤ 305 (12) T > 305 (12)	3.8 TO 4.6 (12.5 TO 15) 4.6 TO 6.1 (15 TO 20) 6.1 (20) MAX
SLAB WITH REINFORCEMENT (MINIMUM 0.05% STEEL IN BOTH DIRECTIONS)	ALL THICKNESSES	7.6 (25) MAX

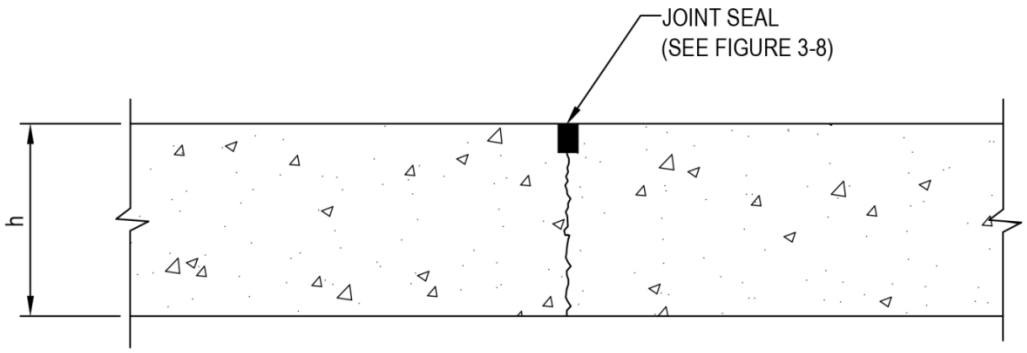
*Minimum thickness allowed is 205 mm (8 inches).



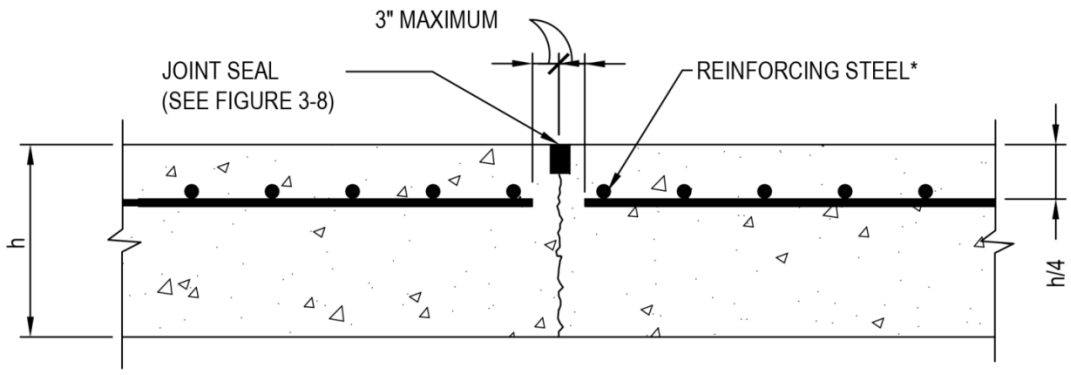
3-4.2.3.3 Aircraft Maintenance Bay - Concrete Slab on Ground Joint Details.

In the Aircraft Maintenance Bay use the following types of joints, joint sealant details and dowels.

Figure 3-5: Concrete Slab on Ground Construction Joint



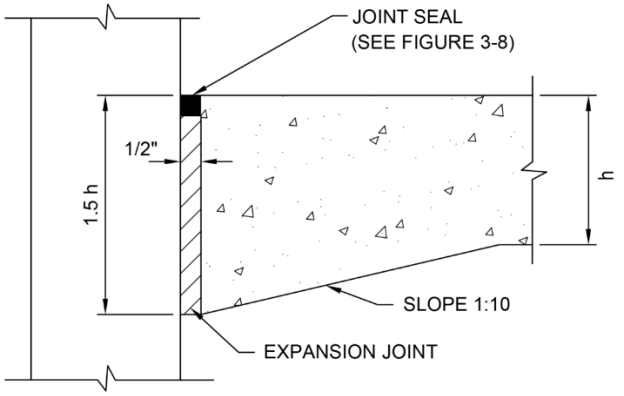
DETAIL A - NONREINFORCED SLAB



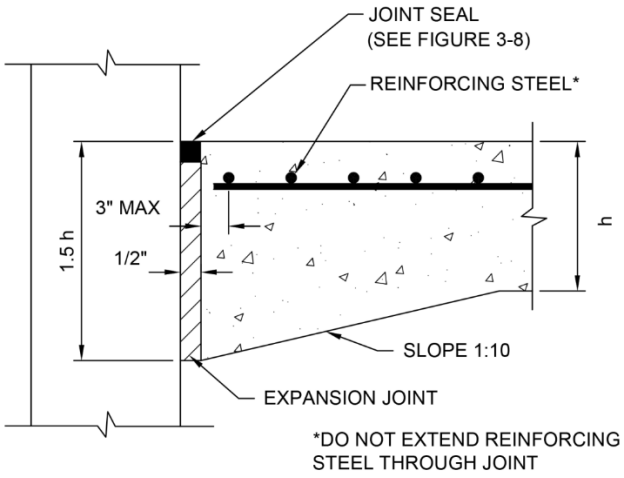
* DO NOT EXTEND REINFORCING STEEL THROUGH JOINT

DETAIL B - SLAB WITH REINFORCEMENT

Figure 3-6: Concrete Slab on Ground Contraction Joint



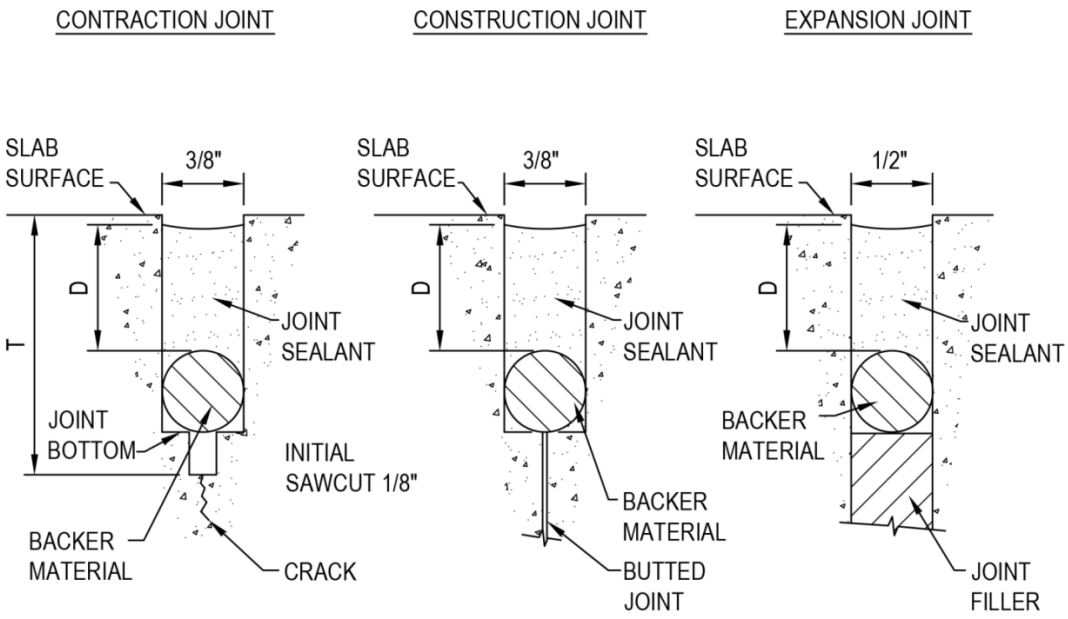
DETAIL A - NONREINFORCED SLAB



* DO NOT EXTEND REINFORCING STEEL THROUGH JOINT

DETAIL B - SLAB WITH REINFORCMENT

Figure 3-7: Concrete Slab on Ground Expansion Joint



DETAIL A - NONREINFORCED SLAB

DETAIL B - SLAB WITH REINFORCMENT

Figure 3-8: Joint Sealant Details for Concrete Slabs on Ground

T = DEPTH OF INITIAL SAWCUT
- a. 1/4 SLAB THICKNESS ± 1/2" FOR SLABS LESS THAN 12 INCHES.
- b. 3 INCHES FOR SLABS 12-18 INCHES.
- c. 1/6 SLAB THICKNESS FOR SLABS MORE THAN 18 INCHES.
- d. DIAMETER OF BACKER MATERIAL = JOINT WIDTH PLUS 1/8 INCH

D = DEPTH OF SEALANT AS REQUIRED BY SEALANT MANUFACTURER

NOTE: TOP OF SEALANT TO BE 1/4" TO 1/16" BELOW TOP OF SLAB

CONVERSION FACTORS
METERS = 0.3048xFEET
MILLIMETERS = 25.4xINCHES

Table 3-2: Concrete Slab on Ground Dowel Size and Spacing

CONCRETE SLAB THICKNESS IN INCHES	\2\ MINIMUM DOWEL LENGTH IN INCHES /2/	\2\ MAXIMUM DOWEL SPACING IN INCHES /2/	DOWEL DIAMETER AND TYPE
8 TO AND INCLUDING 11.5	16	12	1 INCH BAR
12 TO AND INCLUDING 15.5	20	15	1 TO 1-1/4 INCH BAR
16 TO AND INCLUDING 20.5	20	18	1-1/4 TO 1-1/2 INCH BAR
21 TO AND INCLUDING 25.5	24	18	2 INCH BAR
OVER 26	30	18	3 INCH BAR

3-4.2.3.4 Aircraft Maintenance Bay - Slab on Ground Floor Heating

For slabs on ground with in floor heating, provide the following:

- A minimum 0.06% distributed reinforcement in each direction.
- Slab on ground thickness to be at least the depth of slab calculated by procedure described in this UFC, plus the additional depth of the radiant tubing.
- Under slab insulation as required by mechanical calculations for R value with sufficient strength to support the design loads without permanent deformation. Insulation to be placed under slab wherever there is radiant

floor tubing. Refer to ACI 360R-10, Chapter 13 for additional guidance on under slab insulation.

- Coordinate closely with the in-floor radiant heat systems supplier on the design of the hangar floor slab, location of insulation, location of radiant tubing and radiant tubing manifolds within the slab on ground.

3-4.3 Superstructures

3-4.3.1 Aircraft Maintenance Bay

Traditionally, the superstructure of the Aircraft Maintenance Bay is steel framed, however, alternate framing systems can be considered with approval. Design Pre-Engineered Metal Building systems to the standards applicable to traditional steel framing, including adherence to all requirements of the American Institute of Steel Construction and this UFC.

Design the aircraft maintenance hangar in accordance with UFC 4-010-01. Aircraft Maintenance Hangars are generally considered "inhabited" buildings due to the occupancy and population density within the administration and office areas. However, the Aircraft Maintenance Bay may be considered "low occupancy" buildings if it meets all the requirements of UFC 4-010-01.

3-4.3.2 Aircraft Maintenance Bay Superstructure and Hangar Doors

Design the sliding hangar door guide systems to allow total roof live load deflection. Coordinate the total anticipated roof deflection with the door guide manufacturer to ensure that the design stroke of the hangar door guides is not exceeded. Show on the construction documents the expected maximum deflection, both upward and downward, as well as the allowable deflection of the hangar door guide system. For cantilever roof systems, design the hangar door guide system to have adjustment capability to allow for final leveling after all loads are in place.

Design the Aircraft Maintenance Bay superstructure to be compatible with the requirements of the vertical-lift fabric door manufacturer. Show on the construction documents the expected maximum deflection, both upward and downward of the superstructure, as well as the allowable deflection of the Vertical Life Fabric Door (VLFD) framing. Design the VLFD door jamb members to be secondary members, independent of the main structural system, to allow for field adjustment during erection of the building.

3-4.3.3 Administration and Shops Superstructure

If the administration and shops area is constructed as an isolated structure from the Aircraft Maintenance Bay, it may be a bearing wall or frame system of concrete, steel, or reinforced masonry. If the administration and shops area is constructed as an integral part of a steel-framed Aircraft Maintenance Bay structure, the administration and shops structure must be steel-framed.

The framing system selected for the Administration and Shops area will provide areas free from isolated columns. Structural bracing will be located so as not to impair functionality of Administration and Shops areas. Exposed structural bracing will not be permitted in office areas without prior approval.

3-4.4 Main Structural Framing Materials

Select exposed steel shapes to minimize their surface area. Design all exposed steel connections to shed water. Design and detail exposed steel to permit the complete inspection of all fasteners and welds. Seal Hollow Structural Sections (HSS) to keep water from entering the section and animals from nesting inside.

Do not use weathering steel for framing material.

3-4.5 Secondary Structural Systems

Design the walls and partitions of the Aircraft Maintenance Bay to be non-load bearing and not be considered as elements of the lateral load resisting system. The walls of the office/shop portion of the facility may be designed as load-bearing if structurally isolated from the Aircraft Maintenance Bay structure. Limit the use of interior load bearing walls to allow for future reconfiguration of the spaces. Consider the relative stiffness of all wall and partition systems and the main framing and provide for structural isolation as required.

Roof framing system will be a galvanized structural steel roof deck on structural steel members, open-web steel joists or light-gage "Z" purlins. The steel deck cannot be used as a diaphragm for the principal building lateral force resisting system. Utilize horizontal truss or other system for the principal building lateral force resisting system. The steel deck can be utilized to brace secondary members, if the designer can show that there is deflection compatibility between the deck serving as a brace, and the main lateral force resisting system. Provide a positive load path from the steel deck to the structural system, which does not rely on the joist seats or purlins to transfer lateral loads. Properly brace roof framing members for stability during construction and for final configuration.

3-4.6 Strength Requirements

Design for all the loads described in or incorporated by reference to UFC 3-301-01, and for all loads imposed by bridge cranes, suspended work docs, personal fall arrest systems, hangar doors or other specialty equipment supported by the structure. Show all relevant design loading and stability assumptions on the construction drawings. Note elements that function as stability bracing and the members that are laterally unstable until the stability bracing is installed. All instances where the installation of multiple secondary elements is required for the proper stability of a primary element or when a bracing element in turn requires stability bracing.

Design to consider the effect of pattern loads resulting from multiple loaded crane hooks and work docks. All crane hardware and lifted loads will be treated as live loads in the load combinations defined in Chapter 16 of the IBC, except for patented tracks, tracks,

supports, sway braces and similar elements which are immobile and may be defined as dead loads.

3-4.7 Serviceability Requirements

Control deflections of structural elements to within the limits imposed by UFC 3-301-01 unless stricter control is necessary to support equipment, fascia or other appurtenances. Design the Aircraft Maintenance Bay roof and wall structural elements to meet a minimum deflection criteria of l/240. Design the office/shops area structural elements to meet the deflection requirements appropriate to finish type.

Control lateral drift (side sway) of the structure to within the limits imposed by UFC 3-301-01 unless stricter control is necessary for the serviceability of the structure and all its components, including, but not limited to, exterior walls and cladding, partition walls, hangar doors, bridge cranes, utilities and other appurtenances. If the Aircraft Maintenance Bay and the office/shops area framing is constructed as a single frame, design the structure to meet the most stringent requirements described above.

3-4.8 Thermal Requirements

In addition to the thermal loads of UFC 3-301-01, design to account for anticipated differential thermal effects from solar heating (e.g., on long sun-exposed exterior steel compared to shaded steel such as roof trusses, joists, or decking) or inside/outside differences (particularly an "attic" effect in the hangar bay). Consider the local climate conditions when selecting the final differential temperature range. Investigate the deflections caused by differential thermal effects using unfactored loads. Some architectural fascia elements and weather seals around hangar doors are particularly vulnerable to detrimental deflections.

3-5 MECHANICAL

Comply with the requirements of UFC-3-410-01, UFC 3-410-02, UFC 3-410-04N and other applicable UFCs. Additional criteria specific to aircraft hangar mechanical systems is included herein.

3-5.1 Heating, Ventilation and Air Conditioning (HVAC)

\3\ Heating and cooling system design loads for the purpose of sizing systems, appliances and equipment are determined in accordance with UFC 3-410-01. Include analysis of UFC 1-200-02, ICC IGCC, and ASHRAE 55 for thermal environmental conditions for human occupancy in the HVAC design. /3/

Size equipment and all system components to maintain the following indoor design conditions. Provide design conditions, including temperature, humidity, filtration, ventilation, and air changes required.

- Administrative/ Office/Shop cooling: 78ºF (26ºC) dry bulb (db) and a maximum of 55ºF (12.8ºC) dew point. Take into account the moisture gain

in the space. During unoccupied hours, set temperatures no lower than 85ºF (29.4ºC).

- Administrative/ Office/Shop heating: 68ºF (20ºC) db. During unoccupied hours, set temperatures no higher than 55ºF (12.8ºC).
- Aircraft Maintenance Bay heating: 55ºF (12.8ºC) db at 99% db outdoor design temperature. During unoccupied hours, set temperature no higher than 50ºF (10ºC) at 99% db outdoor design temperature. The appropriate unoccupied setpoint temperature depends on the system selected and the designer will take this into consideration when selecting the heating system for the facility. Humidification is not authorized. Take into account infiltration in the hangar bay heating loads.
- Locate HVAC air handling equipment serving administration and shop spaces in dedicated mechanical rooms or on the roof. Locate air handling systems(s) floor-mounted in the mechanical rooms and not within the actual spaces served. Make mechanical room large enough to allow a minimum of 2 ft. (610 mm) between the air-handling unit and the wall, adequate coil pull space, and unobstructed access to replace air filters. Provide additional access/maintenance space in accordance with equipment manufacturer's recommendations.

3-5.2 Heating

The type of heating system depends on the outdoor design temperatures. The options are overhead radiant heat, in-floor radiant heat, or forced-air heat. Conduct a 40-year life-cycle cost analysis to support selection from the heating system choices. Include an analysis of the anticipated user occupancy schedule. Include these results in the design analysis. If floor-type or forced-air heaters are installed, direct the discharged air to cover the entire floor area to help reduce accumulation of combustible and flammable vapors and arranged to draw warm air from the top of the hangar for distribution at occupied level. Provide floor-type heater fans with not less than six air changes per hour based on an artificial ceiling height of 15 ft. (4.6 m). Refer to 3-5.3: Ventilation for ventilation requirements.

\3\ In climates where freezing temperatures occur, protect hangar door tracks or the bottom edges of hangar doors with electric or hot water-glycol snow-melting coils in accordance with NFPA 409. Ensure that non-toxic antifreeze is used, such as propylene glycol, to avoid freezing and environmental spill concerns. Use a sump pump to inject the antifreeze into the system. Provide ratio of antifreeze to water between 30 and 50%, depending on the design temperature, to avoid freezing. If a backup generator is provided, connect snow-melting coils to backup circuit. If a backup generator is not provided, consider alternate emergency operation with external generator hook-up or other means. See 3-7.5 Backup Power for more information. /3/

3-5.2.1 Overhead Radiant Heating

Install gas infrared heaters at the height specified in NFPA 409. Install suspended or elevated heaters not less than 5 ft. (1,524 mm) above the hangar door or lower chord of

the roof truss. Use low-intensity tube-type gas infrared radiant heaters. If the outside air temperature is above 40ºF (4.4ºC) and the hangar door is open, automatically shut off the overhead gas-fired, radiant heating system. If the outside air temperature is below 40ºF (4.4ºC) operate the radiant heating system regardless of hangar door position.

For Air Force and Navy: High-intensity type radiant heaters with open flame or glowing elements are not to be installed.

For Army: Refer to Chapter 6 Army Specific Criteria for use of high-intensity type radiant heaters in Army Aircraft Maintenance Bays.

3-5.2.2 In-Floor Radiant Heating

In-floor, radiant heating systems can be considered in colder climates. They can provide savings on energy and operational costs when compared to conventional heating systems. Refer to 3-4.2.3.4: Aircraft Maintenance Bay - Slab on Ground Floor Heating. Include the efficiency of in-floor, radiant tube systems in the cost analysis of heating systems.

3-5.2.3 Humidification

For administration and shop spaces, where the indoor relative humidity for comfort heating is expected to fall below 20%, add humidification to increase the indoor relative humidity to 30%. Coordinate with the architect to design the building envelope to prevent condensation in the wall/roof systems during the time humidification is in operation. Include in the design analysis a dew point analysis profile (ASHRAE Fundamentals Chapter 23) for winter design conditions, showing condensation boundaries. The dew point analysis will consider the effect of air movement into the walls for buildings under positive pressurization relative to the outdoors.

3-5.3 Ventilation

Provide ventilation in shop administration spaces in accordance with the latest versions of ASHRAE 62 and UFC 3-410-01. This is typically provided by a dedicated outdoor air system (DOAS), which is separated from the space-cooling function. Include infiltration into ventilation system design.

The use of high-volume, low-speed (HVLS) fans or high velocity focused destratification fans can be considered for installation in hangar bays to provide air mixing and create air movement for comfort at the floor level. These are not a replacement for the exhaust system described below. These fans can redirect heat back down to the occupied level, can improve comfort and efficiency, and provide a homogeneous volume of air to reduce concentration of local vapors. Coordinate the installation of fans with overhead radiant heaters, fall protection, high-expansion foam generators, lights, bird netting, bridge cranes and sprinklers. Coordinate with sprinklers in accordance with the requirements of NFPA 13.

3-5.3.1 Exhaust

Provide exhaust systems at the heat or contamination sources. Exhaust systems will operate continuously while the building is occupied. Exhaust fans in spaces that are infrequently occupied such as conference rooms and break rooms, can be provided with occupancy sensors or manual switches for operation. Provide energy recovery from exhaust systems in accordance with ASHRAE 189.1. Provide exhaust systems in accordance with ASHRAE and NFPA 90A.

3-5.3.1.1 Rest Room Exhaust

Provide each rest room with an exhaust rate in accordance with the latest version of ASHRAE 62. Restroom exhaust can be combined with janitor's closet exhaust.

3-5.3.1.2 Printer/Copier Rooms Exhaust

Provide printer/copier rooms/areas and break rooms with a dedicated exhaust system. Interlock exhaust systems for printer/copier rooms with the HVAC system serving the area of the building in which the air is being exhausted. Provide minimum exhaust rate in accordance with ASHRAE 62.1.

3-5.3.1.3 Avionics/Electrical Repair Exhaust

Provide a permanently wall mounted local snorkel type exhaust system with articulating arm fume extractor for soldering work stations (if provided). Provide each unit with a stainless steel cabinet, a self-supportive, anti-static flex hose, an energy-efficient fan, and rated for solder use.

3-5.3.1.4 Parts Washers Exhaust

Recommend locating parts washers in separate rooms and not in hangar bays. Provide local exhaust hood above all parts washers. Provide hood size and exhaust rate per the ACGIH Industrial Ventilation Guide. Provide exhaust hood at least 6 inches (152 mm) larger in all horizontal dimensions than the parts washer surface. Size exhaust airflow to provide a capture velocity of between 75 and 100 feet per minute (0.38 and 0.50 meters per second). Locate the exhaust hood at least 36 inches (900 mm) above the parts washer.

3-5.3.1.5 Hangars Exhaust

Ventilate the hangar bay at a general rate of 0.5 cubic feet per minute (cfm)/square feet (2.54 liters/sec/m^2) when aircraft maintenance activities are being conducted for the purposes of odor and fume mitigation. Include ventilation exhaust fans with the exhaust ductwork extended down to a height of 8 ft. (2.5 m) above the hangar floor or lower along the back wall opposite the hangar doors. Install intake louvers with motorized dampers above the hangar doors or in adjacent walls to interlock with the exhaust fans. Refer to the Army Chapter for additional ventilation and exhaust criteria for Army hangars.

3-5.3.1.6 Repair and Maintenance Areas Exhaust

Provide general exhaust in weapons vault and non air-conditioned repair and maintenance areas at a minimum rate of 0.5 cfm/square foot (2.54 liters/sec/ $m^{2)}$ for purposes of odor and fume mitigation. Provide weapons vault with non-sparking exhaust fans, and all exhaust ducted to the exterior of the building. Operate exhaust systems continuously while the building is occupied. Direct exhaust outside through the roof to eliminate possibility of creating nuisances/hazardous situations to personnel at ground level. If Life Cycle Cost effective, include air quality monitoring to reduce the ventilation when it is not otherwise required.

3-5.3.1.7 Specialized or Localized Exhaust

Provide specialized or localized exhaust in shop spaces where indicated or required.

\2 If a battery maintenance shop is required, see UFC 3-520-05 for additional requirements. Lithium-Ion battery maintenance requires significant space and mechanical systems. ***/2/***

For Navy: 7-14.5: Functional Data Sheets for Navy Functional Data Sheets.

Comply with applicable OSHA standards and end user requirements where maintenance operations include working with heavy metals, grinding, sanding, and working with chemicals.

3-5.4 Air Conditioning

The following criteria applies to air conditioning of rooms within the maintenance hangar facility:

- Do not air condition hangar bays unless required for certain aircraft and their maintenance procedures. Verify and coordinate with end user and Facilities Requirements Document (FRD).
- Certain UAS/RPA aircraft have internal avionics systems that are sensitive to high temperatures and can alarm when the inside temperature gets up to 110ºF (43.3ºC) while the aircraft is inside the hangar during maintenance operations. These aircraft may also have fuel systems that need to be maintained below a certain temperature. A conditioned hangar bay can be provided for these aircraft in accordance with the requirements of the aircraft. In dry, arid climates, evaporative cooling systems can meet this requirement and should be evaluated in lieu of air conditioning.
- Provide air conditioning for all maintenance shops and for those functional areas where it is required for quality control of equipment, material, and task.
- Serve shop spaces with a separate air handling/air conditioning system from the administration type spaces.

- Administrative and shop areas will have positive pressurization with respect to the hangar bay area. Administrative areas will have positive pressurization with respect to shop areas.

Where the fire alarm equipment cannot be located in a normally occupied conditioned space as required by UFC 3-600-01 and 3-6.19.2.2 Location of Releasing System Components because this space does not exist (E.g. an Alert Shelter with minimal support space), condition the room housing the fire alarm equipment to meet the conditions defined in 3-6.19.2.2 Location of Releasing System Components.

The following air conditioning system design considerations apply to critical, high-density heat load spaces, such as server rooms and computer rooms, which contain critical equipment that is sensitive to high temperatures:

- Provide redundant cooling units. Ensure that if one cooling unit goes down, the remaining unit(s) can provide cooling for at least 75% of the load.
- Provide a high space temperature alarm that will notify the Energy Management Control System (EMCS).
- Provide condensate pumps in the cooling units if the condensate from the cooling units cannot gravity drain to a nearby drain.
- Depending on the outdoor design conditions, provide a humidifier in each cooling unit for winter humidification of the space.

3-5.5 Plumbing

Provide plumbing in accordance with UFC 3-420-01.

Provide a drainage system for hangar door mullion pits and sliding hangar door tracks.

For Air Force: Connect drainage system to sanitary or storm sewer based on requirements for other building drainage system and as required by Base Environmental Office.

For Army and Navy: Connect drainage system to industrial waste or storm or sanitary sewer based on requirements for other building drainage systems as required by Base Environmental Office.

3-5.5.1 Emergency Showers and Eye Wash Stations

Provide emergency shower/eye wash stations in hangar bay, pneudraulics repair, and shop areas where chemicals, oils, solvents or debris can be sprayed or blown into eyes, or spilled on clothing. Supply tepid water to emergency showers and eyewashes. Provide emergency showers and eyewashes in accordance with ANSI Z358.1 and OSHA standard 1910.151(c) and UFC 3-420-01. Floor drains at emergency shower eye wash stations can be provided if desired by the users, however they are not required.

Do not install floor drains adjacent to emergency shower eye wash stations for Air Force hangars.

3-5.5.2 Wall Hydrants and Hose Bibbs

Provide exterior wall hydrants on perimeter walls of building with a maximum spacing of 100 ft. (30.5 m). Provide freeze-proof exterior yard hydrant in mechanical yards containing chillers, condensers, condensing unit, and cooling towers. Provide all hydrants with a vacuum breaker to prevent back flow.

Provide a hose bibb in all mechanical rooms. Provide hose bibbs with a vacuum breaker to prevent back flow.

3-5.6 Water and Sewer

Size domestic water piping per ASHRAE and international plumbing code. Size the domestic water heating system with storage and recovery for delivery of hot water to every fixture per ASHRAE and international plumbing code. Provide usage diversity factor of one for the showers. Size water heater(s) based upon anticipated usage or this diversity factor. Instantaneous water heaters are permissible for remote fixtures. Install floor drains and cleanouts in accordance with the latest version of International Plumbing Code and UFC 3-420-01. Provide floor drains near ice machines, in rooms requiring HVAC condensate removal, restrooms, showers, and mechanical rooms.

Per Energy Independence Security Act (EISA) Section 523 and UFC 1-200-02, evaluate the cost effectiveness of solar domestic hot water.

3-5.7 Industrial Oil/Water Waste

Since hazardous materials are used in the aircraft maintenance process, provide floor drains in the hangar bay spaces or shops/storage rooms that are tied to the station industrial sewer with outlet to an oil/water separator tied to a collection system that will capture and hold these materials for proper disposal. Drainage from interior hangar door trench drains may be included in this system. Design in accordance with all applicable environmental codes. Coordination of the collection system is required with the Base or Station to determine the size of the collection system based on the frequency of evacuating it (such as weekly, bi-monthly, monthly), volume of potential liquid spill, and the size of the site where it is to be located.

Design trench drain system for easy cleanout of oil or other residue. Convey waste to an oil/water separator prior to discharge to the sanitary sewer system. Refer to 3-11.3: Trench Drains.

For Air Force: Do not install floor drains or trench drains in the hangar bay except where explicitly indicated in Chapter 5 Air Force Specific Criteria.

3-5.8 Process Systems

3-5.8.1 Compressed Air

Provide compressed air for all hangar bays and shop spaces. Include a refrigerated air dryer in the compressed air systems. In shops, provide wall-mounted compressed air drops, with lubricator on every wall at spacing of every 25 ft. (7.6 m). In hangar bays, provide compressed air drops, with lubricator, along back wall and side walls at spacing of every 50 ft. (15.2 m). Coordinate with users any requirements for compressed air hose reels in shops and hangar bays.

For Navy: Refer also to Chapter 7: Navy Specific Criteria, 7-14.5: Functional Data Sheets for Functional Data Sheets for specific requirements. **\2** Provide instrument quality compressed air. Size air compressor system to accommodate all tool loads, fuel cell evacuation equipment, fuel vacuum equipment, air pressure cabin leakage tester (APCLT), and any other high-volume, air-driven equipment. Create a loop by connecting the compressed air piping at the end of the system back to the compressed air main. Provide particulate filter, oil removal coalescing filter, air dryer, and receiver tank sized for minimum 10 minute recycle (stop - start) storage time to protect compressor motor from burn-out. Provide a cooler as necessary to limit compressed air temperature to 120F max. Provide high-volume compressed air drops, 150 scfm minimum, for every two hangar bays, minimum 1-1/4” pipe size. Provide 12-inch drip legs for water removal with forged steel globe valves at all risers and throughout the system. Refer to NAVAIR System Specification for the Aircraft Pressurized Cabin Leakage Tester (APCLT) Number PMA260C21/3490/V20. Request air consumption loads from maintenance activity for each piece of air-driven maintenance equipment. If loads are not available for specific equipment, assume 150 scfm and 125 psig per item. Size all compressed air piping per Compressed Air and Gas Institute (CAGI) Handbook with a load factor of 25%.***/2/***

For Army: In hangars, mount compressed air connections on utility pedestals located inside the perimeter access aisle.

3-5.8.2 Preconditioned Air Systems \2\

These criteria provide detailed requirements for the preconditioned air (PCA) system and incorporates lessons learned to ensure PCA systems are fully mission capable. The intent is to make the system accessible, minimize maintenance requirements, and maximize system reliability. Strict adherence to criteria herein is necessary to ensure system functionality and integrity. Provide PCA system in accordance with the requirements of the aircraft. The required flow rate, temperature, pressure, moisture content and particulate content of cooling air at the aircraft connection is specified by the aircraft program documentation and must be confirmed by the end user on a per project basis. See Chapter 4 \3\ AIRCRAFT SPECIFIC REQUIREMENTS for F-35 aircraft cooling air requirements. PCA systems are considered process loads in the building energy compliance calculations.

Provide one PCA unit per aircraft parking position. PCA units are not designed to serve multiple aircraft. Manifolded systems create unnecessary complexity. Do not manifold

units together. If PCA system backup is required, it is intended that the system is supplemented with user provided ground support equipment (GSE). Do not install any valves between the PCA unit and the aircraft. Design and provide PCA system in accordance with UFGS 23 75 15 *Aircraft Pre-Conditioned (PCA) Air System* and the requirements of this UFC.

For Air Force: PCA units are not real property and maintenance is the sole responsibility of the using organization.

3-5.8.2.1 PCA System Operating Procedure

The control points, components, and capabilities specified herein will support the PCA system standard operating procedures (SOP) as follows.

1. Remove dust cap from PCA piping.

2. Start PCA purge mode.

3. Prepare to connect flex duct to aircraft. If present, open manual blow-down valve(s) to purge any trapped condensation.

4. When desired temperature is reached as indicated at temperature gauge, and there is no visible moisture in the pipe, stop PCA purge mode.

5. Connect flexible duct to the PCA pipe and aircraft, then start PCA normal mode.

6. Stop PCA unit, disconnect flexible duct, and replace dust cap.

3-5.8.2.2 Preconditioned Air Unit Location

Locate PCA units and route associated piping above ground and in accessible trenches to minimize the length of flexible duct required between the PCA piping and the aircraft cooling connection. The heat gain and air leakage in insulated flexible duct is much greater than that of insulated rigid pipe. A long hangar with multiple aircraft bays can be served by PCA equipment on each end of the building to minimize PCA pipe length and the time required to cool the system down from ambient temperature. Locate PCA units outdoors in accordance with the requirements of the PCA manufacturer for clearances. If PCA units are located away from the hangar, route exterior piping in a trench with removable covers and a means for drainage. Avoid abrupt turns.

Design PCA equipment and piping supports to minimize vibration and noise levels as recommended by ASHRAE *Practical Guide to Noise and Vibration Control for HVAC Systems*, Second Edition. Do not locate PCA units on roofs above conference rooms, private offices, or training rooms. Do not locate PCA units within 10 feet (3m) of unpaved areas or near potential sources of air particulates/contaminants such as laundry, shop exhaust, sanitary vents, steam traps or relief valves, industrial exhaust, or boiler flue discharge. Locate units in shaded areas where possible.

3-5.8.2.3 Preconditioned Air Unit Maintenance and Airflow Clearances

Provide adequate clearance for PCA unit maintenance and heat rejection in accordance with manufacturer's requirements, OSHA regulations, and standard practices. Periodic maintenance includes changing filters, fan belts, motors, refrigeration components and coil cleaning.

Do not install solid wall enclosures, grates, screens, expanded louvers, or any other impediments to airflow around or above PCA equipment. Equipment may be located within the unobstructed area as defined by UFC 4-010-01 as long as the equipment provides no opportunity for concealment of explosive devices with heights of 6 inches (150 mm) or greater, or the equipment is secured to prevent concealment of the devices. Equipment located within the fenced flight line area is considered secured. If necessary, secure units with chain link fence only. Provide a thru-wall penetration as necessary for ducting a backup cooling cart.

3-5.8.2.4 Preconditioned Air Unit Sizing

Size PCA units for the greatest enthalpy condition when comparing the 0.4% dry-bulb and mean coincident wet-bulb (DB/MCWB) and the 0.4% humidity ratio and mean coincident dry-bulb (HR/MCDB) design conditions using weather data prescribed by UFC 3-400-02. The greatest enthalpy condition usually occurs at the 0.4% HR/MCDB condition. Include PCA pipe and flexible duct heat losses in PCA unit sizing. Use a safety factor of 10% when sizing PCA equipment. Specify PCA unit filtration to meet the aircraft air quality requirements, with a washable pre-filter and MERV-8 final filter.

3-5.8.2.5 Preconditioned Air Piping

Provide welded stainless steel piping suitable for pressures up to 15 psig (416 in. w.g.) for PCA distribution. Perform pipe thermal stress analysis calculations. Piping design including supports must allow and control thermal expansion. Provide bolted and gasketed flanged joints within 18" above the hangar floor and in the trench to preclude the need for hot work in hazardous locations.

A high pressure PCA unit fan can operate at much higher pressures than a typical HVAC fan which allows higher PCA air velocity and pressure. Size air distribution piping using a minimum air velocity of 1,300 ft/min (6.6 m/s). If lower velocity is used, provide a life cycle cost analysis to justify the cost of larger pipe. Assume 50% of PCA units run 40 hours per week.

3-5.8.2.6 Preconditioned Air Pipe Routing

PCA pipe must be routed outside of the crane operating envelope along interior walls and in accessible trenches. Do not route pipe so that it presents a tripping hazard or obstruction in the main circulation aisle between the aircraft and shop spaces. Route the PCA pipe in a trench in the hangar floor from the hangar walls to a flexible duct connection point at each aircraft parking position. Route PCA pipe in a combined trench with other utilities where possible. Routing PCA pipe underground or buried below the

hangar slab is prohibited. All PCA pipe must be fully accessible to allow for repair and replacement. PCA system utility pits are prohibited.

Coordinate PCA pipe and other trenched utilities to ensure PCA pipe is continuously sloped to the flexible duct connection point. Ensure adequate horizontal and vertical clearance to access PCA pipe and other trenched utilities. Provide a mechanical (non-gas) lift-assisted, hinged access cover with safety locking device rated for aircraft loading at each flexible duct connection point. Ensure access hatch weight is no greater than the approved lift weight per occupational safety requirements. PCA pipe must be supported and elevated minimum 6 inches (150 mm) off the bottom of the trench to prevent pipe and insulation from sitting in water and allow insulation to air dry. Slope the trench and PCA pipe with a minimum 0.5% grade, towards a recessed flexible duct connection point. Show PCA pipe slope requirements on drawings. \3\ PCA pipe must turn up and terminate within 6” of the hangar floor for ergonomic access to duct connection without entering the trench. Provide a manual blow-down valve at all PCA pipe low points to allow drainage of any trapped condensation. Provide a handle extension within 6” of the hangar floor so the blow down valve is operable without entering the trench. /3/

For Navy: PCA pipe and fire protection pipe must be in a combined trench. Fire protection pipe is an “other trenched utility” that must be coordinated with PCA pipe as described in this paragraph.

3-5.8.2.7 Preconditioned Air Flexible Duct and Accessories

\3\ Provide a quick-connect system at the connection between PCA piping and flexible duct. Provide 45-degree hard adapters to prevent kinking of flexible hose. Provide a minimum 6-inch (150 mm) diameter insulated flexible hose with a mobile basket or reel to connect from the PCA pipe connection to the aircraft PCA connection in accordance with UFGS 23 75 15 *Aircraft Pre-Conditioned (PCA) Air System*. Provide tapped mechanical temperature and pressure gauges in the PCA pipe immediately upstream of the flexible duct connection point. Provide a water tight, soft rubber cover with lanyard to protect the flexible duct connection opening while not in use. /3/

3-5.8.2.8 Preconditioned Air Pipe Insulation and Jacket

Provide PCA pipe with factory applied insulation. Provide pipe with water-tight embossed aluminum or high density polyurethane (HDPE) insulation jacket to prevent water from hangar floor wash down, foam system activations, and fuel spills from degrading the insulation or infiltrating the pipe. Perform heat transfer calculations. PCA system insulation must be specified to ensure no more than a 5 °F temperature rise between the PCA unit discharge and the aircraft connection at design conditions. Include heat gain within PCA pipe, fittings, and flexible duct in calculations. Heat gain calculations must use the 1.0% DB/MCWB conditions using weather data prescribed by UFC 3-400-02.

Perform a separate calculation determining the length of time it will take the system to achieve aircraft cooling air input specifications from a steady-state ambient condition. The ambient condition is defined as all piping, fittings, and flexible duct at the 0.4%

outdoor design dry-bulb outdoor air temperature. Thirty (30) minutes is the maximum allowed time duration to deliver required PCA temperature, moisture content, pressure and airflow at the aircraft connection from ambient condition. Perform calculation under low-pressure purge mode conditions.

3-5.8.2.9 Preconditioned Air Unit Controls

The PCA is considered a critical support system, and the controls must be designed for "least functionality" per UFC 4-010-06. PCA units must be provided with a low pressure purge mode for initial cool down of the system. Provide one remote control panel per PCA unit along the hangar back wall at each aircraft location with start button, stop button, purge mode start button, unit run status, alarm indication, and digital display of PCA unit discharge temperature (°F), humidity ratio (gr/lb), pressure (psig), and flow rate (lb/min). Provide each remote control panel housed in a gasketed NEMA Type 3R enclosure.

Provide a digital touchscreen control panel integral to each PCA unit capable of displaying the unit run status, alarms, discharge temperature (°F), humidity ratio (gr/lb), pressure (psig), and flow rate (lb/min). PCA unit set points must be adjustable at the PCA unit without the need for proprietary control interfaces, dongles, or removable operator interface terminals. PCA unit status and performance data may be monitored by the base EMCS system with expressed approval from the installation.

3-5.8.2.10 Preconditioned Air Unit Testing and Commissioning

Manufacturer's testing, field performance testing, endurance testing, and season of maximum load performance testing requirements must be performed in accordance with UFGS 23 75 15 *Aircraft Pre-Conditioned (PCA) Air System*. Provide pressure/temperature test ports in the piping immediately downstream of PCA units. ***/2/***

3-5.9 Energy Management System

3-5.9.1 HVAC Control

Follow the mandatory requirements of the section titled "Controls" of ASHRAE 90.1 as modified below. Provide all air distribution systems capable of shutdown to meet the requirements of Standard 18 of UFC 4-010-01.

3-5.9.2 Control Protocol

For Air Force, Navy and Marine Corp: ASHRAE's BACnet® protocol is the preferred control system architecture facilities. Design and construct Facility HVAC control systems based on the BACnet® protocol in accordance with ANSI/ASHRAE Standard 135 and UFGS 23 09 23.13 20.

For Army: LonWorks® protocol is the preferred control system architecture for facilities. Design and construct facility HVAC control systems based on the LonWorks® (American National Standards Institute/Consumer Electronics Association (ANSI/CEA)-

709.1 and related technologies) in accordance with UFC 3-410-02 and UFGS 23 09 23.01.

3-5.9.3 Networked Controls

Prior to designing the DDC system, confirm whether an existing energy management network is available for interface on the Base. Provide DDC equipment that is compatible with existing systems to the maximum extent practicable. Where use of a specific DDC system is mandatory, the Government will provide a Justification and Authorization (J&A) for the utilization of proprietary DDC equipment.

3-5.9.4 Minimum Control Points

Provide the ASHRAE's BACnet® protocol with a control system with at least the minimum points as indicated in UFC 3-410-01 Appendix D. Minimum control points for Lonworks® protocol systems are provided in UFC 3-410-02.

3-5.9.5 DDC Accreditation

Provide hardware equipment utilizing the latest technology which will accomplish the desired control and will meet the Risk Management Framework (RMF) for DoD Information Technology (IT) Process.

3-5.9.6 DDC Training

Require the DDC installer to provide training for government facility personnel on all new DDC equipment.

3-6 FIRE PROTECTION AND LIFE SAFETY

3-6.1 General and Service Requirements Applicability

Provide a building and systems in accordance with UFC 3-600-01 except where additional requirements are added by this UFC. Use NFPA 409 only where explicitly noted. If there is a conflict, this UFC supersedes UFC 3-600-01 and NFPA standards. Where required, provide specifically listed or approved components and assemblies used in this fire protection system and subsystems by a NRTL.

Hangar construction funded by a specific Service for their use on installations under the management control of another service will follow fire protection requirements of the funding service. Hangar constructed for the joint/share use of multiple services will follow the installation’s managing service criteria, unless, approval by all the involved services AHJs. New hangar fire protection criteria/features will not be based simply on which service maintains the real Property records or is responsible for the maintenance of the installed features. Existing hangars will not require new fire protection features simply because the principle user changes between services.

3-6.1.1 Fueled and Unfueled Aircraft

To allow for the greatest mission flexibility, protect hangars housing fueled and unfueled aircraft the same in accordance with this UFC. \2\ For Air Force, see additional guidance in Chapter 5-6 FIRE PROTECTION AND LIFE SAFETYor exceptions. /2/

3-6.1.2 UAV or RPA Aircraft

Where required by UFC 3-600-01, protect hangars housing Unmanned Aerial Vehicles (UAV) or Remotely Pilot Aircraft (RPA) in accordance with this UFC.

3-6.2 Construction, Life Safety, and Fire Fighter Access

Refer to 3-3.1: Construction, Life Safety, and Fire Fighter Access of this UFC for additional construction, life safety, and fire fighter access requirements.

3-6.3 Fire Hydrants

3-6.3.1 Fire Hydrant Supply

Supply fire hydrants from the domestic water service, where it can be supported.

3-6.3.2 Fire Hydrant Location

Install hydrants in accordance with UFC 3-600-01, except at modified below:

- Locate hydrants protecting the building at a maximum interval of 300 ft (91 m), unless noted otherwise.
- Hydrants are not permitted in front of the hangar bay door opening. Where the hangar bay door opening exceeds 300 ft. (91.4 m), place a hydrant at each end of the opening.
- Locate at least one hydrant within 100 ft. (30.5 m) of each corner of the building.
- \3\ Where apron pavement abuts the building, locate required hydrants protecting the building in these areas within 10 ft. (3.0 m) of the building./3/
- Install low profile, conventional hydrants, no higher than 2.5 ft. (700 mm) where within 25 ft. (7.6 m) of airfield pavement.
- Flush-mounted hydrants in the pavement are not permitted.

3-6.4 Fire Water Supply

Design the fire water supply to meet the following fire flow demands for the required duration. When the existing fire water supply cannot meet the flow or duration requirements, modify the system or provide an independent fire water supply to meet the requirements.

- Evaluate fire water supply for suppression systems located in support areas outside the hangar bay in accordance with UFC 3-600-01.
- \2\ For High-Expansion (Hi-Ex) foam and Low Level Water only Trench Nozzle systems within the hangar bay, provide a fire water supply to support the combined demand of the hangar bay ceiling sprinkler system and low level foam/water or low level water only fire suppression system for 45 minutes (min.). /2/
- For other suppression system(s) within the hangar bay, provide additional water supply in accordance with NFPA 409.
- Include the demand of the outside hose stream allowance where supplied from the same fire water supply.
- Include domestic and industrial demands where required by UFC 3-600-01.

3-6.4.1 Fire and Pressure Maintenance Pumps

Provide electric or diesel fire pumps as required by UFC 3-600-01.

3-6.4.1.1 Fire Pump Quantity

\2\ Where supplying a single hangar, provide a pump or pumps meeting the total fire water demand. When multiple pumps are required, they must be of equal capacity. A redundant pump is not required.

Where a fire pump house, station, or pump room supplies more than one hangar, provide a pump or pumps of equal capacity meeting the total fire water demand of the most demanding hangar. A redundant pump meeting the size of the largest pump must be provided. /2/

3-6.4.1.2 Fire Pump Capacity

Do not exceed a nominal fire pump rating of 2,500 gallons per minute (gpm) (9,464 liters per minute (lpm)).

3-6.4.1.3 Fire Pump Control

Start the fire pump automatically upon a drop in system pressure in accordance with NFPA 20. Where the drop in system pressure is not significant enough to automatically start the fire pump such as a fire pump installed in parallel with a large domestic water booster pump, provide the fire pump with a remote start signal from the Fire Alarm Control Unit (FACU).

When starting the fire pump, do not exceed ten seconds before the pump is operating at the design pressure.

3-6.4.1.4 Pressure Maintenance Pump

Provide a pressure maintenance (jockey) pump to maintain normal operating pressure on the system. Size and automatically operate the pump in accordance with NFPA 20. Provide pump controller with an adjustable timer to prevent short cycling. Operate pump for the minimum run time recommended by the manufacturer.

3-6.4.2 Fire Water Service Main

Provide ductile iron or non-metallic piping for fire water service mains.

3-6.4.2.1 Piping Materials

Black steel piping is not permitted for installation below grade.

When non-metallic piping is used, use pipe specifically listed for "Fire Service" applications by a NRTL. Non-metallic piping used for fire water distribution such as High Density Polyethylene (HDPE), Polyvinyl Chloride (PVC), and filament-wound fiberglass, is not permitted to be routed above grade or exposed within the building.

3-6.4.2.2 Corrosion Protection

Cover bolts, nuts, rodding, and couplings located below grade with a bituminous coating and wrapped in a minimum 6 mil polyethylene plastic.

3-6.4.2.3 Piping Entrance into a Building Supplying the Foam/Water System

Enter the building in accordance with one of the following entrances. When a remote fire pump house/station is provided, which supplies the foam/water system, comply with one of the following entrances for the fire water piping entering and leaving the fire pump house/station.

- In geographic locations having a 99.6% dry bulb temperature greater than 40ºF (4.4ºC) per UFC 3-400-02 Engineering Weather Data, water service piping is permitted to rise above grade outside the building and enter the building through the exterior wall.
- Enter the building below grade with a continuous section of welded stainless steel fire water service piping from a point outside the building perimeter to a flanged fitting located at least 1 ft. (305 mm) above finished floor within the building. Non-welded fittings are not permitted within this section of piping such as flanges, mechanical couplings, and push-on fittings. Weld and hydrostatically test the stainless steel pipe at the fabrication shop or manufacturer. Welding in the field is not permitted. Perform the hydrostatic pressure test in accordance with NFPA 24. The fire water service piping is permitted below the building slab for this method of installation.

- Enter the building below grade and directly into a concrete pit with open steel grating. For this method of installation, do not install fire water service piping below the building slab. Only welded or flanged fittings are permitted to transition piping from horizontal to vertical within the pit. Where flanged fitting are used within the pit, only flanges that are threaded or welded to the piping are permitted. Provide thrust restraint bracing where the piping transitions from horizontal to vertical. A minimum 2 ft. (610 mm) clearance is required around the piping within the pit. Provide an access ladder and drainage from the pit.

3-6.5 Surge Arrestors

Provide listed or approved surge arrestors for fire protection systems with a minimum rated working pressure of 275 psi (1,895 kiloPascals (kPa)).

3-6.5.1 Surge Analysis

Manufacturer's calculations are required for determining the minimum surge arrestor capacities where the following distances are exceeded from the fire pump discharge to the most remote dry pipe, preaction, or foam/water riser. Include the surge arrestor calculations performed by the manufacturer in the design calculations.

- 1,500 ft. for a system not exceeding a working pressure of 175 psi.
- 1,000 ft. for a system not exceeding a working pressure of 250 psi.
- 500 ft. for a system not exceeding a working pressure of 175 psi, and plastic piping is used such as PVC or HDPE.
- 300. ft. for a system not exceeding a working pressure of 250 psi, and plastic piping is used such as PVC or HDPE.

3-6.5.2 Size and Location

At a minimum, provide the following surge arrestors. Increase the minimum capacities listed below, when manufacturer's calculations are required and demonstrate a large capacity.

- Provide 10 gallons (gal) (38 liters (L)) of capacity for each dry pipe or preaction riser located on the riser manifold supplying a hangar bay.
- Provide 25 gal (95 L) of capacity for each foam/water riser located on the riser manifold supplying a hangar bay.
- For each riser room, combine the surge capacity of the risers in the room into a single common surge arrestor. Where risers feed different fire areas, only use the greatest combined surge capacity from one fire area. Connect this common surge arrestor to the riser manifold immediately upstream of the protected risers.
- Where the fire pump is not located in the same room as the risers it serves, provide 100 gal (380 L) capacity surge arrestors for each fire

pump. Locate this surge arrestor immediately downstream of the isolation valve on the discharge side of the fire pump.

- The cumulative minimum capacity of each required fire pump surge arrestor may be combined into a single common surge arrestor. Connect this common surge arrestor to the fire pump header immediately downstream of the isolation valve on the discharge side of the most remote fire pump.
- Where surge arrestors are 100 gal (380 L) or larger in capacity, provide floor stands.

3-6.5.3 Surge Arrestor Installation

Provide each arrestor with an indicating isolation valve to separate it from the system. Electrically supervise this valve in the normally open position. Provide a drain after the isolation valve to relieve pressure from the surge arrestor during testing and maintenance. When connecting the surge arrestor to the riser, the use of piping, fittings, and valving smaller than the connecting orifice on the surge arrestor is not permitted.

After the surge arrestor is installed and pressurized in the field with nitrogen per the manufacturer's written directions, provide a permanent label indicating the set pressure of the arrestor. Do not pressurize the surge arrestor during hydrostatic testing of the system.

3-6.6 Backflow Prevention

Where backflow prevention is provided for cross connection control, provide piping and fitting materials upstream of the backflow preventer listed for use with potable water systems such as ductile iron, stainless steel, and galvanized steel. Where fire pumps are supplied directly from the domestic water system, install backflow prevention on the discharge side of the pump.

Exception: Backflow prevention may be installed on the inlet side of the fire pump when the following conditions are met with fire pump(s) operating at 150% capacity. The quantity of pumps used in this calculation is the number expected in normal operation to meet the system demand.

- Not less than 20 psi residual pressure at the backflow preventer inlet.
- Not less than 5 psi residual pressure at the fire pump inlet.
- Use outside stem & yoke (OS&Y) valving in the backflow preventer assembly and locate the assembly a minimum of 10 pipe diameters upstream of the pump suction flange.

3-6.7 Fire Protection Equipment Rooms

Locate foam concentrate tanks, pumping equipment, and riser control valves associated with the protection of the hangar bay in a dedicated fire protection equipment room with a minimum 1-hour fire barrier. Although not required, other fire suppression equipment

is permitted within this room such as the wet pipe system for the support area. Locate fire protection equipment rooms housing fire pumps and/or the incoming fire water service at grade with doors providing direct access to the exterior. Where secondary foam proportioning rooms are provided to facilitate the hydraulic design, provide this equipment in dedicated fire protection equipment rooms with minimum 1-hour fire barriers.

3-6.7.1 Equipment Access

Size equipment rooms to provide access for inspection, maintenance, and repair of all equipment. Configure equipment to permit removal of tanks, valves, pumps, and motors without the removal of other components. Provide double doors with adequate clearance for the removal of the largest piece of equipment. Provide metal roll-up doors when double doors are too small to accommodate the removal of equipment. Where equipment is located more than 8 ft. (2.4 m) above the floor and requires access at frequencies 2 years or less for testing and maintenance per UFC 3-601-02, provide an open steel grate mezzanine and permanent ladder meeting OSHA requirements to access this equipment. Chain operators are permitted for opening and closing valves more than 8 ft. (2.4 m) above the floor where not readily accessible from a mezzanine.

3-6.7.2 Temperature Monitoring

In geographic locations having a 99.6% dry bulb temperature less than 40ºF (4.4ºC) per UFC 3-400-02 Engineering Weather Data, provide temperature sensors in fire protection rooms and secondary foam proportioning rooms that have direct access to the exterior. Provide listed/approved fixed temperature sensors set at 32ºF (0ºC). Alarm low temperature conditions at the FACU as a supervisory condition and the Energy Management Control System.

3-6.8 Fire Suppression Pipe

Do not install piping below a concrete slab within the hangar building. Use concrete trenching with steel grating for all piping located below the floor line.

3-6.8.1 Fire Suppression Pipe Labeling

\2\ Mark all exposed interior piping with plastic wrap around-type pipe labels conforming to American Society of Mechanical Engineers/American National Standards Institute (ASME/ANSI) A13.1, Scheme for the Identification of Piping Systems. Indicate the type of fluid carried and direction of flow. Labels that stick-on (adhesive backed) or are held on with straps/adhesive tape are not permitted. Labels are not required on any fire suppression system branchlines regardless of size, or mains and cross-mains less than a nominal 2-1/2 in (64 mm). Labels are not required on piping routed below the floor line in trenches or pits. At a minimum, the following labels are required.

- FIRE PROTECTION WATER - Used on dedicated potable and non-potable fire protection water supply piping.
- FOAM CONCENTRATE - Used on foam concentrate piping.

- FIRE SPRINKLER - Used on water-only sprinkler piping.
- HIGH-EXPANSION FOAM - Used on Hi-Ex foam/water piping. /2/

3-6.8.2 Fire Suppression Drainage

\2\ Route clear water drains to the building exterior and discharge no greater than 2 ft. (0.6 m) above grade. Provide independent atmospheric and pressurized drainage systems, or provide a means of hydraulic isolation between the systems such as a check valve between the cup drain and the main drain. Drains from the Hi-Ex Foam risers will have the ability to be contained and collected. /2/

Provide a splash block below drain discharge, unless discharging to a paved or concrete surface. Do not locate drainage discharge adjacent to an exit door, nor permit drainage discharge to cross the path of egress from the building. Locate drainage discharge to not cause soil erosion when main drain or inspector's test connections are operated during testing.

3-6.8.3 Riser Manifold

Provide separate risers for systems supporting areas outside the hangar bay.

Provide a wye or basket strainer and an isolation valve for maintenance in the piping ahead of foam system risers. Provide strainer baskets with stainless steel mesh sized no greater than 1/4 in (6.4 mm).

For Navy: Do not exceed a mesh size of 1/16 in (1.8 mm).

3-6.8.4 Fire Department Connection

Do not provide fire department connections supplying foam/water systems.

3-6.9 \2\ Foam/Water or Water Only Flow Control Valves

Provide a flow control valve with remote resetting capability for each foam/water system. Provide flow control valve with automatic re-closing feature and adjustable speed control. Where an inductor is used for foam/water proportioning, provided field adjustable pressure reducing trim. Install the manual release for the flow control valve no higher than 5 ft. (1524 mm) above finished floor. For hydraulic calculations, include the manufacturer's minimum pressure drop across flow control valve for the features indicated. ***/2/***

3-6.10 Foam/Water Proportioning System

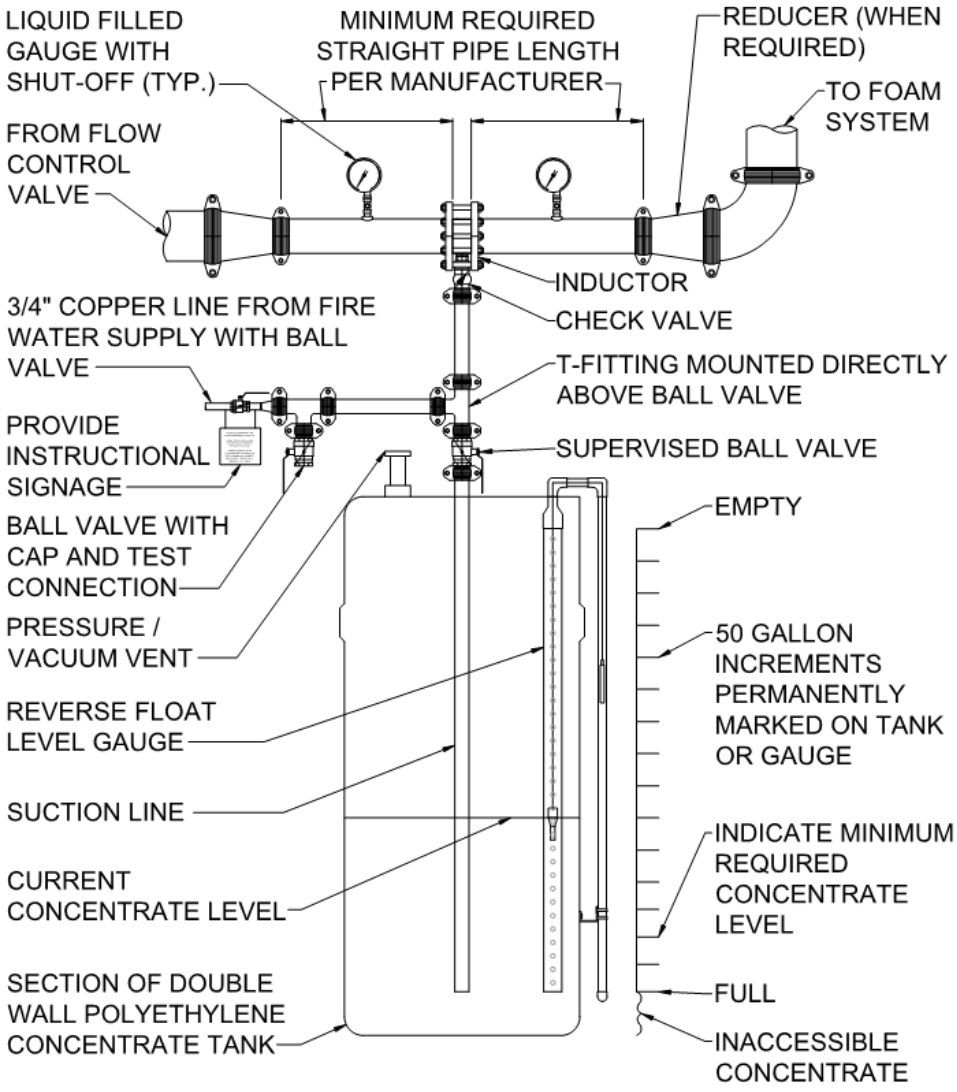
For Army: Refer to Chapter 6 Army Specific Criteria for foam/water proportioning system.

Provide a single foam inductor per foam/water riser meeting the requirements outlined below. Where more than one foam inductor is used, they may take suction from a common concentrate tank. Do not supply more than one fire area from a single inductor.

- Use a venturi to induct concentrate and proportion such concentrate into the flow stream reliably at the design system flow rate.
- \3\ For design calculations, use a pressure drop across the inductor of 42% regardless of the manufacturer’s recommended initial installation stated pressure drop. /3/
- Tune the inductor specifically for the system required flow rate, inlet pressure, back pressure, concentrate type, proportioning ratio, and lift height of a near empty concentrate tank. Off the shelf pre-tuned generic model inductors are not permitted.
- \2\ Design the inductor to 115% of the nominal injection rate such as the inductor for 3% concentrate would be designed for a 3.45% injection rate. /2/
- Size inductor for the exact orifice of foam/water pipe.
- Fit concentrate suction line of the inductor with a low loss brass, bronze, or stainless check valve assembly by the manufacturer that is included in the device's hydraulic design.
- \2\ Provide a design that indicates the inductor's flow rate, inlet pressure, back pressure, and concentrate lift height for a near empty concentrate tank. Hydraulically calculate the back pressure for the inductor using the Hazen-Williams equation with a C-factor of a 120 for all piping downstream of the inductor. /2/
- Potential manufacturers at the time of this publication include Fomtec, Skum, Matre Maskin, Wilson Foam, Ansul, Chemguard, and Delta Fire.
- Inductors meeting the performance criteria within this UFC are approved.

3-6.10.1 Inductor Installation

Install inductor in the horizontal piping over the top of the concentrate tank. Provide the minimum straight pipe on both sides of the inductor in accordance with the manufacturer. Install these sections of piping free of elbows, tees, and reducers. Provide liquid filled gauges, located no closer than 2 ft. (610 mm) before and after the inductor.



3-6.10.2 Concentrate Piping and Valving Installation

Provide a brass, bronze, or stainless steel full bore quarter turn ball valve with an electrically supervised tamper switch in the concentrate line. The use of automatically controlled valves in the concentrate line is prohibited. For testing purposes, equip the concentrate line with fittings and valving to accommodate the connection to an auxiliary tank of alternate test foam concentrate. Cap auxiliary tank connection at all times, except when testing.

Provide a 3/4 inch (19 mm) copper line with ball valve from the fire water supply that is used for flushing the concentrate line after use. Provide sign with the following

instructions, "Flush concentrate line after discharge or testing. Close concentrate tank shutoff valve prior to opening this valve. After flushing, drain concentrate line through test connection prior to re-opening concentrate tank shutoff valve." Refer to Figure 3-9: Inductor and Concentrate Tank Installation.

Figure 3-9: Inductor and Concentrate Tank Installation

3-6.11 Concentrate Storage Tank

Provide a closed cell double wall polyethylene concentrate storage tank compatible with the required concentrate. Provide a reverse float level gauge with minimum 50 gallon increments permanently marked on the tank or gauge. Indicate on the tank or gauge the empty, full, and minimum level required to operate the system. Do not include the inaccessible portion of concentrate at the bottom of the tank that cannot be accessed by the suction line, in the tank's capacity markings. Provide a closeable fill opening and pressure/vacuum vent assembly. When an inductor is used, enter the tank only through the top with no taps on the bottom or sides of the tank.

For Army: Exception, provide a single wall closed cell polyethylene concentrate storage tank.

A reserve supply of concentrate is not required where concentrate can be replenished within 24 hours. Where a reserve supply is required, it is permitted to be a secondary concentrate storage tank, or totes/drums of concentrate stored in the fire protection equipment or secondary foam proportioning rooms.

3-6.11.1 Concentrate Storage Tank Installation

Mount concentrate storage tank on a level surface. Spill or secondary containment outside the storage tank is not required.

For Army: Exception, provide secondary containment for the storage tank and associated foam concentrate pump pad capable of capturing the entire volume from the largest concentrate storage tank.

3-6.11.2 \2\ Deleted Paragraph retained to avoid numbering issues for references. /2/

3-6.11.3 Hi-Ex Foam Concentrate

Provide Hi-Ex foam concentrate listed/approved for use with the foam generation system. Provide a concentrate storage tank with a supply of concentrate to support a 15 minute discharge at the hydraulically calculated waterflow rate and 130% of the nominal concentrate injection rate.

3-6.11.4 \2\ Deleted Paragraph retained to avoid numbering issues for references. /2/

3-6.12 \2\ Foam/Water Solution and Low Level Water Only Piping /2/

Provide listed/approved gaskets for dry pipe service on all foam/water solution piping.

Seismically brace foam/water solution piping regardless of geographic location. Base bracing calculations on the Ss indicated in the seismic analysis.

3-6.12.1 \2\ Low Level Water Only Piping

Provide hot dipped galvanized piping downstream of the flow control valve on trench nozzle distribution systems. Galvanized components include all pipe, fittings, fasteners, hangars, and stands. Do not roll groove galvanized pipe. Clean cutting oils and debris from any cut grooves, threaded ends, and areas where the zinc coating has been damaged. Dry and paint damaged areas with two full coats of a cold galvanizing primer containing a minimum of 95% zinc.

Route water piping in trenches to trench nozzles. Routing piping across the hangar floor is not permitted. Provide end caps tapped with a valve at the end each of branchline in the trench nozzle system. Use these taps for the attachment of pressure gages during testing, and drainage of the piping system after activation. /2/

3-6.12.2 Hi-Ex Foam/Water Solution Piping

Provide black steel foam/water solution piping downstream of the flow control valve on the Hi-Ex distribution system. Galvanized foam/water solution piping is not permitted.

3-6.13 Test Header for Hi-Ex Foam Systems

Provide a linear test header to meet the fire water demand of the foam/water system.

For Air Force: The foam/water test system header and fire pump test header (when provided) may be combined. When a common test header is used, provide valving to permit independent testing of each foam/water riser and each fire pump.

3-6.13.1 Test Header Size

Provide one 2-1/2 inch (64 mm) hose valve connection for each 375 gpm (1420 Lpm) of flow, rounding up. Provide a control valve to isolate the test header from the remainder of the system.

3-6.13.2 Test Header Location

Locate test header inside the aircraft servicing area within 20 ft. (6.1 m) of an exterior door or directly outside the fire protection equipment room on an exterior wall. Locate test header to discharge effluent to a hard surface within 100 ft. (30.5 m) hose lay.

In geographic locations having a 99.6% dry bulb temperature less than 32ºF (0ºC) per UFC 3-400-02 Engineering Weather Data, provide test header with automatic ball drip routed to the exterior.

3-6.14 Hose Demand

3-6.14.1 Interior Hose Demand

Do not provide interior hose stations or fire hose connections in the hangar bay.

3-6.14.2 Exterior Hose Demand

Provide an exterior hose demand of 500 gpm.

3-6.15 Overhead Sprinkler System for the Hangar Bay

Protect the hangar bay with water only closed head wet pipe, dry pipe, or preaction sprinkler systems. Wet pipe automatic sprinkler systems are only permitted in the hangar bay when the following conditions are met:

- Where the geographical location of a hangar bay without doors has a 99.6% dry bulb temperature greater than 40ºF (4.4ºC) per UFC 3-400-02.
- Where the geographical location of a hangar bay with doors has a 99.6% dry bulb temperature greater than 0ºF (-17.8ºC) per UFC 3-400-02 and the hangar bay is provided with a heating system per this UFC.

3-6.15.1 Hydraulic Design

Hydraulically design the sprinkler system to provide 0.2 gpm/sq. ft. (8.0 Liters per minute per square meter (L/min/sq. m)) over the hydraulically most demanding 5,000 sq. ft. (464.5 sq. m) in the hangar bay.

Do not increase design area for sloped ceilings.

3-6.15.2 Sprinkler Systems

Provide upright quick-response sprinklers at the roof or ceiling level with a temperature rating of 175ºF (79.4ºC). Where the geographical location of the building has a 0.4% dry bulb temperature greater than 100ºF (37.8ºC) per UFC 3-400-02, provide sprinklers with an intermediate temperature rating of 200ºF (93.3ºC).

Design the sprinkler piping such that the majority or all of the system drains back to the riser. Minimize or eliminate the requirement for remote drainage connections in the hangar bay.

3-6.15.3 Wet Pipe Sprinkler Systems

Provide automatic air vents at high points in the system to vent at least 95% of the volumetric capacity of the system. Design the sprinkler system to reduce the quantity of automatic air vents such as connecting branchlines or providing a cross-main at the peak.

Where wet pipe systems are installed in areas with a 99.6% dry bulb temperature of 40ºF (4.4ºC) of less per UFC 3-400-02 Engineering Weather Data, adhere to the following piping installation requirements:

- Locate the inspector’s test connections at the riser. Test stations are not permitted in the hangar bay.
- Where drainage piping is required in the hangar bay, do not route the portion of the drainage piping normally containing water and associated drainage valve more than 5 ft. (1524 mm) below the level of the lowest sprinkler head in the hangar bay. Route the remaining normally empty drainage piping to the building exterior.

3-6.15.3.1 Wet Pipe Sprinkler System Temperature Monitoring

In geographic locations having a 99.6% dry bulb temperature less than 40ºF (4.4ºC) per UFC 3-400-02 *Engineering Weather Data*, provide temperature sensors in the hangar bay. Provide listed/approved fixed temperature sensors set at 32ºF (0.0ºC). Locate temperature sensors at the same level as the adjacent sprinkler head branchline. Provide center to center spacing not exceeding 200 ft. (61.0 m), or spacing from the wall not exceeding 100 ft. (30.5 m). Alarm low temperature conditions at the FACU as a supervisory condition and the Energy Management Control System.

3-6.15.4 Dry Pipe Sprinkler Systems

Provide an externally resettable dry pipe automatic water control valve. Provide valve with resettable capability that does not require opening the valve or use of special tools. Increase the design area by 30 percent for dry pipe systems.

3-6.15.5 Preaction Sprinkler Systems

Provide a single interlock, externally resettable preaction automatic water control valve. Provide valve with resettable capability that does not require opening the valve or use of special tools.

3-6.16 \2\ Low Level Water Trench Nozzle System

For Navy: Provide a hydraulically designed low level water only trench nozzle system for hangar bays. Refer to Chapter 7: Navy Specific Criteria for additional requirements regarding the trench nozzle system design.

3-6.16.1 Low Level Water System Performance

For the trench nozzle system, provide water at the most remote nozzle within 30 seconds upon water system activation such as from the manual releasing station. Maintain the discharge pressure for all nozzles between 40 psig (275 kPa) and 45 psig (310 kPa).

Where more than one trench nozzle system is present within a fire area, design the releasing system to only release the trench nozzle system associated with the fire event. Such as where a hangar is subdivided by a non-rated wall into two bays with independent trench nozzle systems or where a large hangar bay is provided with multiple trench nozzle systems, zone the initiation devices to only release the trench nozzle system associated with the fire event. Design the fire flow and concentrate supply to allow for sufficient simultaneous operation of all trench nozzle systems within the fire area that are wholly or partially within a 100 ft. (30.5 m) horizontal radius of any point on the hangar bay floor. /2/

3-6.17 Hi-Ex Foam System

For Air Force and Army: Provide a hydraulically designed low level Hi-Ex foam system for hangar bays. Refer to Chapters 5 and 6 for additional requirements regarding the Hi-Ex system design.

3-6.17.1 Hi-Ex Foam System Performance

\2\ Cover 90 percent of the aircraft's projected silhouette on the floor with Hi-Ex foam within one minute upon system actuation such as from a manual foam releasing station. For fixed winged aircraft, the areas under engines extending beyond the wing edge and under the tail plane are not considered part of the silhouette for this compliance criterion. Additionally, cover the aircraft servicing area and adjacent floor areas not cut-off from the hangar bay with self-closing or automatically closing doors/shutters, with Hi-Ex foam to a depth of 3.2 ft. (1000 mm) within four minutes. Where more than one Hi-Ex

foam system is located in a fire area, this performance criteria only applies to the aircraft and servicing areas protected by its associated Hi-Ex foam system. /2/

Where more than one Hi-Ex foam system is present within a fire area, design the releasing system to only release the Hi-Ex foam system associated with the fire event. Such as where a hangar bay is subdivided by a non-rated wall into two bays with independent Hi-Ex foam systems or where a large hangar bay is provided with multiple Hi-Ex foam systems, zone the initiation devices to only release the Hi-Ex foam system associated with the fire event. However, design the fire flow and concentrate supply to allow for sufficient simultaneous operation of all Hi-Ex foam systems within the fire area.

3-6.17.2 Hi-Ex Foam Generators

\3\ Provide unpowered aspirated, hydraulically (water) powered, or electrically powered foam generators. Electrically powered foam generators are permitted only when the following is provided: /3/

- Electric power to the generators is supplied ahead of the main building disconnect.
- Reliable power is provided in accordance with the definition in UFC 3-600-1 or an on-site standby generator is provided meeting the requirements defined in NFPA 20.

3-6.17.3 Hi-Ex Foam Generator Installation

Install Hi-Ex generators to provide a minimum 20 inches (510 mm) clearance in front of the generator inlet. Seismically brace generators regardless of geographic location. Base bracing calculations on an Ss of 0.95 or as indicated in the seismic analysis, whichever is greater. The use of all-thread rod or cabling for supporting or seismically bracing generators is not permitted.

Tap the generator foam/water supply piping with a valve to allow for the attachment of a pressure gauge or sampling hose during testing. \3\ Foam generators and piping shall be installed with appropriate pitch/slope to naturally drain foam-water solution. Where this is not possible, automatic low point drains must be provided. /3/

3-6.17.4 Hi-Ex Foam Generator Location

Locate Hi-Ex generators to discharge within close proximity, but not directly upon the aircraft or surrounding maintenance platforms. \2\Generators protecting helicopters may discharge within the rotor sweep pattern and discharge directly on rotors, provided there is no discharge directly on any other aircraft surface./2/ When mounting generators in the horizontal position, take into account the throw pattern of the Hi-Ex foam discharge. Do not locate the generator where the Hi-Ex foam discharge is obstructed by items such as structural members, lighting fixtures, or bird screen or in areas that obstruct the use of service equipment such as the crane travel path. Use the initial discharge from the foam generators to protect under the aircraft fuselage and underwing area, prior to spreading to the remaining hangar bay floor area.

Do not provide generators in locations where the developing foam blanket will block exits from the hangar bay within the first minute of discharge. Blocked exits are defined as an exit that is obstructed by a foam blanket exceeding 5 ft. (1.5 m) in depth. In small hangar bays where the entire floor may be covered with foam within the first minute, provide generator locations so exits are one of the last areas blocked.

3-6.18 Hydraulic Calculations

Provide the following calculations.

- \2\ Provide a combined hydraulic demand calculation of the foam/water or low level water only system and the most hydraulically demanding area of the sprinkler system in the hangar bay. Provide exterior hose demand where required. Demonstrate the combined fire water demand calculation does not exceed the available fire water supply. Use the resulting foam/water or low level water only demand from this calculation to determine the minimum quantity of foam concentrate. /2/
- For Hi-Ex foam systems, provide a combined hydraulic supply calculation of the high-expansion foam system and the most hydraulically demanding area of the sprinkler system in the hangar bay. Provide exterior hose demand where required. Use the fire water supply calculation for the sprinkler to determine the rate of foam breakdown.
- At a minimum, provide a hydraulic demand calculation of the most hydraulically demanding area for each additional suppression system in the support areas.
- For Hi-Ex foam systems, provide a foam spread calculation/diagram demonstrating the performance requirements to cover the aircraft silhouette are met within one minute. This calculation method is a reasonable approach to demonstrate the design meets the performance requirements, but does not take all aspects into consideration. This calculation method does not remove the obligation to demonstrate system compliance during testing. Include the following parameters in determining the maximum foam spread after one minute:
    - Time for the Releasing Service Fire Alarm Control Unit (RSFACU) to open the flow control valve after initiation of the manual foam releasing station.
    - Time for the foam/water reach the each generator based on the piping velocities in the hydraulic supply calculation.
    - Time for the foam to reach the floor of the hangar bay after discharging from the generator based on the height and orientation of each generator.
    - Time for the foam to spread across the floor based on the manufacturer's foam spread diagrams, or at a rate not to exceed 1 ft. /sec.

- \2\ For trench nozzle systems, provide a calculation demonstrating the most remote trench nozzle achieves the minimum discharge pressure within 30 seconds. This calculation method is a reasonable approach to demonstrate the design meets the performance requirements, but does not take all aspects into consideration. This calculation method does not remove the obligation to demonstrate system compliance during testing. Include the following parameters in determining the 30 second limitation is met:
  - Time for the RSFACU to open the flow control valve after initiation of the manual releasing station.
  - Time for the water reach the most remote trench nozzle based on the piping velocities in the hydraulic supply calculation. /2/

3-6.18.1 High-Expansion Foam Calculations

Where Hi-Ex foam is used, calculate the discharge rate as follows. However in no case is the discharge rate permitted to be less than 2.6 $ft.^3/min/ft^2$ (0.8 $m^3/min/m^2$). Hi-Ex foam generators may use either outside or inside air. Using air from inside the hazard requires no additional increase in foam discharge rates.

$R = ([V/T] + R_S) \times C_N \times C_L$

Where:

- R = Rate of foam discharge in $ft.^3/min$ (m^3/min)
- V = Submergence volume in $ft.^3$ (m^3). Determine the submergence volume by multiplying the area of the hangar bay and adjacent floor areas not cut-off from the hangar bay in $ft.^2$ (m^2) by a depth of 3.2 ft. (1000 mm)
- T = Submergence time of 4 minutes
- R_S = Rate of foam breakdown in ft^3/min (m^3/min). Determine the rate of foam breakdown by multiplying 10 $ft^3/min*gpm$ (0.0748 $m^3/min*L/min$) by the fire water supply calculation of the sprinkler discharge rate in the hangar bay.
- C_N = Provide a 1.15 compensation value for normal foam shrinkage.
- C_L = Provide a compensation for loss value of not less than 2.0 for hangar bays less than 15,000 ft^2 (1,394 m^2), 2.5 for hangar bays between 15,000 and 30,000 ft^2 (1,394 - 2,787 m^2), and 3.0 for all other hangar bays.

3-6.19 Fire Alarm and Releasing System

Provide a separate FACU and RSFACU for each building. Where multiple releasing systems are provided within a single building, they may be combined into a single RSFACU.

Install the FACU and RSFACU in a location readily accessible to the emergency responders and maintenance personnel.

3-6.19.1 \2\ Fire Alarm Control Unit/Autonomous Control Unit (FACU/ACU)

Provide a FACU for devices and appliances installed throughout the building that are not part of the foam/water or low level water only releasing system or other releasing systems such as a preaction system. Provide a mass notification system throughout the support areas and hangar bay in accordance with UFC 4-021-01 and this UFC. In addition to other building alarm, trouble, and supervisory signals required by other codes and standards, provide the following functional requirements in accordance with Table 3-3: \3\ Sample FACU Functional Matrix.

3-6.19.2 Releasing Service Fire Alarm Control Unit (RSFACU)

Provide a RSFACU for the control and release of the foam/water or low level water only system. Design the system so the loss of a FACU or another RSFACU in the fire alarm system does not prohibit the RSFACU from functioning as intended. Do not connect the RSFACU to other control unit through the use of a network cable. Communicate functionality between panels through addressable modules only. A common RSFACU may control multiple releasing systems or agents.

3-6.19.2.1 RSFACU Connected Devices

Connect and supervise only initiating and notification devices used by the foam/water or low level water only system as outlined in the RSFACU functional matrix in the Service-specific Chapters 5, 6, and 7. Release the foam/water or low level water only system only by the initiating devices indicated in these RSFACU functional matrices. Additional devices beyond those indicated in the RSFACU functional matrix are not permitted to release the foam/water or low level water only system, such as do not release the foam/water or low level water only system from the pressure switch on the foam/water or low level water only riser.

3-6.19.2.2 Location of Releasing System Components

\2\ Locate the RSFACU, releasing modules, and monitor modules integral to the releasing and stopping of the foam/water system in a normally conditioned space with the following parameters: temperature between 60-80ºF (15.6-26.7ºC) and a relative humidity of 85% at 86ºF (29.5ºC). Do not install these components in the hangar bay or unconditioned mechanical/electrical space. This equipment should not be used to justify conditioning a space normally not conditioned rather the equipment must be located to take advantage of spaces otherwise required to be conditioned. Locations must provide ready access to emergency responders and maintenance personnel.

3-6.19.2.3 Foam/Water, Low Level Water Only, and Preaction Supervised Solenoid Disconnect

Provide a key operated supervised disconnect switch to physically disable the solenoid for each foam/water, low level water only and preaction riser (if provided). Provide

switch that disables the releasing functions without the use of programming, while leaving all other functions of the panel operational. Do not provide a trouble signal upon operation of the disconnect. Monitor the disconnect switch at the RSFACU. Provide a supervisory signal to the receiving station upon operation of the disconnect.

Locate the disconnect switch in the riser room, in a readily accessible location near the solenoid. Provide a sign near the disconnect switch with a white background and a minimum 1/2 inch wide blue border, with "DISABLE FOAM SYSTEM", “DISABLE LOW LEVEL WATER ONLY SYSTEM”, or "DISABLE PREACTION SYSTEM" in red lettering not less than 1 inch (25.4 mm) high. Provide engraved labels on the disconnect switch indicating when the system is "ENABLED" or "DISABLED". Do not install backboxes or route conduit in front of sign in a manner that obstructs any lettering. /2/

3-6.19.2.4 Optical Flame Detection Inhibit Switch

Provide a 2-position non-key operated switch located within the RSFACU enclosure, that when activated disables the releasing function of all optical flame detectors in the hangar bay through programming at the RSFACU. \3\ When the switch is placed in inhibit mode, the releasing and alarm functions of the optical flame detectors are disabled while leaving all other functions of the RSFACU operational. /3/ Monitor the inhibit switch at the RSFACU. Provide a supervisory signal to the receiving station indicating the optical flame detectors are inhibited, a trouble signal is not permitted. Label the switch "INHIBIT OPTICAL FLAME DETECTION." Provide engraved labels on the inhibit switch indicating when the optical flame detectors are in "NORMAL" or "INHIBIT" mode.

3-6.19.3 Fire Alarm Reporting System

Provide a fire alarm reporting system that is fully compatible with the existing fire alarm receiving station without field modifications to system hardware. Independently circuit the FACU and RSFACU to a common fire alarm reporting system. Design the system so failure of the FACU does not prohibit the RSFACU from providing separate and distinctive release signals to the receiving station.

Provide notification from the fire alarm reporting system to the receiving station in accordance with the FACU and RSFACU matrixes.

Table 3-3: \3\ Sample FACU Functional Matrix /3/

NOTE: This sample table is intended to be specifically tailored/edited for each project.

		ANNUNCIATION AT LOCAL PANEL			NOTIFICATION											AUXILARY FUNCTIONS		
		AUDIO-VISUAL ALARM INDCATION	AUDIO-VISUAL TROUBLE INDICATION	AUDIO-VISUAL SUPERVISORY INDICATION	GENERAL FIRE ALARM SIGNAL TO RECEIVING STATION	COMMON FIRE ALARM TROUBLE SIGNAL TO RECEIVING STATION	COMMON FIRE ALARM SUPERVISORY SIGNAL TO RECEIVING STATION	COMMON FOAM SUPERVISORY SIGNAL TO RECEIVING STATION	FOAM SYSTEM DISABLED SUPERVISORY SIGNAL TO RECEIVING STATION	LOW TEMPERATURE SUPERVISORY SIGNAL TO RECEIVING STATION AND ENERGY MANAGEMENT CONTROL SYSTEM	FIRE SUPPRESSION CONTAINMENT SYSTEM SUPERVISORY SIGNAL TO RECEIVING STATION AND ENERGY MANAGEMENT CONTROL SYSTEM	INITIATE FIRE ALARM VISUAL NOTIFICATION	INITIATE GENERAL FIRE ALARM AUDIBLE NOTIFICATION	DISABLE GENERAL FIRE ALARM VOICE MESSAGE (IF ENABLED)	INITIATE FOAM RELEASE VOICE MESSAGE	FIRE PUMP START SIGNAL (IF PROVIDED)	ACTUATE DIVERTER VALVE FOR CONTAINMENT SYSTEM (IF PROVIDED)	SHUT DOWN SUPPLY, RECIRCULATING, EXHAUST, AND HIGH VOLUME SLOW ROTATING FANS IN HANGAR BAY

* GENERAL FIRE ALARM CONDITIONS MAY INCLUDE MANUAL PULL STATIONS, SMOKE DETECTORS, AND OTHER DEVICES NOT USED FOR FOAM/WATER RELEASE BY THE RSFACU.
** WHERE PROVIDED AND NOT USED FOR FOAM/WATER RELEASE BY THE RSFACU.

3-6.19.4 FACU, RSFACU, Auxiliary Panels and Component Installation

\3\ Control units and panels located in finished areas where electrical and other utilities are concealed within walls or other chases must be recessed to provide an aesthetically similar appearance. When auxiliary batteries and charging is required, these may be located remotely to avoid recessing these components. Controls in industrial areas may be surfaced mounted when other utilities including electric conduits are surface mounted.

Where panels, devices, and appliances are subjected to water spray/runoff under normal operating conditions, provide National Electrical Manufacturers Association (NEMA) 250 Type 4 enclosures and water tight conduit. Regardless of environmental conditions, do not provide openings or conduit entry into the top of the RSFACU or any associated terminal cabinets containing releasing modules or EDIOs. /3/

3-6.19.5 Conduit Installation

Flexible conduit is only permitted when connecting to the following devices and appliances. Devices located on fire suppression equipment such as flow/pressure switches, solenoids, and tamper switches. Devices and appliances located in removable ceiling tiles, and where flexible conduit is specifically noted in this UFC such as for optical flame detectors. Where flexible conduit is permitted, it is limited to 6 ft. (1.8 m).

3-6.19.5.1 \2\ Conduit and Enclosure Installation within the Hangar Bay

Provide NEMA 250 Type 4 wall mounted devices and appliances within the hangar bay (including backboxes). Provide watertight conduit and junction boxes throughout the hangar bay.

Route conduit into the bottom of the backbox for manual foam and low level water releasing stations, stop stations, and flame detectors. Provide the low point of this conduit with a drain. Where the conduit is in a hazardously classified area, provide breathers in isolated portions of the conduit such as where sealed offs are provided. Rate drains and breathers for the electrical hazard classification in which they are installed, but not be less than NEMA 250 Type 4.

3-6.19.6 Surge Protective Devices (SPD)

Provide SPDs to protect all power supply circuits to the FACU and RSFACU, including any subpanels such as autonomous control units, amplifier panels, and Notification Appliance Circuit (NAC) booster panels. Provide SPDs to protect all fire alarm circuits leaving or entering the building. Devices mounted on an exterior wall such as wall mounted exterior speakers do not require a SPDs when Lightning protection is provided on the building. Provide SPDs in accordance with UFC 3-520-01. Mount SPDs in a separate enclosure, unless the SPD is listed and installed in the control panel by the factory. Installing SPDs not listed with the panel is prohibited.

3-6.19.7 Manual Fire Alarm Pull Stations

Where required by the UFC 3-600-01, provide general fire alarm manual pull stations that are red in color and labeled "FIRE".

3-6.19.8 Manual Foam and Low Level Water Releasing Stations

Provide distinctively different NEMA 250 Type 4 manual foam releasing stations and signage from the manual fire alarm pull stations. Provide station and tamper cover with colored portions in yellow and lettering reading "FOAM" or “LOW LEVEL WATER”; the words "FIRE", "ALARM", or "AGENT" are prohibited to appear on the cover or station. Provide locking type manual releasing stations that when activated require a key to be reset. Provide conventional manual releasing stations. Do not locate addressable monitor modules for the manual releasing stations in the hangar bay.

3-6.19.8.1 Manual Foam and Low Level Water Releasing Station location

Install manual releasing stations within the hangar bay so they are unobstructed, readily accessible, and located within 10 ft. (3.0 m) of each required exit or exit access from the hangar bay. Manual releasing stations are not required outside the hangar bay, unless required elsewhere in this UFC. Maintain a minimum separation distance of 5 ft. (1.5 m) between general fire alarm pull stations (if provided) and the manual releasing stations. Where possible, install the manual releasing stations on the opposite side of the door from the general fire alarm pull stations.

Where foam/water or low level water systems are zoned per 3-6.16.1: Low Level Water System Performance or 3-6.17: Hi-Ex Foam System Performance, provide manual releasing stations within each zone for the release of that zone. Provide additional 1 inch (25 mm) high black block lettering on the sign indicating which zone is served by the manual releasing station.

For Army: Zoned manual foam release stations are not permitted. Program the foam release stations to simultaneously release the foam/water discharge from all zones viewable from the foam release station.

3-6.19.8.2 Manual Foam and Low Level Water Releasing Station Protection

Protect releasing stations located in the hangar bay from mechanical damage. Provide a clear plastic tamper cover over the manual releasing station that when lifted emits an audible alarm. Exception: Audible alarm is not required where a manual releasing station is installed in a hazardous (classified) location.

3-6.19.9 Manual Foam and Low Level Water Stop Stations

Provide NEMA 250 Type 4 manual stop stations of the "dead-man" type at each manual releasing station. Use stop stations in conjunction with valves and equipment to stop the discharge of foam and water from the suppression system. Provide manual stop stations with distinctive signage at each device. Provide a red mushroom type push button and include the word "PUSH". Provide the colored portions of the station and tamper cover in blue and lettering reading "STOP"; the words "FIRE", "ALARM", or

"AGENT" are prohibited to appear on the cover or station. Do not locate addressable monitor modules for the manual stop stations in the hangar bay.

3-6.19.9.1 Manual Foam and Low Level Water Stop Station Operation

Once depressed, and so long as the button is held down, design the system so the stop station prevents/stops discharge of the foam and water system regardless of whether or not the foam and water system was activated automatically or manually, and whether or not the activation occurs prior to or after the stop station is pressed and held. Program the stop stations to simultaneously stop the foam and water discharge from all zones viewable from the depressed stop station. Unless the RSFACU has been reset and all activation alarms (manual and automatic) have been cleared; restore the foam and water system operation when the stop station button is released. Do not exceed 15 seconds to fully close the flow control valve when the stop station button is depressed under full flow. Where the foam and water system is still in alarm, do not exceed 5 seconds to fully open the flow control valve upon release of the stop station button.

3-6.19.9.2 Manual Foam and Low Level Water Stop Station Protection

Protect manual stop stations located in the aircraft servicing area from mechanical damage. Provide a clear plastic tamper cover (without audible alarm) over the manual stop station.

3-6.19.10 Manual Foam and Low Level Water Releasing and Stop Station Signage

Provide two separate but adjacent metal signs a minimum of 24 inches (610 mm) high by 20 inches (508 mm) wide. Provide no more than 12 inches of separation between the two signs. Do not use the words "FIRE", "ALARM", or "AGENT" on these signs. Do not install backboxes or route conduit in front of sign in a manner that obstructs any lettering. See Figure 3-10: Start Foam System Signage, Figure 3-11: Stop Low Level System Signage, Figure 3-12: Stop Foam System Signage and Figure 3-13: Stop Low Level System Signage.

3-6.19.10.1 Manual Foam and Low Level Water Releasing Sign

Provide the sign for the manual releasing station with a yellow or lime-yellow background with "START FOAM SYSTEM" or “START LOW LEVEL SYSTEM” as appropriate in red lettering not less than 3 inches (76 millimeters) high. Locate the manual releasing station with tamper cover on the lower portion of the sign. Provide the word "START" in minimum 1 inch (25.4 mm) high green lettering placed directly above the manual releasing station.

3-6.19.10.2 Manual Foam and Low Level Water Stop Sign

Provide the sign for the manual stop station with a white background and a minimum 1/2 inch wide blue border with "STOP FOAM SYSTEM" or “STOP LOW LEVEL SYSTEM” as appropriate in blue lettering not less than 3 inches (76 millimeters) high.

Locate the manual stop station with tamper cover on the lower left portion of the sign. Provide the word "STOP" in minimum 1 inch (25.4 mm) high red lettering placed directly above the manual stop station.

To the right of the stop button provide the following in minimum 1/2 inch (12 mm) high black lettering "To stop the system, press and continuously hold STOP button until relieved by emergency responders. There may be up to a 30 second delay after pressing the STOP button before the flow stops." /2/

Figure 3-10: Start Foam System Signage

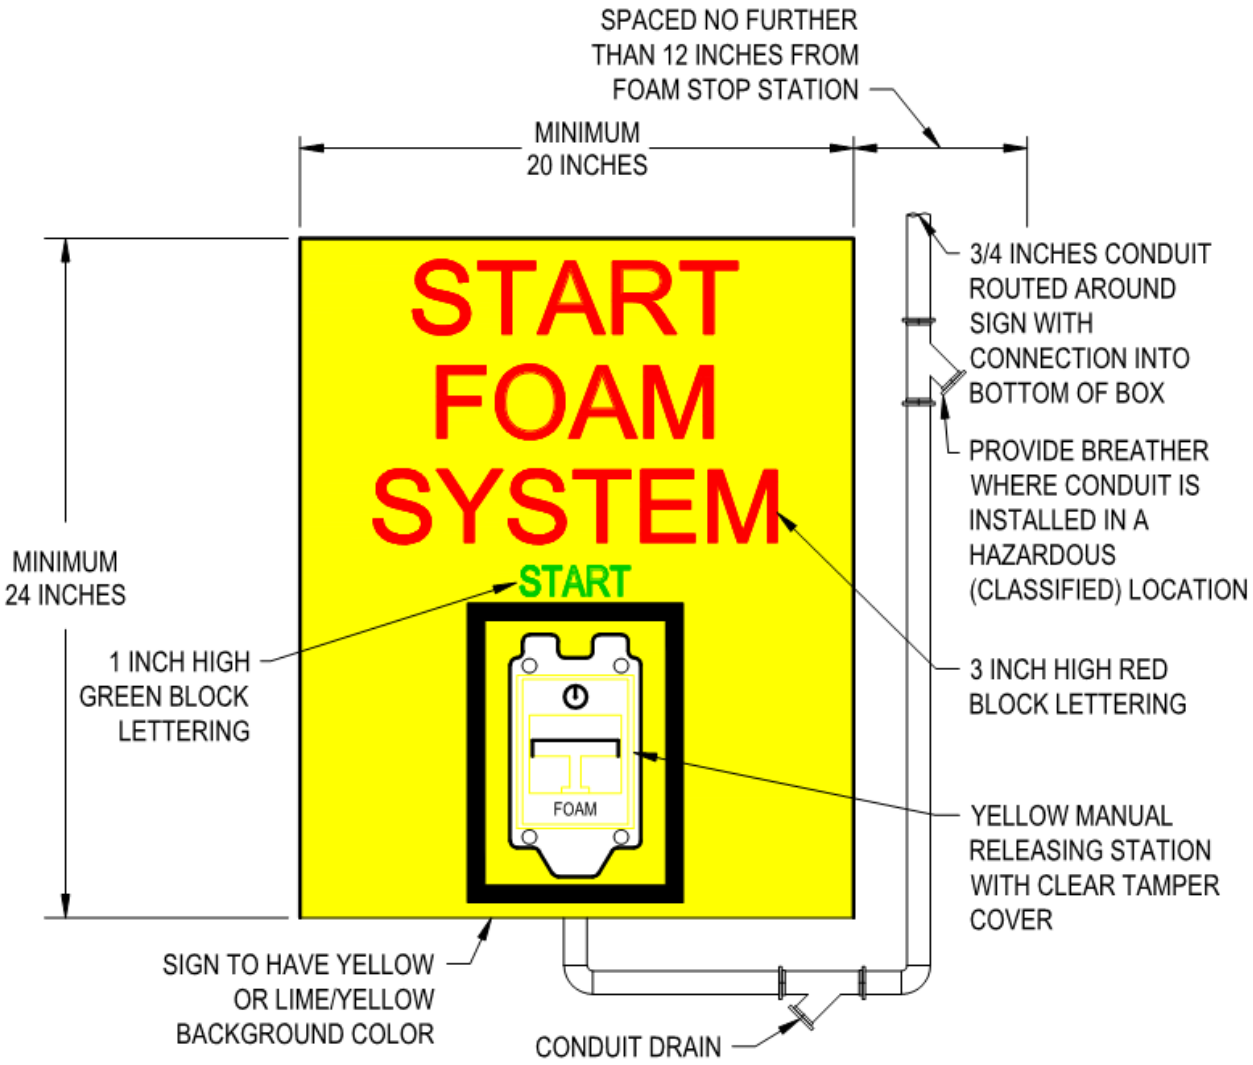

Figure 3-11: Stop Low Level System Signage

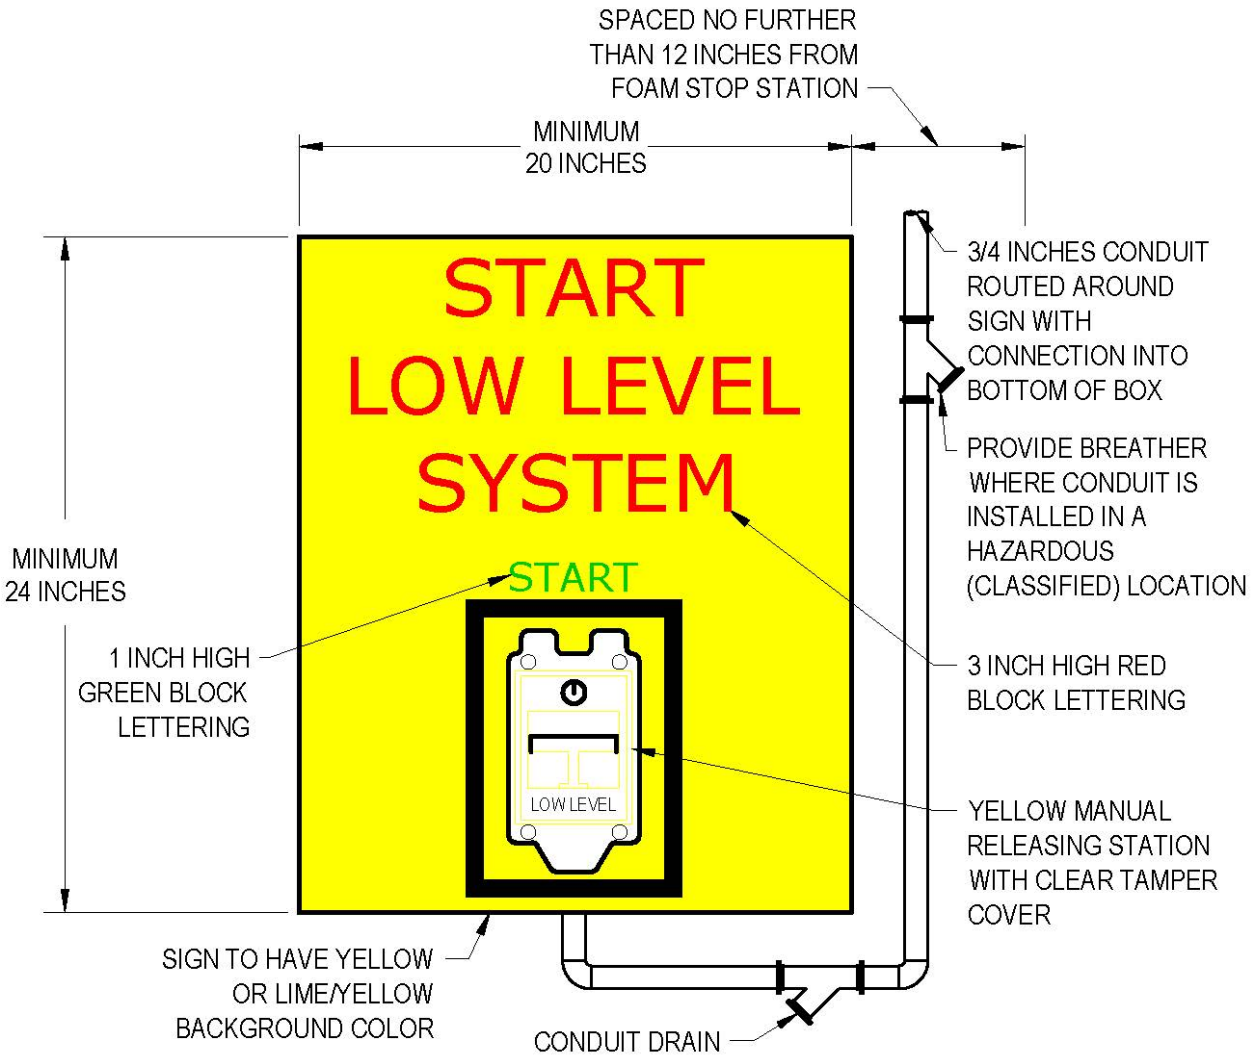

Figure 3-12: Stop Foam System Signage

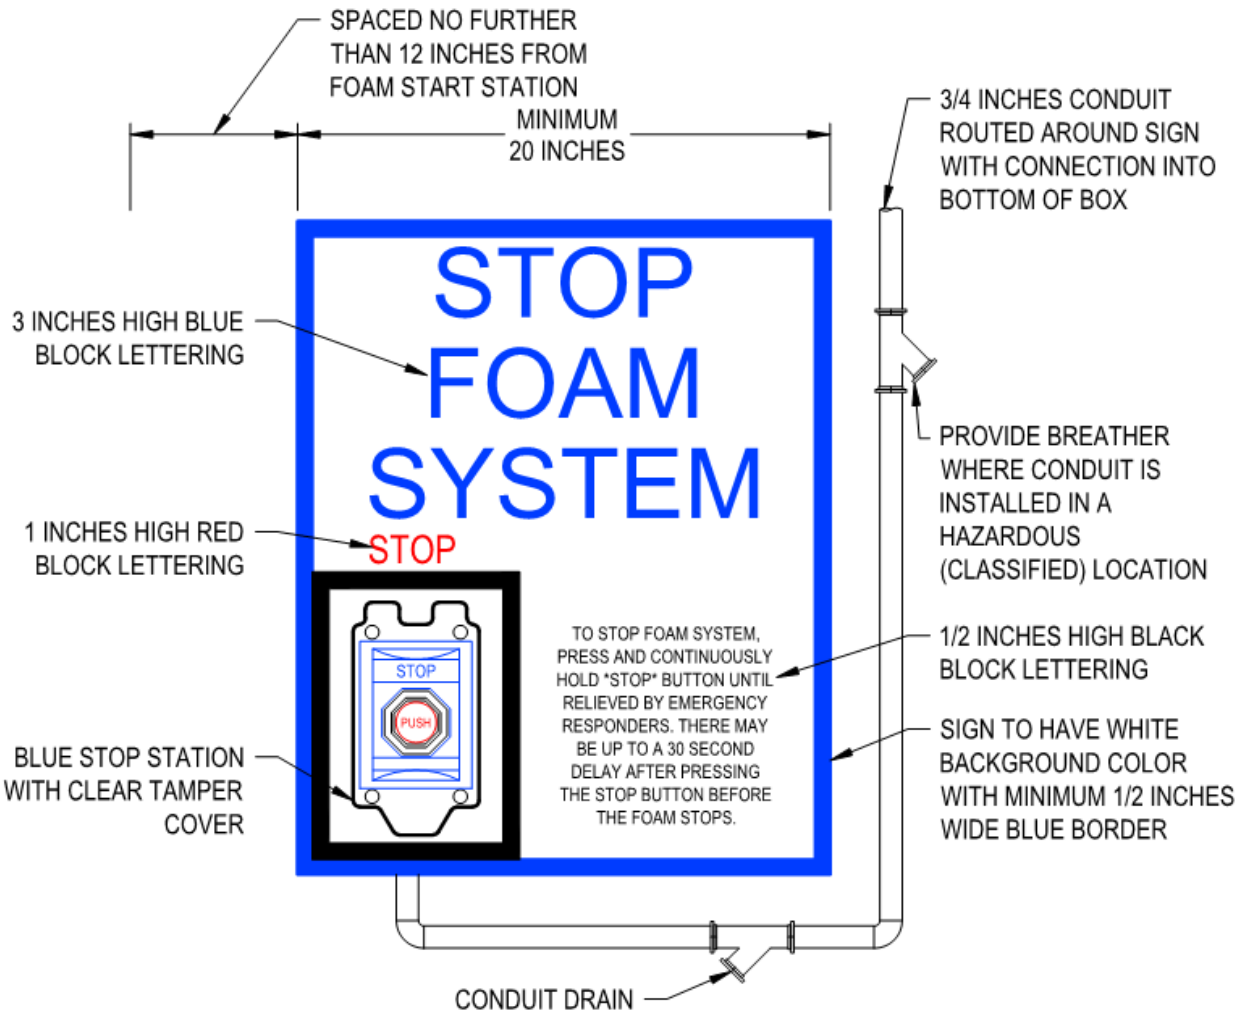

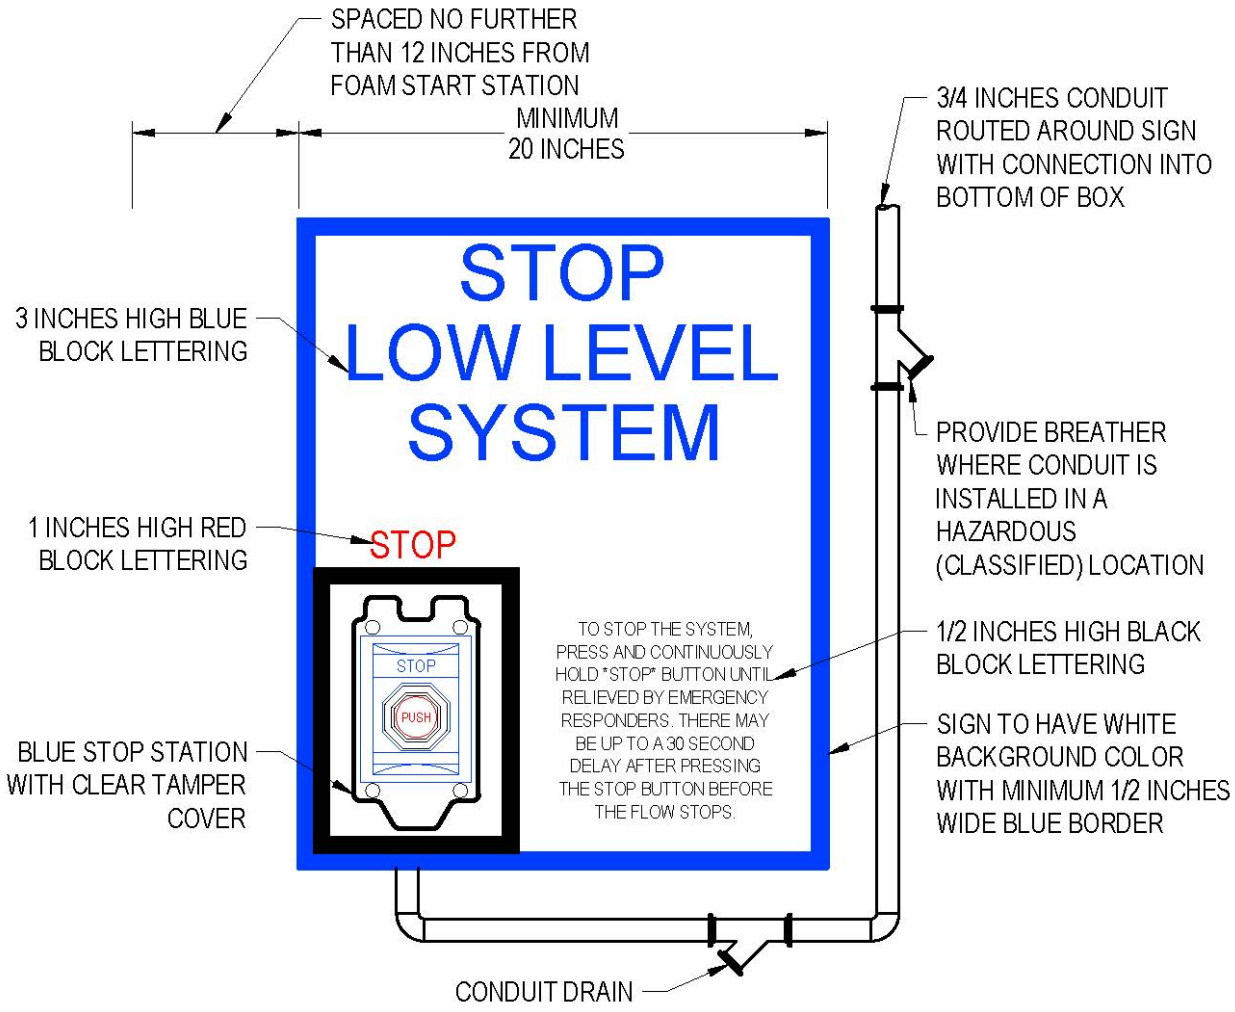

Figure 3-13: Stop Low Level System Signage

3-6.19.11 Optical Flame Detection

Provide optical flame detection in accordance with this section.

3-6.19.11.1 Optical Flame Detectors (OFD)

Provide triple infrared (IR) optical flame detectors that are listed/approved for the expected fuel hazards in the hangar bay. Provide detectors that are immune to radar and radio frequency emissions from hand held equipment or equipment on-board the aircraft. Provide shielded circuiting for both the SLC and power from the optical detectors to the RSFACU and ground shielding in accordance with the optical flame detector manufacturer.

3-6.19.11.2 Optical Flame Detector Location

Provide a sufficient number of optical flame detectors around the perimeter of the hangar bay, such that all portions of the hangar bay are within the range and cone-of-vision of at least three detectors. Exception: The area of the hangar bay within 5 ft. (1.5 m) of the perimeter wall is not required to be within the cone-of-vision of an optical flame detector. No aircraft silhouette will be solely visible from optical flame detectors located on one side of the fuselage. A minimum of two optical flame detectors covering the aircraft silhouette are required on each side of the fuselage.

Angle detectors and provide blinds (field of view inhibitors) so the cone-of-vision is contained within its designated suppression zone and does not extend more than 5 ft. (1.5 m) outside the hangar bay, into another fire area such as through a normally open roll-up fire door, or is within the view of hot sources such as radiant heaters. Locate optical flame detectors at a sufficient distance per the manufacturer's recommendations from sources that may cause false alarms such as welding, solar glare, radiant heaters, aircraft engine exhaust, strobes, hot surfaces and other relevant sources.

3-6.19.11.3 Optical Flame Detector Installation

Mount detectors in accordance with their listing at approximately 8 ft. (2.4 m) above the finished floor of the hangar bay. Do not mount optical detectors in inaccessible locations. Provide optical flame detectors with 5 ft. (1.5 m) of flexible conduit to allow for minor adjustments during testing or changes in the mission of the hangar bay.

3-6.19.11.4 Optical Flame Detector Performance.

Provide detector coverage to meet the performance criteria outlined in Service-specific Chapters 5, 6, and 7. Calibrate optical flame detectors to operate upon viewing the flame signature of the expected fuel(s) to be in the hangar bay. Use a 2 ft. x 2 ft. (610 mm x 610 mm) pool fire as the bases to set the sensitivity of the optical flame detectors. Upon the 2 ft. x 2 ft. (610 mm x 610 mm) pool fire reaching full development, all detectors within the cone-of-vision are required to activate within 30 seconds.

3-6.19.12 Thermal Fire Detectors for Preaction Sprinkler System

Provide an automatic thermal fire detection system to activate any preaction sprinkler systems in the hangar bay.

3-6.19.12.1 Thermal Fire Detector System

Provide one of the following heat detection systems located at the underside of the roof or suspended ceiling (if provided) in the hangar bay.

- Non-addressable rate-compensated heat detectors having a temperature rating between 160ºF (71ºC) and 170ºF (76ºC). Install heat detectors in accordance with NFPA 72. Except, space heat detectors in accordance with their listed spacing without reduction in spacing due to ceiling height. The maximum spacing between heat detectors is limited to 40 ft. (12.1 m).

- Linear thermistor (line-type electrical conductivity) fire detector having a temperature setting of 170ºF (76ºC). Space detection lines with a maximum spacing of 30 ft. (9.1 m). Use the manufacturer's approved testing method to verify the detector's response setting after installation. On curved roofs or roof exceeding a 2 in 12 pitch, install thermistor detectors perpendicular to the slope or arc (along the axis of the curve).

3-6.19.12.2 Thermal Fire Detector Installation

Provide a fire detection zone for each corresponding preaction sprinkler system. Activate the associated preaction valve for the floor area covered by the zone.

3-6.19.13 Waterflow Detection Devices

Provide waterflow detection devices on sprinkler systems. Waterflow detection devices for wet pipe sprinkler systems may either be a paddle type with built-in adjustable retard set to approximately 60 seconds or pressure type with retard chamber equivalent to approximately 60 seconds. Provide waterflow detection with no retard on preaction and dry pipe sprinkler systems.

3-6.19.14 Notification Appliances

3-6.19.14.1 Audible Notification

Provide voice evacuation / mass notification in support areas of the building and throughout the hangar bay. Broadcast prerecorded and live message content such that it is adequately understandable to occupants within the hangar bay. Within the hangar bay, meet or exceed the intelligibility criteria for cavernous-type open areas in accordance with UFC 4-021-01. Upon the activation of an initiating device within the hangar bay, provide the following conceptual message throughout the building. Adjusted the message for installation specific requirements.

Three Pulse Temporal Pattern <Three Rounds>

"May I have your attention. There is a fire emergency in the hangar bay. Please leave the building by the nearest exit. Do not exit through the hangar bay."

<Pause 2 seconds>

Repeat

3-6.19.14.2 Visual Notification

In addition to the visual notification required in support areas per UFC 3-600-01, provide visual notification for general fire alarm throughout the hangar bay. Where full coverage of the hangar bay cannot be accomplished using wall mounted strobes without exceeding 110 candela (cd), the following spacing criteria applies.

- Visual notification coverage is not required in the center of the hangar bay.

- Provide strobes not exceeding 110 cd around the perimeter of the hangar bay, not including the hangar bay door opening, in accordance with the room spacing requirements for wall-mounted visible appliances in NFPA 72.

For Air Force and Army: Strobes not exceeding 177 cd are permitted.

3-6.19.15 Supervision and Signage

Report supervisory alarms as independent addresses to the FACU, RSFACU, or Energy Management Control System as indicated on the functional matrixes. Grouped switches on common addresses are not permitted. Provide non-latching electronically supervisory devices.

3-6.19.15.1 Control Valves

Electrically supervise normally open control valves.

Electrical or mechanical supervision is not required for normally closed control valves, unless opening the valve is detrimental to the system operation. When supervision is required on normally closed valves, provide electrical supervision such as cable type monitoring.

3-6.19.15.2 Trim Valves

Mechanically lock or provide tamper seals such as zip-ties on trim valves, that when opened or closed are detrimental to the operation of the foam/water system such as the shutoff for the foam system pressure switch. Provide signage indicating the valve’s normal operating position.

3-6.19.15.3 Drain Valves

Mechanically lock or provide tamper seals such as zip-ties on drain or trim valving in the closed position, that when opened will cause the discharge of the foam/water system such as the manual release valve on the foam/water system riser. Provide this valve with the following signage, "OPENING THIS VALVE WILL RELEASE THE FOAM SYSTEM."

3-6.19.15.4 Emergency Foam/Water System Shutdown

Provide sequential signage on the control valves for the emergency shutdown of the foam/water system. Locate these signs so they are readily visible near each valve used in the shutdown sequence.

Provide signs with white background and a minimum 1/2 inch wide blue border with red lettering not less than 1 inch (25.4 mm) high. At a minimum, provide each sign with the language "EMERGENCY FOAM SHUTDOWN PROCEDURE" and the order and action to be performed such as "1 - CLOSE FOAM CONCENTRATE VALVE", "2 - CLOSE FOAM/WATER RISER CONTROL VALVE". Continue the sequence as required for shutdown.

3-6.20 Testing

At a minimum, provide the testing and reports outlined in this section. Coordinate testing personnel as required to demonstrate the coordination and communication of the fire protection systems through full functional testing. Independent testing of each individual fire protection system is not a substitute to the functional testing requirements. Such as depressing the stop button and witnessing the de-energizing of the solenoid, does not adequately demonstrate the flow control valve will stop the foam/water under full flow.

3-6.20.1 Testing Personnel

Provide a Qualified Fire Protection Engineer (QFPE) meeting the requirements of UFC 3-600-01 for the witnessing and/or review of testing/reports as outlined in this section.

At a minimum, provide a factory authorized representative for the startup and/or testing of the following systems as outlined below:

- Fire Suppression System (Preliminary and Final Testing)
- Foam Proportioning System (Preliminary and Final Testing)
- Fire Pump System, When Provided (Start Up)
- Fire Alarm and Mass Notification System (FACU/ACU) (Preliminary and Final Testing)
- Foam/Water Releasing System (RSFACU) (Preliminary and Final Testing)

3-6.20.2 Foam/Water Discharge Testing Plan

Provide a testing plan certified by the QFPE that includes the following:

- Who will perform the testing and who will be the onsite factory authorized representatives.
- What are the safety precautions taken during testing.
- How will the foam/water system be tested to demonstrate the performance criteria has been met.
- How will the event be recorded for future review.
- What are the testing procedures to demonstrate the coordination and communication of the fire protection systems associated with the foam/water discharge.
- How will the hangar bay be protected during the discharge of foam.
- How will the foam be captured during the discharge and disposed.

3-6.20.3 Preliminary Testing

Provide acceptance testing for the fire suppression and fire alarm systems complying with NFPA 11, 13, 20, 24, and 72 as applicable. At a minimum, provide the following preliminary testing reports.

- Contractor's Material and Testing Certificate for Underground Piping per NFPA 13 and 24. Provide photos of installation prior to burial. (Reviewed by the QFPE)
- Contractor's Material and Test Certificate for Aboveground Piping per NFPA 13 for each riser, manifold, and fire department connection. (Reviewed by the QFPE)
- Fire pump test report demonstrating compliance with NFPA 20 acceptance testing criteria. Where a concentrate pumping system is also provided, demonstrate compliance with NFPA 11 and 20 acceptance testing criteria. (Reviewed by QFPE)
- With the use of a time stamped video, demonstrate the performance criteria for foam coverage is within the limitations upon the actuation of a manual foam releasing station. The use of foam concentrate for this test is required to demonstrate preliminary compliance. (Witnessed by the QFPE)
- Demonstrate the performance criteria for opening and closing the flow control valve is met upon actuation of the manual foam stop stations. A water only test is acceptable. (Witnessed by the QFPE)
- **For Air Force and Navy:** Provide the residual pressure at the most remote nozzle or generator with only the foam/water system operating. Provide the inlet and outlet pressures of the flow control valve and inductor. A water only test is acceptable. Use this information to verify the hydraulic performance of the system. (Reviewed by the QFPE)
- **For Army**: Provide the residual pressure at the most remote generator with the simultaneous operation of the foam/water system, overhead hangar bay sprinkler system simulation, and exterior hose demand (when applicable). Simulate the overhead sprinkler system and hose demand through the test header. Provide pitot measurements and type of equipment used for this simulation. Provide the inlet and outlet pressures of the flow control valve. A water only test is acceptable. Use this information to verify the hydraulic performance of the system. (Reviewed by the QFPE)
- Provide a proportioning system test report demonstrating compliance in accordance with NFPA 11. (Reviewed by the QFPE)
- System record of Inspection and Testing, Notification appliance supplementary Record of Inspection and Testing, Initiating Device Supplementary Record of Inspection and Testing, Interface Component Supplementary Record of Inspection and Testing, and Mass Notification

System Supplementary Record of Inspection and Testing per NFPA 72 for the FACU and RSFACU. (Reviewed by the QFPE)

- Test the mass notification system in accordance with the requirements of UFC 4-021-01. At a minimum provide sound power levels (Decibel A Weighted Scale (dbA)) and intelligibility scores (CIS) throughout the facility. (Reviewed by the QFPE)
- Demonstrate the functionality of the fire alarm system is in compliance with the FACU and RFSACU functional matrixes. (Witnessed by the QFPE)
- \2\ Demonstrate the performance requirements of the optical flame detector coverage has been met through pan fire acceptance testing. Use a propane based testdevice calibrated to be equivalent to a JP 4/5/8 fuel fire in a 2 ft. x 2 ft. (610 mm x 610 mm) test pan, with closable lid. Refer to Figure E-17: Example of Fire Pan, for Acceptance Test of Optical Detectors. Minimum acceptable performance: (1) three detectors must activate within 30-seconds of full flame development (propane 2.0 seconds) with the test burner centered in the designated aircraft parking position. (2) With the test fire located 10 ft (3.0 m) outside the hangar bay opening entered on the parking position, no detector is permitted to operate after 30 seconds of full fire exposure. (Witnessed by the QFPE) /2/

3-6.20.4 Request for Final Testing

Provide a break-in period of at least 14 consecutive days after the FACU and RSFACU have been enabled, prior to any final testing. Provide a written request for a final test from the QFPE, after preliminary testing is complete, adjustments have been made to the system, and the system is ready for service.

3-6.20.5 Final Testing

Final testing to be witnessed by the AHJ, as defined by UFC 1-200-01. Such as for an Air Force project the AHJ is the Air Force Civil Engineer Center, Operations Director (AFCEC/CO), even if the project is constructed by NAVFAC or the Army Corps of Engineers. AFCEC/CO would witness final testing in this example. The final testing may be witnessed by a delegated representative at the discretion of the AHJ. With the exception of system flushing and hydrostatic testing, repeat preliminary tests during the final testing at the discretion of the AHJ. Correct system failures or other deficiencies identified during the final testing and retest in the presence of the AHJ, at their discretion.

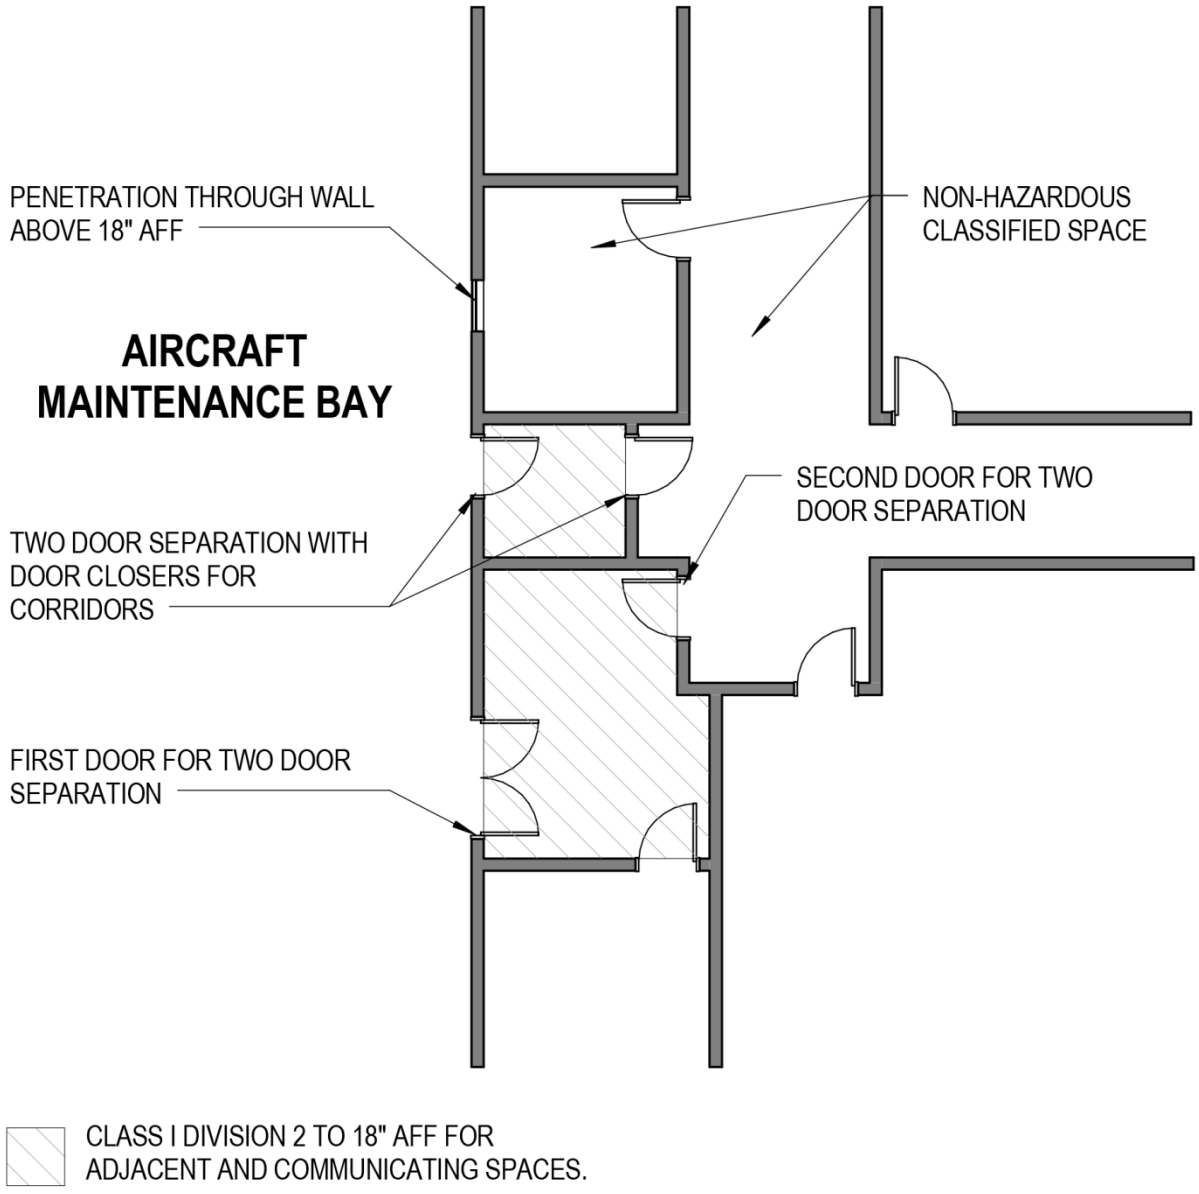
3-7 ELECTRICAL

Provide a 3-phase wye-connected, underground secondary service rated at 480 Volts Alternating Current (VAC). For projects outside of the United States and its territories and possessions, provide electric power in accordance with UFC 3-510-01.

3-7.1 Hazardous (Classified) Locations

Design hazardous (classified) locations including the hangar bay and adjacent spaces in accordance with NFPA 70 requirements for hazardous locations. At a minimum, classify adjacent spaces that are not suitably cutoff as Class I Division 2 up to 18 inches (460 mm) above the floor of the hangar bay adjacent to the space.

\2\ Note: The area within 5 feet of any aircraft fuel vents and any fuel containing portion of the aircraft is Class I Division 2. For practical use and mission-flexibility, this is generally simplified to within 5 feet horizontally of any aircraft surface and vertically from 5 feet above the surface down to the floor. /2/



If a space is adjacent and communicates with a hazardous location, the term "suitably cutoff" in NFPA 70 is defined as either of the following conditions as shown in Figure 3-14: Adjacent Space Electrical Hazardous Classifications:

- Two normally closed (self-closing) doors in series with a minimum separation of 5 ft. (1.5 m). Classify the space between these doors as Class I Division 2 up to 18 inches (460 mm) above the floor of the hangar bay adjacent to the space.
- A wall that has sealed openings up to a minimum of 18 inches (460 mm) above the floor of the hangar bay adjacent to the space. This condition is not permitted where the hazardous classification of hangar bay adjacent to the space is greater than 18 inches (460 mm).

\2 If a battery maintenance shop is required, see UFC 3-520-05 for additional requirements. Lithium-Ion battery maintenance requires significant space and mechanical systems. ***/2/***

\3 For Navy, see 7-7.1 Hazardous Classification. Additionally, see 3-9.3 Hazardous Classification for bridge crane operating environment and requirements. /3/

Figure 3-14: Adjacent Space Electrical Hazardous Classifications

3-7.2 Hangar Bay Door Power

Provide a separate and dedicated power supply from the facility transformer or ahead of the main service disconnecting means. Provide power to the hangar bay door such that the door remains energized when the main disconnect switches for general hangar power are shut off.

Provide a key-operated or other access-controlled switch on the exterior of the facility to open the hangar bay door in the event of an emergency.

3-7.2.1 Hangar Bay Door Portable Generator Connection

As a minimum, provide a portable generator connection on the exterior of the building with a manual transfer switch for hangar bay doors.

3-7.2.2 Vertical Lift Fabric Doors

Design the power source for vertical lift fabric doors to have the capability of being operated by an emergency generator or an Aerospace Ground Equipment (AGE) power cart during power outages. At a minimum, size the service to allow operation of one door panel at a time.

3-7.3 Electric Door Track Heating

Provide an electric door track heating system in accordance with heating requirements listed in 3-5.2: Heating. A heated antifreeze system may be used in lieu of an electric door track heating system. Coordinate which system is to be used with the mechanical design.

3-7.4 Renewable Energy Sources

\2 Photovoltaic (PV) systems on flight line facilities are a concern due their glare. See 2-1.6 Solar Glare Hazard Analysis. Also see UFC 3-540-08 *Utility-Scale Renewable Energy Systems* and UFC 3-440-01 *Facility-Scale Renewable Energy Systems* for facility requirements of renewable energy systems. See also UFC 3-260-01 *Airfield and Heliport Planning and Design* for system siting information, requirements and other approvals on airfields. ***/2/***

3-7.5 Backup Power

3-7.5.1 Portable Generator Connection

Provide a portable connection size and type based on the following criteria.

- Activities and missions, approved in accordance with UFC 3-540-01, to be supported by the generator connection.
- Type of portable generators and connections available at the installation.

3-7.5.2 Backup Generator

Backup generators and Uninterruptible Power Supply (UPS) backup power systems are not generally required for this facility type.

\3\ Backup generators may be considered for situations in which backup power is required for the hangar door operation (door opening and heat coils for rails) or for missions attached to the hangar. When authorized, provide backup generator power in accordance with UFC 3-540-01. See 3-5.2 Heating for snow-melting coils. See C-10.2 for discussion on Vertical Lift Fabric Door operations. /3/

3-7.6 Aircraft Power Distribution

Aircraft have specific power requirements, including unique voltages, frequencies, and capacities. Review the aircraft requirements of the aircraft being maintained in the hangar bay to determine the appropriate services. Provide appropriate services in voltage, frequency, and capacity to service the aircraft.

Provide permanently-mounted equipment located within the hangar bay or an adjacent space as follows.

- Permanently-mounted equipment may be installed within the hangar bay or within an adjacent space to the hangar bay. If equipment is installed in the hangar bay it may be either floor-mounted or mounted on the wall at a higher elevation. If the equipment is mounted at a higher elevation, coordinate the support of the equipment with the structural engineer. If the equipment is mounted on the floor, provide a stand for the equipment to elevate the equipment a minimum of 18 inches (0.46 m) AFF to avoid having the equipment in the Class I Division 2 hazardous space. Coordinate location of equipment to maintain the clear zone. Refer to 2-3: Minimum Aircraft Maintenance Bay Clearances for clear zone requirements.
- Provide solid-state equipment for special power units.
- Permanently-mounted equipment typically has controls mounted on the face of the equipment. If the equipment is mounted at a higher elevation, or an adjacent space provide remote control and displays at an elevation with the hangar bay that is accessible by the user.

3-7.6.1 Power Distribution Service Points

\3\ Distribute aircraft power from permanently-mounted equipment located on the wall. /3/

3-7.6.1.1 Wall-mounted connection points

Different aircraft have different power requirements and connections. Match receptacle and cable type to aircraft being maintained. Provide wall-mounted connection points close to the distribution equipment. Coordinate the location of the connection points with the location of the aircraft connection point to minimize the length of the cable from the wall to the aircraft. Provide one of the following connections:

- Provide wall-mounted cable storage racks for storage of the cable when receptacles are installed. Mount receptacles above electrical hazardous location. Provide floor-mounted cable protectors from the wall across the service lane to the aircraft side of the service lane. Lay cables in the cable protector to protect cable from cross traffic while the cables are extended and in use.
- When approved, electrically or air driven reels may be provided. Install electric motors above the electrical hazardous location. Provide reel controls as part of the cable assembly. Coordinate motor size and type with length and weight of cable provided.
- **For Army and Navy:** Cables connecting to the service point may or may not be provided as part of the service.
- **For Air Force:** Refer to Chapter 5 Air Force Specific Criteria for additional requirements.

3-7.6.1.2 Permanently-Mounted Pedestal

For Air Force and Navy: Permanently-mounted pedestals are not permitted.

For Army: Refer to Chapter 6 Army Specific Criteria for additional requirements.

3-7.6.1.3 Retractable (Pop-up) Pedestal

Retractable (Pop-up) pedestals are not permitted.

3-7.6.1.4 Aircraft Power Distribution Point Utility Coordination

Other services including compressed gasses, water, and preconditioned air are required to maintain aircraft. Coordinate the location of electrical services with all other utilities.

3-7.7 Aircraft Power Systems

Aircraft have specific power requirements, including unique voltages, frequencies, and capacities. Review the requirements of the aircraft being maintained in the hangar bay to determine the appropriate special power systems required. Provide the appropriate aircraft power systems in voltage, frequency, and capacity to service the aircraft being maintained.

3-7.7.1 Aircraft 400 Hertz (Hz) Service

Design a complete, functioning 200Y/115VAC, 400 Hz power system, including converter, cables and connectors, to support the aircraft maintenance activities. Provide 400 Hz service in the hangar bay and in shops where 400 Hz is required by the users. Coordinate the exact number and sizes of converters with the users supported. Design the system to provide power to each aircraft parking spot. Design system to compensate for voltage drop and sufficient voltage at the point of service. Provide voltage drop calculations, in accordance with the equation below, to meet the voltage

requirement at the aircraft point-of-service and to meet the requirements of the aircraft power monitor.

For Army and Navy: The use of centralized systems servicing more than two aircraft are prohibited.

400 Hz Equation

2L x I x Xr1 / 10,000 = VD single-phase line to neutral of three-phase

SQRT(3)L x I x Xr1 / 10,000 = VD three-phase line to line

L = circuit length in feet.

I = current in Amps.

Xr1 = Impedance of a particular size wire, = SQRT(R^2 + $X1^2$)

R = AC resistance of the wire.

VD = voltage drop in Volts.

X1 = Reactance

For Army and Navy: 400 Hz converters, cables, and connector are Real Property Installed Equipment (RPIE) equipment. The use of centralized systems servicing more than two aircraft are prohibited.

For Air Force: Refer to Chapter 5 Air Force Specific Criteria for additional requirements.

3-7.7.1.1 Aircraft 400 Hertz (Hz) Special Power Distribution Cables

Provide 30-100 ft. (9.1 - 30.5 m) 400 Hz cable consisting of six power conductors, two per phase, helically laid around one central neutral conductor and six control conductors, minimum of #18 American Wire Gage (AWG), specifically designed for 400 Hz applications. Base the size of the power conductors on the kilovolt-amperes (kVA) rating of the aircraft. Base the length of the cable on the distance from the distribution equipment to the aircraft location.

Coordinate how the cables are being provided for the project with the users. The cables may be part of the Military Construction (MILCON) or the cables may be equipment provided by the user. If the cables are permanently affixed to the facility distribution system, the cable is considered to be part of the MILCON. If the cables can be disconnected from the facility distribution system, the cable is provided by the user.

3-7.7.2 Aircraft 28 Volts Direct Current (VDC) Service

Design a complete and functioning 28VDC ground power unit. Provide 28VDC service in the hangar bay and in shops where 28VDC is required by the users. Coordinate the

exact number and sizes of ground power units with the users supported. Design the system to provide power to each aircraft parking spot.

For Army and Navy: 28VDC ground power units, cables and connector are RPIE equipment. The use of centralized systems servicing more than two aircraft are prohibited.

For Air Force: Refer to Chapter 5 Air Force Specific Criteria for additional requirements.

3-7.7.2.1 Aircraft 28VDC Distribution Cable

Provide 30-100 ft. (9.1 - 30.5 m) 28VDC cable consisting of two individual power conductors banded together with non-metallic bands, strain relief, and appropriate connector. Base the size of the conductor on the kVA rating of the aircraft. Base the length of the cable on the distance from the distribution equipment to the aircraft location.

Coordinate how the cables are being provided for the project with the users. The cables may be part of the Military Construction (MILCON) or the cables may be equipment provided by the user. If the cables are permanently affixed to the equipment, the cable is considered to be part of the MILCON. If the cables can be disconnected from the facility distribution system, the cable is provided by the user.

3-7.7.3 Aircraft 270VDC Service

For Air Force and Navy: Design a complete and functioning 270VDC ground power unit. Provide 270VDC service in the hangar bay and in shops where 270VDC is required by the users. Coordinate the exact number and sizes of ground power units with the users supported. Design the system to provide power to each aircraft parking spot.

For Air Force: Refer to Chapter 5 Air Force Specific Criteria for additional requirements.

For Navy: Refer to Chapter 7: Navy Specific Criteria for additional requirements.

3-7.7.3.1 Aircraft 270VDC Distribution Cable

Provide 30-100 ft. (9.1 - 30.5 m) 270VDC cable consisting of a single jacketed multi-conductor cable with power and controls incorporated into the cable with the appropriate connector. Base the size of the conductor on the kVA rating of the aircraft. Base the length of the cable on the distance from the distribution equipment to the aircraft location.

Coordinate how the cables are being provided for the project with the users. The cables may be part of the Military Construction (MILCON) or the cables may be equipment provided by the user. If the cables are permanently affixed to the equipment, the cable

is considered to be part of the MILCON. If the cables can be disconnected from the facility distribution system, the cable is provided by the user.

3-7.8 Grounding and Bonding

Provide grounding and bonding in accordance with UFC 3-575-01.

Coordinate the requirement for ordnance grounding with the users supported. Areas of consideration may include, but is not limited to, the following:

- Seat maintenance for seats with explosives
- Canopy maintenance for canopies with explosives
- Seat storage for seats with explosives
- Canopy storage for canopies with explosives
- Canopy shop and storage areas
- Armament Room

For Air Force: Refer to Chapter 5 Air Force Specific Criteria for additional ordnance grounding requirements.

For Army: Refer to Chapter 6 Army Specific Criteria for for additional ordnance grounding requirements.

For Navy: Refer to Chapter 7: Navy Specific Criteria for additional ordnance grounding requirements.

3-7.9 Lightning Protection

Provide lightning protection in accordance with UFC 3-575-01.

3-7.10 Lighting and Lighting Controls

Design lighting and lighting controls in accordance with UFC 3-530-01.

3-7.10.1 Apron Lighting

Lighting may be provided on the exterior of the facility for apron lighting. Coordinate lighting with activities on the apron. Design apron lighting in accordance with UFC 3-530-01.

3-7.10.2 Aviation Obstruction

Provide aviation obstruction lighting in accordance with UFC 3-535-01.

For Navy: Refer to Chapter 7: Navy Specific Criteria for additional requirements.

3-7.11 Industrial Controls

Coordinate industrial controls systems including, but not limited to, energy management systems, building management systems, HVAC controls, mechanical controls systems, crane controls systems, diverter valves, and plumbing control systems, with project location existing systems. Provide the ability to connect industrial controls systems with local site control systems as required, to report to installation-wide systems. Design industrial control system in accordance with NFPA 70 and manufacturer's requirements for each system.

Plan, design, acquire, execute and maintain all control systems (including systems separate from an energy management control system) in accordance with DoD Instruction 8500.01 and DoD Instruction 8510.01, and as required by individual Service implementation.

3-7.12 Associated Mission Requirements

Mission(s) associated with the aircraft may be incorporated into the maintenance hangar. These missions may include but are not limited to the following:

- UAS/RPA operations
- Command Operations
- Medical Evacuation Operations
- Flight Operations
- North Atlantic Treaty Organization (NATO) Operations
- Training Operations

These mission(s) may have significant impact on the electrical system including:

- The requirement for emergency generators
- Increase sized of electrical utility service to the building
- Special grounding requirements
- Power filtering requirements
- Radio Frequency (RF) shielding requirements

If mission-associated activities and spaces are attached to the maintenance hangar, coordinate and incorporate all specific requirements for the mission.

3-7.13 \2\ Aerospace Ground Equipment (AGE) Electrical Power Provisions

Permanently installed electrical power receptacles supporting portable AGE equipment provided with electrical control interlocking shall utilize the electrical interlocking circuit. • Hangar mounted AGE equipment receptacles shall not provide three phase power until the interlocking pins have been correctly mated, utilizing a control interlock circuit. • It has been shown that specific AGE plugs, such as 480VAC 60 Hz Hydraulic Mule 200-

300 amp equipment, can be inserted into AGE supporting receptacles 180 degrees out of rotation causing a personnel safety and equipment risk. Electrical circuit control interlocking is required to reduce this risk. /2/

\3\

3-7.14 Dedicated Electrical Distribution for Fire Protection Features

Provide a dedicated branch off of the service entrance equipment for fire protection, life safety, and mass notification (when provided) features. /3/

3-8 COMMUNICATIONS

3-8.1 Communication Systems Infrastructure

Provide communication infrastructure in accordance with UFC 3-580-01.

Coordinate with the users and provide additional communications infrastructure, as required by the mission. Segregate and construct the infrastructure systems, as required by the specific system requirements. Additional required communications systems may include:

- Global Positioning System (GPS) systems in the hangar bay
- Secret Internet Protocol Network (SIPRNet)
- Combined Enterprise Intelligence Exchange System (CENTRIXS)
- Joint Worldwide Intelligence Communications System (JWICS)
- Logistics Maintenance System (LMS) Triton
- Notebook/Laptop networked storage cabinets
- Integrated Maintenance Information System (IMIS)
- Unit Level Logistics System - Aviation (ULLS-A)

3-8.1.1 Classified Communication Systems Infrastructure

Coordinate the requirements for classified communication with user activities. Provide classified communication infrastructure and Protected Distribution System (PDS), in accordance with UFC 3-580-01.

3-8.1.2 Wireless Communications

Provide Wireless Access Points (WAP) in the hangar bay, as required for maintenance activities, and use of notebook/laptops. Wireless networks may require encryption for some aircraft. Coordinate the use of wireless and encryption with the maintenance user group and local telecommunications manager. If wireless is provided, coordinate the wireless frequency with the local frequency manager.

Consider potential obstructions that may cause interference, including aircraft and maintenance stands, when designing the wireless system.

3-8.2 Public Address

Provide a Public Address (PA) system with coverage to all areas of the facility. Provide a complete and functioning integrated public address system. Coordinate the PA system with the activities. Integrate the PA system with the MNS per UFC 4-021-01. Interface the PA system with the telephone system such that the telephone system provides access to the PA system.

3-8.3 Cable Television (CATV) Systems

Where required, provide CATV system in accordance with UFC 3-580-01.

3-8.4 Audio/Visual System

Provide the infrastructure to support all Government Furnished Government Installed (GFGI) and Government Furnished Contractor Installed (GFCI) Audio/Video (A/V) systems including but not limited to, projectors, sound systems, video teleconferencing, combined audio/visual systems, smartboards, screens, monitors, microphones, and specialized communication systems. Coordinate location and connection of all devices with the architectural and interior design.

A/V System infrastructure includes raceway systems and cabling only. Coordinate cabling types and raceway size with the GFGI and GFCI equipment provided. Provide power for A/V equipment per the A/V requirements.

3-8.5 Closed Circuit Television (Non-Security) System

Closed Circuit Television Systems (CCTV) may be required to monitor maintenance operations within the hangar bay and on the apron adjacent to the hangar. Provide a CCTV infrastructure system including raceways, and cables where required and authorized, as follows.

- Coordinate the infrastructure size and location with the design of the CCTV system.
- Provide power for CCTV equipment per the CCTV requirements.

Where specifically authorized to also provide CCTV equipment as follows.

- Provide cameras within the hangar bay and on the exterior of the building to monitor the apron.
- Provide monitoring equipment in user identified locations.

Refer to 3-8.7: Electronic Security Systems for CCTV for security systems is covered under Electronic Security Systems.

3-8.6 Radio and Satellite Systems

When required by the users and authorized, provide radio system antenna, cable and raceways to support GFGI radio systems. Provide radio system drops in locations identified by the users.

When required by the users and authorized, provide satellite system cable and raceways to support GFGI satellite systems. Provide satellite system drops in locations identified by the users.

3-8.7 Electronic Security Systems

When required by the users and authorized, provide Electronic Security Systems (ESS) in accordance with UFC 4-021-02.

3-8.8 Associated Mission Requirements

3-8.8.1 Mission Types

Missions associated with the aircraft may be incorporated into the maintenance hangar. These missions may include, but are not limited to, the following:

- UAS/RPA operations
- Command Operations
- Medical Evacuation Operations
- Flight Operations
- NATO Operations

3-8.8.2 Mission Impacts

These missions may have significant impact on the communication system including:

- The requirement for a data center
- Specialized radio, satellite, and communication systems
- Communication separation requirements.

If mission-associated activities and spaces are attached to the maintenance hangar coordinate and incorporate all specific requirements of the mission authorized.

3-9 OVERHEAD BRIDGE CRANES

Provide all cranes in accordance with the relevant portions of the following standards:

- Crane Manufacturing Association of America (CMAA) 70, *Specification for Top Running Bridge and Gantry Type Multiple Girder Electric Overhead Traveling Cranes*

- Crane Manufacturing Association of America CMAA 74, *Specification for Top Running and Under Running Single Girder Electric Overhead Cranes Utilizing Under Running Trolley Hoist*.
- American National Standards Institute ANSI MH27.1, *Specifications for Patented Track Underhung Cranes and Monorail Systems*.
- ASME HST-1, *Performance Standard for Electric Chain Hoists*.
- ASME HST-4, *Performance Standard for Electric Wire Rope Hoists*.
- All cranes to be a minimum Duty Service Class C.

3-9.1 Crane Operating Envelope

The crane operating envelope, including clearances, will not have interferences with the electrical, HVAC, or similar equipment, as specified by OSHA 29 Code of Federal Regulations (CFR) 1910.179. Clearly identify the crane operating envelope on the floor plans and building section drawings.

3-9.1.1 Hook Height

The minimum hook clearance height requirements, (measured from the finished floor elevation to the saddle of the hook at full elevation) are referenced in each specific Service's Chapter.

3-9.1.2 Hook Coverage

Provide loaded hook coverage to the maximum extent possible in the Aircraft Maintenance Bay. Design the crane equipment, hooks and wire ropes to clear the catwalk of 3-10.1.3 - Catwalk, in all operating configurations. Service-specific requirements are listed in appropriate Chapters of this UFC.

3-9.2 Motors and Controls

Provide overhead bridge crane with infinitely variable-speed electric motors and controls for the bridge, trolley and hoist. Crane is to be operable from the floor. Provide a crane disconnecting means for maintenance in a location that is accessible without the use of lifts or ladders.

3-9.2.1 Controls

Provide crane control interfaces, which are accessible at floor level. Provide controls for accessibility of the entire coverage area, horizontally and vertically.

Cranes may have wire connected controls or wireless controls. Coordinate the selection of wire connected controls and wireless controls with the users. When wireless controls are provided, coordinate the frequency of wireless controls with local frequency manager.

3-9.3 Hazardous Classification

\3\ Consider the operational environment of the crane and if that may be considered hazardous per NFPA 70 as is the case in the hangar bay. Crane elements entering hazardous area such as near the floor or around aircraft (Crane control pendant, hook or hoist and cable) may need to be upgraded per NFPA 70 or be anti-spark. For Navy, see 7-9 Overhead Bridge Cranes. /3/

3-10 HANGAR DOORS

Provide either a vertical lift fabric door system or horizontal sliding hangar doors. Coordinate with the user to provide type of hangar door and controls required for maintenance operations. Refer to C-10: HANGAR DOOR for guidance on best practices for hangar door selection and design. Refer to 2-4: Net to Gross Area in Aircraft Maintenance Hangars for requirements on calculating building gross square footage at different types of hangar doors. Hangar doors are to be fully operational when subjected to wind pressures up to a minimum of 15 psf. Include signage noting operational wind speed at which doors should be closed and secured with wind lock activation.

Design hangar doors to resist the component and cladding wind pressures determined in accordance with UFC 1-200-01. Consider the full deflection range and wind uplift to design the interface between the superstructure and the door systems. Design hangar doors in accordance with all provisions of UFC 4-010-01 where applicable.

\2\ NOTE: Certain door types are limited in hurricane and high windborne debris zones. See UFC 3-301-01 Structural Engineering for additional requirements and restrictions. /2/

3-10.1 Vertical Lift Fabric Doors (VLFD)

3-10.1.1 Doors

Provide the vertical lift fabric doors, as a complete system from a single source manufacturer for the purpose of closing a hangar maintenance bay space. Design the Aircraft Maintenance Bay superstructure to support the doors vertically and laterally. Design for the different load combinations imposed by open and closed door panels resulting in eccentric wind loads or mechanical loads from the door and mullion hoisting equipment. The mullions of the door system connect to pits at grade which serve to restrain the mullions from motion perpendicular to the face of the doors. Design the pits to resist the concentrated mullion loads and provide a means of draining water from the pits.

\3\ Design VLFD hangar doors to be individually operated with an upward acting lightweight framing system with polyvinyl fabric facing. Design doors in sections with lifting mullions between door sections. Design features include electric operation, personnel exit doors, and translucent fabric. See 3-7.5 Backup Power for emergency door operation. /3/

3-10.1.2 Safety

Provide an intrinsically safe electric safety edge on the bottom of the edge of each door, continuous over the full length of the door.

Provide fabric doors with a wind lock to secure the door prior to extreme wind conditions and to prevent door uplift. Provide the wind lock with a proximity switch to show proper engagement of the wind lock for the operator's benefit. Design VLFDs in accordance with UFGS 08.34.16.20.

3-10.1.3 Catwalk

Provide a catwalk for accessing the motors and other serviceable items of the fabric door. Provide access to maintain vertical lift fabric door equipment, motors, limit switches, and other serviceable door parts. Provide access to the catwalk from inside the hangar. **\2** The catwalk must be provided for safety of critical maintenance, repairs, and manual emergency operations and must not be omitted for any reason. ***/2/***

3-10.2 Horizontal Sliding Steel Hangar Doors

Hangar doors are to be a series of insulated, horizontal sliding leaves with protected, preformed metal or sheet-steel siding. Support each sliding door on hardened steel wheels rolling on continuously supported recessed rails with guide rails at the top of the doors. Hangar doors are to be of hot-rolled steel construction and designed and built to the same standards as the main Aircraft Maintenance Bay superstructure. Provide hot-rolled steel tension and compression bracing members. Hangar door frames will not depend on the metal or steel siding to provide diaphragm actions. Provide insulation values equal to the minimum values required for the exterior walls of the Aircraft Maintenance Bay. Provide waterproof weather stripping at all door system joints.

\3\ Support the hangar doors at grade with a concrete hangar door rail foundation. Design the foundation to be compatible with the building foundation and consider the potential for differential settlement. In the hangar door rail support foundation, provide for surface drainage with intermediate drainage, at a maximum spacing of 10 ft. (3.0 m). In cold climates provide a door track heating system. Design the hangar door rail foundation to have contraction joints constructed in the top slab placement to prevent random cracking of the surface of the hangar door rail foundation. Integrate the contraction joints with the door rail drainage structures. See 3-5.2 Heating for door track heating coils and see 3-7.5 Backup Power for emergency operation. /3/

3-10.2.1 Ingress/Egress Operations

Sliding door leaves need to be moved out of the way for aircraft to ingress or egress. In hangars with a small number of aircraft parking positions a door pocket is required of sufficient depth to stack the leaves out of the way to allow a 100% clear opening. Enclose all door pockets. As the number of parking positions rises, door pockets are still preferred, but are not required because the door leaves can be temporarily stacked on multiple tracks within the door opening and only a small percentage of the aircraft parking positions are blocked. Refer to Table 3-4: Sliding Hangar Door Pockets to

determine if the hangar requires a door pocket or if door pockets are allowed to be excluded. Coordinate with user to allow for efficient aircraft ingress/egress operations and conformance with required safety clearances. The requirements of Table 3-4: Sliding Hangar Door Pockets does not apply to hangars with an interior taxi lane leading to multiple aircraft parking positions.

Table 3-4: Sliding Hangar Door Pockets

<table>
<tr><th>NUMBER OF DESIGN AIRCRAFT IN HANGAR</th><th>AIR FORCE</th><th>ARMY</th><th>NAVY</th></tr>
<tr><td>1</td><td rowspan="3">POCKET REQUIRED FOR 100% OF THE DOOR PANELS TO ALLOW 100% CLEAR OPENING</td><td rowspan="2">POCKET REQUIRED FOR 100% OF THE DOOR PANELS TO ALLOW 100% CLEAR OPENING</td><td rowspan="3">POCKET REQUIRED FOR 100% OF THE DOOR PANELS TO ALLOW 100% CLEAR OPENING</td></tr>
<tr><td>2</td></tr>
<tr><td>3</td><td>NO POCKET REQUIRED - STACK DOORS ON MULTIPLE TRACKS, BLOCKING NO MORE THAN 33% OF THE DOOR OPENING</td></tr>
<tr><td>4</td><td rowspan="2">NO POCKET REQUIRED - STACK DOORS ON MULTIPLE TRACKS, BLOCKING NO MORE THAN 25% OF THE DOOR OPENING</td><td rowspan="2">NO POCKET REQUIRED - STACK DOORS ON MULTIPLE TRACKS, BLOCKING NO MORE THAN 50% OF THE DOOR OPENING</td><td rowspan="2">NO POCKET REQUIRED - STACK DOORS ON MULTIPLE TRACKS, BLOCKING NO MORE THAN 25% OF THE DOOR OPENING</td></tr>
<tr><td>> 4</td></tr>
<tr><td colspan="4">NOTE: CLEAR 100% DOOR OPENING IS PREFERRED EVEN WHEN NOT REQUIRED. COORDINATE REQUIREMENTS WITH USERS.</td></tr>
</table>

Hangar door panels may be individually electric motor operated and controlled or may be operated in groups. Coordinate with the user to provide hangar door controls as required for maintenance operations. Individually operated panels are preferred because they are the most flexible system. They allow any panel to be moved anywhere in the door opening without moving any other panels. The least flexible operation is anchored groups. The lead panel of an anchored group is motorized and all other panels in the group are interconnected by a cable system anchored to the building, typically in a door pocket. All panels in each anchored group start to move at the same time and arrive at their fully-open or fully-closed positions simultaneously. Floating groups are more flexible than anchored groups, but not as flexible as individually operated panels. The panels on each end of a floating group are motorized and each can collect the other doors of the group as they move in either direction. Floating groups can be collected and stored anywhere on in the opening, or in a pocket, but operate as a group. Design each drive unit with a release mechanism and provide a means of movement in the event of power failure. The normal mode of operation will be an electric drive and the minimum speed of door travel will be 60 feet per minute. Control the doors with momentary contact-type push buttons located near the leading edge of

the door and limit switches on each door leaf. Install safety devices to prevent injury to personnel and damage to equipment during movement of the door sections. Design steel sliding hangar doors in accordance with UFGS 08 34 16.10.

For Navy: Refer to Chapter 7: Navy Specific Criteria for criteria for hangar door types, operation and control.

3-10.3 Hangar Door Power

Refer to 3-7.2: Hangar Bay Door Power for hangar door electrical requirements.

3-11 FLOOR AND TRENCH DRAINS

3-11.1 Floor Slope

Arrange floor elevations within the hangar bay to prevent fuel/liquid spills within the hangar bay from flowing into adjacent shop/storage areas or from one aircraft to an adjacent aircraft. The finished floor elevation of the remainder of the facility is required to be above the highest floor elevation of the hangar bay. Coordinate hangar floor elevations with the existing sanitary sewer elevation to avoid the need for ejection pumps where feasible. Provide hangar floor sloping at a minimum 0.5% towards the flight line door. Provide additional cross-slopes to keep liquid spills from flowing into adjacent bays, or to direct flows towards trench drains, when provided.

3-11.2 Existing Apron Slope

At existing facilities, if the required grade cannot be achieved, provide an appropriately sized trench drain across the entire apron side of the hangar with a discharge to a remote safe location in accordance with environmental requirements for stormwater and spill containment.

3-11.3 Trench Drains

Provide trench drains where required by Service-specific Chapters 5, 6, and 7.

3-11.3.1 Trench Design

Slope drainage trench inverts at a minimum 0.5% towards and empty into the hangar bay door trench. Provide drainage from the door trench. Capture oily wastewater contaminants from the hangar bay trench system, as directed by the department overseeing environmental policy for the installation; this may include an oil/water separator.

\2 Trench covers will be ductile iron or galvanized steel. Typical trench covers are ductile iron but can be upgraded to galvanized steel where conditions may warrant but this is not common. Trench covers must be designed and manufactured to withstand a minimum proof-load from all vehicle wheel loads anticipated to be supported by the slab and wheel loads listed in the Service-specific chapters. ***/2/***

3-11.3.2 Location and spacing

Locate trench drains within the hangar bay to restrict the spread of fuel in order to reduce the fire and explosion hazards from fuel spillage. A trench drain is often provided just inside and parallel to the hangar bay doors to intercept wind-driven rain that may enter through the hangar doors.

3-12 FUEL CELL MAINTENANCE

For Navy: Refer to Chapter 7: Navy Specific Criteria for criteria for fuel cell maintenance bays

For Air Force: Refer to Chapter 5 Air Force Specific Criteria for additional criteria for fuel cell maintenance bays.

3-13 WASH BAY

3-13.1 General

If limited aircraft wash function is expected to be performed within a hangar bay provide the features as described below. This function within the hangar bay is not intended to replace the function of an outdoor wash rack or wash apron, nor is it intended for full aircraft cleaning, dry media stripping or Painting/Chemical De-Paint operations. High pressure washing is not allowed and not intended to be covered by these requirements. Refer to UFC 4-211-02 for Aircraft Corrosion Control and Paint Facilities including wash racks in hangar bays.

3-13.2 Architecture

Provide moisture resistant interior face of walls such as painted Concrete Masonry Unit (CMU) up to 10 ft. (3.0 m) above finished floor elevation. Provide a moisture-resistant interior face on the hangar door such as enameled metal panels up to 10 ft. (3.0 m) above finished floor elevation.

3-13.3 Plumbing

Provide the following for any aircraft bay in the hangar used for limited aircraft wash:

- Cold water hose bibb located on the wall or utility pedestal.
- Optional hot water hose bibb located on the wall or utility pedestal.
- Floor drain or trench drain connected to industrial waste system or storm or sanitary sewer based on requirements for other building drainage system as required by Base Environmental Office.
- Hose reels for storage of hoses.

3-13.4 Electrical

Provide the following for any aircraft bay in the hangar used for limited aircraft wash:

- NEMA 250 Type 3R rated electrical enclosures.
- Weatherproof while in use covers for convenience receptacles.
- Weatherproof receptacle and receptacle covers for electrical connections.
- Galvanized rigid steel conduit.
- Wet location light fixtures within 10 ft. (3.0 m) of the aircraft envelope.

3-13.5 Communications

Installation of communication outlets is prohibited in any aircraft bay if the hangar is used for limited aircraft wash.

3-14 FALL PREVENTION AND PROTECTION SYSTEMS

Design the aircraft maintenance facility to eliminate fall hazards. If fall hazards cannot be eliminated, ensure that a viable fall prevention and protection system is identified by the user and provide where applicable. Provide path and fall protection system for all roof-mounted lighting, equipment and platforms from the interior roof access platform.

These systems can be facility based systems such as horizontal life lines and retractable life lines and non-facility based systems such as aircraft stands/platforms, aircraft safety line attachments, or mobile cranes. Refer to APPENDIX C: BEST PRACTICES, for further discussion.

This Page Intentionally Left Blank

CHAPTER 4 \3\ AIRCRAFT SPECIFIC REQUIREMENTS

4-1 UNIQUE AIRCRAFT REQUIREMENTS /3/

Chapter 4 provides aircraft specific requirements that are in addition to other requirements of this UFC. These requirements apply only to Aircraft Maintenance Hangars designed for the specific aircraft below.

The airframe manufacturer's Facility Requirements Document (FRD) or equivalent document is an integral requirement of hangar design that contains additional airframe specific facilities requirements that must be considered and satisfied in addition to this UFC. The FRD is particularly useful for new or emerging aircraft requirements that have not yet become an established feature of this UFC or standard hangar designs of the DoD. FRD's are typically authored by the airframe manufacturer and can contain many specific details, be quite voluminous and difficult to obtain. The FRD may have additional technical facility requirements, special spaces, special clearances, special maintenance procedures, systems, data or other items that may impact the hangar design. This UFC is not a substitute for the FRD of the design airframe(s) being hangared.

4-2 F-35 JOINT STRIKE FIGHTER

The F-35 Lightning II (F-35) is a 5th Generation fighter, combining advanced stealth with fighter speed and agility, fully fused sensor information, network-enabled operations and advanced sustainment. There are three variants to the F-35 that will replace fighter aircraft of the US armed forces as well as at least 10 other countries. The F-35A fixed-wing variant will replace the A-10 and F-16 for the US Air Force. The F-35B VTOL variant will replace the AV-8B Harrier for the U.S. Marine Corps. The carrier variant F-35C will replace the F/A-18 for the US Navy and the U.S. Marine Corps.

4-2.1 Architectural

For Navy: F-35 hangars may require a Special Access Program Facility (SAPF) space. Refer to 2-2.3 - Secure Spaces for standards that apply to the construction of secure spaces. Refer to Chapter 7: Navy Specific Criteria for additional Navy SAPF requirements.

4-2.1.1 Minimum Aircraft Maintenance Bay Clearances

Coordinate with the maintenance unit staff to determine if additional space is required to maintain the aircraft beyond the clearances indicated in Table 2-1: Minimum Aircraft Maintenance Bay Clearances. Specific airframe or Service requirements may increase these minimum clearances. Provide additional clearances where required by an approved document such as the design aircraft's Facility Requirements Document (FRD) or a Service-specific standard design, defined Service hangar type, or other approved criteria. For example, the FRD may require additional clearance aft of the aircraft to remove the engine.

4-2.2 Mechanical Systems \2\

See 3-5.8.2 Preconditioned Air Systemsfor PCA system design requirements.

PCA requirements of the F-35 are as follows:

Fluid Element	Aircraft Cooling Air Spec
Capacity/Minute	46.5 lb/min. (21.14 kg/min)
Temperature	35 °F - 55 ˚F (1.67°C -12.78˚C)
Minimum Pressure at Aircraft, PSIG	5.25 [-0.25/+0.50 psig]
Moisture per pound of air	0-55 grains with no condensed moisture (No Droplets)
Particulates per pound of air	0.02 grams with maximum particle size of 50 microns

PCA air quality specifications are based on the Lockheed Martin 2020 FRD Rev Q and are minimum requirements. Validate against the most recent FRD and use the most restrictive requirements. Maximum time duration noted in this UFC to deliver the required PCA must not be increased regardless of any circumstances. ***/2/***

\3\ **Compressed Air Requirements**: Lubricators are not required for compressed air drops. /3/

4-2.3 Electrical Systems

4-2.3.1 Hangar Bay Requirements

Refer to 3-7: Electrical for aircraft service requirements.

4-2.4 Communication Systems

The F-35 system requires the Autonomic Logistics Information Systems (ALIS) communication systems. Segregate the ALIS System from all other communication systems within the maintenance hangar building.

Coordinate locations of ALIS and network connections with the user. The Navy requires SAPF for all ALIS spaces. Air Force and Army may require a SAPF. Coordinate the requirement for secured spaces with the project's site security officer. Refer to 2-2.3: Secure Spaces for additional information on secured spaces.

For Navy: Refer to Chapter 7: Navy Specific Criteria for additional requirements.

4-3 UNMANNED AIRCRAFT SYSTEMS AND REMOTELY PILOTED AIRCRAFT

New Unmanned Aircraft Systems (UAS) and Remotely Piloted Aircraft (RPA) are being introduced at a relatively fast rate and may be considered emerging aircraft. Specific requirements and direction are provided in previous Chapters.

For Air Force: Refer to Chapter 5 Air Force Specific Criteria for additional RPA specific requirements.

For Army: Refer to Chapter 6 Army Specific Criteria for additional UAS specific requirements.

For Navy: Refer to Chapter 7: Navy Specific Criteria for additional UAS specific requirements.

This Page Intentionally Left Blank

CHAPTER 5 AIR FORCE SPECIFIC CRITERIA

5-1 INTRODUCTION

This UFC is organized with general requirements and Service-specific requirements. Apply Chapters 1, 2, 3, 4 and Appendices to all Services. Additionally apply Chapters 5, 6 and 7 to Air Force, Army and Navy respectively for Service-specific requirements. This UFC additionally applies to all Air Force RPA hangars. Refer to the Air Force RPA General Maintenance Hangar Facility Design Guide located on the Whole Building Design Guide for additional RPA hangar requirements.

5-1.1 US Air Force Aircraft Maintenance Strategy

Current US Air Force aircraft maintenance strategy indicates centralized services are provided at an installation level for most maintenance functions performed on the aircraft. Typical unit maintenance operations include removing and replacing components within the hangar and transporting components to the centralized service location for repair.

The US Air Force has the largest variety of aircraft of the three branches of the US armed Services. Due to the variability of both type and size of the aircraft within the Air Force, aircraft maintenance facilities are built specifically for each aircraft or similar type of aircraft.

5-1.2 \2\ US Air Force Standard Designs for Aircraft Maintenance Hangars

US Air Force Standard Designs for Aircraft Maintenance Hangars refer to the US Air Force Standard Designs for Aircraft Maintenance Hangars for functional program areas requirements and descriptions. US Air Force Standard Designs are available on the Whole Building Design Guide: http://www.wbdg.org/ffc/af-afcec/prototypes-standard-designs. ***/2/***

5-2 CIVIL

5-2.1 Airfield Pavement Markings

Design and layout all Airfield pavement markings for Air Force in accordance with ETL 04-2, AF1 32-1042 and UFC 3-260-04 *(Draft) Standard Airfield Pavement Marking Schemes*.

5-2.2 Containment of Fuel Spill in Hangar Bay

\3\ A fuel spill capture trench drain is provided in the hangar bay. Route the captured fuel to an underground containment tank unless required otherwise by local environmental regulations. See 5-11 Floors and Trench Drains for additional guidance.

[C] 5-2.2 Maximum rate of fuel spillage is the maximum discharge rated at the aircraft fuel dump **valve**. /3/

5-2.2.1 Environmental Regulations

Remove and dispose of a captured fuel spill as directed by the department overseeing environmental policy for the installation.

5-2.2.2 Capacity

Provide capacity to contain the maximum fuel spilled from the failure of a single fuel tank/bladder on the anticipated aircraft(s) in the hangar bay. Do not provide less than 5,000 gallons of containment. Do not include any anticipated fire suppression discharge in this containment volume. Design the containment system to accommodate the anticipated fuel spill. Do not use the trenches or piping of the containment system to contain any of the required volume.

5-2.2.3 Containment System Monitoring

Provide the containment system with a remote capacity monitoring panel. Provide monitoring panel with audible and visual (yellow strobe or beacon) alarms. Automatically activate audible and visual alarms when the capacity level exceeds 5%. Provide a silence switch for the audible alarm. Constantly illuminate visual alarms at the panel until the level condition is returned to normal. Locate containment system monitoring panel in the hangar bay. Provide an alarm to the FACU and Energy Management Control System when the capacity level exceeds 5%.

5-2.2.4 Monitoring System Construction

Provide a containment system monitoring panel with a minimum NEMA 250 Type 4 panel.

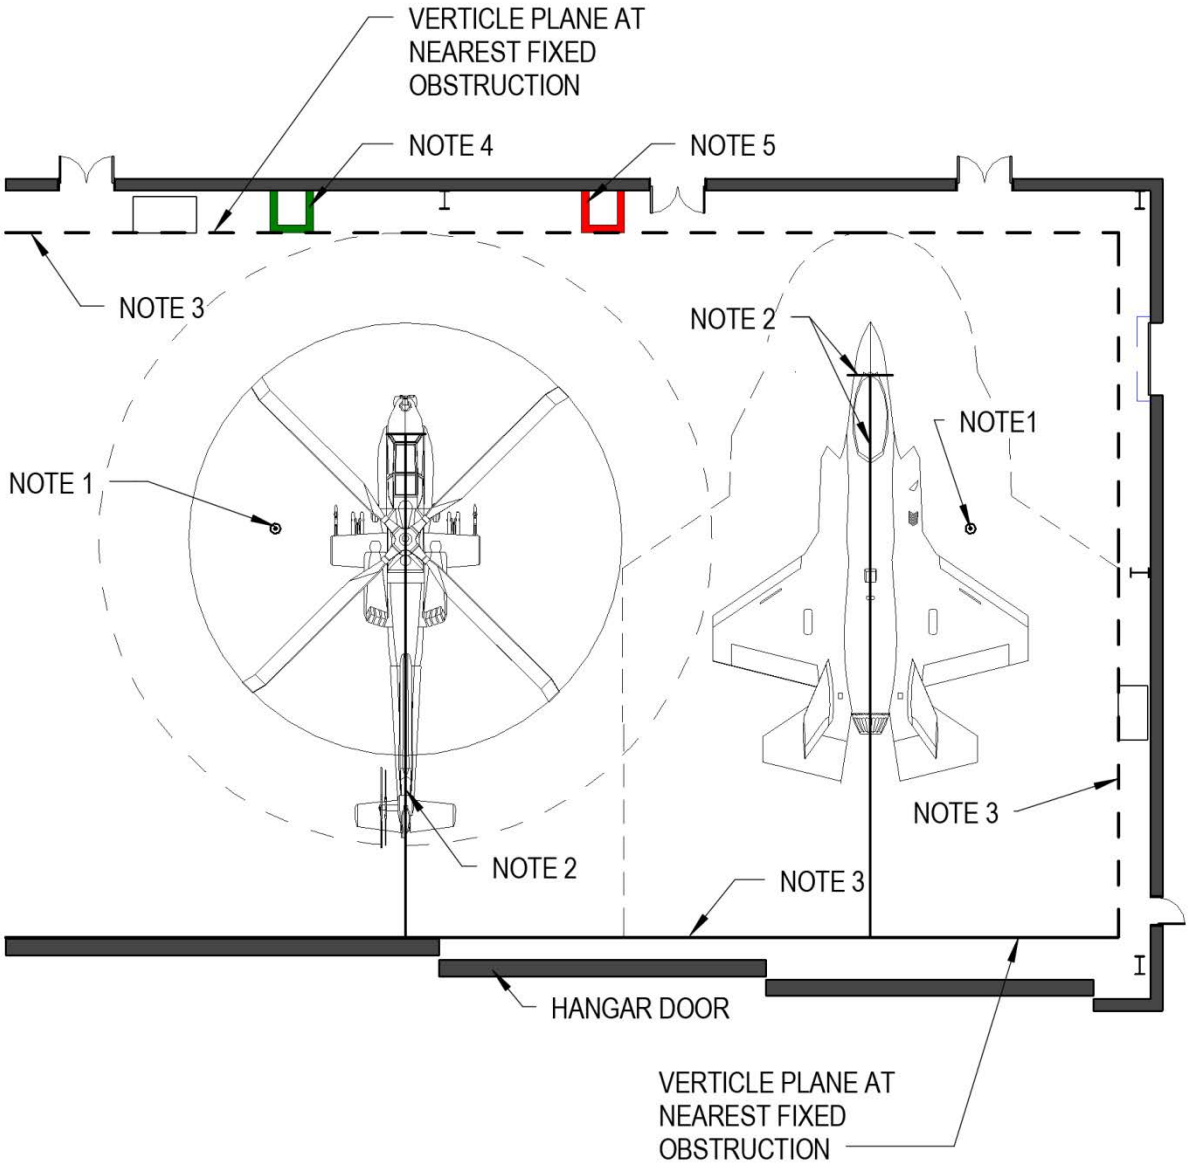
Rate any devices, conduits, or electrical enclosures installed below grade for prolonged submersion, minimum NEMA 250 Type 6P. Provide any devices, conduits, or electrical enclosures within the tank for an electrical (hazard) classification of Class I Division 1.

5-3 ARCHITECTURAL

5-3.1 Internal Fire-Rated Separations

At a minimum, provide a 2-hour fire barrier between dissimilar hangar bay operations including:

- Fuel Cell Maintenance
- Integrated Combat Turn
- Indoor Defueling and Refueling Operations
- General Maintenance Areas
- Corrosion Control



Where a 2-hour fire barrier is required for internal fire-rated separation between fire areas or different operations, a 1-hour fire barrier may be substituted where constructed

of concrete construction such as masonry, cast-in-place, pre-cast, tilt-up, block, or similar.

5-3.2 Aircraft Maintenance Bay Striping Requirements

Provide striping in the aircraft maintenance bay per paragraph 3-3.4.3: Protective Coatings and Figure 5-1: Aircraft Maintenance Bay Striping Requirements.

Figure 5-1: Aircraft Maintenance Bay Striping Requirements

Striping Notes:

1. Grounding receptacle; paint per UFC 3-575-01, figure 2-3.

2. **\2** Aircraft position centerline & nose gear stop; 6 in (152 mm) wide stripe; color – yellow or white to match the marking from outside the hangar to inside the hangar. **/2/**

3. Aircraft clearance boundary line; 6 in (152 mm) wide stripe; color - yellow.

4. Safety eyewash/shower; color - green; provide 2 ft. (610 mm) clearance from safety equipment.

5. Fire Extinguishers; color - red. Provide 2 ft. (610 mm) clearance from extinguishers.

5-4 STRUCTURAL

5-4.1 Aircraft Maintenance Bay - Slab on Ground Loading

Air Force traffic loadings are designated in Table 3-1 of UFC 3-260-02 Pavement Design for Airfields. Air Force hangar pavement thickness will be designed in accordance with UFC 3-260-02, Chapter 3, paragraph 2c, titled Type C Traffic Areas. Obtain approval for deviations of aircraft traffic mixes or deviation of airfield design type (heavy, modified-heavy, medium, light) from the AFCEC pavements engineer.

5-5 MECHANICAL

5-5.1 Plumbing

Refer to 5-11: Floors and Trench Drains for trench drain criteria.

5-6 FIRE PROTECTION AND LIFE SAFETY

\2\ deleted /2/

5-6.1 General

\3\ Classify hangars as Group I, II, III, or IV in accordance with NFPA 409. /3/

5-6.1.1 Group III Hangars

Buildings used exclusively for small aircraft such as T-3, T-41, TG-3, TG-4, TG-7, TG-9, and S-10, aero club aircraft, and similar aircraft that meet the space requirements of NFPA 409 for Group III structures are permitted to be classified as Group III hangars. Comply with criteria in NFPA 409 for Group III hangars and the requirements in this UFC specific to Group III hangars for these facilities.

Where Group III hangars are provided, hydraulically design an overhead fire suppression system to provide 0.3 gpm/sq. ft. (12.0 L/min/sq. m) over the hydraulically most demanding 3,000 sq. ft. (278.7 sq. m). A Hi-Ex foam system is not required in the hangar bay.

5-6.1.2 Group IV Hangars

Group IV hangars as defined by NFPA 409 (tension fabric structures on metal structural frames) are permitted when sited and constructed in accordance with this UFC specific to Group IV hangars.

Where Group IV hangars are provided, protect them in accordance with the requirements of this UFC, including overhead sprinkler protection, Hi-Ex foam, fire alarm and mass notification, and hangar bay egress.

5-6.2 \2\ Deleted /2/

5-6.3 Releasing Service Fire Alarm Control Unit (RSFACU)

\3\ Provide a factory assembled Model EQ30XX Eagle Quantum Premier releasing service fire alarm control unit to monitoring and control the optical flame detectors, manual start stations, manual stop stations, and high-expansion releasing devices. Only activate the high-expansion foam fire suppression system by the manual activation of a foam start station or the simultaneous flame detection of two or more non-latching optical flame detectors.

Provide a 2-position non-key operated switch located within the RSFACU enclosure, that when activated inhibits the releasing and notification function of all optical flame detectors in the hangar bay through programming at the RSFACU. When the switch is placed in the inhibit mode, only the releasing and alarm functions of optical flame detectors are disabled while leaving all other functions of the RSFACU operational. See Table 5-1: \3\ Sample Air Force RSFACU Functional Matrix for additional control requirements.

[C] 5-6.3 UTC Fire & Security, Detector Electronics Corporation, 6901 W 110th St, Minneapolis, MN 55438 manufacture the Model EQ30XX releasing service fire alarm control unit. Each project will require an individual Sole Source Justification and Approval (J&A) document as required by the Federal Acquisition Regulations (FAR) (Subpart 6.3) that justifies and obtains approval for contract solicitations that use Other than Full and Open Competition (FOC). /3/”

5-6.4 \2\ Radiant Energy (Optical) Flame Detection

\3\ Provide Model X3301 Multi-spectrum IR Flame Detectors. Detectors will be factory configured with the manufacturer's "Hangar Mode".

[C] 5-6.4 UTC Fire & Security, Detector Electronics Corporation, 6901 W 110th St, Minneapolis, MN 55438 manufacture the Model X3301 detector. Each project will require an individual Sole Source Justification and Approval (J&A) document as required by the Federal Acquisition Regulations (FAR) (Subpart 6.3) that justifies and obtains approval for contract solicitations that use Other than Full and Open Competition (FOC).

[C] 5-6.4 No current commercial optical detector including the Model X3301is suitable for aircraft hangars, HAS, hot refueling shelters, weather shelters or other structures where aircraft engines are started/run or aircraft taxi into or out of the structures. Contact AFCEC/COSM for additional guidance./3/

/3/

Table 5-1: \3\ Sample Air Force RSFACU Functional Matrix

NOTE: This sample table is intended to be specifically tailored/edited for each project.

\3\ /3/	ANNUNCIATION AT LOCAL PANEL			NOTIFICATION							AUXILARY FUNCTIONS				
ALARM CONDITIONS	AUDIO-VISUAL ALARM INDCATION	AUDIO-VISUAL TROUBLE INDICATION	AUDIO-VISUAL SUPERVISORY INDICATION	GENERAL FIRE ALARM SIGNAL TO FACU AND RECEIVING STATION	FOAM/WATER RELEASE SIGNAL TO FACU AND RECEIVING STATION	COMMON FOAM/WATER TROUBLE SIGNAL TO FACU AND RECEIVING STATION	COMMON FIRE ALARM SUPERVIORY SIGNAL TO FACU AND RECEIVING STATION	COMMON FOAM/WATER SUPERVISORY SIGNAL TO FACU AND RECEIVING STATION	OPTICAL FLAME DETECTION INHIBITED SUPERVISORY SIGNAL TO FACU AND RECEIVING STATION	ENABLBE BLUE BEACONS IN HANGAR BAY	OPEN FLOW CONTROL VALVE FOR FOAM/WATER SYSTEM	CLOSE FLOW CONTROL VALVE FOR FOAM/WATER SYSTEM	RE-OPEN FLOW CONTROL VALVE FOR FOAM/WATER SYSTEM IF STILL IN ALARM	RELEASE PRE-ACTION SPRINKLER SYSTEM (IF PROVIDED)	DISABLE THE RELEASING AND ALARM FUNCTION OF THE THE OPTICAL DETECTORS THROUGH THE RSFACU

/3/

5-6.5 Auxiliary Notification Devices

\3\ Provide blue rotating or flashing beacons not less than 400 cd (120/208VAC) or equivalent 360 degree LEDs. Control the beacon activation through the RSFACU. A backup power supply or supervision of the power supply supplying the beacons is not required when supplied from the dedicated fire protection features panel. Mount beacons 20 - 30 ft. (6.1 - 9.1 m) above the floor of the hangar bay. Provide a sign below each device with 3-inch red letter on a yellow or lime-yellow background, with wording

"FOAM RELEASE". Blue beacons are in addition to any general fire alarm clear visual notification devices. /3/

- For single door hangars, provide one beacon approximately centered on each of the three walls.
- For drive through hangars, provide one beacon 10-25 ft. (3.0-7.6 m) from each corner of the hangar bay. /2/

\3\ 5-6.6 through 5-6.7.9 moved and revised. /3/

5-7 ELECTRICAL

5-7.1 Aircraft Power Distribution

Aircraft power distribution equipment is government furnished. Power distribution equipment may be provided as Service Equipment (SE) carts or permanently mounted equipment.

Government-furnished SE carts may be diesel powered or electrical powered. If an SE cart is diesel powered, park the SE equipment outside of the hangar bay and extend cables to the aircraft from the SE equipment. If an SE cart is electrical powered, provide a 480V, 3-phase plug on the wall or pedestal and extend the power from the connection to the equipment. SE carts are government furnished equipment. Coordinate the sizes and type of connection with the users and equipment available at the installation.

5-7.1.1 Aircraft Power Distribution Service Points

Distribute aircraft power from government furnished SE carts. Government-furnished SE equipment is mobile and provides a flexible solution. The aircraft cables are typically connected to the SE cart. The equipment is owned and maintained by the maintenance mission and typically the equipment will be shared for hangar and on-ramp maintenance. A storage area may also be required for the equipment.

The cables connecting to the aircraft power distribution service point may or may not be provided as part of the service. Coordinate the provision of the cables with the mission owner.

5-7.2 Aircraft 400 Hz Service Distribution

Aircraft 400 Hz systems are provided using government-furnished SE or government-furnished fixed equipment. A fixed 400 Hz system may be provided for a building, if approved by Civil Engineering (CE).

5-7.3 Aircraft 28VDC Service Distribution

Aircraft 28VDC systems are provided using government-furnished SE cart or government furnished fixed equipment. A fixed 28VDC system may be provided for a building, if approved by CE.

5-7.4 Aircraft 270VDC Service Distribution

Aircraft 270VDC systems are provided using government-furnished SE carts or government-furnished fixed equipment. A fixed 270VDC system may be provided for building if approved by CE.

5-7.5 Grounding and Bonding

Provide ordnance grounding in accordance with Air Force Manual (AFMAN) 91-201. Provide the design in accordance with specific details from NAVSEA OP-5.

5-7.6 Aviation Obstruction Lighting

The Air Force prohibits the use of Light Emitting Diode (LED) Obstruction Lighting.

5-8 COMMUNICATIONS

5-8.1 CATV Systems

Refer to the Air Force dynamic prototypes for required CATV locations.

5-8.2 Audible Warning System

Where required and authorized, provide an audible warning horn and warning lights for aircraft maintenance safety. Provide an audible warning system capable of being heard or seen at any location in the hangar bay. Provide unique color warning lights and horn tones to differentiate the system from other warning systems in the hangar bay.

Activate the audible warning system to alert maintenance personnel of maintenance activities including pressurizing the aircraft hydraulics.

5-9 OVERHEAD BRIDGE CRANES

Refer to Air Force dynamic prototypes for required overhead bridge cranes.

5-10 HANGAR DOORS

Provide hangar doors in accordance with 3-10: Hangar Doors.

5-11 FLOORS AND TRENCH DRAINS

5-11.1 \3\ Trench Drains – Fuel Spill Capture

Provide a fuel spill capture trench drain in the hangar bay to remove an inadvertent fuel spill from a ruptured aircraft fuel tank/bladder. This is the only drain required in the aircraft servicing area floor. Exception: A fuel spill capture trench drain is not required in a wash bay provided in accordance with this UFC.

[C] 5-11.1 This is the only **drain** required in the aircraft servicing area floor. /3/

5-11.1.1 Trench Design.

Size the trench drain to account for the anticipated flow from a ruptured aircraft fuel tank or bladder.

5-11.1.2 Trench Location and Floor Slope

Locate the trench drain inside the hangar bay, within 5 ft. (1.5 m) of the hangar bay door opening. Do not locate the trench drain near or under the aircraft. Use hangar bay floor sloping to direct the discharge from a rupture aircraft fuel tank/bladder away from the aircraft and towards the hangar bay door opening.

5-11.1.3 Trench Cover

Provide ductile iron or galvanized steel trench covers, manufactured to withstand a minimum proof-load of 50,000 pounds from a tire with a 250 psi pressure or the most critical of the aircraft wheel loads listed in this UFC, whichever is greater.

5-12 FUEL CELL MAINTENANCE HANGARS

5-12.1 General

The use of segregated repair facilities/areas for fuel systems repair is essential for safe and efficient operations and is primarily an Air Force Hangar operation. The repair facilities/areas described in this paragraph provide necessary protection for both the aircraft and personnel from a variety of hazards. This paragraph is based on Chapter 3 of Technical Manual TO 1-1-3 Inspection and Repair of Aircraft Integral Tanks and Fuel Cells

Facilities meeting the previous fire and safety requirements for fuel systems repair facilities in accordance with Air Force guidelines are compliant if they meet the requirements of ETL 98-8, Existing Aircraft Hangars.

5-12.2 Permitted Operations

Fuel systems repair facilities are intended to support the complete range of operations normally restricted from being conducted inside other hangars and structures. Normally restricted operations permitted in fuel systems repair facilities include, but are not limited to: fuel cell repair, partial/complete defuel/refuel, fuel transfer, de-

puddling/purging of fuel tanks/cells and fuel systems components and fuel tank/cell pressurization testing.

5-12.3 Definitions

Conduct open fuel tank/cell repair only in predesignated repair facilities/areas approved by the appropriate using organization. The facilities and areas are defined as follows:

5-12.3.1 Primary Repair Facility

A primary repair facility is one that was specifically built, or modified, for use as an aircraft fuel systems repair hangar. Open fuel tank/cell repair operations are required to be performed in a safe condition and in a safe space not occupied by aircraft maintenance actions and in a facility meeting the requirements of this UFC.

5-12.3.2 Alternate Repair Facility

An alternate repair facility is one that was specifically built, or modified, for use as an aircraft fuel systems repair hangar, and serves as a "back-up" or "overflow" repair facility. If the unit has a designated alternate repair facility, it is the next recommended or preferred location at which to perform open fuel tank/cell repair; it should be used when the primary repair facility is unavailable. An alternate repair facility is required to meet the same requirements as a primary repair facility.

5-12.3.3 Fuel Cell Hangar

A hangar facility primarily utilized for fuel cell maintenance and repair. The space may also be used for general maintenance, but not at the same time.

5-12.3.4 Fuel Foam/Cell Repair Room

\2\ A fuel foam /cell repair room must be separated from the aircraft maintenance area and provides a location where a fuel bladder or fuel cell foam removed from the aircraft is stored, repaired, maintained, or tested. Fuel foam/cell repair rooms are only required if the installation assigned aircraft use fuel bladders or fuel cell foam. If an alternate tank repair "area" is required to service an unassigned aircraft with bladders or foam, see T.O. 1-1-3 for options. /2/

5-12.3.5 Positive / Negative Pressure

Positive pressure is pressure greater than the surrounding environment. Consequently, any leak will egress into the surrounding environment. The opposite is true for negative pressure.

5-12.3.6 General Ventilation

Exchanges of inside and outside air to prevent the buildup of vapors and gases that may be flammable or explosive or harmful to occupants.

5-12.3.7 Trench Drain Ventilation

Ventilation is not specifically required for the trench; however the system should provide a passive means to prevent the accumulation of vapors, by utilizing monitoring equipment and general or emergency ventilation to maintain proper conditions.

5-12.3.8 Purge Ventilation

Ventilation used to purge fuel cells while maintenance is performed. Although the preferred method is the use of supply and exhaust fans, the use of exhaust- or supply-only is also an acceptable method of purging the fuel cell.

5-12.3.9 Emergency Ventilation

Exhaust system used to quickly pull air directly out of the space and away from the hangar. This system is designed to remove vapors and prevent the buildup of contaminants above the lower flammable/explosive limit established by this UFC.

5-12.4 Fire Protection, Life Safety, and Other Design Criteria

Provide a well-coordinated multi-disciplined approach (e.g., fire protection, electrical, mechanical, architectural, civil.) and application of applicable design criteria to the design of fuel system repair facilities.

5-12.4.1 Fire Protection

Provide fire protection systems in accordance with this UFC.

5-12.4.2 Life Safety

Provide life safety systems in accordance with this UFC

5-12.4.3 Facility Design and Construction Standards

Fuel systems repair facilities are to be designed and constructed in accordance with this UFC. Address facility design and construction standards or other technical support questions to the AFCEC Reach Back Center at AFCEC.RBC@us.af.mil

NOTE: Due to changes in fuel cell maintenance hangar requirements, some related references may be inaccurate/inadequate in mandating additional fume and sensing alarms, and wash down drainage trenches. Fume Sensing and Alarm systems are not installed as part of the facility project but are to be provided as equipment. Wash-down drainage trenches are not to be provided in United States Air Force (USAF) fuel system repair facilities.

5-12.5 Architectural

5-12.5.1 Internal Fire-Rated Separation

Provide internal fire-rated separation in accordance with this UFC. An internal fire barrier is not required between adjacent fuel system aircraft servicing areas, unless they

are designed as separate fire areas. Where these are separate fire areas, provide internal fire barriers in accordance with this UFC.

5-12.5.2 Emergency Eyewash/Shower

Provide operational emergency eyewash/shower with privacy enclosures to permit complete disrobing in the aircraft servicing area. Install units in locations to meet the requirements of AFI 91-203, OSHA, ANSI Z358.1 and the manufacturer of the unit. Refer to paragraph 3-4.5: Secondary Structural Systems of this UFC.

5-12.5.3 Washing Facilities

Provide changing areas, locker space, scrub sinks and personnel showers for both male and female personnel. To prevent fuel contamination, design these areas for accessibility to aircraft servicing areas without passing through break rooms or offices. Where two or more fuel systems repair facilities are located adjacent to one another, changing areas, locker space and personnel showers for the total personnel assigned to all facilities may be combined and located in one facility. **\2** To prevent fuel contamination, design these areas to allow for direct access from aircraft servicing areas without passing through break rooms, hallways, or offices. ***/2/***

5-12.5.4 Scrub Sinks

Provide scrub sinks in facility and locate them adjacent to fuel system maintenance operations. In facilities without changing areas, locker space and showers, scrub sinks may be located in the aircraft servicing area.

5-12.5.5 Shop Spaces

Provide shop space to include fuel foam/cell repair rooms to service/repair fuel systems components as required.

5-12.5.6 Support Spaces

Provide office space, break room, support equipment/tool room, restrooms, and locker rooms as required.

5-12.5.7 Utility Spaces

Provide rooms for telecommunications, utility/mechanical and fire protection systems as needed.

5-12.6 Mechanical

Heating, Ventilation and Air Conditioning (HVAC) Systems. Draw return air from the aircraft servicing area above 10 ft. (3.0 m). Refer to UFC 3-410-01 for direction regarding heating/cooling the hangar. In general, heating is required, and cooling is not allowed unless required for the task.

Climate Control Units (CCU). Provide CCUs to provide environmentally-stable conditions for air purging, sealant cure and general repair. The air intake for CCUs should be located in areas free from contamination.

5-12.6.1 Ventilation

Provide ventilation in accordance with this UFC, UFC 3-410-01, and UFC 3-410-04N. The ability to vary the amount of outside air needs to be in the design. Locate outside air intakes in areas free from contamination.

- Toxic Fumes and/or Combustible Vapors. Exhaust toxic fumes and combustible vapors that are produced in work areas directly to the outside. Provide fuel-systems repair facilities, including the Fuel Foam/Cell Repair Room, which are likely producers of toxic vapors and gases, with exhaust ventilation.
- Maintenance Hangar Bay. Provide fuel cell vapor exhaust system capable of ventilating the bay up to 1.7 cfm/ft^2 during periods of normal maintenance. Ventilate the hangar bay space at all other times at a minimum ventilation rate of 0.05 cfm/ft^2. Provide a system capable of ventilating the bay up to 1.7 cfm/ft^2 during periods of normal maintenance. Control the ventilation system by monitoring the concentration of vapors in the space. The use of photoionization detectors (PID) is the preferred method. The level should be maintained below 100 milligram per meter cubed milligram per meter cubed (mg/m^3) (14.4 parts per million (ppm)) for JP-8 per the National Institute of Occupational Safety & Health (NIOSH) recommended exposure limit. During maintenance periods, operate the system to maintain fuel vapor concentrations below 14.4 ppm. A minimum of three monitoring points should be used, unless the size of the hangar is such that the use of two sensors will adequately protect the space.
- Fuel Foam/Cell Repair Room. Provide a fuel foam/cell repair room vapor exhaust system. As a minimum, provide ventilation in accordance with Maintenance Hangar Bay Vapor exhaust requirements as outlined in previous paragraph.
- Positive Pressure Ventilation. Provide office space, break room, and support equipment/tool room with positive pressure ventilation to prevent vapors and gases from migrating from the aircraft repair area.
- Negative/Neutral Pressure Ventilation. When appropriate, provide negative pressure ventilation in restrooms and locker rooms. When these spaces are located next to, and thus will pull air from, areas with fuel/toxic vapors, provide sufficient supply air to allow this space to be at a neutral pressure (to prevent fuel/toxic vapor infiltration.)
- Purge Ventilation System. Provide a system for purging the fuel line and the tanks to fuel systems maintenance/repair facilities. Provide a system to ventilate the aircraft fuel tank using filtered outside air. Exhaust air from the fuel tank directly to the outdoors. Monitor the inside of the tanks being

worked on and maintain purge system exhaust below 600 ppm or 10% of the Lower Explosive Limit (LEL) for JP-8 to ensure the space is adequately ventilated prior to and during maintenance. The use of a supply and exhaust fan is the preferred method, followed by exhaust only, supply only and finally no ventilation if the vapors in the tank are shown to remain within the limits above. Locate outside-air intakes at locations free from contamination by the exhaust of other ventilation systems.

- Emergency Ventilation System. A separate emergency ventilation system will be used to ventilate the hangar bay in the event of high fuel vapor concentrations in the hangar. The emergency ventilation system will energize to maintain the space at or below 14.4 ppm. The ventilation rate should be based on providing a minimum of 20 air changes per hour (ACH) at up to 2 ft. (610 mm) above the finished floor. In hangar bays with lifts, landing gear pits and recessed inspection areas, locate an additional detector in each below-floor area, and increase the emergency ventilation rate to 30 ACH to ensure proper ventilation and removal of the vapors.

5-12.6.1.1 Exhaust Systems

Exhaust systems discharging to the exterior of the facility may draw air at any level above the floor, but exhaust location should be selected to best remove fuel/toxic vapors.

5-12.6.1.2 Trench Drain Ventilation

Repair of trench drain ventilation is not specifically required as long as the general and/or the emergency ventilation can maintain the ventilation concentrations within the trench below 14.4 ppm. Provide a separate detector in each trench drain.

5-12.6.1.3 Air Purifying System

Provide a permanently-installed air purifying system suitable for respirator use, with connections (in groups of 3) throughout the fuel cell hangar. If a permanently-installed air purifying system is not available, make provisions for fresh air inlet hoses to be routed outside of the facility.

5-12.6.1.4 Heating Systems

Heating devices with a flame or glowing element open to the atmosphere are not permitted in the aircraft servicing area or fuel cell rooms. Provide steam or hot-water forced air heating throughout the facility. Radiant tube heating systems may be used in the aircraft repair area if the flame is contained in a sealed chamber with combustion air taken from outside the repair area, and the combustion products are exhausted outside the repair area. Where radiant heating is used, install only overhead radiant tube systems. Refer to UFC 3-410-01 for additional direction regarding heating, and the types of heating systems allowed.

5-12.6.2 Plumbing

Emergency Eyewash/Shower. Provide privacy enclosures at emergency eyewash/shower combinations to permit complete disrobing in the aircraft servicing area. \3\ Provide tepid water to emergency eyewash/showers. /3/

Scrub Sink and Showers. Provide hands-free type scrub sinks to permit the washing of hands and arms to the shoulder. Provide water to scrub sinks and showers through a thermostatic mixing valve.

5-12.6.2.1 Drainage

Wash-down drains and drainage trenches are not required in new USAF fuel system repair facilities except where specifically noted in Chapter 5 Air Force Specific Criteria. If existing drainage is provided, drainage trench ventilation is not required.

5-12.7 Electrical

Grounding. Provide sufficient grounding points throughout the facility to include grounding bars in the hangar bay along the walls with a maximum space of 50 linear feet (15.24 m) and along the walls near tank storage and repair workbenches in the Fuel Foam/Cell Repair Room.

5-12.7.1 Hazardous (Classified) Locations

\2 Design hazardous (classified) locations including the fuel cell hangar bay, fuel bladder/cell repair room, and adjacent spaces in accordance with 3-7.1: Hazardous (Classified) Locations and TO 00-25-172 *Ground Service of Aircraft and Static Grounding/Bonding* paragraph 1.2.7 for definitions and 4-14 specific requirements and TO 1-1-3 *Inspection and Repair of Aircraft Integral Tanks and Fuel Cells.* ***/2/***

Design the fuel bladder/cell repair room as a Class I Division 2 hazardous (classified) location to the ceiling/deck in accordance with NFPA 70. At a minimum, classify adjacent spaces that are not suitability cutoff as defined in 3-7.1 Hazardous (Classified) Locations as Class I Division 2 up to 18 inches (460 mm) above the floor of the fuel bladder/cell repair room. In the hangar bay, provide wall mounted outlets designed for Class I Division 1 or 2 hazardous (classified) locations even though they may be outside the classified area. This is an aircraft maintenance (user) safety requirement, and is intended to prohibit the use of unclassified tools or equipment in the classified area around the aircraft. \3\ When operations in hangar bay will include refueling or defueling, regardless of fuel type (other than testing during fuel system maintenance), electrical equipment above the floor in the aircraft servicing area up to the height of the highest hangar door must satisfy NEC criteria for Class I Division 2 locations./3/

5-13 WASH BAY

Provide in accordance with 3-13: Wash Bay.

5-14 FACILITIES FOR UNFUELED AIRCRAFT

\2 Air Force Air Logistics Complexes (ALCs) have existing programmed depot maintenance (PDM) hangars where aircraft are disassembled, repaired, maintained, refurbished, and/or returned to flying status. These hangars are dedicated to specific industrial processes as part of the intermediate and depot level maintenance activities. Air Force Plants (AFPs) are Government-Owned/Contractor-Operated (GOCO) industrial installations which have production, fabrication, and test facilities dedicated to specific industrial processes as part of their aircraft production activities. These facilities were constructed in accordance with protection features detailed in NFPA 409 Aircraft Hangars and previous Air Force Engineering Technical Letters (ETL) for never-fueled or unfueled aircraft.

5-14.1.1 Unfueled Requirement

Aircraft are considered to be unfueled after having been defueled in accordance with Air Force Technical Order (T.O.) 00-25-172 and having all residual fuel drained from all the fuel system low points drains. Aircraft processed in accordance with Air Force Technical Order (T.O.) 1-1-3 are also considered to be unfueled.

5-14.1.2 Limitations

Defueling, alone, is not considered adequate to render an aircraft unfueled regardless of the fuel quantity remaining in the aircraft tanks and systems.

The maximum cumulative fuel remaining in aircraft within a single fire area must not exceed 240 gallons of fuel (JP-4, JP-8, Jet-A, Jet A-1)with a flash point equal to or less than 139 °F or 660 gallons of fuel (JP-5) with a flash point of 140 °F and greater.

5-14.1.3 Upgrade Thresholds for PDM and AFP Hangars for Unfueled or Never-Fueled Aircraft

Existing PDM and AFP hangars are not required to comply with this UFC, unless they house fueled aircraft, regardless of how infrequently. These facilities must continue to only house never-fueled or unfueled aircraft.

When UFC 3-600-01 Chapter 34 would require fire protection features in these facilities to meet new construction, existing serviceable fire suppression systems complying with NFPA 409 for never-fueled or unfueled aircraft must be retained and maintained in service.

When UFC 3-600-01 Chapter 34 would otherwise require fire protection features in these facilities to meet new construction and the existing installed fire suppression features requires life cycle replacement; the suppression requirements of NFPA 409 must be followed for unfueled and never-fueled aircraft, provided the mission is unimpaired by the continued prohibition of any aircraft not complying with the requirements for unfueled aircraft.

5-14.1.4 Marking

These facilities must be identified by permanent ANSI or OSHA compliant warning signs indicating “Only unfueled aircraft are permitted to be stored or serviced in this hangar See UFC 4-211-01 & T.O. 1-1-3”. Signs must be not less than 12” wide x 18” tall. Signs must be displayed on the exterior and interior of the hangar at the following locations. The exterior side of the hangar aircraft movement doors within 5 feet of the opening edge. Each interior wall centered along the wall’s length. Signs must be mounted 7 feet to the bottom edge of the sign above the hangar floor or pavement surface. See Figure 5-2: ANSI Warning Sign.

Figure 5-2: ANSI Warning Sign

5-15 \3\ HANGARS FOR WHERE FUEL SERVICING EXCEPTION IS APPROVED

Aircraft fuel servicing is not permitted in hangars by simply complying with this UFC per USAF Technical Order (T.O.) 00-25-172 and NFPA 417 Aircraft Fuel Servicing. Inside facility refueling must be approved specifically through the System Safety Engineering Analysis (SSEA) for a specific aircraft type in the specific hangar that complies with requirements of this UFC and section 5-15 \3\ Hangars for Where Fuel Servicing exception is approved in its entirety. The complete SSEA process can only be accomplished after the construction is complete and the aircraft is available. The system safety engineering process is managed by AFMC/AFLCMC and AFSEC. /2/

In-hangar fuel servicing criterion is based on a single aircraft in a fire-separated area undergoing fuel servicing in accordance with approved SSEA operating procedures after a Formal SSEA approval process through AF/SE. A System Safety Engineering Analysis (SSEA) may require additional facility features for specific aircraft, fueling methods, facility types before fuel servicing is allowed.

[C] 5-15 Under the conditions of pressurized fuel servicing fuel type (AVGAS, JP-4, JP-5, JP-8, JP-10, and all similar fuels) does not change/modify the requirements of 5-15. This criteria in 5-15 is not appropriate/adequate for gaseous or liquefied gaseous fuels, propellants or oxidizers.

5-15.1 Facility Criteria Limitation

Fuel servicing operations inside of structures must be authorized in accordance with AFI 91-202 . Compliance with this facility criteria alone is not authority to conduct fuel servicing operations inside of structures. The criteria in this Section are the minimum general facility requirements necessary to apply for a SSEA specific evaluation for approval of fuel servicing inside structures.

[C] 5-15.1 Previous SSEA approvals do not apply to new construction or existing construction not specifically identified in the in the SSEA report.

5-15.2 Minimum Facility Requirements For Aircraft Fueling Servicing Inside New Structures

5-15.2.1 Fire Protection/Suppression

As required by this UFC 4-211-01

5-15.2.2 Separation

2-hour fire resistive wall construction in accordance with 3-3.1.3 between aircraft fuel servicing area the rest of the building and/or other servicing areas.

[C] 5-15.2.2 Only one aircraft may be in a fuel servicing area during fuel servicing operations.

5-15.2.3 Drainage

Listed ignitable liquid drainage floor system, or 18-inch wide concrete box trench set on 25 ft centers. Drainage collection – approved double wall tank(s) capable of containing the largest single aircraft fuel tank capacity.

5-15.2.4 Electrical

Class I Division2 (CID2) to not less than the height of highest door.

5-15.2.5 Fueling System

Type V fuel system preferred; in absence of Type V, pantographs inside the hangar supplied by aircraft refueler vehicle connected to a single point connection outside the hangar. The requirements of section 1.2 will apply to fuel system maintenance hangars when a Type V fuel system is provided.

[C] 5-15.2.5 Authorization to use fuel supply methods other than the requirements in 1.2.5 is outside this installed facility criteria and is a post construction operational safety approval process.

5-15.2.6 Wall Surfaces

Wall surfaces in direct line with aircraft fuel vents must have an impervious surface that is unaffected by aircraft fuels and fuel sprays. Concrete, CMU, and metal surfaces painted or unpainted meet this requirements, sheetrock including type X and other moisture resistant types painted or unpainted do not meet this requirement. Other materials must be submitted for individual approval

5-15.2.7 General Fuel Servicing Area Ventilation

Provide ventilation in accordance with this UFC, UFC 3-410-01, and UFC 3-410-04N. The ability to vary the amount of outside air needs to be in the design. Locate outside air intakes in areas free from contamination. Provide a system capable of ventilating the bay at not less than 1.7 cfm/ft2 during fuel servicing and for a period of time not less than 1 hour following fuel servicing. Ventilate the hangar bay space at all other times at a minimum ventilation rate of 0.05 cfm/ft2. Control the ventilation system by monitoring the concentration of vapors in the space. The use of photoionization detectors (PID) is the preferred method. The level should be maintained below 100 milligram per meter cubed milligram per meter cubed (mg/m3) (14.4 parts per million (ppm)) for JP-8 per the National Institute of Occupational Safety & Health (NIOSH) recommended exposure limit. During maintenance periods, operate the system to maintain fuel vapor concentrations below 14.4 ppm. A minimum of three monitoring points is required, unless the size of the hangar is such that the use of two sensors will adequately protect the space.

5-15.2.8 Emergency Fuel Servicing Area Ventilation

A separate emergency ventilation system will be used to ventilate the hangar bay in the event of high fuel vapor concentrations in the hangar. The emergency ventilation

system will energize to maintain the space at or below 14.4 ppm. The ventilation rate is based on providing a minimum of 20 air changes per hour (ACH) at up to 2 ft. (610 mm) above the finished floor. In hangar bays with lifts, landing gear pits and recessed inspection areas, locate an additional detector in each below-floor area, and increase the emergency ventilation rate to 30 ACH to ensure proper ventilation and removal of the vapors.

5-15.2.9 Positive Pressure Ventilation

Provide office space, break room, and support equipment/tool room with positive pressure ventilation to prevent vapors and gases from migrating from the aircraft fuel servicing area.

5-15.2.10 Negative/Neutral Pressure Ventilation

When appropriate, provide negative pressure ventilation in restrooms and locker rooms. When these spaces are located next to, and thus will pull air from, areas with fuel/toxic vapors, provide sufficient supply air to allow this space to be at a neutral pressure (to prevent fuel/toxic vapor infiltration.)

5-15.3 Facility Requirements For Aircraft Fueling Servicing Inside Existing Structures

Existing legacy approvals to conduct fuel servicing inside, documented in Service technical guidance remain valid. This criterion applies to the facility requirements for facilities being considered for approvals to conduct fuel-servicing operations in existing structures.

5-15.3.1 Fire Suppression

As required by UFC 4-211-01 or other previously approved aircraft hangar, PAS, or HAS approved fire suppression system.

5-15.3.2 Separation

2-hour firewall(s) between the rest of the building and/or other bays; Operations alternative in existing building evacuate building of all personnel not part of the fuel servicing operation and stop all other aircraft maintenance activities.

[C] 5-15.3.2 If separation in accordance with 1.2.2 is not provided all persons not directly associated with the specific fuel servicing must evacuate the entire building (T.O. 00-25-172)

5-15.3.3 Drainage

Listed ignitable liquid drainage floor system or other previously approved aircraft hangar, PAS, or HAS drainage system. Drainage collection – approved double wall tank(s) capable of containing the largest single aircraft fuel tank capacity.

5-15.3.4 Electrical

Class I Division 2 (CID2) to height of highest door. Operations alternative in existing building provide a shunt trip to de-energize all electrical not required for the fuel servicing operation.

5-15.3.5 Fueling System

Type V fuel system preferred; in absence of Type V, pantographs inside the hangar supplied by aircraft refueler vehicles outside the hangar or other SSEA approved fueling means previously approved for the specific structure.

[C] 5-15.3.5 Authorization to use fuel supply methods other than the requirements in 3-15.4.5 is outside this installed facility criteria and is a separate post construction operational safety approval process.

5-15.3.6 Wall Surfaces

Wall surfaces in direct line with aircraft fuel vents must have an impervious surface that is unaffected by aircraft fuels and fuel sprays. Concrete, CMU, and metal surfaces painted or unpainted meet this requirements, sheetrock including type X and other moisture resistant types painted or unpainted do not meet this requirement. Other materials must be submitted for individual approval.

5-15.3.7 General Fuel Servicing Area Ventilation

Provide ventilation in accordance with this UFC, UFC 3-410-01, and UFC 3-410-04N. The ability to vary the amount of outside air needs to be in the design. Locate outside air intakes in areas free from contamination. Provide a system capable of ventilating the bay at not less than 1.7 cfm/ft2 during fuel servicing and for a period of time not less than 1 hour following fuel servicing. Ventilate the hangar bay space at all other times at a minimum ventilation rate of 0.05 cfm/ft2. Control the ventilation system by monitoring the concentration of vapors in the space. The use of photoionization detectors (PID) is the preferred method. The level should be maintained below 100 milligram per meter cubed milligram per meter cubed (mg/m3) (14.4 parts per million (ppm)) for JP-8 per the National Institute of Occupational Safety & Health (NIOSH) recommended exposure limit. During maintenance periods, operate the system to maintain fuel vapor concentrations below 14.4 ppm. A minimum of three monitoring points should be used, unless the size of the hangar is such that the use of two sensors will adequately protect the space.

5-15.3.8 Emergency Ventilation

A separate emergency ventilation system will be used to ventilate the hangar bay in the event of high fuel vapor concentrations in the hangar. The emergency ventilation system will energize to maintain the space at or below 14.4 ppm. The ventilation rate should be based on providing a minimum of 20 air changes per hour (ACH) at up to 2 ft. (610 mm) above the finished floor. In hangar bays with lifts, landing gear pits and recessed inspection areas, locate an additional detector in each below-floor area, and

increase the emergency ventilation rate to 30 ACH to ensure proper ventilation and removal of the vapors.

5-15.3.9 Positive Pressure Ventilation

Provide office space, break room, and support equipment/tool room with positive pressure ventilation to prevent vapors and gases from migrating from the aircraft fuel servicing area.

5-15.3.10 Negative/Neutral Pressure Ventilation

When appropriate, provide negative pressure ventilation in restrooms and locker rooms. When these spaces are located next to, and thus will pull air from, areas with fuel/toxic vapors, provide sufficient supply air to allow this space to be at a neutral pressure (to prevent fuel/toxic vapor infiltration.)

5-15.4 Minimum Facility Requirements For Aircraft Fueling Servicing Under New And Existing Weather Shelters

Weather shelters are generally considered organizational equipment (not facilities), however, certain utility features as such electrical features are considered real property or are maintained as real property similar equipment. Weather shelters with 2 or fewer sides (including doors) are allowed to be considered open ramp. Structures with more than 2 sides (including doors) are classified for protection purposes hangars, regardless of identifying nomenclature and must meet the requirements of this UFC for hangars.

[C] 5-15.4 Weather shelters in compliance with 2 or fewer sides and the following sub-paragraphs may conduct fuel servicing operations in accordance with service specific operations guidance: AF T.O. 00-25-172 as open ramp location without additional approvals.

5-15.4.1 Electrical Equipment

Below the surface of the parking ramp must be Class I Div 1 (Zone 1). Above the surface of the parking ramp and within the fuel safety servicing zone (FSSZ) area up to within 12 inches of the roof of the weather shelter electrical equipment and devices must be Class I Division 2 (Zone 2).

[C] 5-15.4.1 Operational alternative in existing weather shelters allows a shunt trip to de-energize all electrical not required for the fuel servicing operation. New construction would have to comply with 5-15.4.2.1.

5-15.4.2 Wall Surfaces

Wall surfaces in direct line with aircraft fuel vents must have an impervious surface that is unaffected by aircraft fuels and fuel sprays.

5-16 PROTECTIVE AND HARDENED/SEMI-HARDENED AIRCRAFT SHELTERS (PAS AND HAS)

Protective and hardened/semi-hardened aircraft shelters are sited and constructed in accordance UFC 3-340-01 and UFC 3-340-02.

[C] 5-16 These shelters are combat assets intended to be fully operational under combat conditions with no installation utility support capable of launch and recovery of aircraft for multiple missions.

5-16.1 Hazardous (Classified) Locations

Classify the entire HAS/PAS and personnel shelters, offices, or other structures located within the HAS/PAS as Class I, Division 2. Where approved in overseas areas, electrical equipment may be installed in accordance with local codes with equivalent electrical hazardous location requirements. Example: Directive 94/9/EC – ATEX95; EU Zone 2, UK Zone 2, JP Zone 2.

[C] 5-16.1 These shelters have been evaluated through the SSEA process for most aircraft types to permit in-shelter fuel servicing when these electrical requirements are present. Failure to provide these electrical features would compromise a significant operational mission capability. See T.O. 00-25-172 for additional information.

5-16.2 Fire Protection Technology

Provide one of the following fire control technology options:

Option 1:

Provide a manual fixed low-level foam fire suppression system providing a 4-minute low expansion foam application to the floor area at a rate of not less than 0.1 gpm/sqft. Activation stations must be provided at any doors into the shelter and at a location on the opposite side of the shelter separated by 180 degrees from the entrance door. Primary power will be from the installation power distribution and secondary power will be the shelter generator.

Option 2:

Provide a listed ignitable liquid drainage floor system. System must be gravity operated. Flushing water will be from the installation water distribution; no secondary flushing will be required; on loss of water distribution the system will rely on gravity alone to flush capture liquids from the shelter. Effluent control outside the shelter must comply with appropriate environmental controls and agreements, however, it must be designed to function without any installation utility support.

[C] 5-16.2 Technology and legislative requirements are rapidly evolving; therefore; prior to programming or commencing work in these shelters consult with AFCEC/COSM for the most current technical direction.

5-16.3 Fire Controls and Notification

Fire controls for the manual fixed low-level fire suppression system must be a listed releasing panel. No detection or manual pull stations are required. The controls will supervise the low level system and the manual start stations (see Figure 3-11). Notification will be visual and audible (NFPA temporal pulse) using high noise area speakers.

Fire controls for the ignitable liquid drainage floor must be a listed fire alarm panel. No detection or manual pull stations are required. The controls will supervise the ignitable liquid floor drainage system controls. Notification will be visual and audible (NFPA temporal pulse) using high noise area speakers.

5-16.4 Egress Marking

Photo luminescent marking will be used. The door leaf will be outlined with a 1-inch wide band and the door frame will be outlined in a 1-inch side band on the sides and top. A running man not less than 6-inch x 6-inch (15mmx15mm) will be mounted at the floor level centered on the door just above the 1-inch band. A second running man will be mounted either top center on the door or just above the door depending on which provided the best general visibility through-out the shelter. The installation may add additional egress marking, if desired.

The secondary means of escape is normally out the exhaust opening; locations of the photo-luminescent marking will be locally determined. Pathway marking to either the door or the secondary means of escape is not required.

5-17 MODERNIZATION OF EXISTING FIRE PROTECTION SYSTEMS

This section provides criteria for the modernization and life-cycle sustainment requirements of existing aircraft hangar fire protection Apply this section to existing hangar bay fire protection systems that are wholly or partially designed to criteria other than contained in this UFC.

Lifecycle obsolesce should be evaluated on several factors frequency of repair, component condition, availability of parts or new component availability. Age, generally is not a factor in lifecycle obsolesce.

[C] 5-17 The target minimum lifecycle for installed hangar fire suppression systems is 50 years with ITM in accordance with UFC 3-601-02 and periodic modernization. AF/A4 has directed all out-of-service hangar fire suppression systems must be operational not later than the end of FY26 or may no longer be used for aircraft storage, maintenance and repair.

5-17.1 Existing Unprotected Hangars

Program unprotected hangars to comply with the requirements of this UFC.

[C] 5-17.1 AF/A4 has not currently established a target date for the elimination of unprotected hangars.

5-17.2 Existing Water Only Deluge Systems

For a hangar bay protected with an existing overhead water only deluge system, at the end of its life cycle or during a major hangar renovation project, replace the fire suppression and releasing system with a new foam fire suppression and releasing system per Chapter 3. Provide an overhead hangar bay sprinkler system and supplemental Hi-Ex foam system in accordance with this UFC. This includes but is not limited to the fire water and foam/water distribution, foam proportioning, and fire water supply system. Provide a releasing system in accordance with this UFC including but not limited to manual foam releasing stations, manual foam stop stations, and optical flame detection. Horns with NFPA temporal audible notification may be used where voice evacuation capability does not currently exist in the building.

5-17.3 Existing High-Expansion Foam/Water Systems

Existing Hi-Ex foam water system must be modernized to meet the radiant energy (optical) detection requirements in 3-6.19.11Optical Flame Detection and the manual releasing requirements in 3-6.19.8 Manual Foam and Low Level Water Releasing Stations. Modify the existing low level Hi-Ex foam suppression system to only activate the foam/water system from either:

Option 1:

Activation signal/input a manual foam releasing station complying with 3-6.19.8 Manual Foam and Low Level Water Releasing Stations and 3-6.19.10 Manual Foam and Low Level Water Releasing and Stop Station Signage.

Option 2:

Activation signal/input from two or more enabled radiant energy (optical) flame detectors and controls complying with 3-6.19.11Optical Flame Detection, 5-6.3 Releasing Service Fire Alarm Control Unit (RSFACU), and 5-6.4 Radiant Energy (Optical) Flame Detection.

No other activation signals/inputs are permitted to activate discharge of any low level or open discharge foam fire suppression system. For hangars constructed before 2015, evaluate the individual hangar evaluation report and program Evaluate the feasibility to provide a foam/water proportioning system in compliance with Chapter 3 General Hangar Requirements. Where this change cannot be made without extensive modifications to the fire water supply that is outside the original scope of the project, such as upgrades to the fire water infrastructure distribution, addition of a fire water storage tank, or addition of a fire pump house, repairs will be made to restore the existing system without altering its original design. The addition of an inline fire water booster pump on the foam/water riser only is often considered a feasible solution.

[C] 5-17.3 AF/A4 has directed these modernization must be completed by the end of FY26.

5-17.4 Existing Low Level AFFF and Overhead AFFF Systems

(Left blank intentionally pending DoD phase-out/life cycle extension guidance.)

5-17.5 Existing Fire Protection Water Supply

Where upgrades are made to the fire water supply per this section such as adding a fire water booster pump, provide a foam/water flow control valve and manual foam stop stations in accordance with this UFC. Where manual foam water stop stations are provided, surge arrestors are required accordance with this UFC. Reconfigure the bladder pressurization piping so the bladder is not under constant pressure, which may include relocating the pressurization piping downstream of the deluge or flow control valve. /3/

CHAPTER 6 ARMY SPECIFIC CRITERIA

6-1 INTRODUCTION

\2\ This UFC is organized with general requirements and Service-specific requirements. Apply Chapters 1, 2, 3, 4 and Appendices to all Services. Additionally apply Chapters 5, 6 and 7 to Air Force, Army, and Navy, respectively, for Service-specific requirements./2/

6-1.1 US Army Aircraft Maintenance Strategy

Current US Army aircraft maintenance strategy is designed to Service-specific needs of the aviation mission and specific aircraft type (Rotary Wing (RW), Fixed Wing (FW) or Unmanned Aircraft Systems (UAS); refer to the *Army Standard for Aircraft Maintenance Hangar (HGR) Complex* for additional details. The Army performs the majority of all repair maintenance in the shops or on the hangar floor. The Army also co-locates unit operations for aviation missions/operations within the hangar facility to coordinate aviation mission requirements/operations and aircraft maintenance requirements. The Army has developed a high level of aircraft maintenance facilities standardization including common spaces, functions, typical floor plans and room data sheets for a variety of hangar types. The US Army Corps of Engineers, Aviation - Center of Standardization (AVN-COS), Mobile District has developed and maintains standard plans and criteria for RW and UAS hangar facilities. The AVN-COS hangar standard design documents and points of contact are maintained on the USACE Center of Standardization website (https://mrsi.erdc.dren.mil/cos/). \2\ The current Army Standard for Aircraft Maintenance Hangar Complex (HGR) along with this document is to govern the planning and design of Army Fixed Wing hangars. /2/

6-1.2 Army Standard for Aircraft Maintenance Hangar (HGR) Complex

The *Army Standard for the Aircraft Maintenance Hangar (HGR) Complex* applies to the planning, design, and construction of all active Army Tables of Organization and Equipment (TOE) aircraft maintenance and repair requirements worldwide. The Army Standard applies equally to Tables of Distribution and Allowance (TDA) hangars. While the Army Standard is based on the Combat Aviation Brigade (CAB), the criteria are applicable to all aircraft maintenance and repair facilities. The current version of the Army Standard is maintained on the MILCON Requirements and Standardization Integration (MRSI) website https://mrsi.erdc.dren.mil.

\3\

6-1.3 Applicability

Additionally, this UFC applies to all new Army rotary wing, fixed wing, and UAS hangars regardless of organization (i.e. MTOE, TDA) or mission type (i.e. operational, training, etc.). Design non-standard hangars to accommodate minimum safety clearances shown in Table 2-1: Minimum Aircraft Maintenance Bay Clearances for the design airframe(s). Comply with all safety and life-safety related criteria when renovating or re-purposing

existing hangar(s) including, but not limited to: Fire Protection, Occupant Loads and Egress, Aircraft minimum safety clearances. Follow all other criteria of this UFC and standard designs to the maximum extent practical for the renovation. The intent of meeting all criteria is to provide for future hangar flexibility to maintain alternate and emerging aviation platforms. If meeting those additional criteria is not technically or financially feasible for a renovation project addressing a specific aircraft platform, then it is only necessary to meet the mission requirements for that specific platform and all safety and life-safety criteria as stated above. Planning documents are to specify the scope and intent of the renovation on the 1391 planning document including listing specific criteria and design aircraft. /3/

6-2 CIVIL

6-2.1 Airfield Pavement Markings

Design and layout Airfield Pavement Markings for Army Hangars in accordance with ETL 1110-3-512.

6-2.2 Containment of Fire Suppression Effluent

Route the wet pipe, dry pipe, preaction or foam/water system runoff from the hangar bay to automatically discharge to an underground containment tank, unless required otherwise by the local environmental regulations.

6-2.2.1 Environmental Regulations

Consider the local environmental regulations to determine the control, treatment and/or remediation measures for the discharge of fire suppression effluent from the hangar bay. Discharge effluent from the containment system as directed by the department overseeing environmental policy for the installation. Base the conditions for disposal upon the capability and location of the facility that would treat the effluent from the containment system. Verify fire suppression effluent containment discharge requirements with the appropriate installation environmental engineer, including local and state environmental requirements.

6-2.2.2 Capacity

Provide capacity to contain 15 minutes of the hydraulically calculated demand from the overhead sprinkler system in the hangar bay, plus the hose stream demand. Do not include the Hi-Ex foam system fire flow in the containment capacity. Design the containment system to accommodate the entire calculated fire suppression effluent discharge volume for the duration noted. Do not use the trenches or piping of the containment system to contain any of the required volume.

6-2.2.3 Containment System Monitoring

Provide the containment system with a remote capacity monitoring panel. Provide monitoring panel with audible and visual (yellow strobe or beacon) alarms. Automatically activate audible and visual alarms when the capacity level exceeds 5%. Provide a silence switch for the audible alarm. Constantly illuminate visual alarms at the panel until the level condition is returned to normal. Locate containment system monitoring panel in the hangar bay. Provide an alarm to the FACU and Energy Management Control System when the capacity level exceeds 5%.

6-2.2.4 Sump Pump

Empty tank in accordance with environmental regulations. Install the sump pump inside the tank and operate the pump manually. Discharge the fire suppression effluent from the sump pump in accordance with environmental regulations. Locate controls for the sump pump near the inspection port to the containment tank.

6-2.2.5 Diverter Valve/System

Provide a system that automatically diverts the floor trench drainage flow to a foam/water containment system upon system activation. Where a containment system uses a diverter valve, provide actuation and monitoring of the valve as indicated in this paragraph. Automatically actuate the valve upon release of the fire suppression system in the hangar bay. Provide indication of the diverter valve position at the monitoring panel through the use of limit switches. Provide indication of when the valve is fully open or closed. Provide the valve with remote manual reset capability through a "Valve Position Restore" button. Provide the panel with a visual alarm (yellow strobe or beacon) that automatically illuminates when the valve position is "off normal" or "closed", and remains illuminated until valve is restored to the full normal "open" position. Locate diverter valve panel in the hangar bay adjacent to the containment system monitoring panel. Provide an alarm to the FACU and Energy Management Control System when the diverter valve is in the off normal position. Install the diverter valve motorized operator above grade or list it for a submersible environment.

6-2.2.6 Monitoring System Construction

The containment system monitoring panel and diverter valve panel (when provided) may be combined. At a minimum, provide NEMA 250 Type 4 panel(s).

Rate any devices, conduits, or electrical enclosures installed below grade or within the containment tank for prolonged submersion, minimum NEMA 250 Type 6P.

6-3 ARCHITECTURAL

6-3.1 Aircraft Maintenance Module Size

The Army Standard has established standard aircraft maintenance module sizes for rotary wing aircraft and UAS aircraft. Refer to the USACE Centers of Standardization website (https://mrsi.erdc.dren.mil/cos/) or via links on the National Institute of Building

Sciences (NIBS) Whole Building Design Guide (WBDG) site (http://www.wbdg.org/references/pa_dod.php).

6-3.1.1 Rotary Wing Aircraft

The Army Standard established two maintenance module sizes for rotary wing (RW) aircraft. The module sizes are as follows:

- 84 Feet Long by 64 Feet Wide (25.6 m Long by 19.5 m Wide) - Utility, Attack, and Reconnaissance (UAR) Aircraft Maintenance Module. Typical RW aircraft serviced include the UH-60, AH-64, and OH-58.
- 110 Feet Long by 70 Feet Wide (33.5 m Long by 21.3 m Wide) - Cargo Aircraft Maintenance Module. Typical RW aircraft serviced include the CH-47.

6-3.1.2 UAS Aircraft

\2\ The Army Standard established a maintenance module size for Group 3 and Group 4 UAS aircraft as follows:

- Group 3: 26 Feet Long by 17 Feet Wide (7.92 m Long by 5.2 m Wide). Typical UAS aircraft serviced is the V2 Shadow RQ-7B-1E.
- Group 4: 40 Feet Long by 68.34 Feet Wide (12.2 m Long by 20.84 m Wide. Typical UAS aircraft serviced is the MQ-1C Gray Eagle Extended Range. /2/

6-3.2 Coordinate Interior Systems

Coordinate Interior Systems with the APPROVED Army Standard Design for Aircraft Maintenance Hangar Complexes.

6-3.3 Aircraft Maintenance Bay and Heavy Maintenance Shop Floor Finishes

Provide one of the following floor finishes for the Aircraft Maintenance Bay and Heavy Maintenance Shops consistent with the user requirements, facility purpose, and the intended design life cycle of the facility:

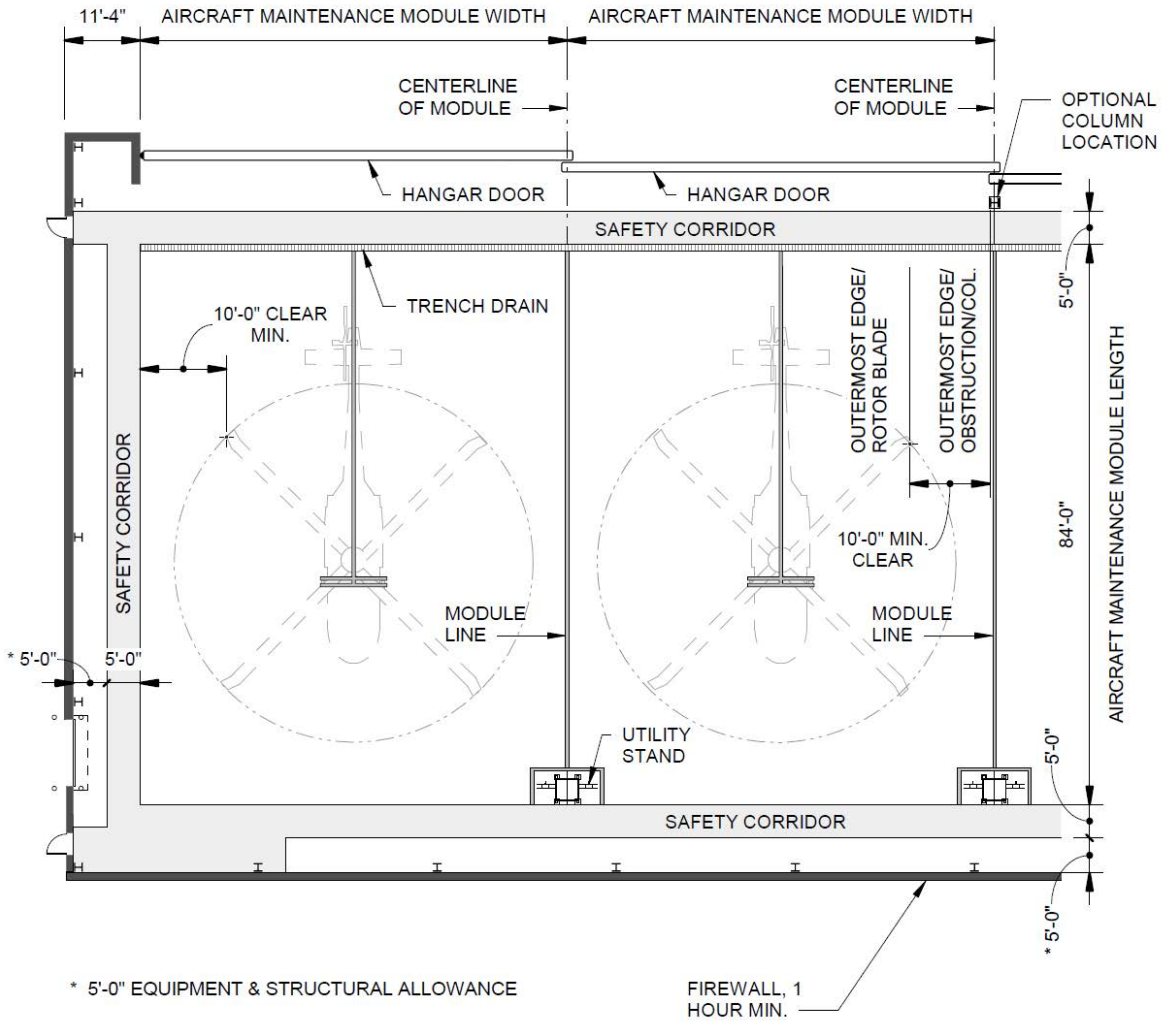
- Smooth Trowelled Finish with a Sealer
- Fuel Resistive Resinous Floor Coating system, commonly referred to as a 3 Coat System in UFGS Section 09 67 23.15
- Fuel Resistive Resinous Floor Coating system, commonly referred to as a 5 Coat System in UFGS Section 09 67 23.16

If the Project Delivery Team (PDT) selects the 5 Coat System, provide a life cycle cost analysis in the Design Analysis confirming the life cycle cost effectiveness of this floor coating selection for the project.

6-3.4 Aircraft Maintenance Bay Pavement Marking

Design and layout all Aircraft Maintenance Bay pavement markings in accordance with ETL 1110-3-512 and Figure 6-2: Maintenance Bay Pavement Markings. All paint for pavement markings to be in compliance with FS TT-P-1952, Paint, Traffic and Airfield Marking, Waterborne.

Figure 6-1: Typical Maintenance Bay Configuration



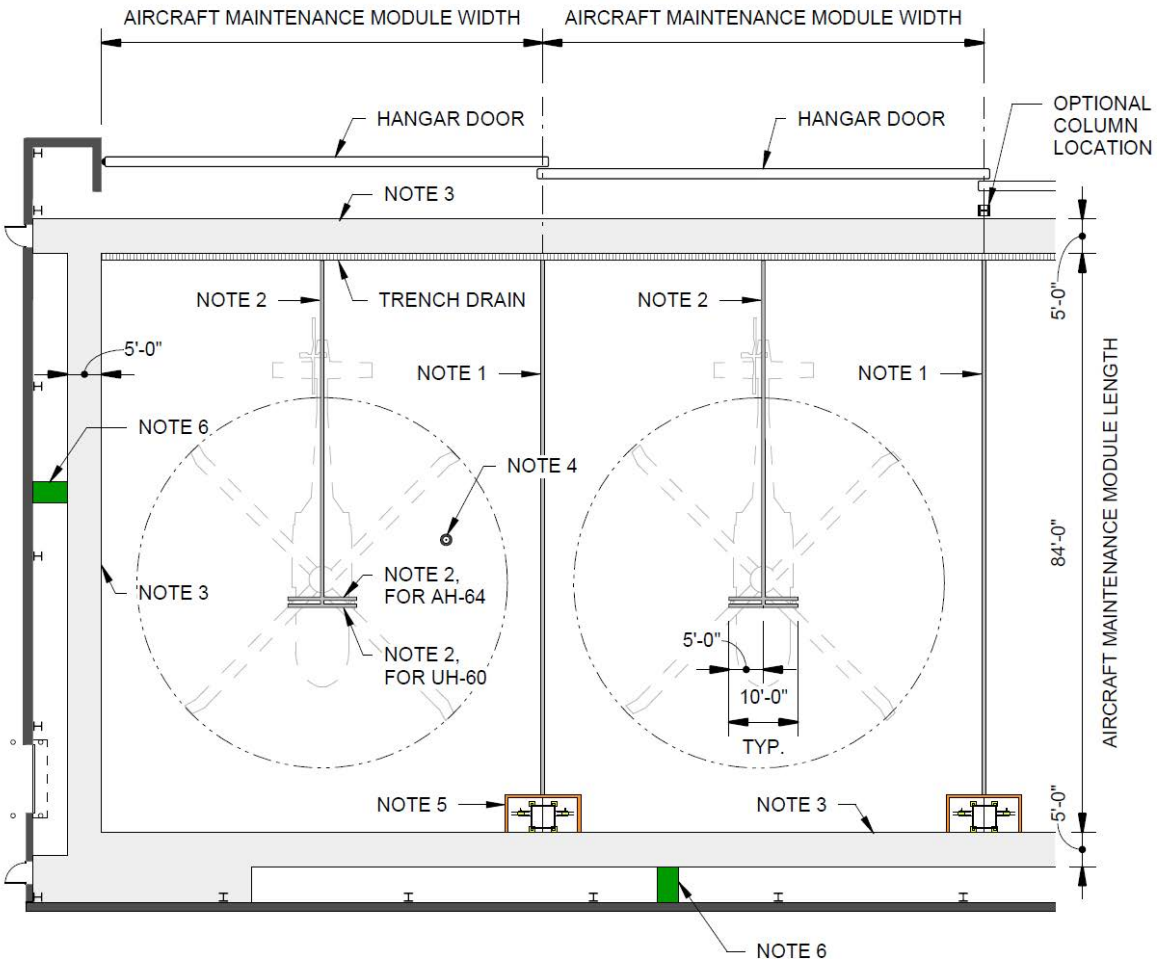


Figure 6-2: Maintenance Bay Pavement Markings

Floor Marking Notes:

1. Maintenance module boundary; 6 in. (152 mm) wide stripe; color - dark grey.
2. Maintenance module centerline & nose gear stop; 6 in. (152 mm) wide stripe; color - dark grey.
3. Safety corridor; 5 ft. (1.5 m) wide; color - yellow.
4. Grounding receptacle; paint per UFC 3-575-01, figure 2-3.
5. Utility stand; 6 in. (152 mm) wide stripe; color - orange. Provide 2'-0" clearance from utility stand equipment.
6. Safety eyewash/shower; color - green; provide 2 ft. (610 mm) clearance from safety equipment.
7. Provide markings for required clear area on floor around electrical and life safety features.

6-4 STRUCTURAL

6-4.1 Aircraft Maintenance Bay - Slab on Ground Loading

Design Army Aircraft Maintenance Bay slabs on ground in accordance with the minimum following traffic requirements. Add project specific additional vehicles to the mix as required. Make no reductions to these traffic mixes without the approval of the USACE Transportation Systems Center (TSC).

6-4.1.1 \2\ UAS Hangars – Group 3 and Group 4 /2/

Use Type B traffic area with the following minimum traffic mix:

- UH-60 Aircraft (16,300 pounds (lbs.)) - 20,000 passes
- ATLAS forklift (6,000 lbs. - loaded carriage)- 25,000 passes
- P-15 Crash/Fire Truck (130,860 lbs.) - 1,200 passes
- Transport Truck M1088 and M871A3 Trailer (80,000 lbs.) - 1,000 passes

6-4.1.2 Rotary Wing Hangars

Use Type B traffic area with the following minimum traffic mix:

- CH-47 Aircraft (37,500 lbs.) - 40,000 passes
- ATLAS forklift (10,000 lbs. - loaded carriage)- 10,000 passes
- P-15 Crash/Fire Truck (130,860 lbs.) - 1,200 passes
- Transport Truck M1088 and M871A3 Trailer (80,000 lbs.) - 1,000 passes

6-4.1.3 Fixed Wing Hangars

Use Type C traffic area with the following minimum traffic mix:

- Design Aircraft - Most critical aircraft expected to use the maintenance hangar bay - 40,000 passes
- P-15 Crash/Fire Truck (130,860 lbs.) - 1,200 passes
- Transport Truck M1088 and M871A3 Trailer (80,000 lbs.) - 1,000 passes
- 10K forklift - 10,000 passes

6-5 MECHANICAL

6-5.1 Heating

Low or high-intensity infrared heaters may be installed as suspended or elevated heaters in hangar bays in accordance with NFPA 409 in hangar bays. Evaluate overhead radiant heat systems as one of the alternatives when determining the most life-cycle cost effective way of heating the hangar bay(s). **\2** Where it is determined that

infrared radiant heat is not effective, evaluate radiant floor heat in the life-cycle cost analysis. **/2/**

6-5.2 Ventilation and Exhaust

Provide general hangar exhaust in accordance with Chapter 3. In addition, consider local ventilation where contaminants are generated. Provide calculations that identify and quantify the contaminant of concern in accordance with OSHA standards. Ventilate under floor pits, duct, and tunnels per NFPA 409 even if the JP-8 (kerosene based fuel) is below its flash point temperature.

Ventilation may be used in economizer cycles for increased thermal comfort where climatic conditions are appropriate. One example would be where diurnal temperature variation allows night time cooling. Natural air movement through locating louvers and dampers near the ceiling and floor should be evaluated for life cycle cost effectiveness versus a fan powered economizer cycle. Evaporative cooling is not allowed in Army hangar maintenance bays.

6-5.3 Plumbing

\2\ Mount hose bibbs and compressed air connections on all utility pedestals located inside the perimeter access aisle. /2/

6-6 FIRE PROTECTION AND LIFE SAFETY

6-6.1 General

Classify hangars as Group I, II, III, or IV in accordance with NFPA 409.

6-6.2 Fire Pumps

\2\ In addition to pressure drop, start fire pumps automatically upon receiving a fire pump start signal from the FACU. /2/

6-6.3 Foam/Water Concentrate Proportioning Systems

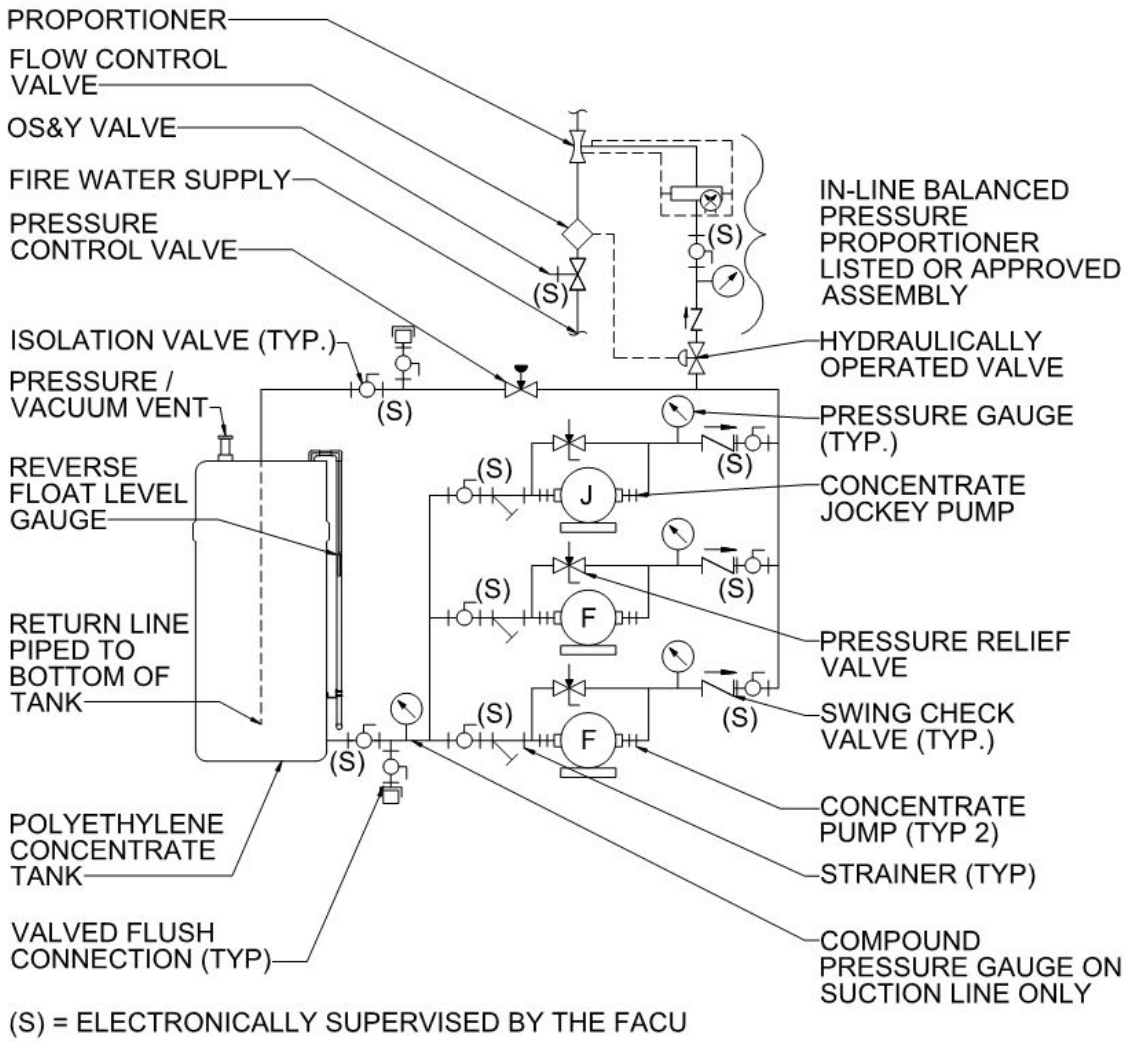
Proportioning foam concentrate through the use of a ratio flow controller and bladder tank, or a foam inductor is not permitted. Provide a foam concentrate pumping system, with an atmospheric foam concentrate storage tank. Provide a foam concentrate pumping system in compliance with NFPA 11, NFPA 20, and NFPA 409, except as modified by UFC 3-600-01 and this UFC. Refer to

Figure 6-3: Army Foam Pump Detail.

6-6.3.1 Foam Concentrate Pumps

Provide positive displacement concentrate pumps with electric motor drivers, supplied by a reliable power source. Use UFC 3-600-01 for reliable power requirements. Where reliable power is not available, provide diesel driven concentrate pumps.

Provide a reserve foam concentrate pump of equal capacity. Automatically operate the reserve pump upon failure of the primary pump. Arrange concentrate supply piping to meet the foam concentrate demand from either the primary or reserve foam pump. \3\ Floor drains in fire pump enclosures required by NFPA 20 shall not be required for enclosures for fire pumps dedicated to the delivery of fire suppression foam concentrate. /3/



6-6.3.2 Foam Concentrate Jockey Pump

When the foam concentrate line to the proportioner exceeds a linear distance of 50 ft. (15.2 m), provide a positive displacement foam concentrate jockey pump to maintain pressure in the foam concentrate piping.

6-6.3.3 Foam Concentrate Pump and Jockey Pump Control

Upon activation of the foam/water system, remote start the foam concentrate pump from the RSFACU. Do not start the foam concentrate pump upon a drop in pressure. Upon depressing the manual foam stop station, stop the foam concentrate pump and the foam concentrate jockey pump (where provided) to prevent excessive concentrate from being pumped into the foam solution piping. Remote stopping of these pumps from the RSFACU is approved. Releasing the manual foam stop station will restart the foam concentrate jockey pump (where provided). As long as the foam/water system is in alarm, releasing the manual foam stop station will restart the foam concentrate pump.

Figure 6-3: Army Foam Pump Detail

6-6.3.4 In-line Balanced Pressure Proportioners (ILBP)

Provide ILBP proportioners that are listed or approved by a NRTL and are factory assembled and tested by the manufacturer. Disassembly, reassembly, or modification of the ILBP by the installing contractor is prohibited. Install ILBP proportioners downstream of the flow control valve.

6-6.3.5 Concentrate Storage Tank

The concentrate storage tank is permitted to have a tap on the side of the tank for the foam concentrate suction line. Additional taps into the side of the tank are not permitted.

6-6.3.6 Foam/Water Concentrate Proportioning Performance

Increase the capacity of the foam concentrate tanks and pumps, to compensate for proportioner tolerance and the maximum anticipated fire water pressure. Calculate this increase to enable the foam concentrate system to deliver foam for the required discharge duration.

6-6.4 Releasing Service Fire Alarm Control Unit (RSFACU)

Provide waterflow detection devices to monitor the overhead wet pipe, dry pipe, or preaction sprinkler systems in the hangar bay.

Only release the Hi-Ex foam system from a manual foam releasing station, or two simultaneous votes from non-latching initiating devices in the releasing zone. These initiating devices are required to be an optical flame detector in simultaneous operation with either another optical flame detector or waterflow detection device within the same releasing zone. Refer to Table 6-1: \3\ Sample Army RSFACU Functional Matrix for additional functional requirements.

6-6.5 Manual Foam Stop Stations

In addition to stations required by 3-6.19.9: Manual Foam and Low Level Water Stop Stations, provide a manual foam stop station in the corridor of each required exit from the hangar bay through the support space. Locate the station on the support side of the door, such that it is within 5 ft. (1.5 m) of the door and not obstructed when the door is fully open. Provide a 100 sq. in. (0.065 sq. m) fire rated door vision panel in these doors, such that an occupant can view into the hangar bay while operating the manual foam stop station.

6-6.6 Optical Flame Detection Supervised Disconnect

Provide a key operated supervised disconnect switch to disable all optical flame detectors in the hangar bay through programming at the RSFACU. Provide a switch that disables the releasing and notification functions of the optical flame detectors, while leaving all other functions of the RSFACU operational. Operation of the switch will not create a trouble signal. Monitor the disconnect at the RSFACU. Provide a supervisory signal to the receiving station upon operation of the disconnect. While the switch is in the disable mode, the optical flame detectors will not retain any history of alarm conditions such that when the switch is placed in the enable mode the RSFACU will not immediately go into alarm.

Locate the disconnect switch in the hangar bay, in a readily accessible location near a manual foam stop station. Provide a NEMA 250 Type 4 switch and backbox or house the components in a NEMA 250 Type 4 enclosure. Provide a non-flashing or rotating red indicating light not less than 400 cd (208/120VAC) powered from a dedicated \3\ fire protection features \3\ panel provided in accordance with UFC 3-520-01. Control light initiation through the RSFACU. A backup power supply or supervision of the power supply to the light is not required when supplied from the dedicated \3\ fire protection features /3/ panel. Mount the light above the disconnect switch. \3\ Provide a sign, near

the disconnect switch, with a white background and a minimum 1/2 inch wide blue border, with "OPTICAL FLAME DETECTION DISABLED WHEN ILLUMINATED" in red lettering not less than 1 inch (25.4 mm) high. /3/ Provide engraved labels on the disconnect switch indicating when the optical flame detectors are "ENABLED" or "DISABLED". Do not install backboxes or route conduit in front of sign in a manner that obstructs any lettering.

6-6.7 Notification Devices

Provide blue rotating beacons not less than 400 cd (208/120VAC) powered from a dedicated \3\ fire protection features /3/ panel provided in accordance with UFC 3-520-01. Control beacon initiation through the RSFACU. A backup power supply or supervision of the power supply supplying the beacons is not required when supplied from the dedicated \3\ fire protection features /3/ panel. Mount beacons 20 - 30 ft. (6.1 - 9.1 m) above the floor of the hangar bay. Provide a sign next to each blue beacon with a yellow or lime-yellow background matching the manual foam releasing station signage, with "FOAM RELEASE WHEN ILLUMINATED" in red lettering not less than 3 inches (76 millimeters) high. Blue beacons are in addition to any general fire alarm notification such as the fire alarm strobes.

- For single door hangars, provide one beacon approximately centered on each of the three walls.
- For drive through hangars, provide one beacon 10-25 ft. (3.0 -7.6 m) from each corner of the hangar bay.
- Provide additional beacons where at least one beacon is not viewable from normally occupied areas of the hangar bay. Locate beacons to take into account building construction, aircraft configuration and positioning in the hangar bay.

6-6.8 Supervision Devices

Provide a supervisory level alarm monitoring for foam concentrate. Indicate when the foam concentrate in the storage tank is below the amount required to meet the performance criteria.

Table 6-1: \3\ Sample Army RSFACU Functional Matrix

NOTE: This sample table is intended to be specifically tailored/edited for each project./3/

Integrate the system with the building power system and complete with all cables and connectors required to interface with the aircraft. No ground power units (carts) are allowed. Design system to provide access to each aircraft parking space without any cables or equipment passing thru the five foot clear zone around the hangar bay floor.

6-7.1.1 Permanently-Mounted Pedestal

Provide permanently-mounted pedestals. Coordinate the connection point in the hangar floor space with the location of the aircraft. Permanently mount the pedestal to the hangar floor. Locate pedestals to avoid aircraft movements. Coordinate the location of pedestals with the clearance requirements listed in 2-3: Minimum Aircraft Maintenance Bay Clearances. Pedestal may have multiple mechanical, electrical, and communication services including power, compressed air, network connections, and water. Coordinate types of all service utilities to be provided on pedestal with activity. Route utility connections under the hangar floor from the wall to the pedestal. Mount all electrical utilities a minimum of 18 inches (0.46 m) AFF. Seal all electrical penetrations from the floor, per NFPA 70.

6-7.2 Grounding and Bonding

Provide ordnance grounding in accordance with Department of the Army Pamphlet (DA PAM) 385-64.

6-7.3 Electrical Equipment

All electrical equipment in the hangar bay is required to be in a NEMA 250 Type 3R or weather proof enclosure.

6-8 COMMUNICATIONS

6-8.1 CATV Systems

Refer to the Army Hangar Center of Standardization for required CATV locations.

6-9 OVERHEAD BRIDGE CRANES

Provide in accordance with 3-9: Overhead Bridge Cranes and the Army Standard for Aircraft Maintenance Hangar Complex.

6-10 HANGAR DOORS

Provide in accordance with 3-10: Hangar Doors.

6-11 FLOORS AND TRENCH DRAINS

6-11.1 Trench Drains

Provide trench drains in the hangar bay to comply with NFPA 409 *Floor Drainage Requirements* for the removal of hazardous fuels and fire suppression system discharges.

6-11.1.1 Trench Design

Size trench drains to account for the simultaneous flow of the hydraulically calculated demand of the overhead sprinkler system in the hangar bay and the exterior hose stream demand.

6-11.1.2 Location and Spacing

\2\ Provide trench drain parallel to hangar door track located per

Figure 6-1: Typical Maintenance Bay Configuration. Slope the floor from the back wall to the trench drain. /2/

6-11.2 Trench Covers

Provide ductile iron or galvanized steel trench covers, manufactured to withstand a minimum proof-load of 50,000 pounds from a tire with a 250 psi pressure or the most critical of the aircraft wheel loads listed in this UFC, whichever is greater.

6-12 FUEL CELL MAINTENANCE

Fuel cell maintenance is performed in Army helicopter maintenance hangars in accordance with approved maintenance procedures. Mobile helicopter fuel tank ventilating equipment is used to remove local fuel vapors.

6-13 WASH BAY

Provide in accordance with 3-13: Wash Bay.

CHAPTER 7 NAVY SPECIFIC CRITERIA

7-1 INTRODUCTION

This UFC is organized with general requirements and Service-specific requirements. Apply Chapters 1, 2, 3, 4 and Appendices to all Services. Additionally apply Chapters 5, 6 and 7 to Air Force, Army, and Navy respectively for Service-specific requirements. This UFC and Chapter 7 also applies to United States Marine Corps (USMC).

7-1.1 US Navy Aircraft Hangar Overview

7-1.1.1 Applicability

Refer to 1-4: Scope of Facility. Additionally, this UFC applies to all new Navy or USMC hangars including the defined Navy standard hangar Types I, II, III, and IV, variations of the hangar Types, as well as any non-standard hangars. All new Navy and USMC standard hangars must meet all hangar Type I-IV requirements for the respective standard. In any case, design all hangars to accommodate the minimum safety clearances shown in Table 2-1: Minimum Aircraft Maintenance Bay Clearances for the design airframe(s). Clearances for non-standard hangars should be conservatively selected by comparing the design airframe size to those found in the various standard hangar Types.

Selective portions of this UFC apply only when renovating or re-purposing an existing hangar. As a minimum, renovation projects must comply with all safety and life-safety related criteria. This includes, but is not limited to, fire protection, egress, and aircraft minimum clearances. Follow all other criteria of this UFC, including all standard hangar Type requirements (Table 7-1: \3\ Standard Hangar Bay Module Dimensions and Crane Capacities*), to the maximum extent practical for the renovation. The intent of meeting all criteria in this UFC is to provide for future hangar flexibility to maintain alternate aviation platforms. If meeting those additional standard hangar Type requirements is not feasible or possible for a renovation project addressing a specific aircraft platform, then it is only necessary to meet the mission requirements for that specific platform and all safety and life-safety criteria as stated above. This is not an option for new hangars which must meet this entire UFC including Table 7-1. It is important for the planner to clarify the intent of the renovation scope on the 1391 planning document.

7-1.1.2 Hangar Design Philosophy

Since the 1990s, the Navy has chosen to maintain several standard hangar types primarily with regard to hangar bay size. The fundamental planning concept is to group similar Navy aircraft by size and function and to establish a common hangar bay envelope size (length, width, height), that efficiently suits that aircraft grouping with established aircraft quantity and layout of each airframe. This approach allows for some flexibility should there be a change in mission, aircraft layout, or introduction of new airframes during the lifespan of the hangar. The expectation is that if the hangar bay has been designed with adequate flexibility in size, then other renovations to the hangar can be reasonably accommodated for the change in mission. It is understood that there

will always be substantial renovation costs to accommodate a new airframe. Hangars also often provide shelter for many different transient aircraft or short duration missions and deployments.

With these concepts in mind, flexibility of the hangar bay is critical and has been incorporated into these criteria where reasonable. Specific areas of consideration include hangar bay sizes, minimum slab design loading, maximization of door sizes, bridge crane capacities, and elimination of fixed obstructions or other features on the hangar bay floor that would impact revised aircraft layouts. The theory is that although hangars are being designed and optimized for an initial airframe and layout, the Navy and USMC are building multi-purpose hangars with reasonable flexibility that can be utilized through their lifespan. Custom, non-standard, single purpose hangars should be avoided when possible and special caution should be given where frequent airframe changes are expected.

7-1.1.3 US Navy Aircraft Maintenance Strategy

US Navy operational guidelines allow aircraft maintenance to be performed ashore similarly to how it is performed shipboard. The strategy includes reducing the total movement of the aircraft once it has entered the maintenance cycle by performing most levels of maintenance on the aircraft in the same hangar assigned to the aircraft custodian. The majority of the shops within the maintenance hangar facility are used as maintenance work shops, maintenance management offices, and tool and equipment storage. Repairs on parts removed from aircraft and extensive depot-level maintenance are typically performed in centralized shops remote from the hangar.

This UFC is geared towards accommodating Organizational “O” level aircraft maintenance, although some limited Intermediate “I” level and more limited Depot “D” level maintenance can be performed if approved and compatible with the facility design. "O" level maintenance is the day-to-day work that a unit performs in support of its own operations to maintain its aircraft and equipment in a full mission capable status. "O"-level maintenance includes aircraft inspections, servicing, handling, removal and replacement of defective parts and components and limited aircraft service changes and modifications. Extensive D-Level inspection, service changes and modifications are performed in separate facilities located on or off site of the aircraft custodian’s assigned base. Refer to "COMNAVAIRFORINST 4790.2B CH-1 15 Jun 2013, Chapter 3" for more discussion on aircraft maintenance levels.

7-2 CIVIL

7-2.1 Hangar Safety Clearance

Orient hangar such that it is in compliance with all runway safety zones and imaginary surface criteria of UFC 2-000-05N, UFC 3-260-01, and 3-2.1.2: Airfield Clearance Criteria.

7-2.2 Airfield Pavements

Design and Layout all airfield pavements, including hangar access aprons, in accordance UFC 2-000-05N, UFC 3-260-01, and 3-2.3: Airfield Pavements.

7-2.3 Airfield Pavement Markings

Design airfield pavement markings for Navy and Marine Corps facilities in accordance with Naval Air Systems Command (NAVAIR) 51-50AAA-2.

7-2.4 \2\ Low Level System Containment

Route the foam system runoff from the hangar bay to automatically discharge to an underground containment system, unless required otherwise by local environmental regulations.

7-2.4.1 Environmental Regulations

Follow all the local environmental regulations to determine the control, treatment and/or remediation measures for the discharge of foam. Discharge effluent from the containment system as directed by the department overseeing environmental policy for the installation. Conditions for disposal will depend upon the capability and location of the facility that would treat the effluent from the containment system. Verify foam containment discharge requirements with the appropriate installation environmental engineer, including local and state environmental requirements.

7-2.4.2 Capacity

Provide capacity to contain 15 minutes of the hydraulically calculated demand from the foam system. Design the containment system to accommodate the entire calculated foam system effluent discharge volume for the duration noted. Do not use the trenches or piping of the containment system to contain any of the required volume. No allowance is required for the water only sprinkler systems or hose streams. /2/

7-2.4.3 Containment System Monitoring

Provide the containment system with a remote capacity monitoring panel. Provide monitoring panel with audible and visual (yellow strobe or beacon) alarms. Automatically activate audible and visual alarms when the capacity level exceeds 5%. Provide a silence switch for the audible alarm. Constantly illuminate visual alarms at the panel until the level condition is returned to normal. Locate containment system monitoring panel in the hangar bay. Provide an alarm to the FACU and Energy Management Control System when the capacity level exceeds 5%.

7-2.4.4 Diverter Valve/System

Provide a system that automatically diverts the floor trench drainage flow to a foam/water containment system upon system activation. Where a containment system uses a diverter valve, provide actuation and monitoring of the valve as indicated in this paragraph. Automatically actuate the valve upon release of the fire suppression system

in the hangar bay. Provide indication of the diverter valve position at the monitoring panel through the use of limit switches. Provide indication of when the valve is fully open or closed. Provide the valve with remote manual reset capability through a "Valve Position Restore" button. Provide the panel with a visual alarm (yellow strobe or beacon) that automatically illuminates when the valve position is "off normal" or "closed", and remains illuminated until valve is restored to full the normal "open" position. Locate diverter valve panel in the hangar bay adjacent to the containment system monitoring panel. Provide an alarm to the FACU and Energy Management Control System when the diverter valve is in the off normal position. Install the diverter valve motorized operator above grade or list it for a submersible environment.

7-2.4.5 Monitoring System Construction

The containment system monitoring panel and diverter valve panel (when provided) may be combined. At a minimum NEMA 250 Type 4 panel(s).

Rate any devices, conduits, or electrical enclosures installed below grade or within the containment tank for prolonged submersion, minimum NEMA 250 Type 6P.

7-3 ARCHITECTURAL

7-3.1 Types of Hangars

7-3.1.1 General

Refer to 7-1.1.2: Hangar Design Philosophy for additional discussion on the Navy Hangar Type concept. The Navy has established four (4) standard maintenance hangar bays including Type I, Type II, Type III and Type IV to efficiently meet the needs of its current aircraft inventory. Each Type is designed to accommodate commonly grouped aircraft which are categorized by size and function and are further defined in paragraphs below and in Table 7-1: \3\ Standard Hangar Bay Module Dimensions and Crane Capacities*. These hangar Types are based on the controlling aircraft size, controlling aircraft layout, additional maintenance clearance required (if any), and minimum required aircraft clearances shown in Table 2-1: Minimum Aircraft Maintenance Bay Clearances. Do not reduce the minimum clearances for standard hangar Types below the thresholds indicated. If necessary, increase the selected standard Hangar Type dimensions to accommodate the specific design airframe(s) layout with adequate clearances (Table 2-1: Minimum Aircraft Maintenance Bay Clearances) and any additional maintenance clearance per the manufacturer's Facilities Requirements Document (FRD). The intent is to prevent a situation where a new airframe or larger variant is introduced prior to an update of Hangar Type standard definitions. Refer to UFC 2-000-05N for hangar planning requirements, modular sizing, and square footage guidance.

7-3.1.1.1 Organization

Navy aircraft hangars are comprised of three distinct areas; the hangar bay Organizational Hangar (OH) space, the Shop and Maintenance Administration (O1 level); and the Operations, Training and Administration (O2 level). The levels are

designations from shipboard levels and are not specific to the hangar design. The hangar bay provides sheltered space to primarily perform Organizational "O" level maintenance to aircraft and limited additional levels as previously discussed in

7-1.1.3: US Navy Aircraft Maintenance Strategy. Layout of this space is determined by the planning documents for the module configuration identified. The net area of the hangar bay is defined in the module layout and is considered a fixed area.

7-3.1.1.2 Standard Configurations

Hangar configurations, including heights, are provided to allow for maximum flexibility in accommodating all of the existing and proposed aircraft in the Naval Aviation Fleet. Do not modify the size of any hangar bay module without approval from Naval Facilities Engineering Command Atlantic, Capital Improvements Criteria and Programs Office (CIENG), Naval Air Systems Command (NAVAIR) and Commander, Navy Installations Command (CNIC). Additionally, Marine Corps hangar bay configurations may be modified by Headquarters, Logistics Facilities (USMC) (LF).

7-3.1.2 Type I Hangar

The Type I maintenance hangar is primarily designed for carrier aircraft, but is adaptable to meet requirements for rotary wing and various types of smaller aircraft, including Navy and Marine Corps variants of the F-35. The O1 and O2 level spaces in this type of hangar are configured for a typical strike fighter squadron, two carrier airborne early warning squadrons, or one H-60 helicopter squadron.

Provide one bridge crane per modules for all Type I hangars. When a single large hangar includes more than one module, additional cranes are required.

7-3.1.3 Type II Hangar

\3\ The Type II hangar is primarily provided for US Marine Corps Aviation. The hangar is designed to accommodate CH-53 Helicopters, MV-22 Tilt-Rotor and C-130 Refueler/Transport Aircraft. This type of hangar may also accommodate Navy versions of the C-130, MV-22 and CH-53 aircraft. Provide one bridge crane per modules for all Type II hangars. When a single large hangar includes more than one module, additional cranes are required. /3/

7-3.1.4 Type III Hangar

The Type III maintenance hangar is principally designed for land based patrol aircraft such as the P-8A Poseidon and large transport aircraft. Type III hangars are not authorized to have a bridge crane.

7-3.1.5 Type IV Hangar

The Type IV Navy Hangar is intended for the largest Unmanned Aircraft Systems (UAS). At this time, only the MQ-4C Triton is targeted for the Type IV hangar. The MQ-4C Triton is an (UAS) and will be a forward deployed, land-based, autonomously operated system that provides a persistent maritime intelligence, surveillance and

reconnaissance capability using a multi-sensor mission payload. The MQ-4C Triton air vehicle is a Navy variant based upon the USAF RQ-4B Global Hawk. The Type IV hangar will be periodically updated to accommodate other similarly sized aircraft should they be acquired by the Navy. \3\ Provide one bridge crane per modules for all Type IV hangars. When a single large hangar includes more than one module, additional cranes are required. /3/ For UAS other than Triton, planners may consider non-standard hangars or other facility types as appropriate to meet the mission.

7-3.1.6 Hangar Bay Column-Free Layout and Module Concept

Table 7-1: \3\ Standard Hangar Bay Module Dimensions and Crane Capacities* contains dimensions for a single hangar module as defined by UFC 2-000-05N. A single module is intended to be the minimum size hangar for the intended aircraft and can be combined with additional fractional or whole modules per UFC 2-000-05N to produce a larger hangar bay. Provide a framing system with a completely column-free hangar bay and flight line regardless of the number of hangar modules. This allows for maximum bay utilization and aircraft layout flexibility. If future hangars are planned adjacent to a new hangar, the framing system should be adaptable so as to allow for future expansion and combined column-free hangar bay. Refer to Appendix C-4: STRUCTURAL for more discussion on cantilever hangar bay framing systems.

Table 7-1: \3\ Standard Hangar Bay Module Dimensions and Crane Capacities*

\3\ /3/	HANGAR TYPE					
	TYPE I		TYPE II	TYPE III	TYPE IV	SEE NOTES
	NAVY	USMC				
WIDTH	212' 64.62 M	270' 82.30 M	325' 99.1 M	165' 50.3 M	161' 49.07 M	1, 2, 3
DEPTH	95' 28.96 M		119' 36.3 M	165' 50.3 M	141' 42.98 M	1, 2, 3
CLEAR HEIGHT	32.5' 9.91 M		44' 13.41 M	50' 15.24 M	32.5' 9.91 M	2, 4
BRIDGE CRANE CAPACITY	5-TON 4.5 METRIC TON		7 TON 6.5 METRIC TON	NONE	5-TON 4.5 METRIC TON	6
HOOK HEIGHT	29.5' 8.99 M		39' 11.9 M		29.5' 8.99 M	5, 6

DOOR HEIGHT	25' 7.62 M		44' 13.41 M	50' 15.24 M	25' 7.62 M	2
*DIMENSIONS ARE FOR A SINGLE HANGAR BAY MODULE BASED ON TABLE 2-1 CLEARANCES. SEE UFC 2-000-05N FOR WIDER INCREMENTS						

/3/

Table 7-1 Notes:

1. The Width and Depth of the hangar are defined as the respective net clear horizontal dimension between the nearest fixed obstructions. Horizontal fixed obstructions along back walls and side walls include, but are not limited to the inside face of the wall, a structural column or bracing, bollard, liner panel, an open door extending into the Aircraft Maintenance Bay, mechanical equipment or ductwork, plumbing equipment, valves and pipes, electrical equipment (such as power transformers), or other fixed items. Fixed obstructions do not include furniture, tables, desks, benches, cabinets, tools, parts, carts or other movable objects. The depth at the hangar door is to the interior face of the innermost panel of a rolling steel door, or to the interior face of a vertical lift fabric door.

2. Dimensions for width, depth, and height are considered to be "standard." Variations in hangar bay sizes are not permitted without authorization of the NAVFAC HQ Chief Engineer. Additionally, Marine Corps hangar bay configurations may be modified by Headquarters, USMC (LF).

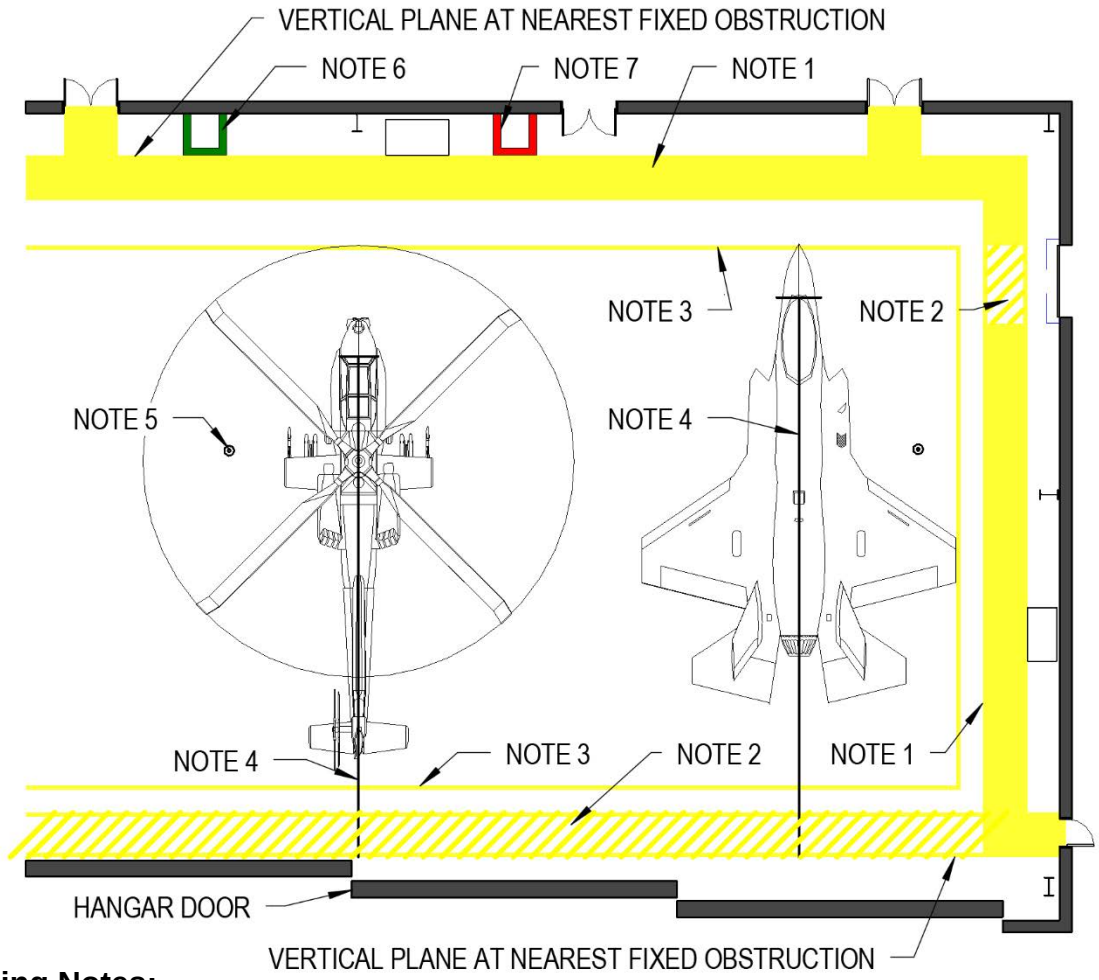
3. Table includes required NET clear hangar dimensions that are also to be used for square foot planning calculations. See UFC 2-000-05N for guidance and requirements on Net to Gross planning calculations. See also paragraph 2-4: Net to Gross Area in Aircraft Maintenance Hangars.

4. The clear height is the lowest obstruction including but not limited to, an overhead structure, and MEP equipment such as lighting, fans, heaters, ductwork, and sprinklers.

5. Hook height is to the saddle of the hook. Hook heights are minimum requirements. Increase height where possible to maximize for available structure height. Refer to crane requirements in 0:

6.

7. General Hangar Requirements and 7-9: Overhead Bridge Cranes.



8. Refer to Figure 7-11: Section through Type II Hangar Crane Configuration and Vertical Clearances to clarify minimum hangar crane coverage area for Type II hangars. The bridge crane coverage must be designed to account for the possibility of servicing a C-130 aircraft. Coordinate crane coverage with the user.

9. The elements at the edge of the hangar door opening determine the width of the opening. Provide an opening not less than 3 ft. (1 m) less than the width of the aircraft maintenance bay.

7-3.2 Aircraft Maintenance Bay Striping Requirements

Provide striping in the aircraft maintenance bay per paragraph 3-3.4.3: Protective Coatings and Figure 7-1: Aircraft Maintenance Bay Striping Requirements.

Figure 7-1: Aircraft Maintenance Bay Striping Requirements

Striping Notes:

1. Safety Lane; 5 ft. (1.5 m) wide stripe; color - yellow.
2. Safety Lane; 5 ft. (1.5 m) with 6 in. (152 mm) boundaries and 6 in. (152 mm) diagonal stripes at locations where there is risk of being hit by vehicles; hangar door and rolling service doors, e.g.; color - yellow.
3. Six inches wide solid white aircraft safety perimeter line following clearances per Table 2-1: Minimum Aircraft Maintenance Bay Clearances.
4. **\2** Aircraft position centerline & nose gear stop; 6" wide stripe; color – yellow or white to match marking from outside the hangar to inside the hangar. May not be required at multi-aircraft position hangars. Coordinate with users. ***/2/***
5. Grounding receptacle; paint per UFC 3-575-01, Figure 2-3.
6. Safety eyewash/shower; color - green; provide 2 ft. (610 mm) clearance from safety equipment. Slope to drain, if provided.
7. Fire Extinguishers (if provided); color - red. Provide 2 ft. (610 mm) clearance from extinguishers.

7-4 STRUCTURAL

7-4.1 Aircraft Maintenance Bay - Slab on Ground Loading

Design Navy/USMC Aircraft Maintenance Bay slabs on ground in accordance with the minimum following traffic requirements. Add project specific additional vehicles to the mix as required. The mixes represent a 50-year traffic loading. These slab loadings have been developed to maximize Aircraft Maintenance Bay use and flexibility. Make no reductions to these traffic mixes or loadings without the approval of NAVFAC HQ Chief Engineer.

\1\ For Navy and USMC standard hangar Types I, II, III, and IV or similar variations, provide a slab on ground of uniform design and thickness throughout the hangar bay. Do not reduce the slab thickness in areas not subject to the design aircraft loads. For single aircraft non-standard hangar types, slab optimization is permitted by section 3-4.2.3.1 Aircraft Maintenance Bay - Slab on Ground Design where applicable. /1/

7-4.1.1 Type I Hangar

Use Type B traffic area with the following minimum traffic mix:

- F-35C Aircraft (70,400 lbs.) - 40,000 passes
- ATLAS forklift (10,000 lbs. - loaded carriage)- 10,000 passes
- P-15 Crash/Fire Truck (130,860 lbs.) - 1,200 passes
- Transport Truck M1088 and M871A3 Trailer (80,000 lbs.) - 1,000 passes

7-4.1.2 Type II Hangar- Type B traffic area with the following minimum traffic mix:

Use Type B traffic area with the following minimum traffic mix:

- C-130J (155,000 lbs.) - 40,000 passes
- P-15 Crash/Fire Truck (130,860 lbs.) - 1,200 passes
- Transport Truck M1088 and M871A3 Trailer (80,000 lbs.) - 1,000 passes
- 10K forklift - 10,000 passes

7-4.1.3 Type III Hangar

Use Type B traffic area with the following minimum traffic mix:

- P-8A (155,000 lbs.) - 40,000 passes
- P-15 Crash/Fire Truck (130,860 lbs.) - 1,200 passes
- Transport Truck M1088 and M871A3 Trailer (80,000 lbs.) - 1,000 passes
- 10K forklift - 10,000 passes

7-4.1.4 Type IV Hangar

Use Type B traffic area with the following minimum traffic mix:

- F-35C Aircraft (70,400 lbs.) - 40,000 passes
- ATLAS forklift (6,000 lbs. - loaded carriage)- 25,000 passes
- P-15 Crash/Fire Truck (130,860 lbs.) - 1,200 passes
- Transport Truck M1088 and M871A3 Trailer (80,000 lbs.) - 1,000 passes

7-5 MECHANICAL

Provide in accordance with 3-5: Mechanical.

7-5.1 Plumbing

Install hose bibbs on all interior walls of the hangar bays.

7-5.2 HVAC

Provide dedicated units for the Communications Room and Secure Office. Provide heating only with a unit heater for the stairs when the climate makes it necessary.

7-6 FIRE PROTECTION AND LIFE SAFETY

7-6.1 General

Classify all hangars as Group I in accordance with NFPA 409.

7-6.2 Tension Fabric Hangars

7-6.2.1 Protection of OH Space

Protect the OH space in accordance with this UFC, except the overhead sprinkler system is not required.

7-6.2.2 Protection of O1/O2 Levels

Unless otherwise noted, protect the O1/O2 Levels in accordance with this UFC and UFC 3-600-01 including sprinkler and fire alarm systems. Provide passive protection of the O1/O2 levels based on their location outside or within the tension fabric structural frame.

7-6.2.2.1 O1/O2 Levels outside the Tension Fabric Structural Frame

Provide a minimum 1-hour fire barrier between the O1/O2 levels and the OH space, or provide fire separation between the tension fabric structure and other structures in accordance with UFC 3-600-01 for tensioned-membrane hangars.

7-6.2.2.2 O1/O2 Levels within the Tension Fabric Structural Frame

Provide a minimum 1-hour fire barrier between the O1/O2 levels and the OH space, inclusive of all sides exposed to the OH space such as side, top, and bottom.

7-6.2.3 Egress from O1/O2 Levels

Do not discharge required exits or exit access from the O1/O2 levels into or through the OH space. When a 1-hour fire barrier is provided between the O1/O2 levels and OH space, convenience openings are permitted where minimum 3/4-hour rated opening protection is provided.

7-6.3 Concentrate Piping

The use of brass piping with brazed or flanged joints is permitted. Provide flanges in the brass piping for equipment and valve removal. The use of threaded connections is not permitted, except at the connection to the inductor or concentrate storage tank.

7-6.4 Releasing Service Fire Alarm Control Unit (RSFACU)

Provide X3301 Multispectrum IR Flame Detectors manufactured by DetTronics. Provide Detectors with Hangar Mode as the factory default. Control and monitor optical flame detectors from a factory assembled Eagle Quantum Premier fire detection/releasing control unit manufactured by Det-Tronics.

\2\ Only release the low level trench nozzle system from a manual releasing station, or two simultaneous votes from non-latching optical flame detectors in the releasing zone. Refer to Table 7-2: \3\ Sample Navy RSFACU Functional Matrix for additional functional requirements. /2/

Table 7-2: \3\ Sample Navy RSFACU Functional Matrix

NOTE: This sample table is intended to be specifically tailored/edited for each project. /3/

	ANNUNCIATION AT LOCAL PANEL			NOTIFICATION						AUXILARY FUNCTIONS				
ALARM CONDITIONS	AUDIO-VISUAL ALARM INDCATION	AUDIO-VISUAL TROUBLE INDICATION	AUDIO-VISUAL SUPERVISORY INDICATION	GENERAL FIRE ALARM SIGNAL TO FACU AND RECEIVING STATION	FOAM/WATER RELEASE SIGNAL TO FACU AND RECEIVING STATION	COMMON FOAM/WATER TROUBLE SIGNAL TO FACU AND RECEIVING STATION	COMMON FIRE ALARM SUPERVIORY SIGNAL TO FACU AND RECEIVING STATION	COMMON FOAM/WATER SUPERVISORY SIGNAL TO FACU AND RECEIVING STATION	OPTICAL FLAME DETECTION INHIBITED SUPERVISORY SIGNAL TO FACU AND RECEIVING STATION	OPEN FLOW CONTROL VALVE FOR FOAM/WATER SYSTEM	CLOSE FLOW CONTROL VALVE FOR FOAM/WATER SYSTEM	RE-OPEN FLOW CONTROL VALVE FOR FOAM/WATER SYSTEM IF STILL IN ALARM	RELEASE PRE-ACTION SPRINKLER SYSTEM (IF PROVIDED)	DISABLE ONLY THE RELEASING FUNCTION OF THE OPTICAL FLAME DETECTION

PREACTION SUPERVISED SOLENOID DISCONNECT (IF PROVIDED)			X				X							
OPTICAL FLAME DETECTION INHIBIT SWITCH			X						X					X

* DO NOT RELEASE THE FLOW CONTROL VALVE FROM THE PRESSURE SWITCH.

7-7 ELECTRICAL

7-7.1 Hazardous Classification

\3\ Design all hangar bays electrically as hazardous areas for maintaining fueled aircraft regardless if the aircraft contain fuel or not. Assume all aircraft in hangar bay will enter fueled. /3/

7-7.2 Special Power Systems

7-7.2.1 Aircraft 270VDC Service

Aircraft 270VDC ground power units, cables and connector are RPIE equipment.

7-7.3 Power Service Points

Coordinate all requirements with users and aircraft manufacturer and dedicate adequate wall space for all equipment. The power service points may include:

- Coordinate required outlet amperage and type requirements with the users. Three-phase, 480V, 4-wire, 60 Hz, receptacles for government

furnished support equipment (SE.). These receptacles are built by very few manufacturers and are identified by part number.

- Single-phase, 120V, 60 Hz, ground fault interrupt duplex utility outlets.
- **\2** For Triton Type IV hangars, as a minimum, provide at each aircraft parking space (minimum four per hangar bay), one - 480 VAC, 100 ampere, three-phase, four-wire, 60 Hz, MIL-C-22992, Class L, Connector Size 44, Insert Arrangement per MS14055 Figure 5, receptacle for Navy Ground Support Equipment (GSE). **/2/**

7-7.4 O1/O2 Level Spaces

Serve shop spaces by distinct panels dedicated to shop and equipment loads only. Do not supply office spaces from shop circuits or panels. Supply loads located in the O1 space from panel boards located in the O1 space; supply loads located in the O2 space from panel boards located in the O2 space.

7-7.5 Grounding and Bonding

Provide ordnance grounding in accordance with NAVSEA OP-5.

7-7.6 Obstruction Lighting

Provide obstruction lighting in accordance with 3-7.10.2: Aviation Obstruction and NAVAIR 51-50AAA-2. Provide LED obstruction lights where the users and airfield manager can verify that night vision goggles (NVG) or vision enhancement systems are not used. \3\ Use of LED lighting must be carefully coordinated with the user on case by case basis due to NVG wavelength issue and compatibility with LED lights. See UFC 3-535-01 Visual Air Navigation Facilities for further guidance. /3/

7-8 COMMUNICATIONS

7-8.1 Communication Systems Infrastructure

Provide additional communications outlets as required by mission. Additional required communications systems may include:

- Naval Aviation Logistics Command Management Information System (NALCOMIS)
- Triton Communication Systems

7-8.2 CATV Systems

Refer to the Navy functional data sheets for locations where CATV is required.

7-8.3 3M Communications (Maintenance and Material Management)

Coordinate with users and determine if 3M system is required. If required, provide an inter-communications system, integral to the telephone system, to allow two-way

communications between different spaces. Provide an independent, stand-alone, Type 1, Direct Connected Keyed, intercommunications system, for use by aircraft maintenance and material operations only. Provide a two-way communication from Line Shacks to, and between, all rooms in the O1 level space except passages, locker and toilet rooms, and mechanical equipment rooms.

7-8.4 Intercommunication System

Coordinate with users and determine if an intercom system is required. If required, provide the necessary infrastructure with provisions for interconnection with other buildings including the following.

- Rooms in the O1 and O2 level space, except corridors, locker and toilet rooms, and storage rooms.
- Department heads and the Commanding Officer and Executive Officers of the squadron.
- Officers' ready room and maintenance control.
- Administration office and maintenance administration.

7-8.5 ALIS Communication System

The ALIS is required for all F-35 hangars. A SAPF area is required for the ALIS. Refer to 2-2.3 - Secure Spaces for standards that apply to the construction of secure spaces.

7-9 OVERHEAD BRIDGE CRANES

\3\

Provide all cranes in accordance with Navy Crane Instruction 11450.2 Design of Navy Shore Weight Handling Equipment and with UFGS 41 22 13.55 Bridge Cranes, Under Running, Aircrat Hangar. For bridge crane capacities and additional crane requirements refer to Table 7-1: \3\ Standard Hangar Bay Module Dimensions and Crane Capacities*.

All overhead bridge cranes to be under running girder electric cranes with under running trolley hoist. Provide either single or double girder type, whichever minimizes the lowest overall crane depth for the configuration. Support all bridge cranes from patented track systems designed by the crane manufacturer.

[C] Per the current Navy Crane Instruction 11450.2 Design of Navy Shore Weight Handling Equipment, Navy/USMC hangar bridge cranes are considered operating in hazardous environments due to fueled aircraft and due to bridge crane span. Contact the Navy Crane center for design review involvement. A procurement waiver may also be required. For bridge crane electrical and anti-spark requirements, all hangars are to be designed for fueled aircraft regardless if the aircraft contain fuel or not.

/3/

7-9.1 Hook Height

The minimum hook clearance height, (measured from the finished floor elevation to the saddle of the hook at full elevation) is as tabulated in Table 7-1: \3\ Standard Hangar Bay Module Dimensions and Crane Capacities*. Increase crane hook height where possible to take advantage of the available structure height.

7-9.2 Hook Coverage

Design bridge crane layout to provide loaded hook coverage to within 12 ft. (3.7 m) of the inside face of all walls and to within 15 ft. (4.6 m) of the inside face of the hangar doors, except for Type II hangars. Refer to Figure 7-11: Section through Type II Hangar Crane Configuration and Vertical Clearances for Type II crane requirements. Where multiple cranes are provided, fully loaded hooks must be capable of being located within 15 ft. (4.6 m) of each other.

\3\

7-9.3 Hazardous Classification

For crane and other electrical hazardous classification requirements, the aircraft hangar bay shall be design as required for maintaining fueled aircraft per NFPA 70 and Section 513 regardless if aircraft contain fuel or not. Per Navy Crane Instruction 11450.2, incorporate “minimum anti-spark” requirements. This includes special requirements for the pendant, hook, hoist, wire rope and other elements per UFGS 41 22 13.55 Bridge Cranes, Under Running, Aircrat Hangar which also contains additional guidance. /3/

7-10 HANGAR DOORS

Hangar door widths to be determined by the elements at the edge of the door opening. Design the width of the opening to be not be less than 3ft. less than the width of the aircraft maintenance bay. Provide individually operated panels if the project includes sliding steel hangar doors.

7-11 FLOORS AND TRENCH DRAINS

At a minimum, provide trenches and nozzles around the perimeter of the hangar bay to enclose the aircraft silhouette and service area. For the purpose of the trench and nozzle locations, the aircraft service area is defined by Table 2-1: Minimum Aircraft Maintenance Bay Clearances. For example, in a Navy Type I Hangar, the aircraft service area starts at 7'-6" from the inside face of the hangar bay door.

7-11.1 Trench Drains

\2\ Provide trench drains in the hangar bay to remove hazardous fuels, fire suppression system discharge, and convey fire suppression system piping to the low level system discharge devices. Trench drains may also be used to convey compressed air and water service lines to support other operational functions of the maintenance hangar.

7-11.1.1 Trench Sizing

Size trench drains to account for the flow of the sprinkler system, low level system discharge, and hose stream allowance. To allow for sufficient space for maintenance in the trench, consider the volume of piping within the trenches and turning radius of the fittings in the design. /2/

7-11.1.2 Trench Covers

At a minimum, provide ductile iron or steel trench covers manufactured to withstand a minimum proof-load of 100,000 lbs. (45,359 kg) from a tire with a 250 psi (1.72 Megapascal (MPa)) pressure. Use nozzles and assembles that are not subjected to damage resulting from forces and torque imposed by a tow cart. Install nozzles, integral trench grate assembly, and supporting framework in accordance with manufacturer's recommendations. Design the top of the nozzle and grate assembly to be flush or level with floor it is protecting.

7-11.1.3 Trench Location

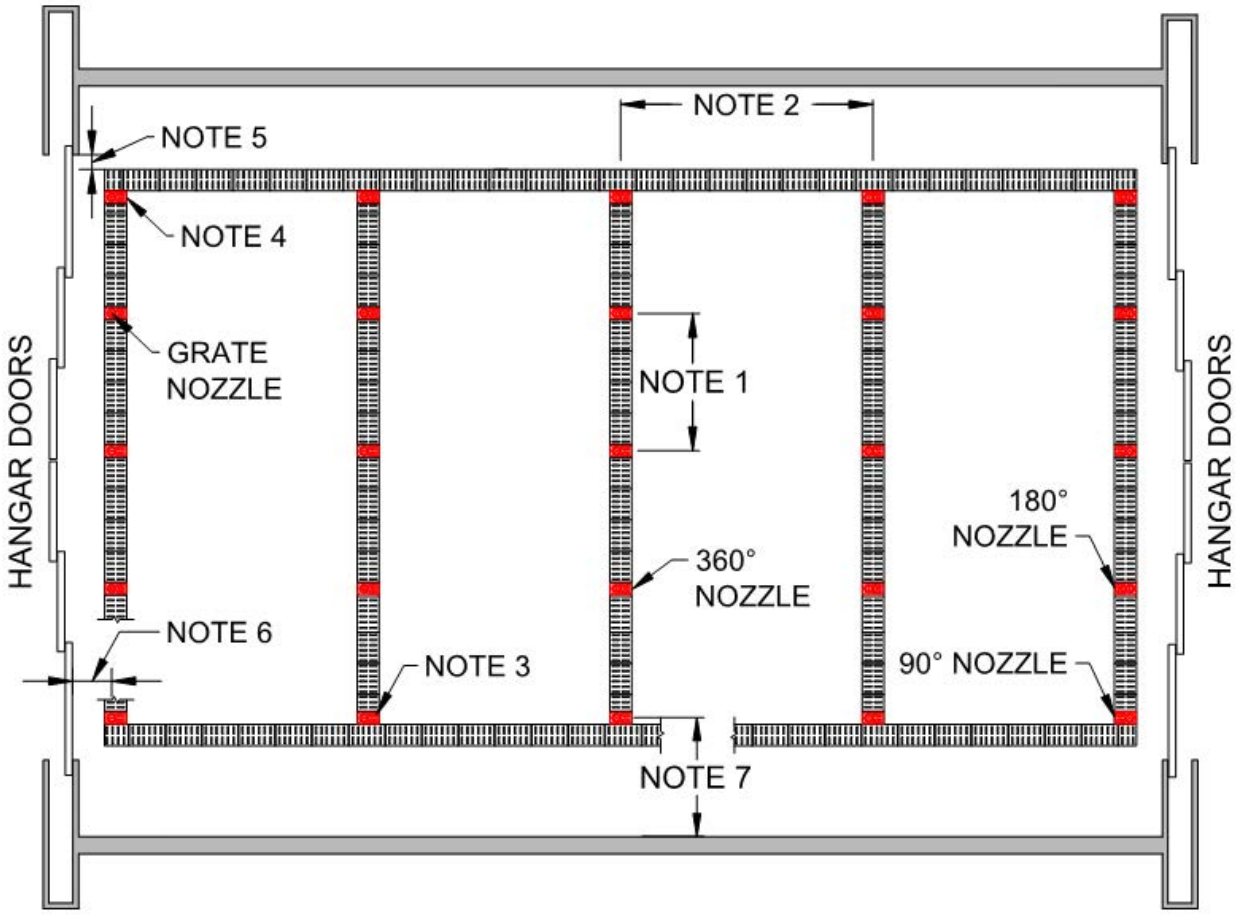
Provide trench drains in a grid pattern, as shown in Figure 7-2: Drive-Through Hangar and Figure 7-3: Pull-In Hangar.

7-11.1.4 Trench Nozzles

Use nozzles that develop a spray pattern from its installation position, with no moving parts. Do not exceed a nozzle spray pattern height of 12 in. (305 mm) above the hangar bay floor. Do not provide nozzles with characteristics that result in foam/water solution being discharged on an aircraft fuselage or wing components through direct impingement or misting. Do not provide nozzles that require high pressure fittings and system components. Provide nozzles compatible with the inductor proportioning system in this UFC.

Provide nozzles that have been tested for obstruction to discharge such as aircraft tires, 55 gal. (208 L) barrels, 3/4 in. (19 mm) rubber hoses, construction materials, with little effect on time of floor coverage. Design the system so the total nozzle obstructions do not negatively impact the hydraulics of the distribution system or the foam induction capabilities.

7-11.1.5 Nozzle Location



Use nozzles that discharge foam/water solution in a 360-degree, 180-degree, and 90-degree patterns. Use only 90-degree or 180-degree pattern nozzles around the perimeter such that foam/water solution is directed onto the aircraft servicing area. Provide uniform discharge of foam/water solution over the aircraft servicing area with a maximum spacing between trenches of 50 ft. (15.2 m) and a minimum and maximum spacing of nozzles within trenches of 22.5 ft. (6.86 m) and 27.5 ft. (8.38 m.), respectively. Do not discharge foam/water solution beyond the perimeter trenching of the hangar bay.

7-11.1.6 \2\ Low Level Discharge Devices

Use Viking Grate Nozzle™, Models GN 200/360, 200/180, or 200/090 or equal for the low level system. Use nozzles that are UL listed (GFUT) or FM approved. In order to use a nozzle other than specifically listed; provide performance capabilities of the alternative nozzle to the Navy for approval.

Install the low level trench nozzle system in a similar arrangement and with the limitations indicated in Figure 7-2: Drive-Through Hangar and Figure 7-3: Pull-In Hangar. /2/

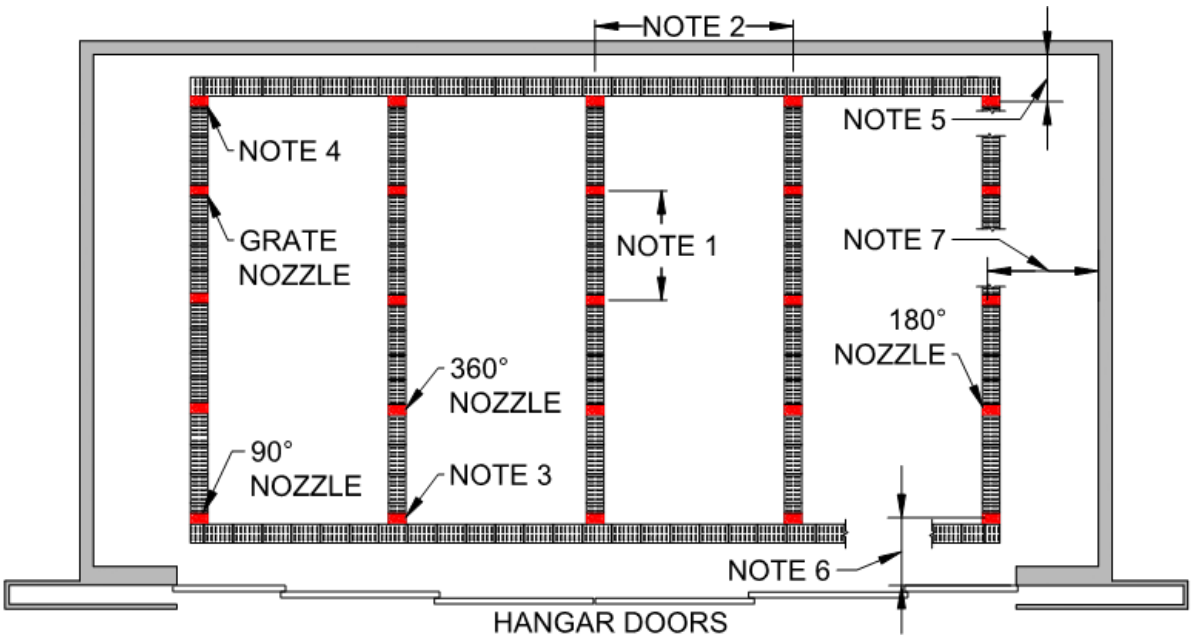
Figure 7-2: Drive-Through Hangar

Nozzle Placement Notes:

1. Center to center nozzle spacing is approved for no less than 22.5 ft. (6.8 m.) and no greater than 27.5 ft. (8.4 m.)

2. The maximum distance between the centerline of distribution trenches is 50 ft. (15.2 m).

3. Provide 180 degree nozzles around the perimeter of the aircraft servicing area.



4. Provide 90 degree nozzles in the corners of the aircraft servicing area.

5. Do not exceed a distance of 3 ft. (1 m) into the hangar bay from the face of the hangar bay door jamb to the nearest parallel edge of the trench.

6. Do not exceed the tabular value in Table 2-1: Minimum Aircraft Maintenance Bay Clearances for the perpendicular distance from the centerline of the nozzles to the inside face of the nearest hangar bay door.

7. Do not exceed the tabular value in Table 2-1: Minimum Aircraft Maintenance Bay Clearances for the perpendicular distance from the centerline of the nozzles to the nearest fixed obstruction along the side wall.

Figure 7-3: Pull-In Hangar

Nozzle Placement Notes:

1. Center to center nozzle spacing is approved for no less than 22.5 ft. (6.8 m.) and no greater than 27.5 ft. (8.4 m.)

2. The maximum distance between the centerline of distribution trenches is 50 ft. (15.2 m).

3. Provide 180 degree nozzles around the perimeter of the aircraft servicing area.

4. Provide 90 degree nozzles in the corners of the aircraft servicing area.

5. Do not exceed the tabular value in Table 2-1: Minimum Aircraft Maintenance Bay Clearances for the perpendicular distance from the centerline of the nozzles to the nearest fixed obstruction along the back wall.

6. Do not exceed the tabular value in in Table 2-1: Minimum Aircraft Maintenance Bay Clearances for the perpendicular distance from the centerline of the nozzles to the inside face of the nearest hangar bay door.

7. Do not exceed the tabular value in in Table 2-1: Minimum Aircraft Maintenance Bay Clearances for the perpendicular distance from the centerline of the nozzles to the nearest fixed obstruction along the side wall.

7-12 FUEL CELL MAINTENANCE

For Navy, fuel cell maintenance is performed in aircraft maintenance hangars in accordance with NAVAIR 01-1A-35 vs. in dedicated fuel cell maintenance hangars. Refer to NAVAIR 01-1A-35 dated 1 July 2009, Aircraft Fuel Cells and Tanks for policy, requirements and procedures. Refer to paragraph 3-5.8.1: Compressed Air for compressed air requirements.

7-13 WASH BAY

Provide in accordance with 3-13: Wash Bay.

7-14 NAVY FUNCTIONAL DATA SHEETS (FDS) AND SPACE TYPES

The Functional Data Sheets (FDS) and Space Types identify the functional spaces and specific design needs for individual spaces within hangars. They are presented as a guide for the designer, planner, or Request for Proposal (RFP) preparer. It is intended that the information in the FDS are the minimum requirements for the respective rooms and spaces. These minimum requirements apply in addition to all other requirements of this UFC and other referenced documents. In the event of a mutually exclusive conflict or where both requirements cannot be satisfied, the FDS take precedence. However, if in the best judgment of the designer, a more restrictive requirement is appropriate, the more restrictive requirement may be applied after consulting with the user. It should not be assumed that these data sheets or space types reflect full requirements of the user or the full requirements of any specific aircraft type. Refer to 7-14.1: FDS Format for blank space references and additional minimum requirements.

7-14.1 FDS Format

Building design criteria are provided in a standard FDS table format that generally follows the Uniformat II/Work Breakdown Structure (WBS). Note that blank spaces found in the FDS indicate building components or systems should follow standard guidance per UFC 1-200-01, as a minimum. The Built-In Equipment/Casework category includes anything physically attached or plumbed to the building such as counters, cabinets, casework, toilet accessories, window shades or blinds, heavy-duty pallet racks, and recessed projection screens. The Furnishings, Fixtures &Equipment (FF&E) category includes loose or moveable items such as desks, chairs, and shelving. Items such as computers, printers, copiers, and flat screen monitors are "user-provided" equipment and are not considered FF&E. Coordinate FF&E and user-provided equipment with the building systems.

7-14.2 Applicability

All of the spaces listed in the following tables may not be applicable to all hangar types. For example, Aviation Ordnance will not generally be provided in a hangar where the aircraft do not have weapons or ejection seats. However, consider future flexibility and future hangar use in the design of functional spaces. Additionally, not all required spaces are listed in these tables, as there are too many variations and unique requirements when considering the range of aircraft inventory. Many aircraft FRD may

further define more specific requirements for these functional areas as well as define other required hangar spaces. Building support spaces such as mechanical, pump rooms, and electrical rooms must be provided as required and all spaces may not be listed. Some data sheets and space types apply only to specific airframes as noted.

7-14.3 Coordination with User and Airframe

Each squadron occupying a hangar has different requirements based on the size of the squadron, the type of aircraft, the type of hangar (see below), the type of squadron (e.g., training, reserve) and various other factors. The functional areas required are dependent on operational requirements and the functions required are determined by the user during the planning/DD 1391 development phase. Designer or RFP preparer must develop and coordinate project specific requirements with the user squadron, based on this UFC, the specific design aircraft(s), respective FRD or equivalent documents, and existing maintenance capabilities at each base.

7-14.4 Hangar Levels and Space Types

7-14.4.1 Hangar Levels

As discussed earlier in this chapter, Aircraft hangars are comprised of 3 distinct areas; the hangar bay (OH space), the Shop and Maintenance Administration area (O1 level); and the Operations, Training and Administration area (O2 level). Hangar spaces are grouped as O1 and O2 for planning purposes, and may be located on 1st or 2nd floors as required for appropriate adjacencies (refer to 7-15: NAVY ADJACENCY DRAWINGS). Additionally, spaces are categorized as to their general function such as the Hangar Bay, a Shop, Admin, Ops or Support (building). These space groupings and categories are reflected in 7-14.4.2: Hangar Space Types.

7-14.4.2 Hangar Space Types

Table 7-3: Hangar Space Table includes a list of spaces and functions that are commonly found in Navy hangars. General (Airframe) spaces indicate those found in every hangar. Airframe specific (i.e. F-35) spaces indicate special spaces for the respective aircraft. Additional FDS are presented for some spaces. Actual user, airframe, or FRD terms may vary from those used in Table 7-3: Hangar Space Table. The US Marine Corps has different designations for similar activities.

Table 7-3: Hangar Space Table

Airframe	Space Category	Space Grouping	Space Name	Space Description	Refer to Functional Data Sheet (Reference Table Number)
General	OH	OH	Hangar Bay (OH)	Maintenance Hangar area	Refer to Table 7-4: Hangar Bay
General	Shop	O1	Air Frames (Shop)	Maintains Air Frames.	Refer to Table 7-5: Air Frames
General	Shop	O1	Aviation Ordnance (Shop)	Maintains aircraft weapons systems including weapons cleaning and storage.	Refer to Table 7-6: Aviation Ordnance

Airframe	Space Category	Space Grouping	Space Name	Space Description	Refer to Functional Data Sheet (Reference Table Number)
General	Shop	O1	Avionics Space (Shop)	Maintains Aircraft electrical systems. This shop also provides storage for specialized communication equipment and may require special secure storage areas. Consider providing a vault within the shop as opposed to making the entire shop a secure space. A separate Avionics shop may be required due to different ratings of work or required security level.	Refer to Table 7-7: Avionics
General	Shop	O1	Corrosion Control/Coating (Shop)	Provides maintenance shop for corrosion control. Includes Low Observability (LO) Maintenance for F-35.	Refer to Table 7-8: Corrosion Control/Coating Shop
General	Shop	O1	Detachment (Shop)	Standard shop for Squadrons employing deployed aircraft. This is generally a workspace without any specific requirements. Coordinate requirements with a squadron configured for detachment components.	Refer to Table 7-9: Detachment
General	Shop	O1	Flight Gear/Paraloft (Shop)	This space is used to repair flight gear. It also provides the storage area for flight gear. Also may be part of AME shop or Flight Equipment	Refer to Table 7-10: Flight Gear/Paraloft
General	Shop	O1	Flight Line Office	Office for flight line shop	None
General	Shop	O1	Hangar Storage (Shop)	Storage area adjacent to hangar bay.	None
General	Shop	O1	Line Shack (Shop)	Flightline personnel waiting area and storage area	None
General	Shop	O1	Night Vision Goggles (NVG) Storage (Shop)	This space provides for storage of night vision gear.	Refer to Table 7-12: Night Vision Goggles (NVG) Storage
General	Shop	O1	Phase Crew (Shop)	Provides planned maintenance on aircraft parts.	Refer to Table 7-13: Phase Crew
General	Shop	O1	Power Plant (Shop)	Maintains Aircraft Engines.	Refer to Table 7-14: Power Plant
General	Shop	O1	Seat Shop (Shop)	Shop and storage area for seats and other components that are part of reconfigurable aircraft.	Refer to Table 7-15: Seat Shop
General	Shop	O1	Secured Classified Storage (Shop)	Secure storage of aircraft weapon system components with roll up door to hangar bay access	None
General	Shop	O1	Tool Room (Shop)	Tool Storage and Issue	Refer to Table 7-16: Tool Room
General	Admin	O1	1st Lieutenant	This space provides for the storage of building maintenance supplies and office space for the 1st Lieutenant.	None
General	Admin	O1	Bunk Room	Sleeping Quarters for Duty Officer	None

Airframe	Space Category	Space Grouping	Space Name	Space Description	Refer to Functional Data Sheet (Reference Table Number)
General	Admin	O1	Chief's Mess	Provides meeting space for Chief Petty Officers (CPO). Coordinate requirement with squadron.	None
General	Admin	O1	Division Office	This space provides office space for the squadron division officers.	Refer to Table 7-17: Division Office
General	Admin	O1	Lobby	This space is located at the main personnel entrance to the hangar. The space may include the quarterdeck. Verify requirement for quarterdeck as not all squadrons have personnel available for manning.	None
General	Admin	O1	Maintenance Administration	This space provides for administration of maintenance activities. This space is a general office area.	None
General	Admin	O1	Maintenance Administration - Private Offices	Provides for separate or combined office for the Maintenance Officer (MO) and the Assistant Maintenance Officer (AMO).	None
General	Admin	O1	Maintenance Control	This space provides for administration of squadron maintenance. The space also provides flight crews to access the maintenance records and flight data. This space may also be used for briefing of maintenance personnel prior to beginning of work day. Includes consolidated printer location and admin supply storage.	Refer to Table 7-18: Maintenance Control
General	Admin	O1	Maintenance Control Private Office	Provides private office for the Maintenance Control Officer in Charge (OIC).	None
General	Admin	O1	Material Control	This space provides for maintenance record storage. This area also provides for receipt and documentation of deliveries.	None
General	Admin	O1	Quality Assurance	This space provides office space and study space for quality assurance activities. This space also provides for storage of aircraft manuals. Manuals may be provided on Compact Disk (CD).	None
General	Admin	O1	Quarterdeck/Duty/Security Office	This space is located at the main personnel entrance to the hangar. The space may be separate from the lobby or open to the lobby as determined. Generally, this space is occupied by one person. Provides a controlled entry to the building.	None
General	Admin	O2	CO/XO Toilet	Private Toilet for CO/XO	None

Airframe	Space Category	Space Grouping	Space Name	Space Description	Refer to Functional Data Sheet (Reference Table Number)
General	Admin	O2	Exam Room	Provides exam space for medical officer	None
General	Admin	O2	General Office (open)	General open office space used for squadron administration.	None
General	Admin	O2	Personnel Office	General open office space used for squadron administration.	None
General	Admin	O2	Private Office - Commanding Officer, Executive Officer	Executive level private offices are generally adjacent to each other and are often interconnected either by direct access or by a vestibule. They may share a toilet with shower if requested. Generally, the spaces are associated with a waiting area and/or clerk's office. They may be a part of a "command suite" that includes the Command Master Chief. Command Suites may have secure environments.	None
General	Admin	O2	Private Office - General	This type of office is provided for various administrative functions on the O2 level. Offices may include: Drug and Alcohol Program Advisor (DAPA), Command Master Chief, Admin Officer, CPO, OIC, CCD, Combat Control Officer (CCO), SAFTO, NATO, Legal, and Contractor.	None
General	Ops	O2	Briefing Room	This space provides for operational briefings associated with flight operations	None
General	Ops	O2	Chart Room	Provides space for flight planning operations and storage of charts.	None
General	Ops	O2	Conference Room	Provides space for meetings and conferences. May be a secure space and may include Video Teleconference Capabilities (VTC).	None
General	Ops	O2	Operations Offices	Office serves as the operations center for all squadron flight operations. This may include other offices such as Intel or Tactics	None
General	Ops	O2	Secure Communications Office	Provides head-in space for SIPRNet	None
General	Ops	O2	Training Room/Classroom	This space provides for training of personnel. May require training storage space for table/chairs. May include operable partitions to create separate spaces.	None
General	Ops	O2	Ward Room (Ready Room)	Ready room for pilots and flight crew.	None

Airframe	Space Category	Space Grouping	Space Name	Space Description	Refer to Functional Data Sheet (Reference Table Number)
General	Support	O1/O2	Men's Toilet	Toilet facilities, locker and shower rooms.	None
General	Support	O1/O2	Break Room/Vending	Provides space for vending machines and snack bar operations. Coordinate specific requirements with the squadron. Multiple break rooms may be required.	None
General	Support	O1/O2	Building Systems Spaces	Provides space for building systems including, but not limited to: Mechanical, Fire Protection, Fire Pump, Electrical, and Elevator Equipment.	None
General	Support	O1/O2	Communications Room	Provides space for telecommunications and Navy Marine Corp Intranet (NMCI) head-in equipment	None
General	Support	O1/O2	Corridors	Provides for horizontal circulation	None
General	Support	O1/O2	Elevator	Elevator cab and shaft space	None
General	Support	O1/O2	Janitor Closet	Provides for cleaning supply storage.	None
General	Support	O1/O2	Stairs	Provides for vertical circulation	None
General	Support	O1/O2	Women's Toilet	Toilet facilities, locker and shower rooms.	None
F-35	OH	OH	Hangar Bay (OH) (F-35 Only)	Maintenance Hangar area	Refer to Table 7-19: Hangar Bay (OH) (F-35 Only)
F-35	Shop	O1	Seat and Canopy Maintenance/AME (Shop) (F-35 Only)	Maintains ejection seats and canopies. Includes arming and de-arming with storage of explosives. Includes storage and maintenance of other Alternate Mission Equipment (AME).	Refer to Table 7-20: Seat and Canopy Maintenance/AME Maintenance (Shop) (F-35 Only)
F-35	Ops	O1/O2	SAPF ALIS Administration (F-35 Only)	Office	None
F-35	Ops	O1/O2	SAPF ALIS Maintenance (F-35 Only)	Office	None
F-35	Ops	O1/O2	SAPF ALIS OMS Operations (F-35 Only)	Office	None
F-35	Ops	O1/O2	SAPF Assistant Intel (F-35 Only)	Office	None
F-35	Ops	O1/O2	SAPF Assistant Security Office (F-35 Only)	Office	None
F-35	Ops	O1/O2	SAPF Avionics Shop Subset (F-35 Only)	Office	None
F-35	Ops	O1/O2	SAPF Intel (F-35 Only)	Office	None
F-35	Ops	O1/O2	SAPF Large Pilot Briefing (2) (F-35 Only)	Briefing - Separate by operable partition	None

Airframe	Space Category	Space Grouping	Space Name	Space Description	Refer to Functional Data Sheet (Reference Table Number)
F-35	Ops	O1/O2	SAPF Mission Planning (F-35 Only)	Office	None
F-35	Ops	O1/O2	SAPF Pilot Briefing (6) (F-35 Only)	Briefing	None
F-35	Ops	O1/O2	SAPF Security Office (F-35 Only)	Office	None
F-35	Ops	O1/O2	SAPF Security Work Space (F-35 Only)	Office	None
F-35	Ops	O1/O2	SAPF SOU Communications (F-35 Only)	Office	None
F-35	Ops	O1/O2	Collateral/SAR Storage	Multiple options are available to meet storage requirements based on type and condition of parts/equipment.	None
F-35	Support	O1/O2	SAPF Toilets (F-35 Only)	Toilet	None
F-35	Support	O1/O2	SAPF Break Room (F-35 Only)	Support	None
F-35	Support	O1/O2	SAPF SIPRNet Communications (F-35 Only)	Support	None
F-35	Support	O1/O2	SAPF Storage (F-35 Only)	Storage	None
MV-22	Shop	O1	Airframe Hydraulic Clean Room (Shop) (MV-22 Only)	This work center performs inspections and proper procedures on flight control systems, hydraulic power systems and associated subsystems, and Blade Fold Wing Stow (BFWS) systems	Refer to MV-22 Functional Data Sheets Table 7-21: Airframe Hydraulic Clean Room (Shop) (MV-22 Only)

7-14.5 Functional Data Sheets

Table 7-4: Hangar Bay (OH)

Description / Usage		Maintenance area for airframes
Minimum Ceiling Height		Refer to mandatory height requirements based on hangar type.
Finishes	Walls	Painted walls between O1/O2 and hangar bay.
	Floors	Fuel Resistive Resinous Flooring, 5-Coat System. Incorporate floor markings if required.
	Ceiling	Exposed construction.
Interior Construction / Built-in Equipment		Incorporate an approved Avian Intrusion Prevention System in the hangar bay.
Furniture, Fixtures & Equipment (FF&E)		Storage cabinets
Plumbing		Emergency Shower and Eyewash stations per Chapter 3. Compressed air drops on walls - Compressed air source of 125 psi with a constant flow rate of 20 scfm. Each service point with the following: One (1) 38 mm (1/2 in.) needle valve shutoff, One (1) pneumatic tool filter, One (1) 861.8 kPa (125.0 psi) pressure regulator, One (1) pneumatic tool lubricator, Two (2) pneumatic tool quick-connectors, One (1) wall-mounted hose rack. Coordinate with users on number of compressed air drops required and requirements for hose reels for water or air. **\2** Provide high-volume compressed air drops, 150 scfm minimum, for every two hangar bays, minimum 1-1/4" pipe size. **2/**
HVAC		Provide per Chapter 3. Specialized exhaust system(s) required. Exhaust directly outdoors through roof. Thermostatic control switch activated by hangar door to shutoff heating if OA temp is above 40ºF. May require air conditioned hangar bay for certain aircraft in warmer climates. May require overhead radiant heating. May require hangar door track heating system in colder climates.
Fire Protection		Provide per Chapter 3 and Chapter 7.
Power		Provide per Chapter 3 and Chapter 7.
Lighting		
Communication		Provide per Chapter 3 and Chapter 7.
Intercommunications Systems		Provide per Chapter 3. Microphone and Auxiliary Jacks, Paging Speaker System (Neoplanar Emitters), GPS Repeater Systems
Electrical Special Systems and Devices		Provide per Chapter 3 and Chapter 7. 400 Hz Frequency Converters, Ground Power Equipment Connections. Security - CCTV Cameras, Access Control (if required by Government)
Special Requirements		Provide Hangar Doors per Chapter 3 and Chapter 7. Provide catwalks and ladders to provide service for Vertical Lift Fabric Doors. Provide bridge crane(s) when required.
Acoustics		Provide acoustical seals including automatic door bottoms and perimeter seals on any doors provided between the O2 level and the hangar bay.

Table 7-5: Air Frames (Shop)

Description / Usage		Maintains air frames.
Minimum Ceiling Height		
Finishes	Walls	Painted with resilient base.
	Floors	Fuel Resistive Resinous Flooring, 5-Coat System. Incorporate floor markings if required.
	Ceiling	Exposed construction.
Interior Construction / Built-in Equipment		Marker Boards.
Furniture, Fixtures & Equipment (FF&E)		Desks and chairs, bookcases, file cabinets, workbench with stools, aircraft parts shelf, vice, storage cabinets.
Plumbing		Service Sink. Compressed air drop at workbench. Compressed air source of 125 psi with a constant flow rate of 40 scfm. Each service point with the following: One (1) 38 mm (1/2 in.) needle valve shutoff, One (1) pneumatic tool filter, One (1) 861.8 kPa (125.0 psi) pressure regulator, One (1) pneumatic tool lubricator, Two (2) pneumatic tool quick-connectors, One (1) wall-mounted hose rack. Coordinate with users on number of compressed air drops and requirements for hose reels.
HVAC		Requires special industrial exhaust system that goes directly to the outside through roof.
Fire Protection		Provide per Chapter 3 and Chapter 7
Power		Dedicated Equipment Connections.
Lighting		
Communication		CATV Outlet
Intercommunications Systems		Call-In and Volume Control Station.
Special Requirements		Due to the potentially large pieces of equipment brought into this shop, provide a minimum of a pair of 3'0" x 7'-0" personnel doors opening onto the hangar bay. If a 4 ft. (1220 mm) wide opening is adequate, provide a single 4 ft. (1220 mm) wide personnel door in lieu of double doors.
Acoustics		

Table 7-6: Aviation Ordnance (Shop)

Description / Usage		Maintains aircraft weapons systems including weapons cleaning and storage.
Minimum Ceiling Height		
Finishes	Walls	Paint with resilient base.
	Floors	Fuel Resistive Resinous Flooring, 3-Coat System. Incorporate floor markings if required.
	Ceiling	Exposed construction.
Interior Construction / Built-in Equipment		Marker Boards.
Furniture, Fixtures & Equipment (FF&E)		Desks and Chairs, bookcases, file cabinets, workbench with stools, aircraft parts shelf, vice, storage cabinets.
Plumbing		Service Sink. Compressed air drop at workbench. Compressed air source of 125 psi with a constant flow rate of 20 scfm. Each service point with the following: One (1) 38 mm (1/2 in.) needle valve shutoff, One (1) pneumatic tool filter, One (1) 861.8 kPa (125.0 psi) pressure regulator, One (1) pneumatic tool lubricator, Two (2) pneumatic tool quick-connectors, One (1) wall-mounted hose rack. Coordinate with users on number of compressed air drops and requirements for hose reels.
HVAC		Specialized exhaust system(s) required. Exhaust directly outdoors through roof. Thermostat/humidistat. Separately controlled zones. Humidifier/Dehumidifier may be required due to the presence of ordnance. Explosion-proof fan motors may be required.
Fire Protection		Provide per Chapter 3 and Chapter 7
Power		
Grounding Systems		Provide Ground Bus Bar per UFC 3-575-01
Electrical Special Systems and Devices		400 Hz Panelboard, 400 Hz Bench Connection, Test Bench Connections
Lighting		
Communication		CATV Outlet.
Intercommunications Systems		Call-In and Volume Control Station.
Special Requirements		Provide direct access to the exterior for the Aviation Ordnance Shop. Provide panic devices on all doors from the shop. May require a vault. Coordinate with the squadron. Special solvents may be used for cleaning - provide special exhaust if required. Coordinate explosive classification requirements with the users.
Acoustics		

Table 7-7: Avionics Space (Shop)

Description / Usage		Maintains aircraft electrical systems. This shop also provides storage for specialized communication equipment and may require special secure storage areas. Consider providing a vault within the shop as opposed to making the entire shop a secure space.
Minimum Ceiling Height		
Finishes	Walls	Paint resilient base.
	Floors	Static Dissipative resilient flooring.
	Ceiling	Exposed construction.
Interior Construction / Built-in Equipment		Marker Boards.
Furnishings		Desks and chairs, bookcases, file cabinets, workbench with stools, aircraft parts shelf, vice, storage cabinets, secure file cabinet if required.
Plumbing		Service Sink. Compressed air drop at workbench. Compressed air source of 125 psi with a constant flow rate of 20 scfm. Each service point with the following: One (1) 38 mm (1/2 in.) needle valve shutoff, One (1) pneumatic tool filter, One (1) 861.8 kPa (125.0 psi) pressure regulator, One (1) pneumatic tool lubricator, Two (2) pneumatic tool quick-connectors, One (1) wall-mounted hose rack. Coordinate with users on number of compressed air drops and requirements for hose reels. Emergency Eyewash per Chapter 3.
HVAC		Specialized exhaust system(s) required per Chapter 3. Exhaust directly outdoors through roof.
Fire Protection		Provide per Chapter 3 and Chapter 7
Power		
Grounding Systems		Provide Ground Bus Bar per UFC 3-575-01
Electrical Special Systems and Devices		400 Hz Frequency Converter, 400 Hz Panelboard, Convenience Outlets, Dedicated Equipment Connections, 400 Hz Bench Connections, Test Bench Connections.
Lighting		
Communication		CATV Outlet
Intercommunications Systems		Call-In and Volume Control Stations.
Special Requirements		Sometimes this space may require a vault or secure file cabinets. Coordinate requirement with squadron.
Acoustics		

Table 7-8: Corrosion Control/Coating Shop

Description / Usage		Maintenance shop for corrosion control. Includes Low Observability (LO) Maintenance for F-35.
Minimum Ceiling Height		
Finishes	Walls	Paint with resilient base.
	Floors	Sealed concrete.
	Ceiling	Exposed construction.
Interior Construction / Built-in Equipment		Marker Boards.
Furniture, Fixtures & Equipment (FF&E)		Desks and chairs, bookcases, file cabinets, workbench with stools, aircraft parts shelf, vice, storage cabinets, hazmat lockers, and corrosive battery lockers.
Plumbing		Service Sink. Compressed air drop at workbench. Compressed air source of 125 psi with a constant flow rate of 20 scfm. Each service point with the following: One (1) 38 mm (1/2 in.) needle valve shutoff, One (1) pneumatic tool filter, One (1) 861.8 kPa (125.0 psi) pressure regulator, One (1) pneumatic tool lubricator, Two (2) pneumatic tool quick-connectors, One (1) wall-mounted hose rack. Coordinate with users on number of compressed air drops and requirements for hose reels.
HVAC		Specialized exhaust system(s) required. Exhaust directly outdoors through roof.
Fire Protection		Provide per Chapter 3 and Chapter 7
Power		
Lighting		
Communication		CATV Outlet.
Intercommunications Systems		Call-In and Volume Control Station.
Special Requirements		Due to the potentially large pieces of equipment brought into this shop, provide a minimum of a pair of 3'-0" x 7'-0" personnel doors opening onto the hangar bay. If a 4 ft. (1220 mm) wide opening is adequate, provide a single 4 ft. (1220 mm) wide personnel door in lieu of double doors.
Acoustics		

Table 7-9: Detachment (Shop)

Description / Usage		Standard shop for Squadrons using deployed aircraft. Coordinate requirements with a squadron configured for detachment components.
Minimum Ceiling Height		
Finishes	Walls	Paint with resilient base.
	Floors	Fuel Resistive Resinous Flooring, 3-Coat System. Incorporate floor markings if required.
	Ceiling	Exposed construction.
Interior Construction / Built-in Equipment		Marker Boards
Furniture, Fixtures & Equipment (FF&E)		Desks and chairs, bookcases, file cabinets, work benches.
Plumbing		
HVAC		Specialized exhaust system(s) may be required. Exhaust directly outdoors through roof.
Fire Protection		Provide per Chapter 3 and Chapter 7
Power		
Lighting		
Communication		CATV Outlet.
Intercommunications Systems		Call-In and Volume Control Stations.
Special Requirements		
Acoustics		

Table 7-10: Flight Gear/Paraloft (Shop)

Description / Usage		This space is used to repair and store flight gear.
Minimum Ceiling Height		
Finishes	Walls	Paint with resilient base.
	Floors	Resilient flooring or Fuel Resistive Resinous Flooring, 3-Coat System. May require static dissipative flooring.
	Ceiling	Exposed construction.
Interior Construction / Built-in Equipment		Marker Boards. Flight Gear Lockers - coordinate requirements with squadron. Generally, lockers are open style with mesh sides. Due to the storage of combustible materials (flares), doors are not desirable on the locker fronts. Size lockers to accommodate helmets and the particular gear associated with the aircraft type. Work table - provide large worktable to provide workspace for working on flight gear. Consider Rolling Storage units in lieu of fixed lockers to save space. Coordinate with structural slab for possible rail installation.
Furniture, Fixtures & Equipment (FF&E)		Desks and chairs, bookcases, file cabinets, workbench with stools, aircraft parts shelf, vice, storage cabinets, commercial washer and dryer, sewing machine.
Plumbing		Washer hook up.
HVAC		Dryer vent required. Specialized exhaust system(s) required. Exhaust directly outdoors through roof. Explosion-proof fan motors may be required.
Fire Protection		Provide per Chapter 3 and Chapter 7
Power		Dryer hookup.
Lighting		
Communication		CATV Outlet.
Intercommunications Systems		Call-In and Volume Control Stations.
Special Requirements		Two (2) exits are required from this space. Swing door outward and provide panic hardware. Verify quantity of Class C/D1.4G explosive material within the space. Provide protective construction if the allowable quantities of explosive material are exceeded. Space may need to be classified as a "Hazardous Occupancy" based on types and quantity of pyrotechnical devices stored in the space. Verify quantity (pounds) of material prior to establishing a special occupancy separation.
Acoustics		

Table 7-11: Flight Line (Shop)

Description / Usage		Flight line personnel shop
Minimum Ceiling Height		
Finishes	Walls	Paint with resilient base.
	Floors	Sealed concrete is the minimum. Resilient flooring or Fuel Resistive Resinous Flooring, 3-Coat System if requested by the squadron.
	Ceiling	Exposed construction. Paint exposed items such as structure, ductwork, conduit, piping, devices.
Interior Construction / Built-in Equipment		
Furniture, Fixtures & Equipment (FF&E)		Desks, desk chairs, tool storage cabinets, workbenches, stools, file cabinets, as required.
Plumbing		Service sink Emergency eyewash per Chapter 3
HVAC		
Fire Protection		Provide per Chapter 3 and Chapter 7
Power		
Lighting		
Communication		CATV Outlet
Intercommunications Systems		Call-In and Volume Control Stations
Special Requirements		Due to the potentially large pieces of equipment brought into this space, provide a minimum of a pair of 3'-0" x 7'-0" personnel doors opening onto the hangar bay. Provide a minimum 8 ft. (2.4 m) high motorized rolling service door to the exterior.
Acoustics		No special requirements

Table 7-12: Night Vision Goggles (NVG) Storage (Shop)

Description / Usage		This space serves as storage room of night vision gear.
Minimum Ceiling Height		
Finishes	Walls	Painted CMU with resilient base.
	Floors	Resilient flooring.
	Ceiling	Suspended Acoustical Ceiling.
Interior Construction / Built-in Equipment		Shelving.
Furniture, Fixtures & Equipment (FF&E)		
Plumbing		Not required.
HVAC		
Fire Protection		Provide per Chapter 3 and Chapter 7
Power		
Lighting		
Communication		
Special Requirements		Provide metal door with a combination lock and deadbolt.
Acoustics		

Table 7-13: Phase Crew (Shop)

Description / Usage		Shop for planned maintenance on aircraft parts.
Minimum Ceiling Height		
Finishes	Walls	Paint with resilient base.
	Floors	Fuel Resistive Resinous Flooring, 5-Coat System. Incorporate floor markings if required.
	Ceiling	Exposed construction.
Interior Construction / Built-in Equipment		Marker Boards.
Furniture, Fixtures & Equipment (FF&E)		Desks and chairs, bookcases, file cabinets, workbench with stools, aircraft parts shelf, vice, storage cabinets.
Plumbing		Service Sink. Compressed air drop at workbench. Compressed air source of 125 psi with a constant flow rate of 20 scfm. Each service point with the following: One (1) 38 mm (1/2 in.) needle valve shutoff, One (1) pneumatic tool filter, One (1) 861.8 kPa (125.0 psi) pressure regulator, One (1) pneumatic tool lubricator, Two (2) pneumatic tool quick-connectors, One (1) wall-mounted hose rack. Coordinate with users on number of compressed air drops and requirements for hose reels.
HVAC		Specialized exhaust system(s) may be required. Exhaust directly outdoors through roof.
Fire Protection		Provide per Chapter 3 and Chapter 7
Power		
Lighting		
Communication		CATV Outlet.
Intercommunications Systems		Call-In and Volume Control Station.
Special Requirements		Due to the potentially large pieces of equipment brought into this shop, provide a minimum of a pair of 3'-0" x 7'-0" personnel doors opening onto the hangar bay. If a 4 ft. (1220 m) wide opening is adequate, provide a single 4 ft. (1220 mm) wide personnel door in lieu of double doors.
Acoustics		

Table 7-14: Power Plant (Shop)

Description / Usage		Maintains aircraft engines.
Minimum Ceiling Height		
Finishes	Walls	Paint with resilient base.
	Floors	Fuel Resistive Resinous Flooring, 5-Coat System. Incorporate required floor markings
	Ceiling	Exposed construction.
Interior Construction / Built-in Equipment		Marker Boards.
Furniture, Fixtures & Equipment (FF&E)		Desks and chairs, bookcases, file cabinets, workbench with stools, aircraft parts shelf, vice, storage cabinets.
Plumbing		Service Sink. Compressed air drop at workbench. Compressed air source of 125 psi with a constant flow rate of 20 scfm. Each service point with the following: One (1) 38 mm (1/2 in.) needle valve shutoff, One (1) pneumatic tool filter, One (1) 861.8 kPa (125.0 psi) pressure regulator, One (1) pneumatic tool lubricator, Two (2) pneumatic tool quick-connectors, One (1) wall-mounted hose rack. Coordinate with users on number of compressed air drops and requirements for hose reels.
HVAC		Specialized exhaust system(s) required. Exhaust directly outdoors through roof.
Fire Protection		Provide per Chapter 3 and Chapter 7
Power		Dedicated Equipment Connections.
Lighting		
Communication		CATV Outlet.
Intercommunications Systems		Call-In and Volume Control Station. Connect all shops, maintenance control, tool room and material control via intercommunication system.
Special Requirements		Due to the potentially large pieces of equipment brought into this shop, provide a minimum of a pair of 3'-0" x 7'-0" personnel doors opening onto the hangar bay. If a 4 ft. (1220 mm) wide opening is adequate, provide a single 4 ft. (1220 mm) wide personnel door in lieu of double doors.
Acoustics		

Table 7-15: Seat Shop (Shop)

Description / Usage		Shop and storage area for seats and other components that are part of reconfigurable aircraft.
Minimum Ceiling Height		
Finishes	Walls	Paint with resilient base.
	Floors	Resilient flooring or Fuel Resistive Resinous Flooring, 3-Coat System.
	Ceiling	Exposed construction.
Interior Construction / Built-in Equipment		Marker Boards. May require heavy industrial shelving for seat storage.
Furniture, Fixtures & Equipment (FF&E)		Desks and chairs, bookcases, file cabinets.
Plumbing		
HVAC		Specialized exhaust system(s) may be required. Exhaust directly outdoors through roof. May require explosion-proof fans and motors for MK16E ejection seats.
Fire Protection		Provide per Chapter 3 and Chapter 7
Power		
Grounding Systems		Provide Ground Bus Bar per UFC 3-575-01
Lighting		
Communication		CATV Outlet.
Intercommunications Systems		Call-In and Volume Control Stations.
Special Requirements		Due to the potentially large pieces of equipment brought into this shop, provide a minimum of a pair of 3'-0" x 7'-0" personnel doors opening onto the hangar bay. If direct access to the hangar bay is not provided, provide an exterior double door.
Acoustics		

Table 7-16: Tool Room (Shop)

Description / Usage		Tool storage and issue
Minimum Ceiling Height		
Finishes	Walls	Paint with resilient base.
	Floors	Sealed concrete resilient flooring or Fuel Resistive Resinous Flooring, 3-Coat System.
	Ceiling	Exposed construction.
Interior Construction / Built-in Equipment		Stainless steel tool issue counter located within the tool room. Provide a stainless steel service counter with overhead rolling service counter door if requested by the users. Marker Boards and Peg Board
Furniture, Fixtures & Equipment (FF&E)		Desks and chairs, bookcases file cabinets, workbench with stools, aircraft parts shelf, vice, storage cabinets, parts storage bins.
Plumbing		Service Sink Compressed air drop at workbench. Compressed air source of 125 psi with a constant flow rate of 20 scfm. Each service point with the following: One (1) 38 mm (1/2 in.) needle valve shutoff, One (1) pneumatic tool filter, One (1) 861.8 kPa (125.0 psi) pressure regulator, One (1) pneumatic tool lubricator, Two (2) pneumatic tool quick-connectors, One (1) wall-mounted hose rack. Coordinate with users on number of compressed air drops and requirements for hose reels. Emergency eye and face wash per Chapter 3.
HVAC		
Fire Protection		Provide per Chapter 3 and Chapter 7
Power		Dedicated Equipment Connections
Lighting		
Communication		
Intercommunications Systems		Call-In and Volume Control Stations. Connect all shops, maintenance control, tool room and material control via intercommunication system.
Special Requirements		Due to the potentially large pieces of equipment brought into this shop, provide a minimum of a pair of 3'-0" x 7'-0" personnel doors opening onto the hangar bay. If a 4 ft. (1220 mm) wide opening is adequate, provide a single 4 ft. (1220 mm) wide personnel door in lieu of double doors. Consider using modular rolling storage shelving units for large tool rooms. Coordinate with structural slab for possible rail installation.
Acoustics		

Table 7-17: Division Office

Description / Usage		This space provides office space for the squadron division office.
Minimum Ceiling Height		
Finishes	Walls	Paint resilient base. Internal separation partitions may be gypsum board on metal studs.
	Floors	Resilient flooring, minimum. Do not provide carpet.
	Ceiling	Suspended Acoustical Ceiling.
Interior Construction / Built-in Equipment		Marker Board.
Furniture, Fixtures & Equipment (FF&E)		Desks and chairs, side chairs, bookcases, file cabinets.
Plumbing		
HVAC		
Fire Protection		Provide per Chapter 3 and Chapter 7
Power		
Lighting		
Communication		CATV Outlet, Secure (SIPRNet) Outlets.
Intercommunications Systems		Call-In and Volume Control Stations.
Special Requirements		
Acoustics		Provide a minimum STC rating of 39, for partition and door construction.

Table 7-18: Maintenance Control

Description / Usage		Squadron Maintenance Administration: The space also allows flight crews to access the maintenance records and flight data. This space may also be used for briefing of maintenance personnel prior to beginning of work day.
Minimum Ceiling Height		
Finishes	Walls	Paint with resilient base.
	Floors	Resilient flooring, minimum on office side; sealed concrete, epoxy coating on the customer side. Do not provide carpet.
	Ceiling	Suspended Acoustical Ceiling.
Interior Construction / Built-in Equipment		Service Counter to provide for maintenance personnel to receive daily assignments and provide a work space for review of records. Counter for flight crew to enter flight records. Marker Board, TV Bracket.
Furniture, Fixtures & Equipment (FF&E)		Desks and chairs, bookcases, lateral files, time zone clock. Flight planning boards, if required.
Plumbing		
HVAC		
Fire Protection		Provide per Chapter 3 and Chapter 7
Power		
Lighting		
Communication		Provide network and telephone per UFC 3-580-01, CATV Outlet, Conduits to Roof Mounted Antenna Farm Platform, Base Radio Outlet
Intercommunications Systems		Master Control Station. Connect all shops, maintenance control, tool room and material control via intercommunication system.
Special Requirements		User may request that this space be combined with Material Control. Sometimes access to the exterior is provided if it is part of Material control. CCTV monitoring and Pan, Tilt Zoom (PTZ) control of hangar and apron cameras. When this space has direct visual access to the hangar bay, provide fixed with fire rated glass.
Acoustics		

7-14.5.1 F-35 Functional Data Sheets

Table 7-19: Hangar Bay (OH) (F-35 Only)

Description / Usage		Maintenance Hangar area
Minimum Ceiling Height		Refer to mandatory height requirements based on hangar type.
Finishes	Walls	Paint walls between O1/O2 and hangar bay
	Floors	Fuel Resistive Resinous Flooring, 5-Coat System. Incorporate floor markings if required
	Ceiling	Exposed construction.
Interior Construction / Built-in Equipment		Incorporate Avian Intrusion Prevention System in the hangar bay.
Furniture, Fixtures & Equipment (FF&E)		
Plumbing		Emergency Shower and Eyewash stations per Chapter 3. Compressed air drops on walls - Compressed air source of 125 psi with a constant flow rate of 20 scfm. Each service point with the following: One (1) 38 mm (1/2 in.) needle valve shutoff, One (1) pneumatic tool filter, One (1) 861.8 kPa (125.0 psi) pressure regulator, One (1) pneumatic tool lubricator, Two (2) pneumatic tool quick-connectors, One (1) wall-mounted hose rack. Coordinate with users on number of compressed air drops required and requirements for hose reels for water or air. **\2** Provide high-volume compressed air drops, 150 scfm minimum, for every two hangar bays, minimum 1-1/4" pipe size. **/2/**
HVAC		Provide per Chapter 3. Exhaust directly outdoors through roof. Thermostatic control switch required. Activate switch by hangar door to shut off heating per Chapter 3. May require overhead radiant heating. Provide Pre-Conditioned Air System per Chapter 3 and Chapter 4.
		May require hangar door track heating system in colder climates.
Fire Protection		Provide per Chapter 3 and Chapter 7
Power		Ground Power Equipment Connection Dedicated Equipment Connections Two 480VAC, 3-phase, 60Hz power connection, at each aircraft parking spot. Electrical Hazardous classified area per Chapter 3.
Grounding Systems		Grounding per UFC 3-575-01.
Electrical Special Systems and Devices		270VDC 72kW power connection. 100-amp minimum ground power connections. 400 Hz Frequency Converters, if required by Legacy aircraft, 270VDC converters.
Lighting		
Communication		SCI Communications Outlets Local Area Network (LAN) connection at each aircraft parking location, and any F-35 wheel and tire maintenance area, GPS Repeater Systems.
Intercommunications Systems		Microphone and Auxiliary Jacks Paging Speaker System (Neoplanar Emitters)
Special Requirements		Security - CCTV Cameras, Access Control (if required by Government)
		Provide Hangar Doors per Chapter 3 and Chapter 7.
		Provide catwalks and ladders to provide service for Vertical Lift Fabric Doors
		Provide Overhead Bridge Crane
Acoustics		Provide doors between the O2 level and the hangar bay with acoustical seals including automatic door bottoms and perimeter seals

Table 7-20: Seat and Canopy Maintenance/AME Maintenance (Shop) (F-35 Only)

Description / Usage		Maintains ejection seats and canopies. Includes arming and de-arming with storage of explosives. Includes storage and maintenance of other Alternate Mission Equipment (AME).
Minimum Ceiling Height		
Finishes	Walls	Paint with resilient base.
	Floors	Sealed concrete is the minimum. Resilient flooring or Fuel Resistive Resinous Flooring, 3-Coat System if requested by the squadron.
	Ceiling	Exposed construction.
Interior Construction / Built-in Equipment		Marker Boards
Furniture, Fixtures & Equipment (FF&E)		Desks and chairs, bookcases, file cabinets, workbench with stools, aircraft parts shelf, vice, storage cabinets.
Plumbing		Compressed air drop: Compressed air source of 125 psi with a constant flow rate of 20 scfm. Each service point with the following: One (1) 38 mm (1/2 in.) needle valve shutoff, One (1) pneumatic tool filter, One (1) 861.8 kPa (125.0 psi) pressure regulator, One (1) pneumatic tool lubricator, Two (2) pneumatic tool quick-connectors, One (1) wall-mounted hose rack. Coordinate with user on quantity and location and requirements for hose reels.
HVAC		Specialized exhaust system(s) required. Exhaust directly outdoors through roof. Thermostat/humidistat. Separately controlled zone Humidifier/Dehumidifier may be required due to the presence of ordnance. Explosion-proof fans and motors may be required for MK16E aircraft ejection seats.
Fire Protection		Provide per Chapter 3 and Chapter 7. Deflagration venting may be required depending upon the type and quantity of explosive stored.
Power		
Grounding Systems		Provide Ground Bus Bar per UFC 3-575-01 and Ordnance Grounding per NAVSEA OP-5.
Electrical Special Systems and Devices		
Lighting		Explosive proof
Communication		CATV Outlet
Intercommunications Systems		Call-In and Volume Control Station
Special Requirements		Due to the potentially large pieces of equipment brought into this shop, provide a minimum of a pair of 3'-0" x 7'-0" personnel doors opening onto the hangar bay. Seat Maintenance Shop should have direct access to the exterior. Provide panic devices on all doors from the shop.
		Accommodate classifications of 1.3c and 1.4c with a Net Explosive Weight (NEW) of 6.31 pounds of explosives (used in each ejection seat within the seat shop). Coordinate requirements for allowable quantities without creating separate occupancy type, if possible.
		Accommodate classifications of 1.4b and 1.4d with a NEW of 0.54 pounds of explosives used in the Canopy Transparency Removal System (TRS) (Canopy NEW = .06 lbs./canopy)
		Criteria for explosive classifications are based on Joint Technical Bulletin 700-2 Department of Defense Ammunition and Explosives Hazard Classification Procedure
		Provide doors wide enough to accommodate the seat dolly. Validate door size adequate to accommodate Rotating Canopy Stand.
Acoustics		

7-14.5.2 MV-22 Functional Data Sheets

Table 7-21: Airframe Hydraulic Clean Room (Shop) (MV-22 Only)

Description / Usage		This work center performs inspections and proper procedures on flight control systems, hydraulic power systems and associated subsystems, and Blade Fold Wing Stow (BFWS) systems
Minimum Ceiling Height		10 ft. (3.0 m)
Finishes	Walls	Paint with resilient base.
	Floors	Fuel Resistive Resinous Flooring, 5-Coat System if requested by the squadron.
	Ceiling	Exposed construction.
Interior Construction / Built-in Equipment		
Furniture, Fixtures & Equipment (FF&E)		
Plumbing		Compressed Air Drops. Compressed air source of 125 psi with a constant flow rate of 20 scfm. Each service point with the following: One (1) 38 mm (1/2 in.) needle valve shutoff, One (1) pneumatic tool filter, One (1) 861.8 kPa (125.0 psi) pressure regulator, One (1) pneumatic tool lubricator, Two (2) pneumatic tool quick-connectors, One (1) wall-mounted hose rack.
HVAC		Provide per Chapter 3 Heating Air Conditioning, 70°F (21°C) with 35%-50% humidity Ventilation 10.0 scfm/person Thermostatic control switch required.
Fire Protection		Provide per Chapter 3 and Chapter 7
Power		
Grounding Systems		
Electrical Special Systems and Devices		
Lighting		
Communication		Category (CAT) 5e Unshielded Twisted Pair (UTP) cable for all connections involving the Portable Electronic Maintenance Aid (PEMA) equipment.
Intercommunications Systems		
Special Requirements		The Hydraulic Particle Analyzer uses a Class 1 Laser, has a rechargeable Nickel-Metal Hydride battery, an Alternating Current (A/C) power cord, a sonic bath with A/C plug, and a compressed air connection (60.0 to 110.0 psi, clean and dry). This unit is portable using Carbon Dioxide (CO2) bottles for compressed air and rechargeable battery for power.
		Provide handling and storage (IAW) local codes and requirements due to HAZMAT.
Acoustics

APPENDIX C: BEST PRACTICES

C-1 GENERAL

Best practices in Aircraft Maintenance Hangar design are contained in this appendix. Design all Aircraft Maintenance Hangars to meet all applicable requirements found in the following:

- UFC 1-200-01, *DoD Building Code (General Building Requirements)*;
- UFC 4-010-01, *DoD Minimum Antiterrorism Standard for Buildings;*
- UFC 3-600-01, *Fire Protection Engineering for Facilities*, supplemented by Chapter 3 of this UFC. NFPA 101; and NFPA 409.

C-1.1 Antiterrorism/Force Protection (AT/FP)

Incorporate AT/FP issues at the initial phase of the design. Formulate the basis for design on UFC 4-010-01. Coordinate all protection features with the current standards and any additional requirements in place at the time of the design. Ascertain the exact requirements for protection based on a site-specific survey, or lacking one, provide the minimum protection standards outlined in the standards. Coordinate all AT/FP issues with the base that may be a part of another project or impact adjacent facilities such as security fencing, parking.

C-1.2 Sustainable Design

In accordance with UFC 1-200-02, *High Performance and Sustainable Building Requirements*, implement an integrated design process at the initial phase of design to reduce environmental impacts, lower energy and operating costs, optimize performance and conserve water, while increasing occupant satisfaction and productivity through improved health and well-being. While certain design strategies are specifically based on varying climatic, site, mission, program and budget requirements, employ an overall approach with focus on sustainable site development, water savings, energy efficiency, resource selection and indoor environmental quality. The best practices below provide a general example of potential strategies, but are not intended to represent a comprehensive list of sustainable design opportunities.

- Incorporate passive energy conservation measures by evaluating optimal site orientation.
- Shape and size the building footprint within close tolerances of the aircraft; finely tuned to the operation taking place. Smaller buildings and support systems translate to direct first cost savings and reduced operating costs of mechanical, electrical and fire protection systems.
- Hangar roofs generally provide large expanses that can be designed and oriented to maximize the efficiency of renewable energy systems, such as solar collection.

- Highly reflective roof surfaces can reduce the heat island effect and decrease solar heat gain to the building interior.
- Use whole building energy simulation and life cycle cost analysis to evaluate high performance building envelope, mechanical and electrical systems.
- Integrate automated controls with high-bay lighting, such as zoned photometric sensors.
- Reflective (white or light colored) interior finishes help reduce the amount of required lighting while ensuring direction to the work zone, instead of absorption by walls and ceilings.
- Air compressor designs to include water cooled equipment strategically located to provide the rejected heat for space heating, domestic hot water pre-heating and tie into building heating systems.
- Solar air preheat for hangar bay area and combination preheating domestic hot water.

C-2 CIVIL

C-2.1 Appearance

Locate HVAC equipment, meters, poles, transformers, vaults, pressure reducing station piping and valving, and other utility items so that they do not detract from the building's appearance. Design should also reduce the negative visual impact of utility items and communication lines.

C-2.2 Energy Concerns

Consider the effect of local sun angles and wind conditions on the hangar.

C-2.3 Winds

In harsh climates, seacoasts and areas of consistently high or changing winds, design hangar entry points (hangar bay, personnel entrance and windows, intake and exhaust vents) to compensate for these adverse conditions, including snow. Consider prevailing and seasonal wind conditions as well.

C-2.4 Security Fencing

Limit the use of fencing to enclose and separate areas within the vicinity of the hangar to those conditions requiring security or the protection of life, separation of a construction site from operational facilities, isolation of a hazardous area, or as stipulated by the Base Security Department.

C-2.5 Landscape Planting

Make use of low maintenance landscape plants that are indigenous to the area. Existing mature trees and vegetation should be retained whenever practical. Landscape design should avoid planting next to the hangar that would permit concealment in accordance with criteria set forth in the Unified Facilities criteria for AT/FP. As hangars are generally in industrial areas, limit landscaping to entrances and other public areas.

C-2.6 Utilities

Consider utilities that are essential to efficient operation and design of adequate size to serve future requirements in the early planning stages. Specifically address the adequacy of existing utilities support and include any additional needs. Plan utility lines to minimize utility easements, capital investments, and maintenance and repair costs.

C-2.7 Underground Lines

Locate underground utilities to minimize the cost and effort of performing maintenance. Do not locate utility lines of any type under hangars except for those portions serving the hangar. Minimize utility lines running under parking lots, sidewalks, and other paved surfaces to minimize cost for maintenance of the systems. Locate all underground utility lines, mains, and conduits at the minimum depth required in accordance with local code, frost line and water table requirements, and, when possible, in common corridors to allow for ready access and maintenance. Locate utilities to allow for future expansion of the flightline.

C-2.8 Storm Drainage

The building up of undeveloped areas may have a noticeable effect on installation drainage facilities; design alterations or extensions to storm sewers and drainage channels as required because of the location and design of new facilities.

C-3 ARCHITECTURAL

C-3.1 Aircraft Maintenance Bay and Maintenance Shop Floor Finishes

C-3.1.1 Performance Requirements

Military maintenance hangars are active workspaces and can be especially abusive environments. An aircraft maintenance bay floor finish must be evaluated on a number of performance characteristics.

- Proper Installation
- Chemical Resistance
- Impact Resistance
- Abrasion Resistance
- Reflectivity

- Slip Resistance
- Ease of Maintenance
- Replacement Timeline
- Life Cycle Cost

C-3.1.1.1 Proper Installation

Coordinate floor finishes with the concrete design. For example UFGS Section 09 67 23.15 and UFGS Section 09 67 23.16 suggest a number of items for the concrete designer to consider, such as types of admixtures, curing strategies, and below slab vapor barriers to keep an epoxy finish from delaminating due to moisture emissivity levels in the concrete. Refer to Figure 3-4: Typical Aircraft Maintenance Bay Slab on Ground Cross-Section for guidance on location of the vapor barrier in the Aircraft Maintenance Bay. Refer also to C-4.2.1: Floor Coatings and Vapor Retarder/Barrier.

C-3.1.1.2 Chemical Resistance

Protect the floor from deterioration from harsh chemicals and solvents commonly used in aircraft maintenance including jet fuel and Skydrol® fire resistant hydraulic fluids. Concrete is porous and can easily be contaminated by spills. Dry shake floor hardeners and polished floors increase resistance to absorption of chemicals, but true protection requires a barrier. Consider Ultra-Violet (UV) resistance in hot climates that have high levels of UV radiation.

C-3.1.1.3 Impact Resistance

Protect concrete from damage from dropped tools and parts. The urethane topcoats of an epoxy system are less brittle and are more resistant to impact and abrasion wear than hardeners or polishing. 5-coat epoxy is more resistant to chipping.

C-3.1.1.4 Abrasion Resistance

An abrasion resistant floor finish will protect concrete from damage incurred by carts, stands and heavy wheels of aircraft and tugs. Sand and dirt left on the floor can become an abrasive and dull the shine of many finishes.

C-3.1.1.5 Reflectivity

Reflectivity improves lighting conditions for maintenance operations under the fuselage or wings and reduces the amount of lighting fixtures required. Provide translucent windows to diffuse the natural light coming into a space with a reflective floor.

C-3.1.1.6 Slip Resistance

Provide a floor finish with an acceptable coefficient of friction to protect maintenance staff from slip and fall conditions.

C-3.1.1.7 Ease of Maintenance

Provide an easily cleaned floor finish to allow small parts and FOD to be easily discovered. Provide a floor finish requiring low maintenance cost and low maintenance effort for users.

C-3.1.1.8 Replacement Timeline

Provide a floor finish requiring fewer replacements over the life of the building.

C-3.1.1.9 Life Cycle Cost

Provide the finish most appropriate for the users' requirements at the lowest life cycle cost.

C-3.1.2 Floor Finish Options

There are a number of floor finishes commonly used in aircraft maintenance bays. The 3-coat system is most common, but has an ongoing problem with low tolerance to moisture emissivity in the slab. There are two floor finish options if the 3-coat system is considered unacceptable and unreliable. You can use a non-coating system which may cost less but provide significantly less protection than a coating system. The other option is to provide the 5-coat system which has high performance ratings, but high initial costs. However, the 5-coat system outperforms the 3-coat system in life cycle cost analyses due to requiring fewer replacements over the life of the building.

- Sealed concrete
- Polished concrete
- Dry shake-on hardener
- 3-coat epoxy systems
- 5-coat epoxy systems

C-3.1.2.1 Sealed Concrete

Concrete sealers are applied to concrete to protect it from surface damage, corrosion, and staining. They either block the pores in the concrete to reduce absorption of water and salts or form an impermeable layer which prevents such materials from passing. This is basically the lowest initial cost solution but it provides almost no protection for the concrete with regard to chemical and impact resistance. Performance:

- No issues in bonding to concrete as are associated with coatings
- No chemical resistance
- Low impact resistance
- Abrasion resistance of the concrete finish is not changed
- Reflectivity of the concrete finish is not changed
- Slip resistance of concrete finish is not changed

- Cleanability depends on the texture of the concrete
- Low maintenance
- Needs to be resealed every couple of years
- Least expensive initial cost and least expensive life cycle cost

C-3.1.2.2 Polished Concrete

Polished concrete is a high-gloss finish attained by using special floor polishers fitted with diamond-impregnated abrasive disks (similar to sandpaper) to grind down surfaces to the desired degree of shine and smoothness. The resulting surface is relatively low cost and low-maintenance but only provides slightly better performance than the sealed concrete. Performance:

- No issues in bonding to concrete as are associated with coatings
- Relatively low chemical resistance. Any non-neutral PH chemical that is highly acidic or alkaline will deteriorate the finish and concrete.
- Relatively low impact resistance
- Relatively low abrasion resistance
- Shiny, but is typically a mottled dark color
- Available in smooth and slip resistant finishes
- Easily cleaned - sweep regularly and scrub weekly. However, spills will absorb into the concrete and stain the floor.
- Only needs to be refinished once every five to ten years
- Relatively inexpensive initial cost and life cycle cost

C-3.1.2.3 Dry Shake-on Hardener

Mineral and metallic dry shake hardeners are hand spread and power-trowelled into the wet concrete to provide additional abrasion resistance for high wear industrial concrete floors. Performance:

- No issues in bonding to concrete as are associated with coatings. Inconsistent color is typical due to uneven spreading and uneven trowelling.
- Low chemical resistance
- Relatively high impact resistance
- Relatively high abrasion resistance
- Relatively high reflectivity, depending on color of dry shake
- Slip resistance of concrete finish is not changed
- Low maintenance - sweep regularly and scrub weekly

- Relatively inexpensive initial cost and life cycle cost

C-3.1.2.4 Fuel-Resistant Resinous Flooring, 3-coat Systems

Commonly known as a thin-film flooring system, this coating system has had delamination problems in the past due to its intolerance to moisture emissivity in concrete slabs. Current moisture vapor emissivity test requirements by the manufacturers as well as the UFGS spec have minimized the installation of this system on slabs where moisture rates are likely to cause delamination. Most manufacturers can provide a moisture vapor barrier coating to reduce the emissivity to acceptable levels. A 3-coat system typically consists of 2 layers of epoxy with a urethane topcoat. Performance:

- It is difficult to attain a concrete moisture vapor emissivity rate below the maximum 3lbs./1000SF/24-hours required by the UFGS spec, and the manufacturer. Include the manufacturer's moisture vapor barrier coating with a requirement to deduct the associated cost if the concrete moisture tests determine this coating is not necessary.
- High chemical resistance
- Relatively high impact resistance. Finishes may chip and peel and are a costly continuous maintenance concern. Exposed concrete where epoxy coatings have chipped/flaked away absorb fluids deteriorating the concrete and complicating future re-coating
- Abrasion resistance based on level of grit applied
- High reflectivity
- Slip resistance based on level of grit applied. There is a fine line between slippery and hard to clean.
- Low maintenance - sweep regularly and scrub weekly. Higher grit levels make cleaning more difficult.
- Needs to be re-coated every 3-5 years
- Relatively expensive initial cost, especially if moisture vapor barrier is required. Highest life cycle cost due to the requirement to recoat more frequently than the 5-coat system over the life of the building.

C-3.1.2.5 Fuel-Resistant Resinous Flooring, 5-coat Systems

This has an epoxy primer, a 1/4" to 3/8" trowelled on epoxy grout coat followed by 2 layers of epoxy and urethane top coat. Basically, the top 3 coats are the 3-coat system bonded to a thick grout layer. Performance:

- Fewer issues in bonding to concrete than 3-coat system due to epoxy grout layer Specs require a maximum 4.5lbs./1000SF/24-hours moisture vapor emissivity rate which is relatively easier to attain than the 3lb rate of the 3-coat system. However, it is still a good idea to include the

manufacturer's moisture vapor barrier coating with a requirement to deduct the associated cost if the concrete moisture tests determine this coating is not necessary.

- High chemical resistance
- High impact resistance due to epoxy grout layer
- Abrasion resistance based on level of grit applied
- High reflectivity
- Slip resistance based on level of grit applied. There is a fine line between slippery and hard to clean.
- Low maintenance - sweep regularly and scrub weekly. Higher grit levels make cleaning more difficult.
- Needs to be patched and a new top coat applied every 8-10 years
- Most expensive initial cost, but lower life cycle cost than a 3-coat system due to a less frequent re-coating schedule than the 3-coat system over the life of the building.

C-3.1.3 Life Cycle Cost Analysis

Sealed concrete, polished concrete and dry shake-on hardeners are lower in cost than the coating systems, but have significant reduced capabilities to protect the concrete from the harsh environment of a military aircraft maintenance hangar. Life Cycle Cost Analysis (LCCA) of the coating systems show the 3-coat system is less expensive initially, but requires recoating more often than the 5-coat system, and therefore, has a higher life cycle cost. The 5-coat system is tolerant of higher moisture vapor emissivity rates and is less likely to require a moisture vapor barrier coating.

C-3.2 Considerations for Large Aircraft Maintenance Bays

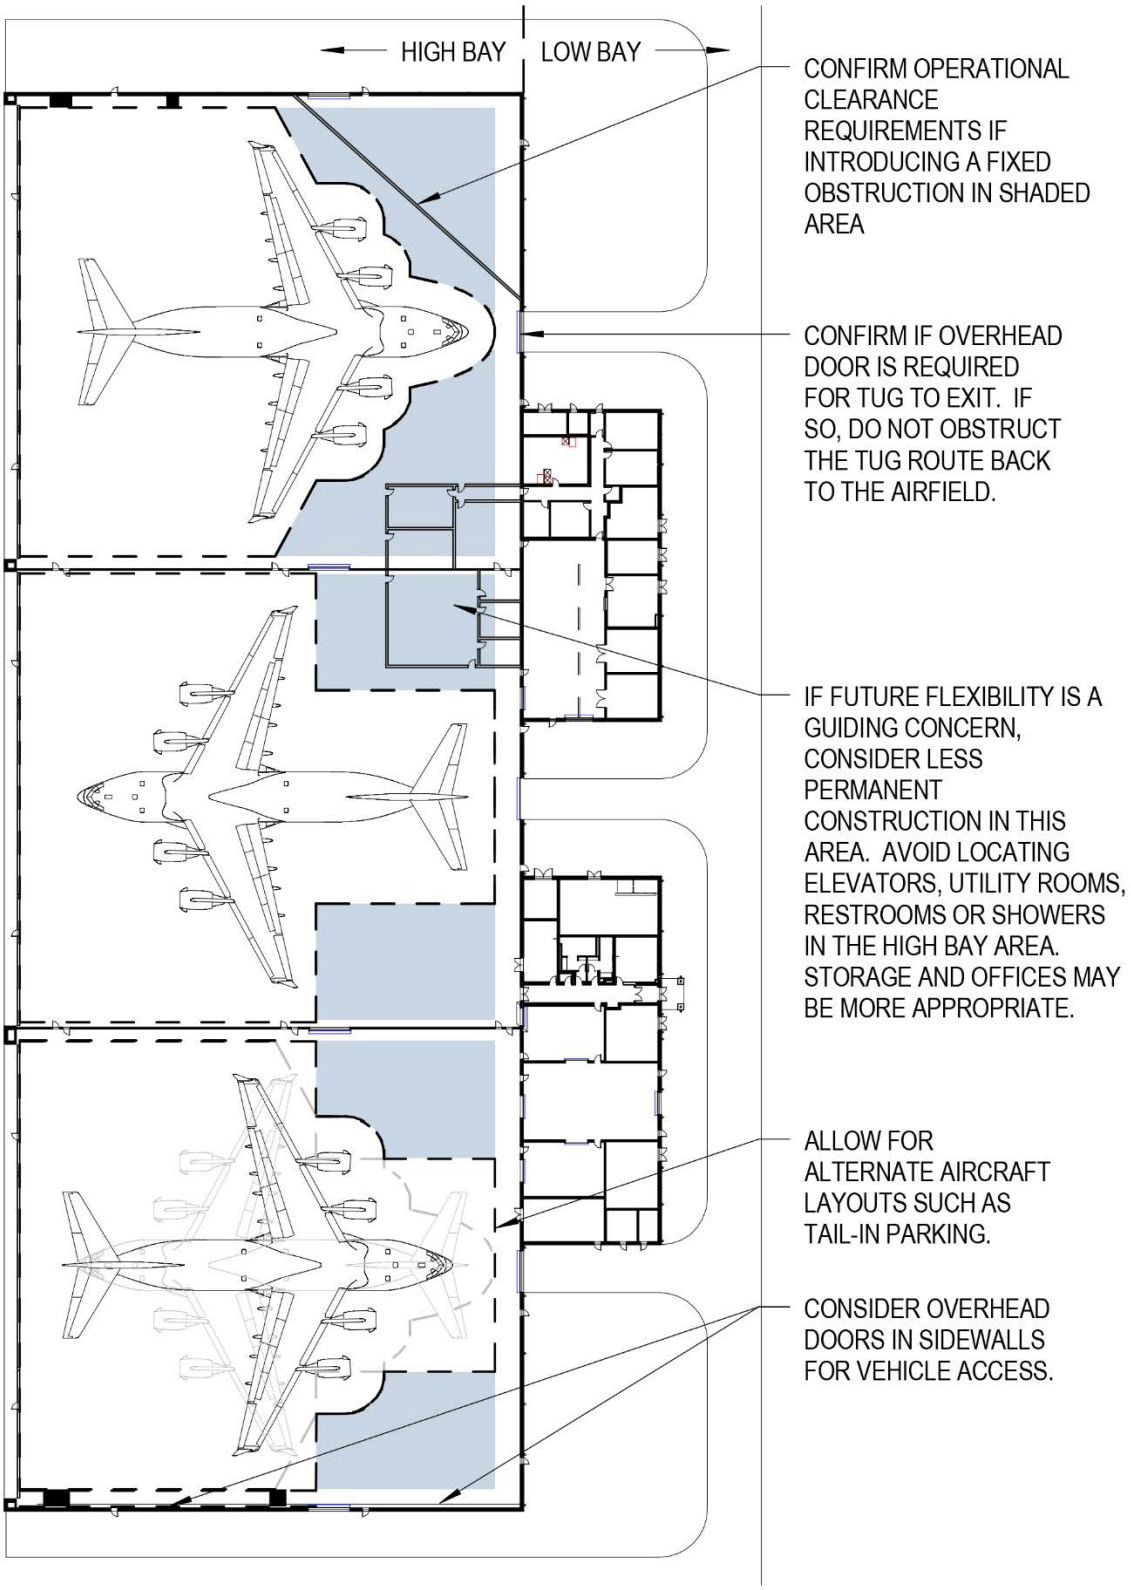
Consider the following issues when designing an Aircraft Maintenance Hangar for large aircraft.

- Hangars designed for smaller aircraft, or hangars requiring large areas of crane coverage have a relatively consistent clear height requirement throughout the Aircraft Maintenance Bay and will usually have very low sloped roofs. Large aircraft with tall tails and limited if any crane coverage area may require significantly less clear vertical height at the nose than at the tail. The roofs often slope down from the tail to the nose reducing exterior envelope surface area and material quantities and structural steel quantities. This also reduces the volume inside the bay, an advantage in areas where the bays are conditioned. This is depicted in Figure 2-4: Vertical Hangar Clearances with Sloped Roofs.
- Large Aircraft Maintenance Bays may have significant space between the wings and the backwall or between the nose of the aircraft and the sidewall. Designers have successfully solved reducing the excess space

in a number of ways. One solution is to shape the building closer to the shape of the clear area requirements of the design aircraft by cutting the outside corners of the Aircraft Maintenance Bay as is allowed by paragraph 2-3: Minimum Aircraft Maintenance Bay Clearances and as depicted by Figure 2-2: Alternate Corner Configuration. This concept is not intended to reduce hangar bay square footage. Total square footage of hangar bay should remain as programmed and redistributed to length or width of bay. This concept is only allowed on end bay of multi-bay hangar. This concept limits hangar expansion options on endwall. This concept may limit "dense packing" options of hangar for additional aircraft if need arises.

- Another common solution involves building the Aircraft Maintenance Bays rectangular but making some other use of the excess area in front of the wings of large aircraft as depicted in Figure C7-1: Considerations for Aircraft Maintenance Bays for Large Aircraft. Obstructions are allowed in front of the wings by Figure 2-2: Alternate Corner Configuration. Confirm all operational clearances in the area before introducing obstructions. Clearance may be required in front of the engine to maneuver a portable crane to remove engines. Allow for alternate aircraft layouts that could be used in the future such as tail-in parking. If future flexibility is a guiding concern, consider less permanent construction in this area. Avoid locating elevators, utility rooms, restrooms or showers in the high bay area. Storage and offices may be more appropriate.
- Figure C-2: Considerations for Aircraft Maintenance Bays for Large Aircraft presents a solution to reduce the depth of the expensive high bay portion of the Aircraft Maintenance Bay and let the nose of the fuselage extend into lower cost conventionally framed nose docks. Again, as with any solution that introduces obstructions in the area in front of the wings, operational clearance requirements are likely to govern over the clearances required in this UFC.
- Allow a path for the tug to get back to the air-side of the hangar. Large hangars often require a rolling service door for the tug to exit the hangar as it pulls an aircraft into a nose-in configuration. In this case do not block the area in front of the aircraft with the lean-to.
- Consider minimizing the Aircraft Maintenance Bay height by providing a taller hangar door in the center of the building to allow the tail in and out of the bay but lower doors over the wings.
- Consider adding rolling service doors on the sidewalls to allow deliveries in front of the aircraft wings and behind the aircraft wings without opening the hangar door.

Figure C-12: Considerations for Aircraft Maintenance Bays for Large Aircraftces



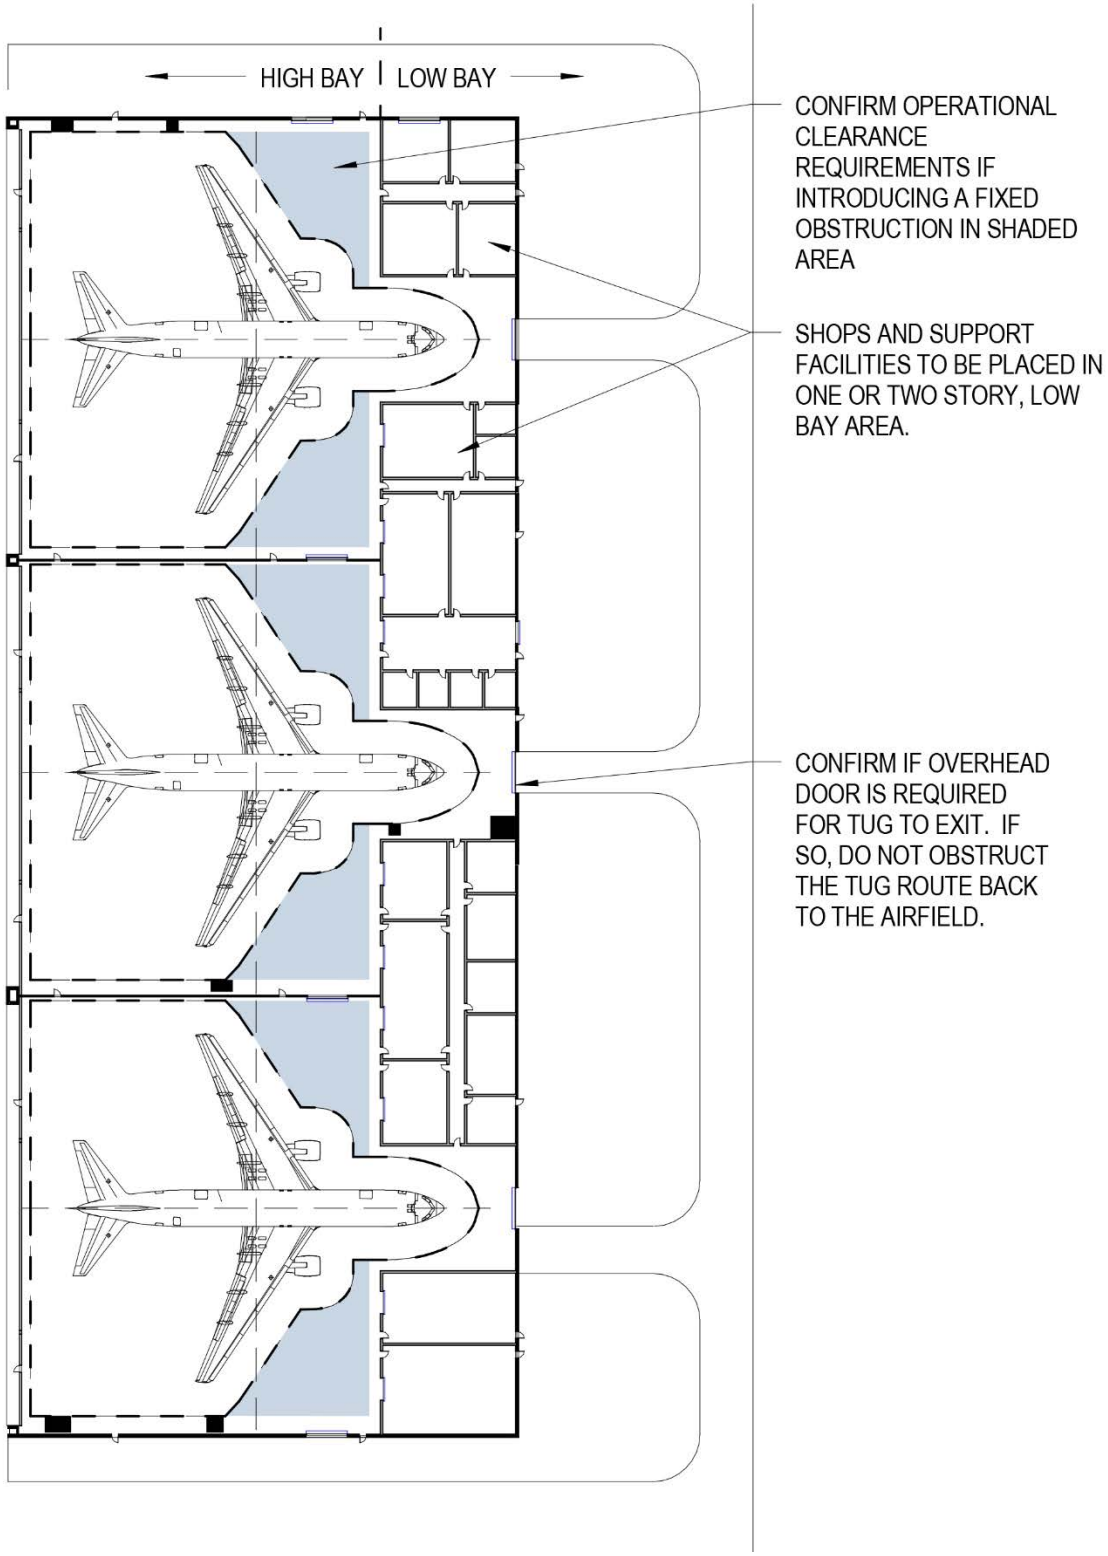


Figure C-12: Considerations for Aircraft Maintenance Bays for Large Aircraft

C-3.3 Interior Design - Furniture and Equipment

Furniture, Fixtures and Equipment (FF&E) should be "heavy duty" for shop spaces. Verify FF&E to be furnished by user (not MILCON funded)." In addition, shops must be easily reconfigurable by the users, so avoid the use of systems/panel furniture. Utilize a freestanding desking systems for ease of configuration.

Office equipment such as printers, copiers, and fax machines are typically user-provided equipment. However, these items should be located on furnishings plans and coordination of supporting building systems such as power, data, and comm should be included. Provide flush recessed floor power/data outlets as required by furnishings layouts. Avoid or limit the use of power poles.

C-3.4 Acoustics

C-3.4.1 Exterior Envelope

Acoustics around operational airfields pose significant questions about what to provide in the way of acoustical enhancements on a hangar. The type of aircraft and the projects proximity to the runways play a significant role in what might be expected on the envelope of the project. At jet bases or other locations employing aircraft with extremely high noise levels, it is important to consult with an acoustical consultant to determine proper noise reduction requirements within various areas of the hangar. The designer should carefully investigate the implications of providing specific acoustical requirements for the envelope of the facility. In Design Build projects it is the responsibility of the RFP preparer to determine the requirements and provide adequate data to allow the Design-Build Contractor to adequately determine the cost for any acoustical requirements.

C-3.4.2 Interior

Interior acoustical requirements should be limited to what is specifically needed by the functional requirements. Do not specify special acoustical requirements if there is not an operational or functional reason to do so. Most shop spaces do not have high noise level equipment so it is not necessary to provide ratings in excess of what will be provided by the standard partition recommended in the UFC. Office and other similar type of administrative spaces should comply with commercial standards for similar type of spaces.

Some military projects specify Noise Reduction Coefficient (NRC) to provide requirements for sound absorption/reflectance in rooms such as tele video conference rooms. NRC is being replaced by the Sound Absorption Average (SAA), which is described in the current ASTM C423-09a.

C-3.5 Bird Intrusion Prevention

Birds entering various openings within aircraft maintenance bay, roost in the available flat areas of the superstructure. Accumulation of droppings, feathers, and other matter pose a big problem. Bird droppings, accumulating on the aluminum skin of airplanes,

can corrode the metal and eventually weaken the structure itself. Another concern is that if droppings, feathers, and other matter get into the engines, clean critically important parts as they could stall an engine during flight. Another concern is the constant maintenance of the hangar floor and other surfaces due to bird inhabitants.

Bird-proofing methods vary from scaring devices, repellents such as screening mists and sonic systems and full netting systems.

C-3.5.1 Scaring Devices

An inexpensive way to try and bird proof facilities is through the use of visual deterrents. Iridescent reflective foil or flash tape can be easily strung around the superstructure and turned into pennants. Inflatable balloons and stuffed bird predators are another economical visual scare device. Their lifelike reflective predator eyes and markings drive birds away by creating an "Optical Distraction Zone." Although inexpensive these devices are usually a short term solution to the issue. The birds get use the scaring devices and eventually ignore them.

A more proactive approach to scaring birds is to employ a falconer to the facility periodically to drive the birds away. This could be fairly expensive and is a recurring cost for the facility.

C-3.5.2 Repellent Devices

C-3.5.2.1 Misting Systems

Bird-misting systems are ideal for both humane and effective bird control. These bird proofing systems work by releasing an ultra-fine mist that pest birds can't see and prefer not to be around. The mist typically employs a chemical called methyl anthranilate, a grape extract that naturally occurs in concord grapes. The extract has been widely used for decades to deter a wide variety of pest birds including, sparrows, pigeons, starlings, crows, blackbirds and geese. Yet it's safe for people, pets, plants and birds. The system requires refilling and maintenance and too much misting can lead to residue on the facility. Too little misting and you are not controlling the issue.

C-3.5.2.2 Electric Track

Another useful bird proofing repellent method is the electric-track bird repeller. Ideal for ledges, rooftops, and flat or curved surfaces, these low-profile electrified tracks deliver a non-lethal electric shock that discourages birds from landing or feeding. Some manufacturers offer a flow-through design to keep water from damming up on rooftops and other surfaces. These systems require maintenance and a constant electric source. It is difficult to install this system on all surfaces of the superstructure birds would use for nesting.

C-3.5.2.3 Bird Slope

A bird slope is a simple solution ideal for many government buildings. Suitable for eaves, ledges, beams and other 90-degree areas where pest birds tend to nest and

roost, the angled, slippery PVC panels cause pest birds to simply slide off when they try to land. For an even easier-to-install solution, there's bird gel. Birds hate this stuff because it creates a sticky surface that birds find very annoying to land in. It's safe for birds (except swallows) and a great way to keep birds from landing on ledges, I-beams, parapet walls, conduit, pipes, and most flat or curved surfaces. It is difficult to install this system on all surfaces of the superstructure birds would use for nesting.

C-3.5.2.4 Bird Spikes

A repellent method of bird spikes can be found on many military facilities. Bird spikes are ideal for pigeons and other large birds. Some bird spikes are made of strong, rigid unbreakable polycarbonate, others have stainless steel spikes. A cousin to the bird spike is the bird spider. The spider arms wave with the breeze, keeping wild birds from landing. Most come in a variety of diameters and install easily. And although they appear menacing, spikes and spiders won't harm birds. Once installed these systems require little maintenance besides fixing areas birds have found to next. It is difficult to install this system on all surfaces of the superstructure birds would use for nesting.

C-3.5.3 Net Systems

To bird proof large areas such as the aircraft maintenance bay, bird netting creates an impenetrable barrier for most birds. Some heavy-duty bird netting is made of polyethylene fabric and is UV stabilized, flame resistant and rot and waterproof. Netting comes in various mesh sizes to deter a wide range of birds. To seal out small openings, there's copper mesh cloth. Available in rolls, it's easily stuffed into cracks or holes to let air circulate but keep birds out. The system is quite noticeable in the aircraft maintenance bay even if it is painted to match the superstructure. The net needs to be located to not interfere with utilities such as fire protection, lighting and crane travel.

The net systems work well once they are installed and all the bird openings are secured. These systems require monitoring to see if and where birds are getting through the netting and getting them out. The netting may become an issue with maintaining equipment located above the netting. Place the outlet of the high-expansion foam fire protection system below the netting because the netting tends to disrupt the foam flow.

C-4 STRUCTURAL

C-4.1 Foundations

C-4.1.1 Geotechnical Investigations

It is recommended that a thorough geotechnical investigation be performed for aircraft maintenance hangars. The large column free hangar space results in highly concentrated foundation loads in remote portions of the building footprint. Areas of particular concern include towers or columns supporting long span trusses, cross-braced bays along the perimeter of the building, towers supporting cantilevered roof trusses and the tension anchorages for such trusses. The geotechnical investigation should pay particular care to these points of load concentration.

C-4.2 Floors

Ground floors are typically slabs on ground. In some circumstances with particularly poor geotechnical properties and schedules which do not allow for remediation, pile supported slabs may be desirable. It is typical for the main structural frame to be built on deep foundations while the ground floor slabs are soil supported. In this circumstance, differential settlement is a potential risk to the serviceability of the facility. The designer may consider careful detailing between the floor slabs and the surrounding structure or, in the most severe circumstances, pile supporting the floor slab.

C-4.2.1 Floor Coatings and Vapor Retarder/Barrier

Floor coatings are moisture sensitive materials and care must be taken in construction of the concrete slab. In the Aircraft Maintenance Bay, install the vapor retarder/barrier as shown in Figure 3-4: Typical Aircraft Maintenance Bay Slab on Ground Cross-Section.

For all other slabs on ground use ACI 302.2R-06 *Guide for Concrete Slabs that Receive Moisture-Sensitive Flooring Materials*. In general, the flow chart in Figure 7-1: Aircraft Maintenance Bay Striping Requirements of ACI 302.2R will be followed to ascertain the location of the vapor Barrier/Retarder relative to the concrete slab and subgrade materials. If the questions asked in the flow chart can't be answered at the time of design, then it is suggested that Figure 3-4: Typical Aircraft Maintenance Bay Slab on Ground Cross-Section be used for locating the vapor retarder/barrier under the slab.

C-4.3 Superstructure

Single points of failure are undesirable in any facility but are historically common in long span-steel structures. A single connection or member failure can result in catastrophic collapse or failure of a large portion of the facility. Investigate secondary or back up load paths for single points of failure and provide them where practical. If secondary or back up load paths can't practically be provided, then thoroughly design and review these single points of failure.

C-4.3.1 Static Determinacy

While the structural engineer is typically advised to avoid interfering with the means and methods of the construction professionals, he should have an understanding of the consequences that accompany any chosen erection method. The design documents should indicate if and when the structure is statically indeterminate. The designer of record should consider the effect which various erection approaches may have on the loads in an indeterminate structure and the documents must clearly indicate any restrictions required on the erection to ensure a safe, serviceable building.

C-4.3.2 Construction and Erection

Hangar construction involves the creation of a long-span, column-free space. These requirements complicate the erection of the building and make the steel erection contractor a much more important partner in the process than is typical of most

government construction. Two general approaches are applicable to the erection of large hangar bays, ground assembly with heavy lift and aerial assembly with shoring towers.

C-4.3.2.1 Ground Assembly with Heavy Lift

While not unique to hangars, lifts of pre-positioned, pre-assembled hardware weighing 30 to 50 tons (27,000 to 45,000 kg) are uncommon in most construction but typical of hangar construction. Ground construction is typically the most common means selected by contractors. Large cribbing is set immediately adjacent to the lift location and leveled. Shims are set to adjust for elevation differences and to establish the proper camber. The structural element is then constructed on top of the cribbing. Once completed, the entire element is lifted into place and the final support connections made. Fabricating on the ground allows for enhanced safety for the bulk of the work as well as greater control of quality and ease of access for inspectors. The drawbacks of the approach include the cost associated with mobilizing a crane or cranes that can lift the assembly. Tight quality control is essential to ensure that the final fit is made.

Some issues for the designer to be aware of include: The rigging and lift may impose loads on a structural assembly that were not anticipated by the designer. Even if the assembly is not damaged by the lift, it may undergo unexpected deformations that may then be locked into the final structure once the last connections are made. The heavy lift may place the large, overhead elements into place prior to the remainder of the facility's framing being completed. This is often a physical requirement given the necessity of getting equipment adjacent to the lift operations. The designer should give some consideration early in the design as to the lateral stability of the building components that support the major roof elements.

C-4.3.2.2 Aerial Assembly with Shoring Towers

This approach is becoming increasingly uncommon with the general availability of large cranes and the increased emphasis on avoiding fall injuries on the work site. The approach involves the fabrication of temporary towers to support the piece-by-piece fabrication of the major components in their final place. The temporary shoring tower’s location will determine the actual deflected shape of the structure resulting from the dead load of the structural steel only.

The advantage of aerial assembly is that it avoids the necessity of having a large capacity crane and fabrication errors may be discovered and corrected without postponing a single milestone-lifting event. The disadvantage of the aerial assembly is the loss of productivity and potential for accidents related to high work. This approach also introduces the risk that unexpected loads may be introduced in the structural framing system by poorly designed shoring towers or long term settlement of the shoring towers. Additionally, the manner in which the temporary towers are removed may also introduce unexpected, albeit temporary, loads in the main structure.

C-4.3.3 Cantilevered Aircraft Maintenance Bay Framing System

A cantilevered system supports all of the gravity loads from the rear wall of the aircraft maintenance bay. Lateral loads are resisted by the structural framing around the perimeter of the structure. The roof framing system should be designed with a means to correct out of tolerance construction without resorting to field modifications of any member. Cantilevered roof systems are generally statically determinate in all phases of construction.

C-4.3.3.1 Advantages

The system is advantageous in that it provides a column-free building face towards the aircraft flightline. This maximizes the usable flightline frontage while decreasing the number of obstructions to aircraft movements and provides for the maximum flexibility to service future aircraft which may enter the inventory long after the hangar was designed. The system provides the maximum flexibility for structural expansion to either side of the hangar. However, if future expansion is anticipated, other disciplines must consider such expansion in their design development. Additionally, the highest point of the structure is generally towards the rear wall of the hangar, which may be advantageous when the hangar is located near a runway and must remain below a glide or transition slope.

C-4.3.3.2 Disadvantages

A cantilevered system is an inefficient method for supporting loads; is prone to larger deflections than other systems; and is more difficult to erect. Thermal cycles are also more likely to result in larger deflections affecting door operation, but will not result in thermal stresses unless the system is restrained in some unconventional manner. Additionally, the landward side of the facility must have some provision for tension anchorage of the rear of each cantilever. This anchorage may be in the form of massive dead-load or tension earth anchorages (typically tension piles). A cantilevered system also requires a more elaborate foundation. The tension anchorages, for both the above and below grade structures, require more elaborate coordination with the shops and office structure. The tension anchorages are also typically located outside of the building footprint and require greater coordinate with the civil site design.

C-4.3.3.3 Considerations

Design documents for a cantilever system need to carefully consider the effect of erection sequencing, actual versus predicted dead load deflection and environmental conditions during the fabrication and erection. Additionally, the possibility of load reversal on the main supporting elements as a result of high uplift forces must be considered.

C-4.3.4 Header Truss Aircraft Maintenance Bay Framing System

A header truss system spans the entire flightline face of the building and either rests upon columns or towers at each flightline corner of the building or is continuous to the foundation. The remaining walls of the hangar are conventionally framed. Lateral

support is provided through the framing in the perimeter walls. The truss is typically supported against lateral loads through dedicated horizontal truss system. The truss should be designed to maintain a slight upward camber after all dead loads have been placed. The truss may be fabricated on shoring towers in the air or on the ground and lifted as a single unit. The truss may be designed as statically determinate, indeterminate or initially determinate but becoming indeterminate at some point during the erection sequence. The design should consider the effect of erection methodology and sequence, in conjunction with determinacy of the system. Additionally, thermal effects on statically determinate header trusses are particularly significant and the designer of record should carefully evaluate these effects.

C-4.3.4.1 Advantages

The header truss is an efficient system to span intermediate lengths and provides a relatively simple erection system, provided that the issues of static indeterminacy are dealt with.

C-4.3.4.2 Disadvantages

The structural efficiency and stiffness decrease exponentially as the span of the truss increases. This may be offset by increasing the depth of the truss. However, the practical limits of transporting the fabricated hardware, erecting the assembled truss and lateral bracing of the system and its individual components limit the truss depth to something on the order of 25 foot (7.5 m). A header truss virtually precludes the use of expansion joints; therefore, the hangar door span may be limited by the thermal response of non-structural components. However, a three-hinged arch system allows an expansion joint along the centerline of the hangar bay and extends the practical thermal expansion limit. The header truss system also requires that flightline frontage be dedicated to structural supports. Finally, the potential expansion of the hangar is constrained by the presence of towers and lateral load resisting systems.

C-4.3.4.3 Considerations

Construction documents for a header truss system must clearly indicate the camber requirements as well as supply the necessary information for the fabricator and erector to predict the truss’s response at various states of construction, handling and loading.

The header truss may be designed as fixed, pinned or partially restrained at its supports in order to balance the strength and deflection characteristics of the header truss with the complexity of detailing and erection. The designer of a statically indeterminate truss must carefully consider the influence that temperature, erection sequence and erection rigging will have on the difficulty of completing connections as well as final camber and this complexity must be communicated on the design documents.

C-4.4 Strength and Serviceability Requirements

The necessity of a large open, column free space will result in the lateral load resisting system being located along the perimeter of the building. Widely separated lateral load resisting elements may lead to high thermal stresses being developed. The designer is

cautioned to balance the needs of other disciplines as to the location of cross-bracing and the desire to produce a more torsionally resistant design against the potential for developing high thermal stresses.

C-4.4.1 Wind Loads

Hangars are prone to large eccentricities between centers of wind pressure and centers of rigidity (especially cantilevered hangars). Even unfactored loads resulting from this eccentricity may be significant. The designer should consider this eccentricity while laying out the lateral load resisting system to locate the center of rigidity as near to the center of applied force as practical.

C-4.4.2 Seismic Loads

Seismic design criteria may impose significant constraints upon the structural frame, not only in the loads applied but also in the fundamental choice of framing system. The allowable seismic force resisting systems and their limitations are identified in ASCE 7-10, Table 12.2.1. A combination of site condition, design approach and structural layout will determine the AISC criteria. A poor selection of framing, arrangement of bracing or large asymmetries may result in expensive connection fabrication and testing requirements or outright prohibition of the fundamental design. The facility designer's should investigate the seismic issues early in the design phase and plan the building's geometry and structure accordingly.

Hangars are prone to large eccentricities between centers of mass and centers of rigidity. This is especially true for hangars with cantilevered roof framing systems. Regardless of the structural system, the unfactored loads from this eccentricity may be significant. For general information about structural loads, refer to UFC 3-301-01. For detailed information, refer to UFC 3-310-04 and ANSI/AISC 341.

C-4.5 Main Structural Framing Materials

C-4.5.1 Hollow Steel Sections

There may be additional benefits derived from efficiency in steel use and minimization of exposed steel surfaces. The bi-axial strength characteristics provide for enhanced electability and greater resistance to progressive collapse resulting from localized damage. However, HSS connections are more challenging to design and often more difficult to fabricate. The engineer of record should consider and clearly represent in the contract drawings the difficulty of the HSS connections. Additionally, a greater reliance on shop connections is the norm in HSS practice. The designer is encouraged to consider the complications of transporting large, built-up elements to the site. HSS connections may involve the use of welds that are not pre-approved and/or more extensive weld testing than normally found on hot rolled steel construction.

C-4.6 Secondary Structural Systems

C-4.6.1 Roof Systems.

Historically, it has been difficult to maintain the necessary level of quality control required to weld decks at side laps and at supports. Mechanical fasteners are the desired option. Additionally, there may be significant economy in erection by allowing pneumatic and powder actuated fastening systems. Most pneumatic and powder actuated systems are proprietary in nature and not covered by the Uniform Guide Specifications UFGS 05 30 00.

C-4.6.2 Coordinating the Structure with the Hangar Doors

Hangar door guide systems are normally sized to allow total roof truss live load deflection not to exceed 200 mm (8 inches). The designer of record is responsible for coordinating the total anticipated roof deflection with the door guide manufacturer to ensure that the design stroke of the hangar door guides is not exceeded. For cantilever roof systems, the hangar door guide system should have adjustment capability to allow for final leveling after all loads are in place. The construction documents must indicate the expected maximum deflection, both upward and downward, as well as the allowable deflection of the hangar door guide system.

C-4.6.3 Diaphragms

Given the difficulty in providing lateral load resistance for the large open spans associated with hangar bay structures, it often appears desirable to incorporate the roof deck into the lateral load system as a flexible diaphragm. However, these same large spans involved in hangar structures often require large deflections in the frame before the deck produces the desired resisting forces. Designers are therefore prevented from relying on a steel deck as a diaphragm in the hangar bay and required to provide a dedicated secondary horizontal lateral load. The deck may, however, be assumed to provide local support to elements, such as top chord/flange support to joists/beams.

C-4.6.4 Wall Systems

Generally bearing or shear wall systems of masonry or concrete are much stiffer that the steel frame used in the hangar bay. Designers are cautioned to carefully consider the differential movement likely to occur between the maintenance bay and the shops/admin space when designing the interface.

C-5 MECHANICAL

C-5.1 Plumbing

C-5.1.1 Water Supply to Emergency Shower/Eyewash Stations

The domestic heating water system will need to be sized to deliver the required hot waterflow and temperature to meet the tepid water requirements for the operation of one shower or eyewash station for 15 minutes.

C-5.2 HVAC

C-5.2.1 Overhead Radiant Heat Systems

Overhead high intensity heaters for hangar bays are not allowed in Air Force and Navy hangar bays for two reasons: clearances to aircraft and bridge crane equipment are greater, presence of fueled, armed aircraft (Air Force). Low-intensity, gas-fired tube type radiant heaters are preferred for overhead heating systems in Air Force and Navy hangar bays.

C-5.2.2 In-floor Radiant Heat Systems

In-floor radiant heat systems must be carefully considered for heating in hangar bays in northern climates. This system is appealing because it does an effective job of heating the floor, but the installation costs and impact on the floor slab design are significant. Consider the amount of maintenance activities performed from the floor. Coordinate closely with the system supplier on the design of the hangar floor slab, location of insulation, and location of radiant tubing within the slab.

C-5.2.3 RPA Hangars

There are RPA aircraft that have internal avionics systems that are sensitive to high temperatures and will alarm when the inside temperature gets up to 100ºF to 120ºF. These aircraft might also have fuel systems that need to be kept below a certain temperature. A conditioned hangar bay might be required which is inconsistent with typical hangar design. Depending on the climate, evaporative cooling might be considered. Portable preconditioned air carts can be considered in lieu of conditioning the hangar bay.

C-5.2.4 Avionics/Electrical Repair

Localized exhaust is typically done using a wall-mounted fume extractor built specifically for small or limited workspace environments where air purification is desired. Includes a free-hanging, self-supportive flex arm that can be easily maneuvered by the operator to the desired location. Several filter combinations can be used depending on the application.

C-5.2.5 Army Hangar Heating Systems

Overhead low or high intensity radiant heaters are often the most life-cycle cost effective method of heating Army hangars and most other high bay facilities. Some quality high intensity radiant heaters have radiant efficiencies as high as 81%, meanwhile low intensity tube heaters typically range from 35% to 60%. It must be noted that radiant efficiency is not the same as thermal efficiency. Where work or maintenance activities may be limited at times to specific areas in a hangar bay (such as where maintenance is being conducted on one helicopter while other spaces have no activity), high intensity radiant heaters applied in a spot or area heating method may be the most life-cycle cost effective method of providing thermal comfort. The spot or area heating

method allows for maximum radiant asymmetry where the ambient temperature may be kept low.

In floor type radiant heating systems are more efficient than warm air systems as well; however, the in-floor systems have long response times which do not allow for effective unoccupied period temperature setbacks. Warm air systems should only be considered in mild climates where there is minimal need to heat, and where air delivery temperatures may be kept within 20 degrees of ambient room temperature. Delivery temperatures which are greater than 20 degrees above the ambient temperature can lead to excessive stratification in high bay facilities such as hangars.

C-6 FIRE PROTECTION AND LIFE SAFETY

C-6.1 Below Grade Water Supply Piping

Avoid locating piping under paved operational surfaces (taxiways and aircraft parking).

C-6.2 Welded Fire Suppression and Concentrate Piping

If using welded joints and fittings, give consideration to the maintenance of the system and the provision of flanged joints at certain locations to allow for maintenance.

C-6.3 Diverter Valve Location

When installing a diverter valve as part of a fire suppression containment system, consider placing the valve and valve pit within the hangar bay as a means reduce the rain water infiltration into the pit. When this is provided, locate the pit outside aircraft/vehicle traffic locations and rate the components in the valve pit for a Class I Division 1 hazardous classified location.

C-6.4 Fan Shutdown in the Hangar Bay

The hangar bay doors are often open for extended periods of time. Therefore, exposing the hangar bay to high humidity, below freezing, and high temperature conditions. Because of this, the hangar bay is considered an outdoor environment. Most addressable output modules (control modules) are not UL listed to operate in these conditions, and installing these devices in the hangar bay would be against the listing.

Therefore, it is recommended modules for controlling fans be located in a controlled environment. One option would be to locate the module next to the shunt trip breaker which removes power from the fan(s) in the hangar bay upon release of the foam system. Another option would be to extend the enable input circuit off the VFD/starter from the hangar bay to a module that is located in a controlled environment. In no case should the fans be shutdown through EMCS unless the EMCS is a UL 864 listed system, as this is not permitted by NFPA 72.

C-6.5 \2\ Trench Drain Location

For Navy: When approved by the NAVFAC FPE, under certain circumstances the dedicated nose-dock area may be excluded from the trench drain boundary.

C-6.6 Alternate Foam/Water Discharge Notification

For Navy: When approved by the NAVFAC FPE, a blue beacon notification system may be provided to indicate trench nozzle discharge where a fire alarm voice evacuation system is not provided. /2/

C-6.7 Voice Notification in the Hangar Bay

In most hangar bays, directional loudspeakers should be used. It has been found that providing directional speakers and aiming the speakers in the same general direction increases message clarity and improves CIS scores. An example of this type of installation includes providing ceiling only mounted speakers directed towards the floor or providing speakers mounted only on the back wall directed towards the hangar bay door opening. When opposing speakers are provided, such as speakers mounted on opposing walls, the sound from one speaker will reach the occupant before the sound from the other speaker. This results in an echo effect, which reduces message clarity. Hangar bays often seem quiet during commissioning. However, during normal operation and with the ventilation systems operating, hangar bays can have an average ambient sound level approaching 75-80 dBA. The speaker system should be designed to deliver a minimum sound power of 90 dBA throughout the hangar bay to account for the variety of operating procedures.

C-7 ELECTRICAL

C-7.1 Electric Door Track Heating System

In locations where snow and freezing temperatures occur and a rolling door is provided for the hangar bay consider a heating system for the tracks. If a heating system is not provided the tracks may accumulate ice and/or snow and then ceases to function properly. A hot water heating system may be used in lieu of an electric door track heating system.

C-7.2 Service Point Connection Pedestals

Pedestal mounted connections are placed within the hangar space. The pedestals are permanently mounted within the space and create a fixed obstruction. The pedestals bring the services closer to the aircraft and reduce the cable lengths. The cables may be reeled up at the pedestal location or stored separately. The pedestals create an obstruction free zone between the pedestal and the wall. Pedestals require little maintenance.

C-7.3 Aircraft Grounding Points

Different grounding points may be used for different types of aircraft based on the size of the aircraft. Consider the use of caps on the grounding point in the hangar bay. The caps on the grounding points are difficult to maintain.

\3\

C-7.4 Hazardous (Classified) Locations

Vestibules complying with 3-7.1 bullet 1 (two doors in close series) is the recommended best practice to provide suitable hazardous location cutoff. Use vestibules unless floorplan configuration precludes their use. /3/

C-8 COMMUNICATIONS

Communications may include many different types of systems including but not limited to unclassified data, classified data, telephone, public address, radios, satellites, and intercom system. Each system has a special set of requirements. Identify the types of systems required in the building early in the project and provision for the systems accordingly.

C-9 OVERHEAD BRIDGE CRANE

C-9.1 Overhead Bridge Cranes

Overhead cranes are often located close to overhead radiant heat systems. Coordinate the two systems to avoid heat damage to the crane equipment. Common approaches include automatic switching which deactivates the heaters located near the crane or, locating shields or deflectors to protect the vulnerable elements of the crane.

C-10 HANGAR DOOR

Coordinate with the user to provide type of hangar door and controls required for maintenance operations.

C-10.1 Horizontal Rolling Hangar Doors

Rolling steel doors require significant depth for multiple tracks. Door pockets are always preferred since they allow all door panels to be moved completely out of the door opening. A door pocket is required unless the hangar door is wide enough that it is acceptable to stack the doors along the tracks. Tracks extending the full length of the door provide more flexibility on where the doors can be stacked. Confirm if the climate requires the tracks to be heated. Specify rolling steel doors to allow them to be moved with an aircraft tug in case of power failure. Tracks usually will be drained. Sand can build up in the track in arid climates, requiring personnel sweep the tracks on a regular basis. Best practices suggest the project Planner consult the installation and users to choose a type of hangar door, and the operation requirements of the door.

Horizontal rolling hangar doors typically support their own gravity load and only impart lateral (wind, seismic) loads to the main structural system through a track system at the door head. The door head track is generally the responsibility of the hangar door manufacturer. The designer of the hangar generally provides the support for the door head track. The designer is cautioned to carefully consider the following:

- The manner in which the door head track is supported by the superstructure
- The vertical movement of the superstructure and the capacity of the door to accommodate the movement.

C-10.1.1 Horizontal Rolling Hangar Door Foundation

The door track foundation will be considered a building foundation since it supports building components. The door track foundation will bear below the building frost line at or near the depth of the Aircraft Maintenance Bay foundations. The designer is reminded that the door track foundation will be subject to aircraft wheel loads which may control the design of the foundation.

C-10.2 Vertical Lift Fabric Doors (VLFD)

Vertical Lift Fabric Doors require less depth and do not require pockets to provide access to the full width of the opening. Larger openings require multiple panels with fold-up mullions. Personnel doors in the hangar door may require the bottom 7 ft. (2.1 m) of the door to be rigid, causing unique header truss design to allow the door to extend up beside the truss. Currently, VLFD backup manual operation requires hand cranking from an elevated walkway at the VLFD hoist motor location and is extremely laborious, difficult and time consuming. For these reasons, the UFC requires backup systems to power the door. In case of a major failure such as a motor failure, the door may be practically unusable for an extended period of time.

C-10.2.1 VLFD Structural Considerations

Vertical lift fabric doors are lighter than rolling doors, but the entire weight is carried by the superstructure. Additionally, beyond a practical limit of about 60 ft. (18.3 m) multiple door leaves are required. A complicated swinging mullion with additional overhead equipment is required for every vertical lift fabric door beyond the first. However, vertical lifting fabric doors do not require door pockets to entirely clear the hangar opening nor do they require extensive support at grade.

The main load collecting members for a vertical lift fabric door panel generally span horizontally, from mullion to mullion. As such, the mullions serve as load collectors for a very large tributary area which is then delivered to the main framing system as a concentrated force. At a basic, conceptual level, the structural engineer is cautioned to consider how these forces will be collected and distributed back to earth. To the maximum extent practical, the principle framing of the hangar structure should align with the mullion locations.

C-10.2.2 VLFD Fabric

At present the fabric utilized on the VLFDs does not meet the minimum blast resistance requirements of UFC 4-010-01. Therefore, to utilize a VLFD in the Aircraft Maintenance Bay, the Aircraft Maintenance Bay needs to be classified as Low Occupancy as defined by UFC 4-010-01. If the Aircraft Maintenance Bay meets this requirement, then it must also be structurally isolated from any shops/office spaces that cannot be classified as Low Occupancy. Otherwise, it must be verified through analysis that the adjacent inhabited office/shops spaces would not collapse if the Aircraft Maintenance Bay collapses in accordance with UFC 4-010-01.

At present the fabric utilized on the VLFDs does not comply with impact-resistance requirements on facilitates located in "Wind-Borne Debris Regions". The fabric does not meet the testing criteria of ASTM E1996 *Standard specification for Performance of Exterior windows, Glazed curtain Walls, Doors, and Storm Shutters Impacted by Wind Borne Debris in Hurricanes* and ASTM E1886 *Standard Test Method for Performance of Exterior windows, curtain walls, doors and Storm Shutters Impacted by Missile(s) and Exposed to Cyclic Pressure Differentials*. The designer is cautioned when using VLFDs in "Wind-Born Debris Regions".

C-10.3 Vertical Lift Canopy Doors

Large maintenance hangars usually opt for either rolling steel doors or vertical lift fabric doors. Vertical lift bi-fold/canopy doors are common on small hangars for private aircraft, but are much less common in military hangars. They have many of the advantages of VLFDs; no pocket required, very little depth. They are significantly limited in size.

Vertical lift canopy doors are typically constructed of steel framing (hot rolled and/or cold formed) and clad with metal panel siding. The entire weight of the door and associated counterweights is carried by the superstructure. Generally, the door width is limited to roughly 100 ft. (30.5 m) but longer spans have successfully been installed. Additionally, the height of the door is limited to roughly 25 ft. (7.6 m) because of the large cantilever that develops on the door jambs as the door opens. At a basic, conceptual level, the structural engineer is cautioned to consider how the weight of the door and counterweights and door opening forces and how they will be resisted by the superstructure and distributed back to earth. There has not been success installing these doors in a multiple leaf configuration with a swinging mullion similar to the Vertical Lift Fabric door.

C-10.4 Other Hangar Door Options

Aircraft Maintenance Hangars require a vertical lift fabric door system or horizontal sliding doors for the purpose of closing the aircraft maintenance bay. Best practices include the project Planner consulting the installation and users to choose a type of hangar door, and the operation requirements of the door before issuing the 1391.

However, less common hangar door options are available in the market place. These optional door types need project specific approval from the appropriate Service design criteria manager or waiver authority for this UFC. The design team is cautioned to consider all facets of these doors effects on the building design when considering these doors. The design team also needs to consider the ease of use, long term maintenance and emergency opening capabilities when considering hangar door types.

C-11 FALL PREVENTION AND PROTECTION SYSTEMS

C-11.1 Personal Fall Arrest Systems (PFAS)

Provide fall prevention and/or fall protection in accordance with UFC 3-110-03. Most hangars do not have mechanical equipment on the Aircraft Maintenance Bay roofs but there may be other equipment such as antenna platforms requiring interior access and fall protection. Aircraft maintenance workers are often required to work on top of aircraft, well above the floor surface. It is common practice and is a requirement in similar circumstances, for workers to be protected against falls from aircraft surfaces through the provision of a Personal Fall Arrest System (including flexible horizontal life line and rigid horizontal rail systems). However, hangars with bridge cranes represent a special challenge in that the cranes and personal fall protection system compete for access to same work space, workers protected from falls by the use of a personal fall arrest system are now at risk of having their self-retracting lanyards (SRL) struck by a moving crane. It is important for the designers of aircraft hangars to understand the conflicts between the two systems and the means by which they can coexist. Additionally, personal fall protection system may experience the same coordination issues with overhead radiant heat systems as do overhead cranes. The designer should consult the discussion on cranes which appear later in this section.

C-11.2 Description of Horizontal Lifeline (HLL) System

The HLL system consists of a flexible, wire rope or synthetic cable (usually a stainless steel cable) that is installed in a horizontal or nearly horizontal plane between two or more anchorages and to which a self- retracting lanyard (SRL) is attached. The SRL has an integral locking snap hook at the end that attaches to the dorsal D ring of the person's full body harness. Both the crane and HLL are usually installed at higher elevations. In order to perform work more efficiently on an aircraft, a network of HLL systems is generally required. The HLLs should be laid out in a system which accounts for the location of the aircraft and maximizes the freedom of movement of the users. Additionally, mobile attachment devices (trans-fasteners) used to have an added mobility to move between intermediate anchorages with 100% tie-off. The HLL may include energy absorber and lifeline tensioner. The self-retracting lanyard attached to the HLL is a deceleration device made of synthetic rope, webbing or wire rope that automatically locks at the onset of a fall. It pays out and automatically retracts onto the drum during normal movement.

C-11.3 Description of Rigid Horizontal Rail (RHR) Systems

RHR system is a pre-engineered anchorage subsystem that uses one or more trolleys on a horizontal track (often and I-beam or slotted tube) designed for the attachment of components of a personal fall protection system. Horizontal Track system is a form of RHR system that typically encloses a trolley inside a formed channel or track. A self-retracting lanyard (SRL) is also attached to the RHR system for tying off to the dorsal D ring of the full body harness.

C-11.4 Quality Control

Flexible HLL systems and Rigid Horizontal Rail systems are typically proprietary in nature. The manufacturer should provide calculation and drawings showing that the system was tested and certified under the supervision of a qualified person and is appropriate for the application. There two types of HLL and RHR systems. Type 1 are designed, tested and certified by the manufacturer of the system and installed and used by the purchaser (or purchaser's representatives) in accordance with the manufacturer's requirements, Type 2 systems are designed, tested, certified and installed by the manufacturer and used by the purchaser of the system (or their representatives) in accordance with the manufacture's requirements.

C-11.5 Issues and Conflicts between Crane Operation and PFAS

The following are few of the conflicts that will occur between the HLL system(s) and the crane(s):

C-11.5.1 If the HLL is installed above the Crane

During the movement and operation of the crane a conflict will exist when personnel are tied to the HLL systems because the SRLs when extended will be in the path of the crane. A Lockout/Tag out program should be in place which precludes the cranes and PFAS from being used simultaneously in a given area. If the crane is activated, personnel should detach themselves from the HLL systems and the lanyards of the SRLs should be retracted inside the elevation of the crane.

There is some difficulty in developing a system which raises and lowers the snap hooks. There are two methods to lower the snap hooks to personnel's level. The first one is using a power tagline system, which is a motorized winch that raises and lowers the lanyards to the users' level, activated by a control panel. The second method is using a manual tagline system to lower the snap-hook manually by a person on the ground level. In practice, the power tagline system is preferable in that it can be interlocked with the crane controls; however, the automatic system involves greater cost and complexity. The manual system is generally simpler but requires greater diligence in use. In any case, a tagline system will be required to ensure that both systems can be safely operated. When the lanyard of the self-retracting device is retracted out of the crane's path, there should be a minimum clearance around the crane envelope of 3 inches (75 mm) from the top and 2 inches (50 mm) on either side.

C-11.5.2 If the HLL is installed below the Crane

If the HLL is installed below the crane rail, there may be interference with the crane operation unless a system to retract the HLL to the sidewalls is provided. Such systems generally come in one of two forms: (1) The HLL is suspended from a bridge beam which is lower than the bridge crane and supported from tracks located outboard of the bridge crane tracks. (2) The HLL is suspended from beams cantilevered off of the side walls, much like a jib crane, which can rotate flush to the side walls. The large open, column-free areas of hangar bays generally make these systems impractical in hangar usage. If the HLL requirements can be narrowed to a smaller portion of the total hangar floor area, these systems may become acceptable. The above conflicts with the crane may also apply to the RHR systems.

C-11.6 Alternate Methods and Systems

There are other personal fall arrest systems that can be specified, but these are typically portable systems which can be more appropriately classified as equipment then building systems:

C-11.6.1 Work Stands

These are costly but safer than the use of PFAS. The work stands should be equipped with guardrails on three sides and a swing gate at the stairs or ladder side. Often, work stands must be customized to fit a small range of aircraft types. This then necessitates providing new work stands should the aircraft being serviced in the hangar change.

C-11.6.2 Portable Fall Arrest Systems

These are typically a single drop eyelet for a D-ring, supported from a jib arm on a portable derrick. The derricks are generally cumbersome, requiring additional equipment to relocate them, and offer only a limited range of movement to the user. These types of systems are generally not appropriate for a maintenance hangar unless the aircraft are expected to be static for long periods of time.

C-12 EMERGING AIRCRAFT

C-12.1 General

The aviation industry is constantly developing new aircraft. Emerging aircraft and variants of existing aircraft are entering the military arsenal more often than this UFC can be updated. When designing a hangar for an emerging aircraft there are a number of issues to confirm.

- Review the Facilities Requirements Document (FRD) for the aircraft for any specific requirements that could affect the hangar design.
- Communicate with the users to find out what is different or unusual about the new aircraft from a maintenance point of view that may require unusual systems or spaces.

- For example, The F-16 engine is dropped out of the aircraft for maintenance. However, the F-35 engine is pulled out of the aircraft, requiring significantly more space aft of the aircraft than the standard clearances in this UFC would provide.

- Emerging aircraft are more likely to have secret components that may require special storage rooms or other security measures.

C-12.2 Unmanned Aircraft Systems

C-12.2.1 General

Unmanned Aircraft Systems (UAS) are composed of the aircraft as well as personnel and equipment to launch, control, recover and maintain the aircraft. The aircraft itself is typically called an Unmanned Aerial Vehicle (UAV). The term Remotely Piloted Aircraft (RPA) is preferred by the Air Force. UAS are currently one of the fastest group of emerging aircraft with a number of different systems in use by each Service and new variants being introduced at an increasing rate. Review the Service-specific chapters for guidance on which UAS this UFC applies to.

C-12.2.2 Similarities and Differences

UAV/RPAs vary in size, range, capabilities, and many other characteristics. Aircraft Maintenance Hangars housing UAS have spaces similar to other military aircraft. The aircraft maintenance bays, maintenance shops, administration and support spaces are not appreciably different from those found in other hangars. As discussed in the C-12.1: General it is important to find out what may be unusual about the design aircraft that could affect the hangar.

C-12.2.3 Communications

Communication systems are more important to UAS than other aircraft and often require line of sight from the aircraft to antennae used to control the aircraft. As a result, the hangar may have an array of antennae on top of the building. Consider location as well as safe access to these antennae for maintenance.

C-12.2.4 Associated Facilities

Aircraft Maintenance Hangars may be stand-alone facilities, or may be connected to a number of difference associated facilities. Often hangars are attached to the administration unit maintaining or piloting the aircraft maintained in the hangar.

The Mission Control Systems (MCS) where the UAV/RPAs are controlled may be either separate or may be attached to the maintenance hangar. MCS spaces may have specific requirements such as higher security and back-up systems for power and communication. The MCS control rooms and electronic rooms may need to be shielded from electromagnetic interference. Designers need to seek requirements for associated facilities elsewhere, as they are not included in this UFC.

APPENDIX D: QUESTIONNAIRE

D-1 MAINTENANCE AND OPERATIONS QUESTIONNAIRE FOR NEW HANGAR DESIGN

D-1.1 Civil

- Will a security fence be required around the hangar?
- What type of lighting will be required in the employee parking lot?
- Will a guard booth be required at roadway entrance to hangar area?
- What type of lighting will be required on the parking apron?
- Will there be a need for exterior space to store deployment equipment/containers?
- Is there a need for a dumpster or waste recycling?
- Is there a need for a pedestrian turnstile gate with a swipe card access system, in the flightline security fence?

D-1.2 Architectural

- Identify the type of aircraft and the aircraft mix that will populate the hangar.
- Will aircraft be brought into the hangar with fuel in them? (Identifies the type of fire suppression system you need.)
- Consider towing vehicles turning clearances, access and egress from hangar bay when sizing hangar bays.
- Will spot repair of corrosion control, grinding, bird interaction repair, sanding, or painting on the aircraft frame or any parts be required inside the hangar? If so, provide Material Safety Data Sheets for all materials solid or liquid being used on the aircraft frame or inside the hangar to determine if engineering control is required to mitigate hazard. (This may impact spaces by requiring larger exhaust systems, specialized filters and other items when exposure to heavy metals is likely)
- Identify any area and/or need to weld, paint, grind, sand, or apply paint or corrosion control materials on the aircraft frame or other aircraft parts. Has a preliminary hazard list been completed and a risk assessment code been determined for the facility which identifies if controls are required? Based on the risk assessment code, is a preliminary hazard analysis required? (Engineering controls may be required) Provide this document to the designers for inclusion in the hangar design.
- Based on the operations and the exhaust from the building, will an air permit be required or will it need to be added as an air emissions source

to the permit for the installation? (Additional filtration may be required by the state for the exhaust. This increases the size of the fans and pollution control costs.)

- What is the total occupant load? How does administration occupancy compare to Aircraft Repair occupancy? (This identifies the size and number of changing rooms and lockers for each group) In addition, are work clothes or disposable suits (i.e. Tyvek suits) provided for those people working in the shops/ hangar bays who may be exposed to hazardous materials and chemical? Identify where laundry facilities or disposal facilities for Tyvek suits are located.
- Identify how the spread of hazardous materials, dust and/or chemicals are controlled, contained, and disposed. Segregation of regulated areas and methods of demarcation may be required (such as full height partitions and ventilation systems). (Note: Areas of facilities utilizing these hazardous materials and/or chemicals must be designated as regulated areas whenever exposure can be expected to be in excess of the permissible exposure limit(s), and must be demarcated from the surrounding workspace in a manner that establishes and alerts building occupants of those boundaries of the regulated area.) Identify containment processes and methods to monitor effectiveness of housekeeping procedures, decontamination procedures, and engineering controls tailored to each facility 8. Is Chromium VI or other toxins being utilized in the hangar bay or workshops? If so, then proper decontamination procedures and separate showers must be in place to protect the personnel and surrounding work areas.
- Will waste oil drains be required? If so, give locations in hangar for receptacles funnels.
- Will there be a drum room? If so, how many drums should it hold? What types of chemicals will be stored?
- Where are hazardous waste containers to be located?
- Will mission functions be incorporated into the hangar building?
- How many employees, both direct and indirect, are expected to occupy the hangar per shift?
- Will tail docks, wing docks, fuselage docks or nose docks be required? If so, what utilities will be hooked up to them?
- What type of power tooling will be mounted in hangar? Examples include drill presses, grinders, shear, and brakes. In what location will this machinery be mounted? What type of utilities will be required for operation?
- Will there be rolling service doors? If so, give location and size. (Will any locations require power for motor operators?)
- Verify shop requirements.

- Type of shops?
- Square footage needed for each shop?
- The location in the building?
- Machinery location?
- Floor coatings required?
- Number and size of roll-up doors to outside of hangar.
- Will the shops require any other services such as shipping and receiving docks? Waste disposal/recycling?

- Will there be an inspection area? If so, give square footage, location and utilities required.
- Will a parts cleaning shop be required? If so, give square footage, location, utilities required. Also, please note any special or heavy drain items such as salt bath ovens or large ovens. Provide material safety data sheets for all cleaning products including application rates, methods, durations and frequencies.
- Will there be a lunch/break room? If so, please indicate square footage, location of building, number of employees per shift, if vending machines will be used, what type of floor, and if suspended acoustical ceilings will be required.
- Will there be a secured area? Verify the requirements.
- What aircraft should the hangar be able to house/maintain?
- Will there be a wash bay in the hangar?

D-1.3 Structural

- Will maintenance platforms or scaffolds be required?
- Will stabilizer platforms or other overhead suspended scaffolding systems be required?
- Will overhead cranes be required?
- Will personal fall arrest systems be required above aircraft? If so, what type?
- Verify shop requirements.
  - Crane coverage and hook heights?
  - Special foundations for equipment?
- Will the hangar be designated an earthquake, hurricane or other emergency shelter?

D-1.4 Mechanical

- Will overhead or in-ground mechanical utilities be required? If so, what locations?
- Will breathing compressed air be required?
- What will be the heaviest cfm drawn from hoses? (Quantity of outlets?)
- Will door track heating be required?
- Will door track drainage be required?
- What type of utilities will be required around the inside perimeter of the hangar? Utilities may include compressed air, water, pre-conditioned air. Provide location and capacity required.
- If there is equipment mounted in the hangar bay what utilities will be required for the equipment?
- Verify shop requirements.
    - What mechanical utilities are required in each shop?
    - Are floor drains needed?
    - Overhead air reels?
    - Machinery utility requirements?
- Any fluid discharges that may harm metal piping that would require an acid waste system? (X-ray room)
- Will there be any operational requirements for emergency eye wash/shower units? (Locations?)
- What locations are required for hose reels for water or air? (Overhead, column mounted or shop areas?)
- What is the expected hangar bay maintenance occupancy?
- Does the maintenance schedule vary with seasons?
- How does the maintenance schedule vary dependent upon peacetime or military conflict status?
- What maintenance activities will be performed, and for what percentage of time?

D-1.5 Fire Protection

- What is the history of the site's domestic/fire water supply? Does the water supply pressure fluctuate throughout the year?
- Is the fire water supply at the site known to have MIC or galvanic corrosion?

- Will there be rack storage in the facility? If so, what is the product stored? How high will it be stored, and how will it be stored? Will open rack shelving be used? Will the product be stored on wood or plastic pallets?
- Will the facility have shelved storage exceeding 8 ft. (2.4 m)? If so, describe the shelving arrangement and products stored.
- Will there be flammable, combustible, or corrosive liquids in the building which will not be located in a flammable storage cabinet? If so, what is the liquid, how is it stored, and how much is stored?
- Will tires be stored in the building? If so, how will they be stored?
- What is the typical parking arrangement of the aircraft in the hangar bay, and what fuels will be used by these aircraft?
- Will ejection seat maintenance be done in the building? What is the largest quantity of ordinance accumulated in the seat maintenance room any one time?
- Are flares stored in the building? If so, what is the quantity of flares stored, how will they be stored, and where will they be stored?
- Is the site considered to have reliable power as defined by the UFC 3-600-01?
- What system is used by the fire alarm receiving station?
- Are there site specific mass notification messages required?
- Will live voice messaging be required in the building from the receiving station?
- Will the activation of pre-recorded mass notification messages by the receiving station be required in the building?
- Will a supervised Knox box be required on the building? If so, how many?

D-1.6 Electrical

- Will overhead or in-ground electrical utilities be required? If so, what locations?
- Will 400 Hz be required? If so, what space will utilize the 400 Hz?
- Will 270 VDC be required? If so, what space will utilize the 270 VDC?
- Will 28 VDC be required? If so, what spaces will utilize the 28 VDC?
- Will standard power be required overhead?
- What type and source of lighting will be preferred in the hangar? (Metal Halide, LED or T8/T5 linear fluorescent?) What lux (foot-candle) levels are required? (Per current UFC handbook.)

- What type of utilities will be required around the inside perimeter of the hangar? Utilities may include 480 volt, 120 volt, 208 volt, 400-Hz, 28VDC, 270 VDC, Provide location and capacity required.
- If there are rolling service doors, will the doors be powered?
- If there is equipment mounted in the hangar bay what power will be required for the equipment?
- What loads should be served with emergency power?
- Will emergency power be provided via a permanent generator or a portable generator?
- Will additional mission functions be incorporated into the hangar that requires a generator connection?
- Verify shop requirements.
    - What electrical utilities are required in each shop?
    - Overhead electric reels?
    - Machinery electrical utility requirements?
    - Will grounding be required in any shops?
    - Will static dissipative floors be required in any shops?
- Will the project site require a high level of corrosion protection? Is the site on the coast where it is susceptible to salt water corrosion?
- Will there be pedestals in the hangar bay?
- Define the limits of the electrical hazardous (classified) locations including the hangar bay, adjacent spaces and shops with hazardous locations.

D-1.7 Communications

- Will outside public address system be required?
- Will a PA system be required? If so, give location and number of microphones.
- Will there be a requirement for special devices to be mounted to hangar roof, such as an antenna, or microwave dishes?
- Will a close circuit television system (CCTV) be provided for operations?
- Will there be dedicated networks? Will the networks require separate communication rooms?
- Will additional mission functions be incorporated into the hangar that requires dedicated communication networks or a data center?
- Verify shop requirements.
    - Provide location and number of telephones.
    - Provide location and number of telecommunication outlets.

- Will satellites be connected to the shop?
- Will radios be connected to the shop?
- Will dedicated networks be connected to the shop?

D-1.8 Security

- Will security systems be required? If so, what types will be required (Intrusion Detection Systems (IDS), CCTV, or access control)?
- What type of door security devices will be used? How many and what locations?

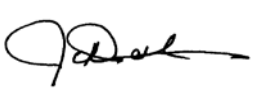
Change No.	Date	Location

This UFC supersedes UFC 4-211-02NF, dated 10 January 2005, with Changes 1-4.

FOREWORD



The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://dod.wbdg.org/.

Hard copies of UFC printed from electronic media should be checked against the current electronic version prior to use to ensure that they are current.

UNIFIED FACILITIES CRITERIA (UFC)
NEW DOCUMENT SUMMARY SHEET

Document: UFC 4-211-02, *Aircraft Corrosion Control and Paint Facilitie*s

Superseding: UFC 4-211-02NF, *Corrosion Control and Paint Finishing Hangars*, dated 10 January 2005, with Changes 1-4

Description: This UFC provides criteria for the planning and design of Aircraft Corrosion Control and Paint Finishing (ACCPF) Facilities for the aircraft of the combined DoD United States Armed Forces.

Reasons for Document: This is a new Joint Service document. This new document represents another step in the Joint Services effort to bring uniformity to the planning, design and construction of military facilities. This UFC was developed to provide design requirements to accomplish the following:

- Assist planners in understanding the facility requirements to ensure accurate space programs and budgets.
- Provide architects, engineers, and construction surveillance personnel with the essential, minimum requirements for the design and construction of Aircraft Corrosion Control or Paint Finishing Facilities.
- Clarify the operational intent of the facility design.

Impact: The following will result from the publication of this UFC:

- This UFC creates a single source for common DoD ACCPF criteria and an accurate reference to individual Service-specific documents.
- This UFC facilitates updates and revisions and promotes agreement and uniformity of design and construction between the Services.

Unification Issues: The following are issues that remain non-unified and the reasoning for each:

- Section 2-1 identifies Service-specific documents for corrosion control requirements. The documents detail Service-specific aircraft corrosion control maintenance procedures and practices that may affect the facility design and are noted for reference.
- Section 2-5.3 identifies different minimum clearances and working space allowances. The exception is based on Service operational requirements for aircraft movement near fixed objects. The exception has little impact on Corrosion Control hangar size, since operational clearances control the size of the hangar bay.
- Sections 3-2.2.1, 3-4.3 and 3-6 identify different Service-specific Fire Protection requirements. These requirements are not currently unified by Fire Protection Working Group. These issues will be discussed in developing unified requirements for General Maintenance Hangars in the near future.

CHAPTER 1 INTRODUCTION

1-2 SCOPE OF DOCUMENT.

This UFC provides requirements for evaluating, planning, programming, and designing Aircraft Corrosion Control and Paint Facilities (ACCPFs). The information in this UFC applies to the design of all new construction projects, to include additions, alterations, and renovation projects in the continental Unites States (CONUS) and outside the continental US (OCONUS). The requirements contained in this UFC apply to Army, Navy, Marine Corps and Air Force facilities unless specifically referenced to a single service. This UFC is not intended as a substitution for thorough review during design by individual Program Managers and Operations Staff in the appropriate Service.

1-3 APPLICABILITY.

This UFC provides planning and design criteria applicable to new construction as well as sustainment, restoration and modernization projects on all Department of Defense (DoD) facilities in the continental United States, (CONUS), and outside the continental United States (OCONUS).

1-3.1 General Building Requirements.

Comply with UFC 1-200-01, General Building Requirements. UFC 1-200-01 provides applicability of model building codes and government-unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, sustainability, and safety. The design requirements in this UFC are to be used in addition to UFC 1-200-01 and referenced UFC's and criteria.

1-4 SCOPE OF FACILITY.

ACCPFs provide space, infrastructure and support facilities to conduct de-paint, paint, and corrosion control activities for DoD aircraft. There are three categories of facilities:

- Depot Facilities (DF) support comprehensive de-paint and paint programs. These facilities may operate almost continuously in support of the corrosion control program.
- Corrosion Control Facilities (CCF) support periodic activities on an as-needed basis. In the past, these facilities have also been called operational/intermediate level facilities, squadron level, field level, and patch and paint facilities.
- Wash Racks fulfill the requirement of periodic corrosion control on aircraft not requiring remedial corrosion maintenance. Wash Racks may be open, covered, enclosed, or integrated into the hangar bay, but the functions performed and the utilities provided at the Wash Rack are limited to the washing and rinsing of aircraft.

The ACCPFs described in this document are indicated in Figure 1-1. A comprehensive list of functional program spaces are listed and described briefly in Table 1-1 and described in greater detail in Chapters 2 and 4 through 7

FIGURE 1-1. ACCPF FACILITIES

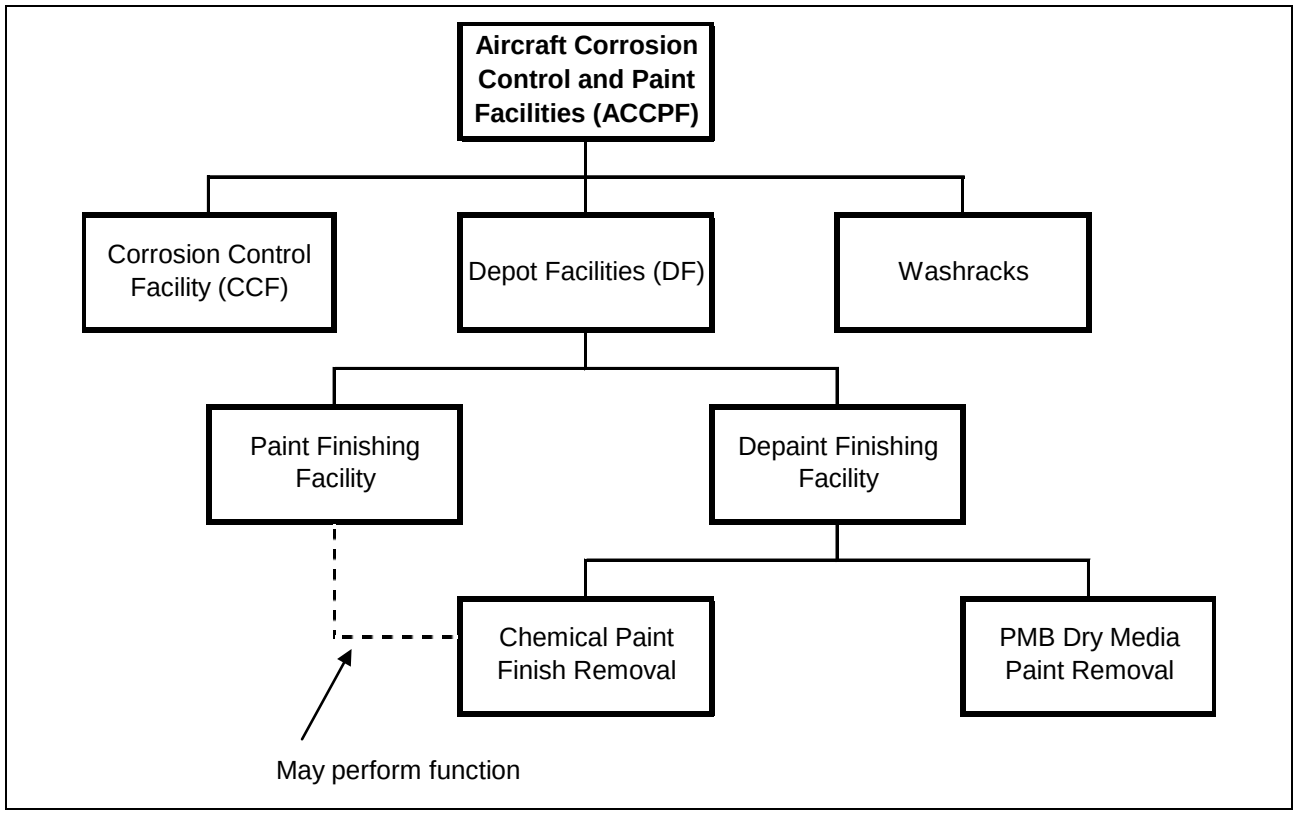

TABLE 1-1. ACCPF FUNCTIONAL PROGRAM AREAS

Functional Program Area	Description
Operational Spaces	
Aircraft Hangar Bay (Paint/Wash/Chemical Depaint)	Houses aircraft and equipment anticipated for the mission of Facility. The bay must be sized for the largest aircraft with additional space for anticipated maintenance platforms and equipment. The bay should also include utility connections required for the mission. Utilities will vary for paint application, and chemical depaint versus dry depaint.
Aircraft Hangar Bay (Dry Media Depaint)	Houses aircraft and equipment anticipated for the mission of Facility. The bay must be sized for the largest aircraft with additional space for anticipated maintenance platforms and equipment. The bay must be designed for a dusty environment and include strategically placed outlets for Dry Media Blast (DMB) distribution and spent DMB pick up /delivery system for DMB reclamation; with additional utilities specific for the mission.
Paint Mix Room	Coating mix and paint pot staging; should be adjacent to paint storage with easy access to paint bay.
Paint Storage Room	Aircraft coating container storage; adjacent to paint mix, with curbed storage area drained to I.W.; should also have access for deliveries.
Tool Crib	Special use equipment tools such as pallet jacks, ladders, facility maintenance items.
Equipment Storage	Paint application equipment storage; typically combined with paint equipment cleaning room.
Equipment Cleaning	Paint application equipment cleaning; room generally contains small paint booth or other solvent cleaning apparatus for use with paint spray guns and paint pots.
Solvent Storage	Large container (typ. 55 gal) paint solvent storage; requires pallet storage with door openings and aisles suitable for deliveries.
Central Acid Storage	Central storage for acid cleaner and conversion coating; may include central chemical mix and storage tanks with pumps and piping for distribution to the hangar bay.
Central Chemical Storage	Central storage/distribution for hot soap/water mix and hot and cold water; typically includes bulk storage of concentrated soap, central hot water heater/tank, soap/HW mix tank and associated distribution pumps.
Material Storage	Secure storage of non-hazardous paint prep materials; typically includes a window for distribution of materials to paint personnel; may also include storage of paint process equipment and parts.
PPE Storage	Room/area designated for secure storage of PPE; storage of PPE is typically combined with PPE cleaning.
PPE Cleaning	Cleaning of personnel protective equipment; typically includes divided sinks; central washer and drier (optional).
Paint Booth	Individual paint spray booth for small parts (may be located inside hangar bay or exterior to building).

TABLE 1-1. ACCPF FUNCTIONAL PROGRAM AREAS

Functional Program Area	Description
Operational Spaces (cont'd)	
Stencil Room	Houses aircraft stencil equipment; room size should consider size of aircraft stencils as well as equipment.
Composite Room	Composite/fiberglass layup/repair room will typically contain work benches with ventilation hoods, and curing ovens for repair of composite parts.
Dry Media Equipment Room	Centralized dry blast media retrieval, processing and distribution equipment
Dry Media Storage Room	Bulk dry media storage (palletized)
Dry Media Blast Booth	Fully enclosed self -contained room specifically designed with the equipment and utilities for the removal of coatings by the DMB method, generally manually performed by a DMB nozzle operator stationed inside the booth.
Wash Rack	Accommodates aircraft cleaning and can be open, covered, enclosed, or integrated into the hangar bay.
Administrative Spaces	
Supervisor's Office	Private office located with view of hangar bay
Offices	Private offices and/or workstations determined by mission requirements
Conference Room	Small assembly with conference table and chairs
Fax/Copy	Centralized fax/copy room
Break Room	Personnel break and assembly room
Locker Rooms (clean)	Male and female locker/shower/toilet facilities
Locker Rooms (dirty)	Male and female lockers used for disposition contaminated clothing worn by operators during the performance of their corrosion control duties
Technical Library	Storage of aircraft technical documents
Maintenance Shops (option)	Optional mission-specific maintenance spaces
Support Spaces	
Mechanical Room(s)	HVAC and miscellaneous mechanical systems
Compressor Room	Plant air and breathing air compressor systems .Note specific requirements for Breathing Air vs. Plant Air
Central Plant	Centralized chilled water and heating hot water supply
Electrical Room(s)	Switchboards, motor control centers, distribution transformers, circuit breaker and lighting panels, VFD equipment
Fire Protection Room	Fire water riser, distribution manifold, AFFF or HEF storage tanks
Communication Room(s)	Telephone switchboard and misc communications equipment

Note: All spaces listed above in Table 1-1 are examples of spaces common to DFs and CCFs. Actual spaces included in the planning phase must be based on the specific mission of the facility.

1-5 FACILITY PROJECT TEAM.

The planning and design team for ACCPF must include the following specialists in addition to the standard architecture and engineering disciplines:

- Aircraft Corrosion Control and Prevention Operations
- Aircraft Maintenance Operations
- Industrial Hygiene
- Environmental Quality and Protection
- Safety
- Fire Marshall
- Facility Maintenance
- Energy Manager
- Flight line and AT/FP Security

1-6 PROGRAM AUTHORITIES.

Prior to project development, confirm the acquisition methodology and coordinate facility requirements with the following contacts for the appropriate Service:

- Army. Aviation and Missile Command Corrosion Program Office
- Air Force. AF Corrosion Prevention and Control Office (AFCPCO)

This Page Intentionally Left Blank

CHAPTER 2 PLANNING AND LAYOUT

2-1 FACILITY FUNCTION.

Design the corrosion control hangar to provide space and equipment for the specific corrosion control functions required by the project mission. These corrosion control functions can be performed at either a DF or CCF.

In general, base facilities designed for DF perform de-paint/re-paint maintenance on the entire aircraft. Base facilities designed for CCF perform de-paint/re-paint maintenance on repaired or replaced components only. Service-specific corrosion control requirements are defined in the following documents:

- Army and Navy. NAVAIR Technical Manual NAVAIR 01-1A-509-1, *Cleaning and Corrosion Control*
- Air Force. *Air Force Corrosion Control Facility Reference Guide*

Aircraft Corrosion Control Facilities, as a whole, encompass the following functions:

- Aircraft washing
- Repair and Touchup Painting
- Full Aircraft Repainting
- Finish Curing and Drying
- Depaint (Chemical and Dry Media)
- Component painting
- Paint mixing
- Chemical/paint storage

2-1.2 Depot Level Facilities.

The primary function of a Depot Level Paint or De-paint Facility is to provide the necessary space and services to perform complete corrosion control activities on aircraft undergoing scheduled major maintenance checks or a scheduled complete corrosion control repaint. Depot level facilities must be capable of providing complete services required for all operations involved with the total paint, or de-paint of an entire aircraft. While chemical de-paint operations are often performed in a depot level Paint Facility, Dry Media Blast operations must be performed only in facilities specifically designed and built for the DMB de-paint function.

2-1.3 Corrosion Control Facilities.

The primary function of a Corrosion Control Facility is the performance of minor corrosion control activities in support of an active squadron as part of non-scheduled maintenance completed on an as needed basis. Corrosion Control Facilities, in general,

must be able to perform all the functions listed above with the exception of the DMB De-paint. As noted above in 2-1.1, the DMB De-paint function should be reserved for a Depot Level Facility. The planner should also be aware that if the mission of the CCF includes the requirement to repaint an entire aircraft or any part of the aircraft, airflow requirements in the CCF paint bay will be the same as the Paint Finishing (Depot Level) Hangar.

In some cases, the mission of the CCF may require special functions such as composite or sheet metal repair. Extra shops will be needed for the completion of these tasks.

The primary difference then between the DF and the CCF is the projected aircraft throughput versus the necessity for operational flexibility.

Table 2-1 ACCPF PLANNING ISSUES, below provides the different functional issues which must be considered when planning a CCF or DF which must fulfill the mission requirements, and also be safe, cost effective, energy efficient, and environmentally compatible.

TABLE 2-1. ACCPF PLANNING ISSUES

Planning Issue	CCF	DF
GENERAL	*Low Aircraft Throughput *Greater Process Variety *Shorter Process durations *Increased Downtime *Limited Number of Personnel *Fueled aircraft	*High Aircraft Throughput *Limited Processes required *Longer Process durations *Minimum Downtime *More Personnel Involved *Defueled and purged Aircraft
SPACE PLANNING	Consider number of hangar bays WRT aircraft throughput & operation specialization. Lower personnel = lower area required for amenities. Higher number of processes = higher number of specialty spaces (Back shops)	Consider number of hangar bays WRT aircraft throughput and processes performed. High personnel reqs = large area needed for amenities. Minimum specialized processes = fewer number of Back Shops.
HVAC DESIGN PLANNING	Increased downtime allows for use of prevailing weather to provide window of opportunity for correct Temp/ humidity conditions. Heating only systems typical. Horizontal air flow offers flexible, economic Supply Air design.	24/7 type operations with minimum downtime call for full temp./ humid. HVAC Systems. Exhaust Recirc + add'l energy recovery systems should be considered. Downflow Air Supply an option; offers high quality "Auto" finish; with fast production for hangars designed for single aircraft.
FACILITY ENVIRONMENTAL	Air: Consider air emissions WRT overall Base Permit.	Air: Consider air emissions WRT overall Base Permit.

TABLE 2-1. ACCPF PLANNING ISSUES

Planning Issue	CCF	DF
IMPACT	Water: Consider Industrial Waste (IW) treatment requirements wrt existing base capabilities and capacity	Water: Consider increased and special CCF Waste treatment reqs. with respect to existing base capacity, and possible need for a new WT system required for pretreatment of IW effluent
MECHANICAL EQUIPMENT REPAIR & REDUNDANCY	Increased available hangar downtime allows for less critical timing for repair/replacement of failed systems.	Longer processes, low available downtime mandate an increased level of redundant equipment.
FIRE PROTECTION	AFFF, HEF and/or DELUGE FP systems required for facilities housing aircraft with any fuel on board.	Typical installation for defueled and purged aircraft requires a closed head sprinkler FP system
	Fewer personnel, shorter processes call for minimal number of Ceiling supported man lifts, high use of ground supported man lifts and maintenance stands	Higher number of personnel with longer processes call for higher density of Ceiling & ground supported man aboard systems
WORKER ACCESS/SAFETY	Fall Protection required.	Fall Protection required.
	Change Rooms, Lockers, Showers and Contamination Control required.	Change Rooms, Lockers, Showers and Contamination Control required.

2-1.4 Wash Racks.

The variety of wash racks are as follows and are discussed in greater detail in UFC 3-260-01, *Airfield and Heliport Planning and Design*:

a. Open (uncovered) Wash Rack – an open air paved area specifically designed for the manual washing of aircraft. This facility should include wash utilities, drainage capability for both storm water and wash water waste, and may include lighting and power outlets for night operations, depending on the mission.

b. The Covered Wash Rack – The Covered facility will provide the same capabilities as noted above in Item A. with the added benefit of a non-climate controlled roof structure, typically with open sides. The covered

facilities are used primarily to keep aircraft out of direct sun to reduce the skin temperature and improve wash conditions.

c. Interior Wash Racks –Interior Wash Racks for the purpose of this document will be considered fully enclosed environmentally controlled facilities with all utilities required for the washing of aircraft. The DF (Paint) and CCF as described in this document are required to provide all services for the Interior Wash Rack. Please refer to the appropriate DF and CCF sections for those requirements.

d. Birdbaths (Aircraft Rinse Facility) – An Aircraft Rinse Facility referred to as a ”Birdbath” provides an unattended taxi-through treadle-operated freshwater deluge system to rinse aircraft typically subjected to accelerated corrosion due to low-level over water operations or a corrosive atmosphere at the installation.

2-1.5 Multi-Use Facilities.

Multi-use facilities, for the purpose of this document, refer to ACCPF that include functions outside the family of corrosion control, such as Fuel Cell or Maintenance activities. This document does not address those functions outside the corrosion control capability nor the special requirements those functions may impose on an ACCPF facility.

2-1.6 Technical Complexity of Ventilation Systems

Corrosion control facilities normally require complex, and expensive ventilation systems in order to comply with applicable environmental, fire protection, and occupational health requirements. It is essential that the system requirements and costs are identified during the project development and are included on the DD Form 1391.

The DD Form 1391 should also note that the facility requirements include the mandatory need for mechanical ventilation to remove paint particulates and solvent vapors. The inclusion of this statement, as well as including the costs for the system (including the acceptance test and associated report), as a separate line item in the facility cost estimate will help ensure that adequate funds are allocated for this extremely costly requirement. An example of a statement that might be included on the DD Form 1391 is shown below:

“Mechanical Ventilation is required to remove paint particulate and solvent vapors from the Corrosion Control Facility. Upon facility completion, an independent ventilation expert must evaluate the effectiveness of the mechanical ventilation system. The ventilation expert must provide a detailed evaluation report with recommendations regarding system acceptance and corrective action for discrepancies”.

2-1.7 Equipment Planning Issues.

It is imperative that all operational equipment anticipated for use in the new facility be identified and programmed early in the planning process in order to ensure the provision of adequate space and utilities in the facility design.

2-2 LOCATION DETERMINANTS.

2-2.1 Geographical Location

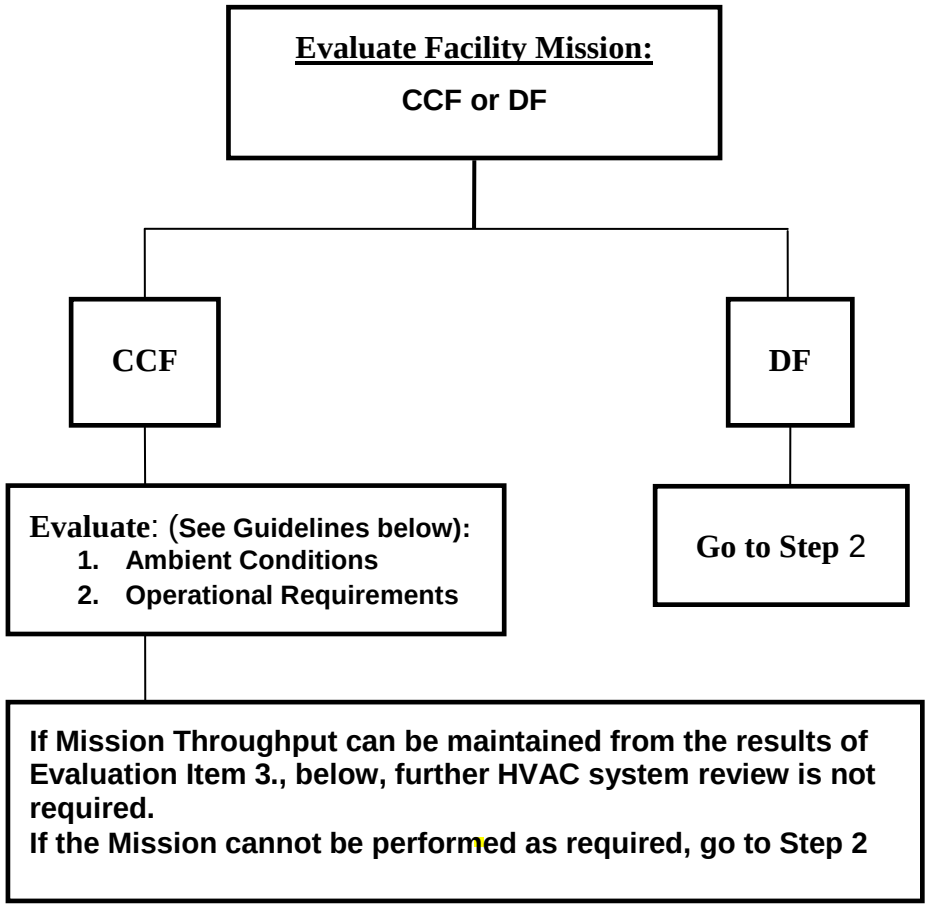
The location of a Depot Level and Corrosion Control Facility is generally predetermined by mission requirements, and climate is typically not a determining factor in location selection. Climate, however, has a significant effect on the design, energy usage and operational constraints of the facility. As part of the statement(s) which will go into DD Form 1391 regarding the mechanical ventilation system (ref. paragraph 2-1.5, above), the steps outlined in Section 2-3 HVAC System Selection must first be followed to determine the level, complexity and estimated cost of the proposed hangar bay HVAC system required to meet the mission of the facility.

2-2.2 Site Orientation.

Consider the prevailing wind in orienting the building in relation to aprons, taxiways, and parking, to avoid exhaust air dispersal over areas affected by solvent vapors and to avoid recirculation into the ventilation system intakes.

Orient hangar such that it complies with all geometric requirements of UFC 3-260-01.

2-2.3 Site Organization.



Locate the corrosion control hangar in close proximity to the maintenance hangars and as close as possible to an aircraft wash rack. Access between the corrosion control hangar, the maintenance hangar, and the aircraft wash rack is required. Locate the paint-finishing hangar with due regard to the requirement for aircraft and vehicle access.

2-3 HVAC SYSTEM PLANNING & SELECTION.

Non-process areas of hangars must meet all energy efficiency goals. Process areas must meet energy goals as much as practical. Systems also must conform to the latest service-specific policies for energy efficiency. See Chapter 3 for design applications and requirements for specific HVAC systems. For the initial facility planning phase, use the following steps in selecting the HVAC system for the Hangar Bay which will house the aircraft spray painting operations.

STEP 1. Define the facility mission to determine facility type (CCF vs. DF) and process requirements to establish HVAC objectives per Figure 2-1.

FIGURE 2-1. HVAC SYSTEM SELECTION STEP 1

1. CCF Baseline is 100% OA. See UFC 3-400-02 for dry bulb & humidity parameters: MEL, MEH@2%, MEH@97.5%, HR@2%. Evaluate need for heating for operations (~75 deg F [23.9 C]) and freeze protection based on ambient conditions. Also evaluate need for heat recovery.

2. Evaluate the operational requirements for temp and humidity and compare to the ambient conditions.

3. Establish the effect of 1. & 2 on the Mission Performance and Throughput

STEP 2. Identify requirements for interior conditions of the process hangar bay per Figure 2-2.

FIGURE 2-2. HVAC SYSTEM SELECTION STEP 2 TEMPLATE

Process Mode	Interior Conditions					
	% Usage Per Year	TEMP (F)*		RH*		Air Flow Requirements
		Max	Min	Max	Min	
Unoccupied						
Paint Prep						
Paint Removal						
Pre-treatment						
Paint						
Cure						
Min-Occupancy						

* Interior Conditions must be based on the more stringent of 1) coating manufacturer's temperature and relative humidity requirements or 2) personnel heat stress limitations per Chapter 3, Mechanical.

STEP 3. Establish a baseline HVAC System which represents the lowest perceived capital first cost that fulfills the requirements of Step 2. Based on the baseline system, develop an energy budget for each process. Service specific guidelines and the minimum guidelines of ASHRAE 90.1 must also be followed for auxiliary spaces.

Note that during the development of the energy budget, consideration should be given to utilization of the ambient conditions as much as possible during processes which require large amounts of outside air.

STEP 4. Analyze alternative HVAC systems and/or energy conserving methods as determined appropriate for the application as potential additions or alternatives to the baseline system. Examples of alternative systems or methods include recirculation, heat recovery, and ice storage.

With the emphasis on energy conservation along with recent improvements in mechanical system technology, recirculation of ventilation air is now being recognized as an accepted alternative to improving energy efficiency in a spray paint environment. The effectiveness of recirculation in reducing energy usage can vary widely depending upon climate. In locations where much energy is expended to keep the temperature and humidity of the facility within operational parameters, recirculation may be easily justified from an economic perspective. In very temperate climates, the mechanical complexity and additional equipment required for a recirculated ventilation system may negate the climate control savings advantage. It is important to evaluate the economic impact of recirculation over time based on anticipated energy savings. Also included in the evaluation for determination of exhaust air recirculation are the OSHA regulatory issues related to personnel safety and the required monitoring of the ventilation air and operations personnel.

STEP 5. Establish the potential Life Cycle Cost Analysis (LCCA) benefit to the project and select system with the lowest Life Cycle Cost (LCC) which fulfills current occupational safety, health, energy efficiency, and other related standards for the facility's process spaces.

2-4 LAYOUT AND ADJACENCIES.

2-4.1 General Building Layout and Adjacencies.

The appropriate building layout and adjacencies are illustrated in Figures 2-3 and 2-4. These diagrams do not convey a building shape. Figures 2-3a and 2-3b represents the DF and Figure 2-4 represents the CCF. Figure 2-5 provides a schematic representation of the personnel flow from the "dirty" or "hot" hangar bay areas and the "clean" or "cold" areas. This is to prevent any contamination from the cleaning, depainting or painting agents used in the hangar bay reaching the clean areas where protective equipment is not required.

Arrange work-bays so that each has ready access to the outside and to equipment and storage spaces of the hangar. Isolate work-bays in which cleaning and stripping are done from work-bays in which painting and curing are done. Administrative spaces such as work control offices may be accommodated in mezzanines. Provide mechanical equipment rooms with outside access. "Break" rooms must be on "clean" side, but areas can be included on "dirty" side for brief breaks without eating.

FIGURE 2-3a. DF PAINT & CHEMICAL DEPAINT BUBBLE DIAGRAM

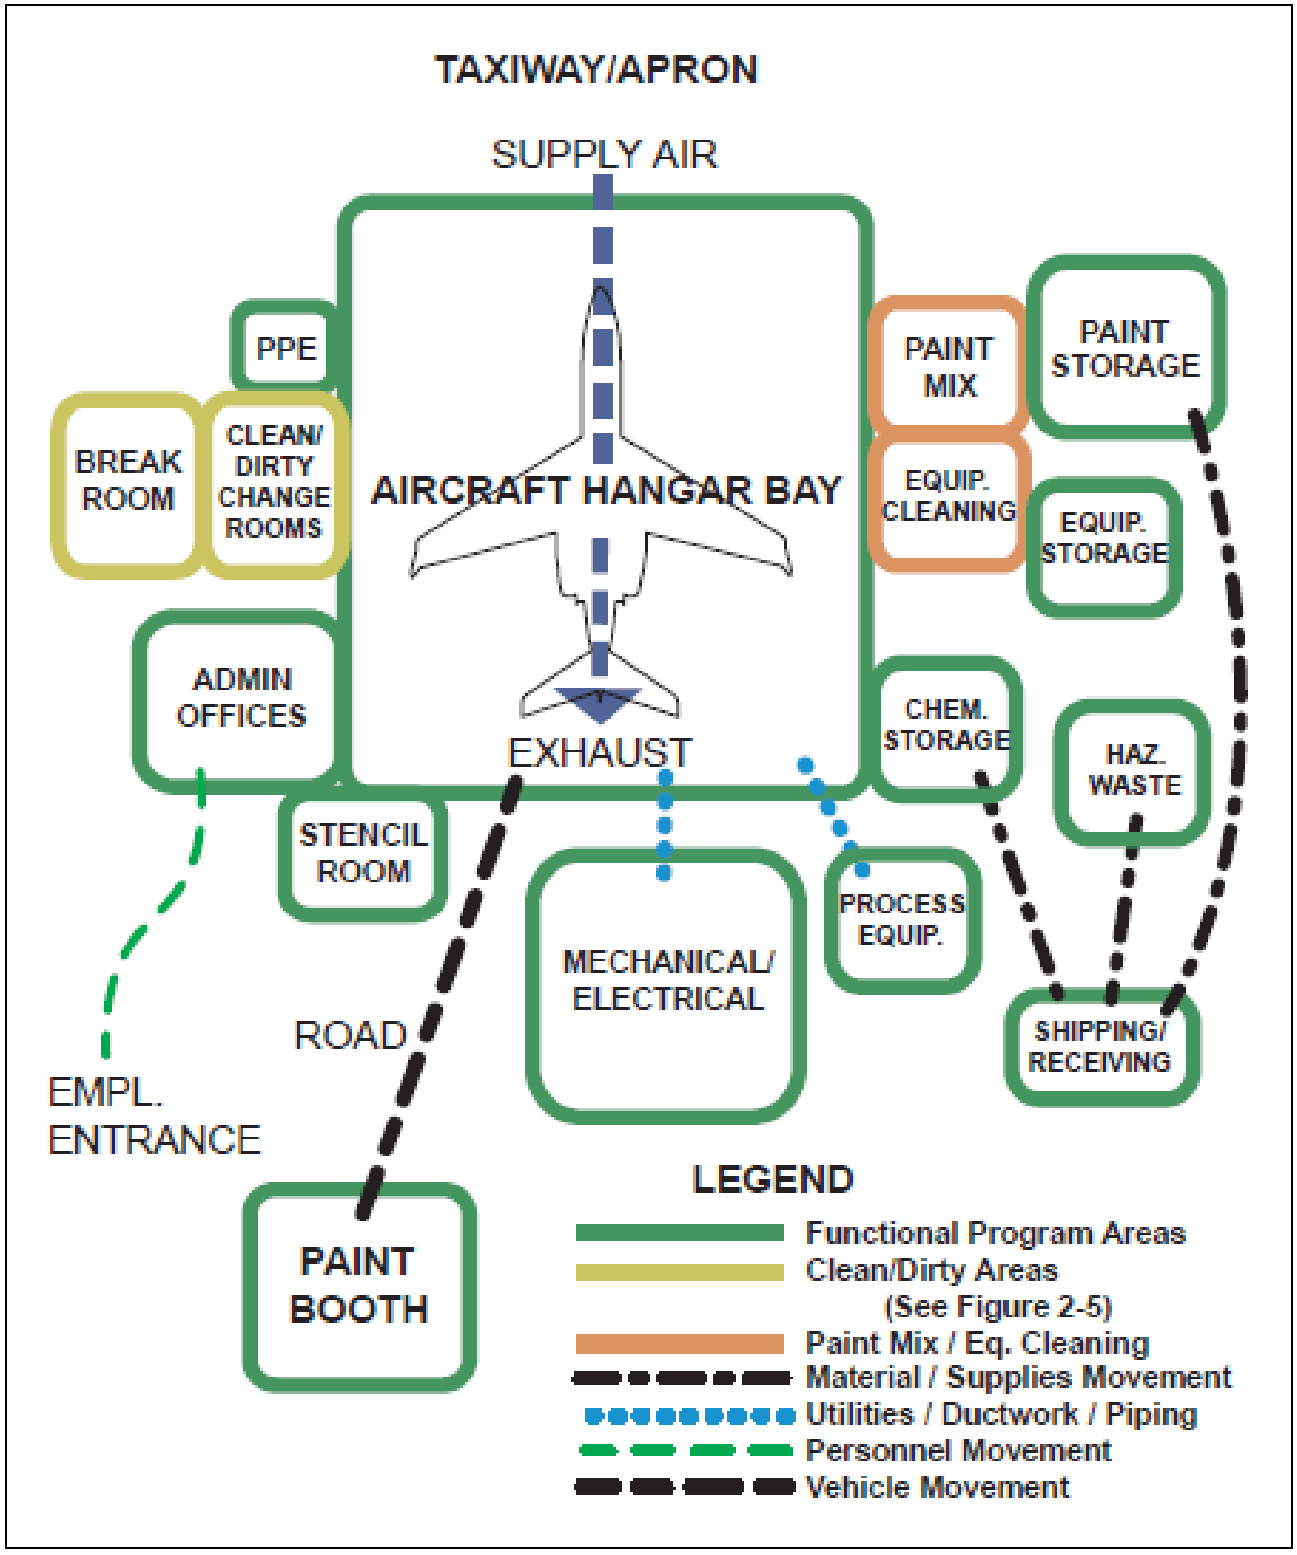


FIGURE 2-3b. DF DRY MEDIA DEPAINT BUBBLE DIAGRAM

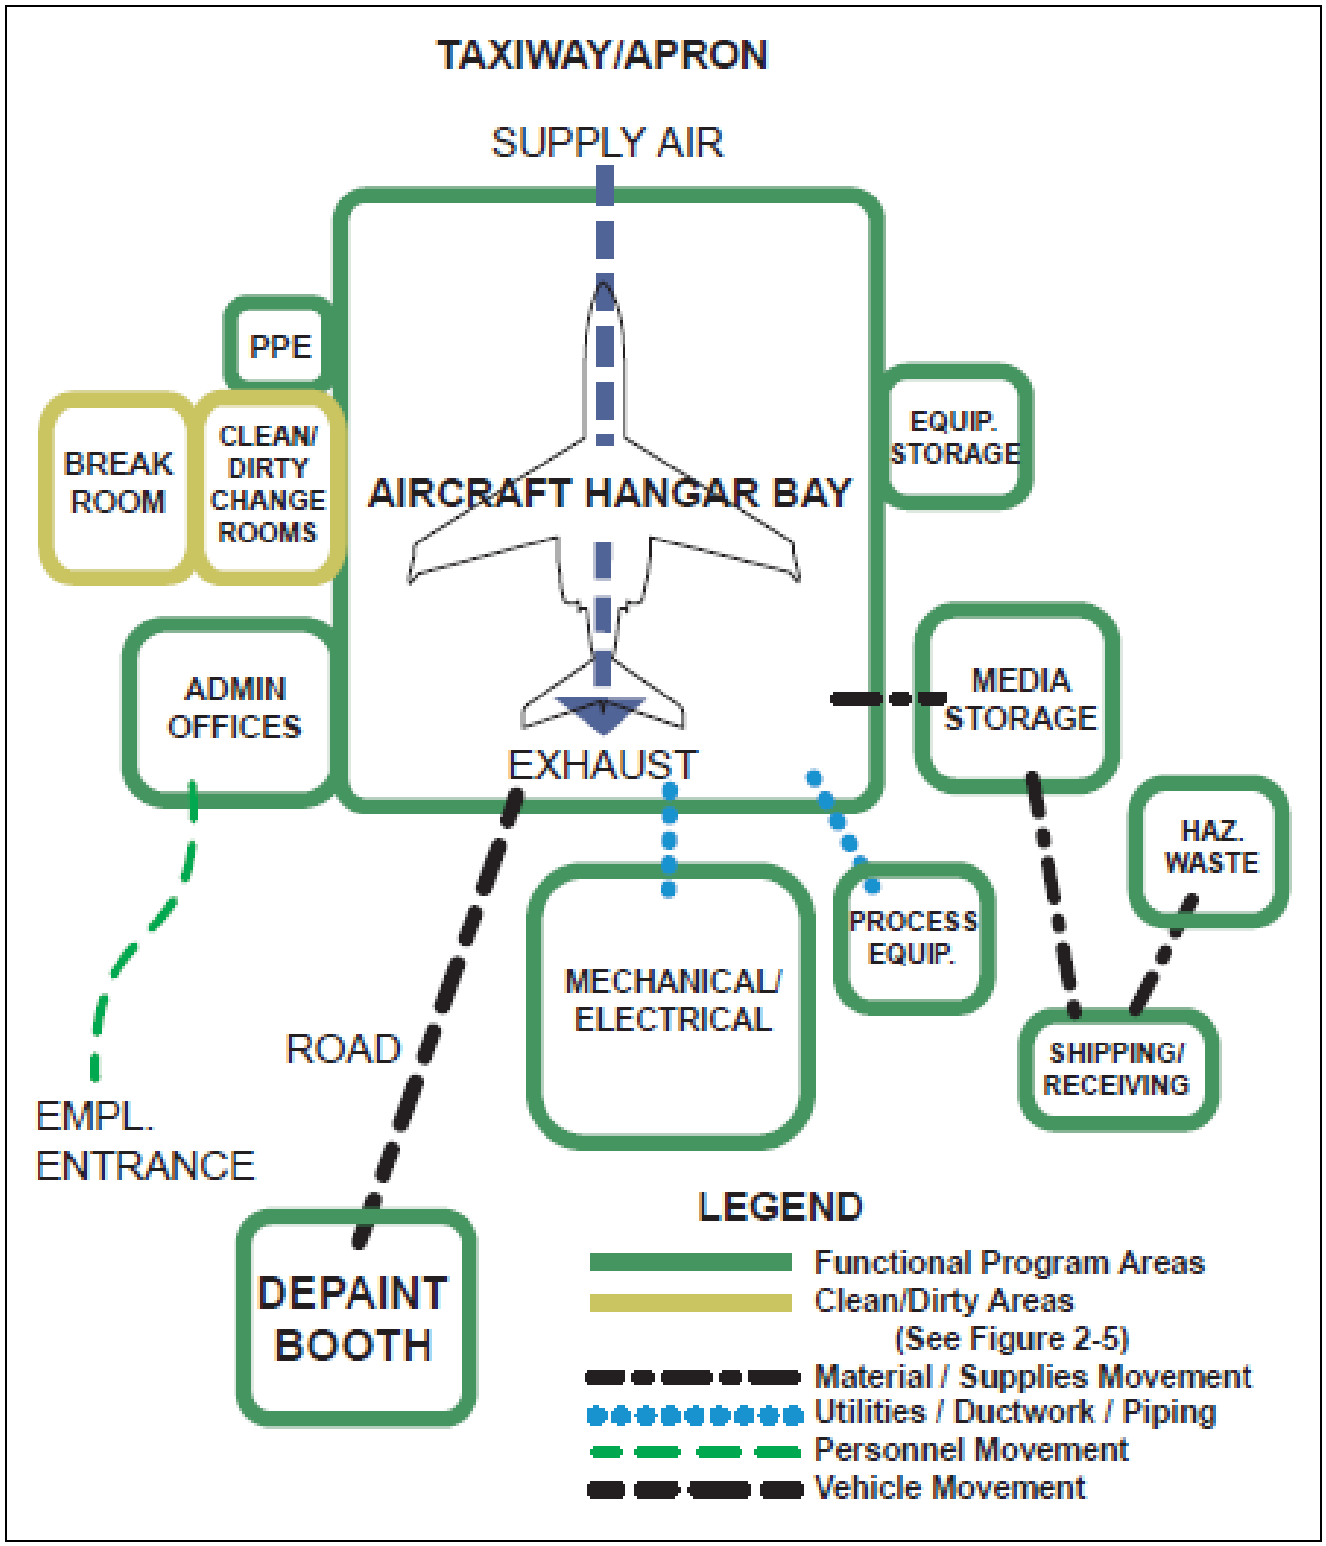

FIGURE 2-4. CCF BUBBLE DIAGRAM

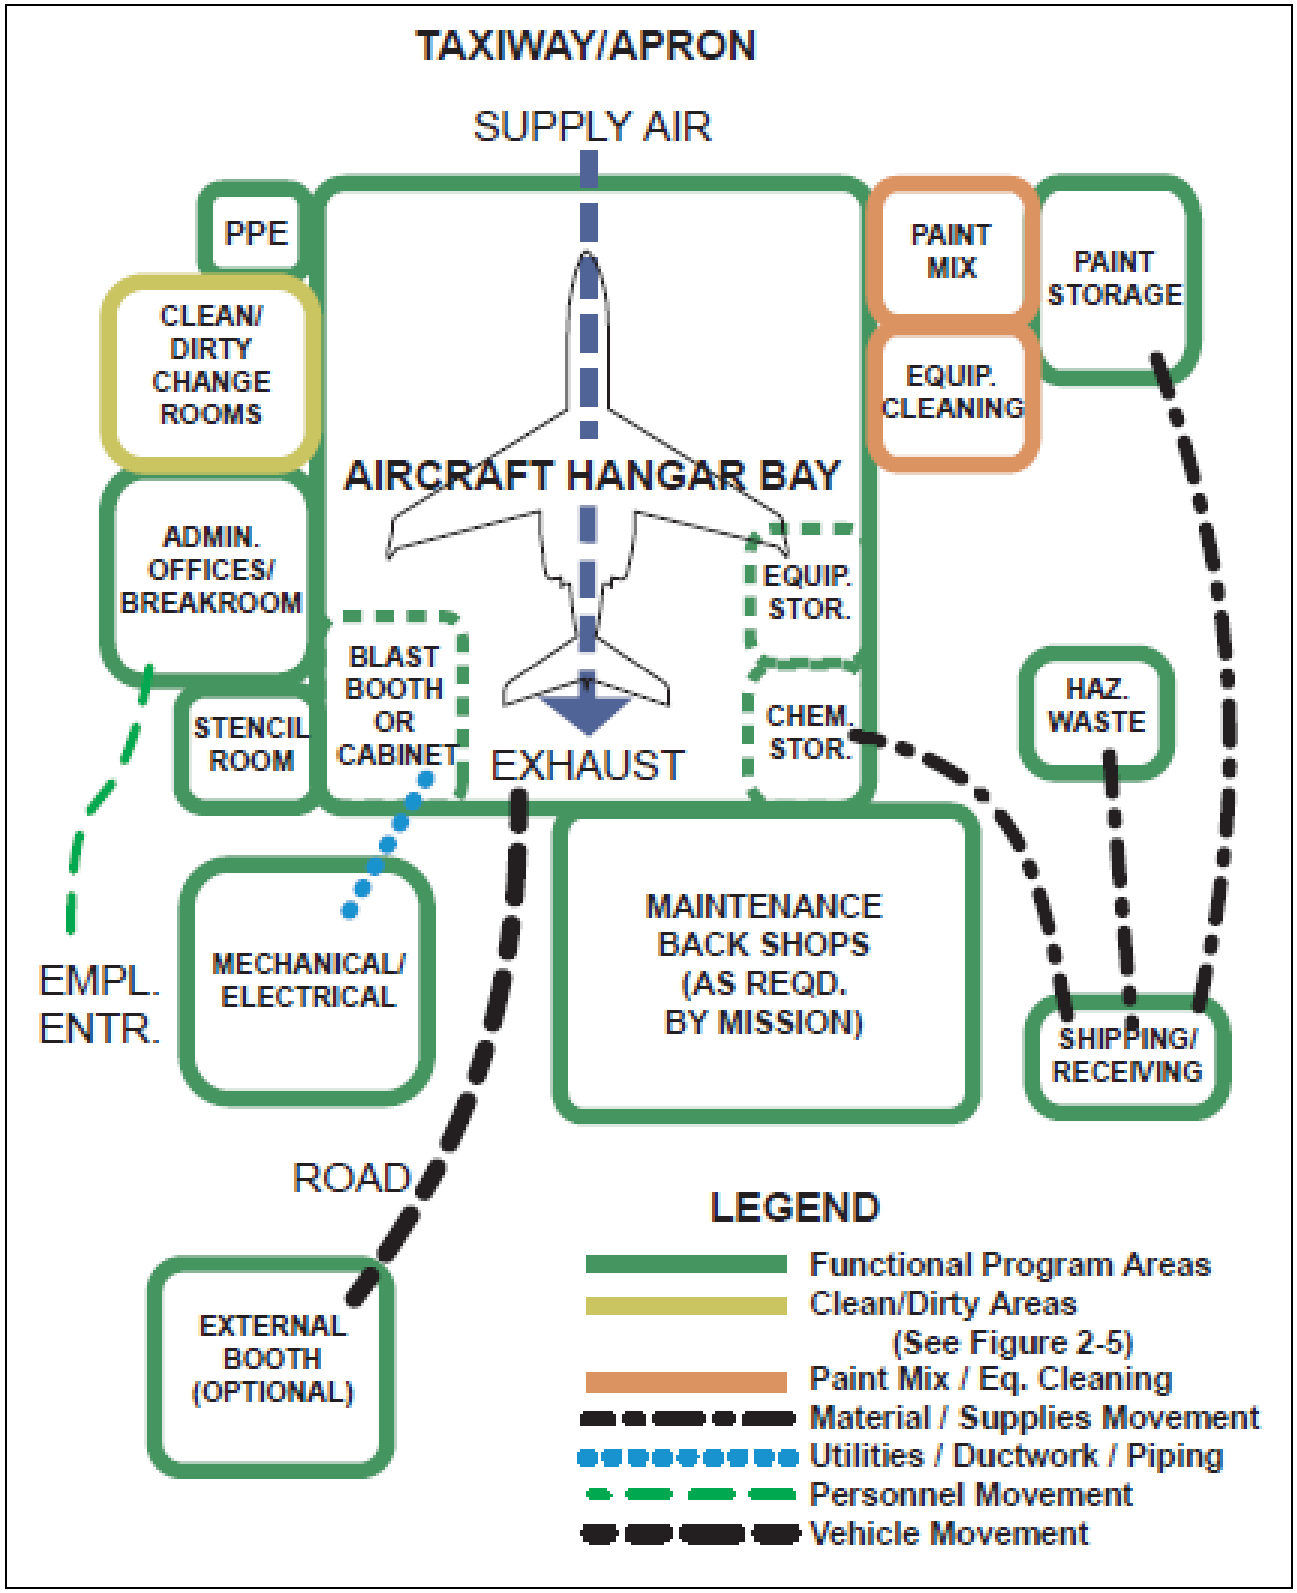

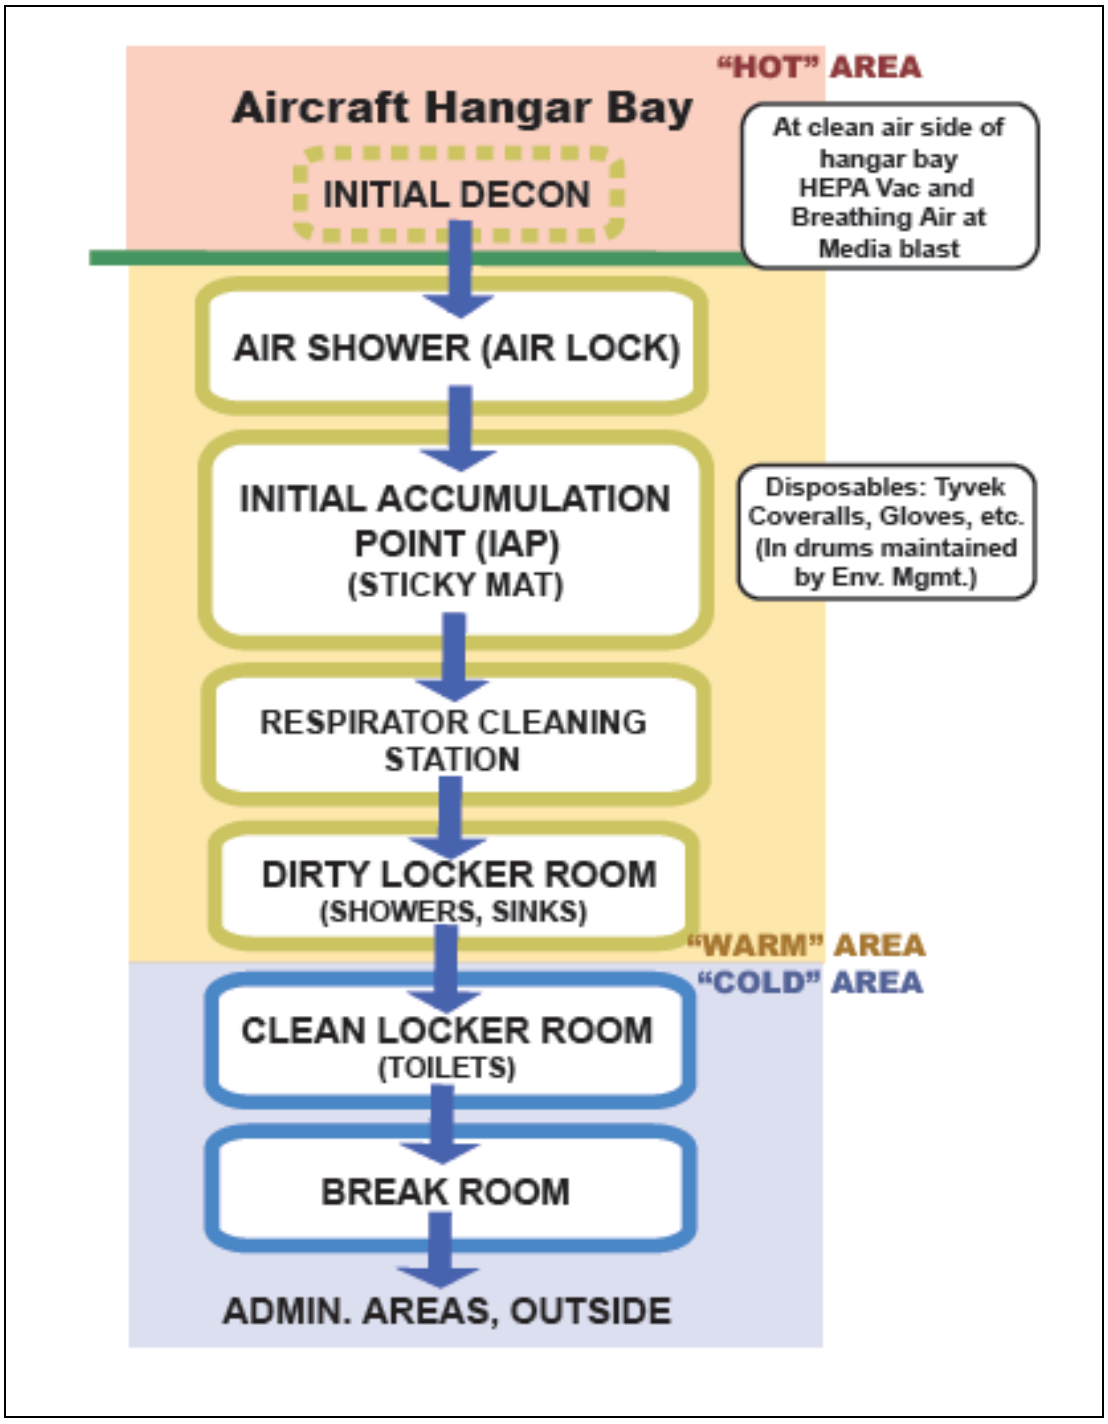

FIGURE 2-5. CLEAN-DIRTY SCHEMATIC

2-4.2 Combining Corrosion Control Functions.

Combining functions within the family of corrosion control tasks may only be considered as follows:

- Paint facilities may include both paint and chemical depaint functions with special care taken to address the industrial waste issues of chemical de-paint operations.
- All CCFs and DFs should have a wash function inside the hangar as described in this document as well as paint spray and/or chemical depaint capability (exception: dry depaint facilities will not have a wash function within the hangar bay, but will coordinate with near or adjacent wash racks).
- Performing Paint or Chemical De-paint functions in a facility where Dry Media Blast stripping operations take place is not allowed due to the critical nature of maintaining a dry environment for the Dry Media and the de-paint equipment. Dry Media Stripping and Painting/Chemical De-paint must always be accomplished in separate areas. If grinding operations (scuff sanding) are performed in a Paint Facility, vacuum pickup equipment must be utilized to minimize the spread of dust in the hangar bay. Every effort must be made to maintain a dust free environment where painting is performed.

2-5 FACILITY STUDY.

Due to the complexity and unique characteristics of Aircraft Corrosion Control & Paint Facilities, a facility study must be performed on all proposed CCF and DF projects to determine space and process system requirements.

2-5.1 Space Criteria.

ACCPF space needs are site and mission specific and must be individually programmed based on a facility study. Space program development guidance is provided in UFC 3-260-01, *Airfield and Heliport Planning and Design* and the following documents:

- Army TM 5-803-5, *Installation Design*
- Navy UFC 2-000-05N (P-80), *Facility Planning Criteria for Navy and Marine Corps Shore Installations*.
- Air Force AFH 32-1084, *Facility Requirements*
- *Department of Defense Unified Facilities Criteria UFC 3-101-01, Architecture*

Certain spaces are not defined specifically in space programming criteria. These spaces include air recirculation rooms, fan rooms, and filter plenums for example. These spaces should be considered and added to the space criteria if anticipated.

2-5.2 Facility Space Criteria Study.

Prepare a facility study with input from Chapter 1, Program Authorities, and Chapter 1, Facility Project Team. Also see Appendix B Section 2.2 for design guidance on programming an accurate estimate of the gross area for a new ACCPF. Ensure that the clearance factors in 2-5.3 are addressed in the facility space study to accurately determine the total square footage for the new facility.

2-5.3 Minimum Clearances and Working Space.

For minimum safety clearances based on aircraft type, reference the following documents:

- Army & Air Force: UFC 3-260-01, *Airfield and Heliport Planning and Design*
- Navy: UFC 2-000-05N, (P-80), *Facility Planning Criteria for Navy and Marine Corps Shore Installations*

The size of the various aircraft scheduled to use the facility will determine the hangar bay dimensions. Determine the interior dimensions of the Corrosion Control facility, by using the dimensions of the largest aircraft that will occupy the facility, and adding the minimum clearances indicated below. Include additional space as required for tow vehicles and turning radii. Size the bay to accommodate fixed-wing aircraft with wings unfolded, and helicopters and V-22 with rotors in place and unfolded unless it has been determined that aircraft surfaces are accessible with the wings/rotors folded. Verify the configuration of rotors on rotary aircraft undergoing corrosion control when sizing the process (hangar) bay.

The following minimum operational clearances are required to allow proper access for work platforms and to minimize paint overspray on hangar walls and ceilings:

- Top of aircraft (vertical fin, radome, rotor head, tail rotor) to underside of ceiling - 10 ft (3.0 m); For hangar bays required to have draft curtains, clearance must be to lowest point of draft curtains.
- Nose of aircraft to hangar door - 10 ft (3.0 m);
- Tail of aircraft or tail rotor to exhaust target wall - 10 ft (3.0 m); and
- Horizontal and vertical clearance from aircraft to inside face of open front door - 5 ft (1.5 m). In addition to these clearances, an approximate thickness of the supply and exhaust plenum (T) is required to properly size the gross area of the hangar bay. The equation T = 1/5H defines this approximate depth where H is the height of the aircraft at its highest point plus 5 ft (1.5 m). Note that the depth (T) does not include the thickness of the structure of the door or the filter media. The actual plenum thicknesses are dependent on the airflow required to ensure laminar flow in the hangar and as appropriate for the corrosion control and painting activities.

- Additional clearance between the work platforms and the hangar walls should be considered with respect to circulation space around the aircraft and avoiding pinch points, particularly at the wing tips. Consider tug and cart travel including turning radiuses in developing the required circulation clearances.

Base the number of hangar bays for each site on an analysis of aircraft types, production schedules, hours required for each corrosion control operation, and number of work shifts. Moveable partitions to subdivide the bay are discouraged, as they introduce complications to exiting, fire protection, air flow and balance. Separate spaces where painting is being done from bays in which dry stripping, blasting, or grinding are done.

2-5.4 Ancillary Spaces.

Provide the following Ancillary spaces as a minimum for the Facility

- Ancillary space requirements will vary based on facility requirements. Provide spaces for paint mixing, paint storage, waste paint area, bead blast rooms, gear equipment and tools, office, nondestructive inspection, strip/rinse, paint spray, and dry storage. Base the size of the rooms on the workload. Provide exit doors to the outside for rooms designated for storing or mixing chemicals or paints. Provide a depressed floor slab or doorsills with ramps to contain spills. Separate spaces where sanding, blasting, or grinding are done from spaces where painting is done.
- Provide storage space for dry filters. Provide stairs for personnel and a jib crane for materials transport to the roof or upper floors.
- Provide a loading dock with a manual dock leveler.
- Provide space for work on composite parts including helicopter rotor blades if applicable.
- Locate utilities on the side walls. Use of utility pits in hangar floors is prohibited.
- Decontamination Facilities (See Figure 2-5 for a schematic showing separation of clean and dirty areas):
- For operations where employees may be exposed to harmful contaminants, provide the following:

  a. An Initial Decontamination Area inside, or adjacent to the hangar bay. Provide HEPA vacuum for removing accumulations of contaminants from PPE. When located in the Hangar Bay, this area must be on the “clean side”, i.e. close to the supply air side and away from the exhaust air side.

  b. A walk-through vestibule with air shower (Air Lock) to capture contaminants between the Initial Decontamination Area and the Initial Accumulation Point.

c. An Initial Accumulation Point with space for drums for disposable PPE.

d. Provide an area with a sink for cleaning, drying and storing respirators.

e. Shower facilities with hot and cold water.

f. Change rooms with separate lockers for protective clothing and street clothes.

g. Toilet facilities must be located on the clean side of the locker rooms.

- Paint Mixing Rooms:

  All dispensing or transfer of flammable liquids from containers, mixing of flammable liquids, and filling of containers, including paint guns and pressure pots must be done only in an approved spray booth or mixing room. A separate paint mixing room will significantly reduce the amount of clutter in the paint booth. A properly designed and located paint mixing room must accommodate all equipment, cabinets, and tables associated with paint mixing and daily-use storage of paints and thinners, which otherwise, would be housed within the confines of the paint booth. Installing prefabricated mixing booth is a simple method to incorporate a separate mixing area into a new or existing facility.

  The design requirements in Chapter 3 are generally applicable to Paint Mixing Rooms. Additional requirements are listed below:

a. The size of the mixing room must not exceed 150 ft2 (14 m2).

b. Must have continuous mechanical ventilation as specified in NFPA 30.

c. Mixing rooms should be provided with a floor drain to make it possible to wash down spills. However, local installations must ensure that collection sumps are installed in the floor drain system and (or) that the wastewater treatment plant can process the spillage. If this is not the case, local installations must develop an alternate means of cleaning up the spillage.

d. Agitators must be driven by compressed air, water, low-pressure steam, or electricity. If powered by an electric motor agitator must meet all electrical codes and standards.

e. An EyeWash/Safety Shower must be located inside or adjacent to a Paint Mixing Room.

- Flammable and Combustible Liquid Storage

  Storage of flammable or combustible storage, in cabinets, specially designed room within the facility or in a detached structure is required.

  Design must comply with UFC 3-600-01, NFPA 80, and 29 CFR 1910.106. AFOSHSTD 91-17 also applies for Air Force Projects.

2-6 HEALTH, SAFETY AND THE ENVIRONMENT.

Planning activities for an ACCPF must address all requirements for worker health and safety, and environmental permitting. Compliance with all health, safety, and environmental regulations is required and is achievable without significantly disrupting the operations if adequate advanced planning and coordination is performed. These issues must be incorporated into the selection of HVAC Systems per this Chapter and Chapter 3. Appendix C provides an overview of the applicable environmental standards.

This Page Intentionally Left Blank

CHAPTER 3 GENERAL DESIGN CRITERIA

3-1 GENERAL.

UFC 1-200-01 provides applicability of model building codes and government-unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, sustainability, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

3-2 ARCHITECTURE.

3-2.1 Exterior Design.

3-2.1.1 Specular Reflectance.

To prevent mirror-like reflections from building surfaces to aircraft in flight, roofs and other external surfaces must have a specular reflectance compatible with the location of the building on the airfield.

3-2.1.2 Operational Hazard Glare.

If the building is located so that glare may be an operational hazard, the critical surfaces of the building must have a light reflectance of not more than 10, measured at an angle of 85 degrees in accordance with ASTM D523, *Standard Test Method for Specular Gloss*.

3-2.1.3 Roof.

The roof must be a smooth surface type or metal standing seam system. Exposed fastener (“Screw Down”) metal roofs must not be specified. If a membrane roof is chosen, gravel or any other material which could become loose and carried off the roof in high winds will not be permitted. The membrane must be specified as being capable of flexing in both directions independent of the roof structure.

Provide exterior access to the high roof the through a secured access panel or hatch, to prohibit unauthorized passage.

Roofs must slope only to the rear or sides of the hangar and not towards the flightline.

3-2.1.4 Exterior Walls.

Exterior walls must be impact resistant material coated with a weather resistant baked on PVDF finish or similar product.

Provide seals at doors, wall penetrations, and building joints in the hangar bays and ancillary spaces to ensure airtight performance to maintain pressure differentials and prevent contamination of the air in the hangar bay.

3-2.1.5 Doors.

3-2.1.5.1 Hangar Doors.

Hangar doors defined in this section are a specialized, insulated, hangar Supply Air type with swinging or sliding leaves. These doors are designed to serve as insulated supply air plenums when closed. Eighteen (18) gauge galvanized steel perforated plates are to be placed on the inside face of in the supply air plenums with a means to allow for balancing air of distribution to achieve evenly distributed laminar flow in the hangar bay. The hangar door acts as a plenum, thus see Section 3-5.2.8 Ventilation System Configurations for additional design criteria to construct Supply and Exhaust Plenums for horizontal laminar air flow. Other arrangements may be used if the required calculations are performed or if alternative successful designs can be proven. A Computational Fluid Dynamics study is required or other means of verification of the air delivery method if the proposed system is unproven.

The hangar doors must be electric motor operated. Each leaf must operate independently from its' own drive unit. Each drive unit must have a release mechanism, and the doors must be provided with a means of mechanical attachment for movement in the event of power failure. The minimum speed of door travel must be 60 feet (18.29 meters) per minute. Thresholds must be designed to minimize dirt accumulation and ice buildup.

Control of the doors must be by momentary contact type push buttons located near the leading edge on both sides of the door with limit switches on each door leaf to stop door movement. Safety devices must be installed to prevent injury to personnel and damage to equipment by moving door sections. If personnel access doors are provided in the hangar door leaves, an interlock must be installed at each access door to prevent operation of the hangar door leaves when the personnel access doors are open and halt the hangar door leaves in the event a personnel access door is opened while the hangar door leaves are in operation. An alarm must sound in conjunction with safety warning beacons when doors are in motion. Sliding steel hangar doors must be in accordance with UFGS 08 34 16, *Corrosion Control Hangar Doors*.

Configure horizontal sliding hangar doors such that they are operable during power outages, by both manual and electrical means (electrical means via emergency power).

3-2.1.5.2 Other Doors.

No hold-open devices are permitted. Take special precautions to seal doors between hangar areas and exterior or adjacent spaces.

Exterior doors with closers must be Level 4, physical performance Level A doors complying with ANSI/SDI A250.8. Frames must match door level. Exterior door frames must be welded type.

Provide Grade 1 hardware typical. Locksets must be mortise type, Series 1000 as defined by ANSI/BHMA A156.13. Hinges for all doors must be rated for heavy-duty. Closers must be the best and highest grade available from each manufacturer. Exterior doors must have overhead rain drips and door drips.

3-2.2 Interior Design.

3-2.2.1 Interior Walls.

See UFC 1-200-01, NFPA 101 and the IBC for general area separation requirements for interior walls. For Army and Navy projects, separate hangar bays in multiple-bay structures by 3-hour fire-rated walls. For Air Force projects, see ETL 02-15 for separation requirements.

Provide wall penetrations and building joints in the hangar bays and ancillary spaces to ensure airtight performance to maintain pressure differentials and prevent contamination of the air in the hangar bay.

The hangar bay must be provided with durable finishes. The exterior walls must have as a minimum, a protective panel along the exterior walls that will prevent damage to the exterior finish system. Generally, a hangar bay will be comprised of metal wall panels and protection must be provided from the interior of the hangar bay. The minimum protection can be provided by a non-insulated metal panel attached to the wall panel girts. The protective panel must extend to at least 7 feet (2.13 meters) above the hangar floor. Alternatively, a masonry panel may be provided.

All unfinished items must be painted. A wall base is not required in the hangar bay.

Partitions must extend to the floor or roof construction above unless allowed in the following sections.

Walls must be painted concrete masonry units or concrete around shop spaces. For shops without ceilings, partitions must extend to floor construction above.

Partitions separating administrative spaces may be gypsum board construction. Partitions may extend to above the ceiling for similar office types and spaces where noise between offices is not an acoustical issue. Extend walls to ceiling adjacent to noise-producing areas. Paint all unfinished materials.

Provide Concrete Masonry Unit (CMU) partitions around toilet and locker rooms. Partitions around perimeter of space must extend to floor or roof construction above. Provide ceramic tile wainscot and ceramic base. Provide ceramic tile wall finishes to the ceiling on all walls in showers.

3-2.2.2 Surface Treatment.

Provide the sidewalls, the inside of hangar doors, and the ceiling of the hangar area with a light color, smooth surface such as white enameled metal panels.

3-2.2.3 Floors.

Floors must meet the following criteria:

- The hangar area floor must be designed in accordance with criteria in UFC 3-260-02, *Pavement Design for Airfields*.
- Design other floors in accordance with UFC 1-200-01. Install resilient tile or sheet floor coverings.
- For new construction, provide a white dry shake floor hardener as the topping on the floor slab in the hangar area. Use of a thin epoxy white reflective floor coating is not recommended

3-2.2.4 Ceilings

Aircraft bays and paint storage, mixing, and spray areas must have water-resistant gypsum ceilings or a metal panel ceiling system. Provide a 1-hour fire-rated ceiling in paint bays. Consideration should be given to utilization of the ceiling deck above the hangar bay as a walking surface for access to the overhead light fixtures and also mechanical and electrical distribution systems generally located in the ceiling space above the hangar bay.

Provide suspended acoustical ceilings for corridors, toilets, locker rooms, and offices. Install suspended acoustical ceiling panels with vinyl plastic surfaces in shower areas.

3-2.3 Acoustics.

Develop a comprehensive acoustical design for the facility as required by UFC 3-101-01. Design the facility to provide a comfortable acoustical environment that limits exterior and interior noise intrusion to sensitive spaces.

Due to the industrial nature of a Corrosion Control Facility, an Acoustical Study must be performed on all occupied spaces during the design phase of each project. This study will entail assigning ambient noise levels to every occupied space, identifying all sound generating equipment and sources, then determining the method of sound isolation or reduction required to meet the required ambient noise levels.

Once the project construction is complete and all noise generating sources are operational, a sound level check must be performed to verify that predicted ambient noise levels have been met. Spaces not meeting the sound design levels will require additional acoustical treatment to bring all areas into compliance.

3-3 CONVEYING SYSTEMS.

3-3.1 Weight Handling Equipment.

Weight Handling Equipment must be of spark-proof construction with an explosion-proof motor. Controls must be operable from the floor level and, when electric, must meet the requirements indicated in Chapter 3, Electrical.

3-4 PLUMBING.

3-4.1 Water and Sewer

Provide plumbing in accordance with UFC 3-420-01 and as follows:

- Provide one shower for every ten (10) employees (or fraction thereof) of each sex who are required to shower during the same shift. Each rest room must have direct access to appropriate lockers and showers.
- Emergency eyewash/safety showers where required must conform to Appendix D of UFC 3-420-01.
- Floor Drains in the hangar area, paint mixing rooms and paint equipment cleaning rooms must be connected to the Industrial Waste system or piped to an isolated holding pit for testing to determine proper disposal of effluent
- Locate storm-water drains at least 12 in (310 mm) from the hangar access door rails.

3-4.2 Industrial Waste.

Provide a connection to an Industrial Waste Treatment System or to a collection containment tank or pit from all drains in process areas.

Provide for zero discharge from the facility unless the facility will discharge to an existing or new industrial waste treatment facility (IWTF) or to a municipal sewer system. The IWTF must be capable of handling both the type and volume of the chemicals that will be discharged. Disposal into a municipal sewer system requires a minimum pretreatment in compliance with 40 CFR Part 403, or AFI 32-7041.

3-4.3 Control of Hazardous Effluents.

Provide AFFF/Sprinkler discharge collection/retention system when required by environmental regulations for testing and pre-treatment prior to discharge into the appropriate waste stream. For design of containment systems and disposal requirements for AFFF solution, refer to ETL 1110-3-481, *Containment and Disposal of Aqueous Film-Forming Foam Solution*.

The corrosion control process generates large amounts of water that could potentially hold solid or liquid paint residue or other solvents and wastes. If the local wastewater treatment plant cannot accept the effluent generated from the facility, on-site treatment or containment and off-site disposal is required. Refer to UFC 4-451-10N, *Design: Hazardous Waste Storage*, and UFC 4-832-01N, *Design: Industrial and Oily Wastewater Control*. Design for accidental spill of paint strippers and thinners, paint, cleaning solvents, pretreatment chemicals, fuel or oil. Provide above-grade containment of accidental spills with appropriate sumps for pumping and cleanup of spilled wastes. Size the containment capacity for the largest possible discharge. Provide a method to prevent the drains from clogging.

3-4.4 Compressed Air.

Provide low-pressure air for operation of tools and for breathing air in accordance with the following criteria:

- Provide low-pressure compressed air at 40 percent to 60 percent humidity and at 125 psig (862 kPa) for shop use. Air should be oil-free to prevent paint contamination. Air outlets supplying tools requiring lubrication should be equipped with an in-line lubricator. Rotary oil-free compressors are recommended since this compressed air may be used as a source for breathing air at lower life cycle costs.
- Provide low-pressure compressed air at 20 psig (138 kPa) or higher if required, at 40 percent to 60 percent humidity for breathing air in the hangar bays. The breathing air compressor must minimize moisture content so that the dew point is 10 degrees Fahrenheit (5.56 degrees Celsius) below the ambient temperature. Breathing air must be obtained from the oil-free shop air source through final purifiers in each bay or from a separate breathing air compressor and piping system that meets requirements by OSHA for minimum Grade D air as described in ANSI/CGA G-7.1 Commodity Specification for Air. Breathing air from the oil-free shop air source is preferred because of lower cost.
- The air outlets (quick connect fittings) for oil-free shop air, lubricated tool air, and breathing air must be different for each service and must not be compatible with each other.
- Typical outlet quantities for each bay are: four breathing and four oil-free shop air and two lubricated tool air. Typically, two oil-free shop air outlets are required per ancillary space. Verify actual requirements for each site.
- Locate the intake for breathing air in an uncontaminated area. Air-line respirators approved with a vortex tube will substantially reduce the temperature of the air supplied to the respirator in cases where the supplied air is from a high temperature environment

3-4.5 Process Systems.

The chemicals used in the aircraft corrosion control process can be hazardous to workers, corrosive to the facility infrastructure, and require considerable floor space to store, access, and distribute. The Using Activity must provide a complete list of all chemicals used in the process with relevant MSDS's to the design team during the planning and design phases to insure that the facility can control the hazards appropriately. The data sheets will also be utilized in the design of the process systems to select compatible materials to contain and distribute the process chemicals used in the aircraft preparation and painting.

3-5 HEATING, VENTILATING & AIR CONDITIONING (HVAC)

General requirements for HVAC design are identified in UFC 1-200-01. Additional design guidelines for LonWorks® based control systems include UFC 3-470-01,

Lonworks (R) Utility Monitoring and Control System (UMCS), and UFC 3-410-02, *Lonworks (R) Direct Digital Control for HVAC and Other Local Building Systems.*

3-5.1 Hangar Bay HVAC Process Requirements.

A. The required hangar bay design heating temperature will normally be between 70 degrees F (24 degrees C) and 90 degrees F (32 degrees C) with a relative humidity between 50 and 70 percent. Some activities may require higher temperatures to accelerate curing cycles. Process temperature & humidity requirements for the CCF Hangar Bay will be the more stringent of either the following:

- environmental requirements from the coating material manufacturer
- personnel heat stress criteria requirements per USACE document EM 385-1-1, *Safety and Health Requirements Manual*, OPNAV Instruction 5100.23G *Navy Safety & Occupational Health (SOH) Program Manual* (specific ref. to Heat Safety) and AETC Instruction 48-101, *Prevention of Heat Stress Disorders*

a. Provide a snow-melting system at the hangar door tracks when the outside design temperature is +25 degrees F (-4 degrees C) or lower and when historical snow data supports the requirement.

b. Heating must be suitable for operation in the vapor hazard condition in the hangar bay, flammable storage/mixing areas and paint equipment cleaning spaces.

c. Refer to the Functional Data Sheets for design conditions in the ancillary spaces.

d. Provide a means to meter separately the ancillary HVAC loads from the Process Ventilation loads.

e. The design of a Depot Level facility must include equipment redundancy relative to the projected aircraft throughput for all systems where a critical component failure would render the facility's mission non-operational and repair or replacement timing would delay the schedule objective.

3-5.2 Ventilation for Control of Air Contaminants and Flammable Vapors

3-5.2.1 Ventilation – General.

The objective of the process ventilation design is to provide a system that is safe, energy efficient and cost effective (installation and maintenance) and environmentally compliant while maintaining the primary goal of ensuring operator health and safety at all times.

NOTE: All facilities must be designed to the requirements of 29 CFR 1910.94 *Ventilation*, 29 CFR 1910.106, *Flammable and Combustible Liquids*, and 29 CFR

1910.107, *Spray Finishing Using Flammable and Combustible Materials* as well as NFPA 33 and Subpart Z of 29 CFR 1910.

3-5.2.2 Paint Spray Systems.

The use of High Volume Low Pressure (HVLP) and HVLP electrostatic paint application techniques greatly reduces the amount of overspray exposure to workers, versus conventional air atomization or air-assisted airless. The reduced overspray increases exhaust filter life. The use of electrostatic paint systems also reduces the airflow requirements (per 29 CFR 1910.107) and related fan size and horsepower. When working *inside* the aircraft, portable supply and exhaust ventilation systems may be needed to control occupational exposures in the enclosed space.

3-5.2.3 Supply Air Requirements.

Provide ventilation in accordance with NFPA 33 and ANSI/AIHA Z9.2, AIHA Z9.4, and ANSI/AIHA Z9.7; refer to Appendix B for further guidance. For conventional air atomization paint spray systems operating within a “Paint Booth”, the supply air system must furnish 100 percent filtered outside air at a horizontal laminar flow velocity of 100 fpm (0.508 m/s) across the entire cross section area of the hangar bay for worker safety and overspray control in accordance with OSHA.

Due to the large volume within aircraft hangars relative to the actual quantity of spray paint being applied, the designer may now define the paint operation envelope as a Paint Area instead of a Paint Booth. The Paint Area interpretation of aircraft paint operations is concerned with the envelop within and immediately surrounding the paint sprayers (29 CFR 1910.107 (a)(2)). The volume of outside air and the velocity of the airflow may be decreased from that required for an entire hangar bay under the conventional interpretation as a Paint Booth in accordance with OSHA and its interpretations for consideration of Paint Spray Areas vs. Paint Booths. The reduction of the airflow cross sectional area must be reviewed with the local Industrial Hygienist and Safety entities and verified with an airflow study as part of the design process. Ultimate interpretation and acceptance of a paint spray envelop designation as a Paint Area will come from the local Industrial Hygienist, Safety entities and the other “Authorities Having Jurisdiction”.

OSHA also allows for a reduction in airflow velocity for paint spray systems which improve capture and reduce overspray. The minimum maintained air velocity required for hand held electrostatic paint spray operations as specified in 29 CFR 1910.107 (b)(5)(i) is 60 linear fpm. However, the requirements currently contained in 29 CFR 1910.94 (c)(6)(i) Table G-10 are somewhat more lenient and allows a range of 50-75 linear fpm. Due to the minor variations in these requirements, any Design Team planning a paint facility that will be used exclusively for electrostatic paint spraying must contact their local fire protection and bio-environmental engineering functions for guidance on current local OSHA interpretations.

Additional considerations for reducing the air volume requirements through a hangar bay during paint spray operations are as follows:

- Minimize the open cross sectional area in the hangar bay during the design of the hangar structure to reduce the total quantity of airflow while maintaining a safe, efficient working environment.
- Airflow recirculation may also be investigated as a means to reduce energy usage while still maintaining worker safety. See Section 3-5.2.7 Consideration of Airflow Recirculation and Section 2-3 HVAC System Planning & Selection.
- NOTE: Recirculation of exhaust air or reduced air flow during painting may result in a DeMinimus violation from OSHA. See Appendix D, Fig. D-2 – OSHA Interpretation regarding the DeMinimus violation.

Ventilation and airflow requirements for chemical de-paint operations are dependent upon the makeup and toxicity of the material being applied to the aircraft for paint removal. The de-paint material manufacturer must be consulted to obtain the applicable MSDSs for the determination of the appropriate ventilation rate.

Filtration must be provided for the Supply Air upstream of the supply fans and in the supply plenum doors. The filters must have a MERV 5 or better rating on the basis of ASHRAE 52.2 *Method of Testing General Ventilation Air-Cleaning Devices Used for the Removal Efficiency by Particle Size.*

Note: MERV or Minimum Efficiency Reporting Value, is a measurement of air filter efficiency established by ASHRAE. The MERV number ranges from 1 to 16; the higher the MERV number, the higher the efficiency of the air filter at removing particulate matter.

3-5.2.4 Space Static Pressure Controls.

The ventilation system must maintain a slightly negative static pressure of -0.02 to -0.04 in. water gage between the hangar area and the exterior to prevent fugitive hazardous emissions from escaping the hangar envelope and entering the atmosphere. Some studies indicate that a slightly negative pressure in the painting area also provides for more superior painting and reduces turbulent flow. (Refer to *System-Level Computational Fluid Dynamics: Advanced CFD Tools to Solve Problems of Operational Conditions, States of Large-Scale Engineered and Natural Systems* for additional guidance.) Maintain a slightly higher pressure in the adjacent ancillary and overhead ceiling spaces outside the hangar area to keep the hazardous vapors given off by painting agents from infiltrating into these spaces. Ventilate the space above the hangar bay ceiling to provide a non-hazardous space for light fixtures.

3-5.2.5 Gauges, Safety Interlocks and Alarms.

Install visual gauges, audible alarms, and/or pressure activated devices on filters to ensure that the minimum air velocity or volume is maintained. Interlock the fans and the process air compressors so that the paint spray air compressors cannot operate when the fans are inoperative or below a preset minimum. Breathing air must **never** have an interlocked shut down. Interlock the fans and the fire protection system so that the fans

cannot operate when the fire protection system is inoperative. The electrical equipment used in the electrostatic spraying process must be interlocked with the ventilation spraying area so that the equipment cannot be operated unless the ventilation fans are in operation. The operation can be verified by a total air volume flow monitor through the hangar bay. Air flow volume, space static pressure, fan status, breathing air system, and other critical component failures must be monitored by the building automated control system. All critical alarms, notifications and status points must also be indicated on a control panel either within or adjacent to the hangar at an operator monitoring station. The location of the Critical Component Monitor and Alarm Panel must be incorporated into the emergency/fire response action plan. An audible and visual alarm system, which activates in the event of a ventilation or other critical system failure must be provided and made active during the paint spraying process.

3-5.2.6 Energy Conservation.

Reference UFC 3-400-01, *Energy Conservation.* Include energy conserving designs such as ice storage, heat recovery or air recirculation for the ventilation system serving the hangar bay as part of the initial design development of the overall ACCPF. Heat recovery systems must not permit contaminated exhaust air from migrating into the supply air system.

Exhaust stacks must be the “no loss” type as shown in ACGIH *Industrial Ventilation, a Manual of Recommended Practice*.

See section 2-3, HVAC System Planning and Selection for guidance in the evaluation of a cost effective, energy efficient ventilation system.

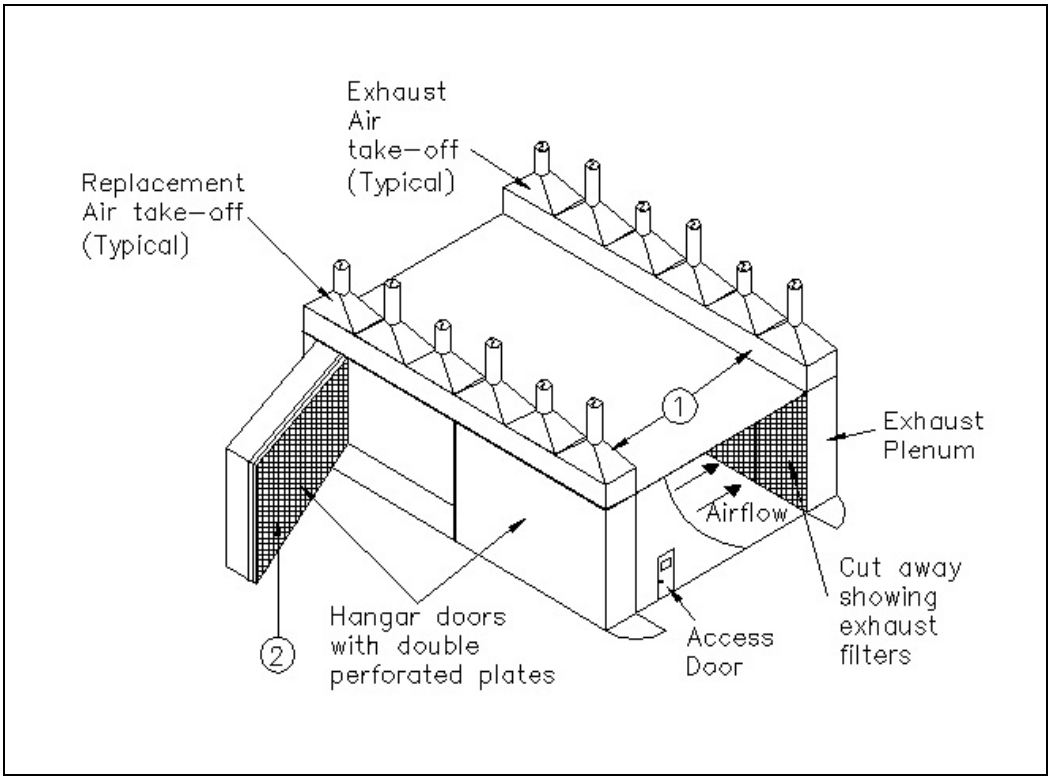
3-5.2.7 Consideration of Airflow Recirculation.

The determination of the most energy efficient process ventilation system includes evaluation of alternative methods designed to reduce or optimize energy usage. One method which can potentially reduce energy usage in a ventilation system is recirculation of the ventilation or exhaust air. See Section 2-3 HVAC System Planning & Selection for the evaluation process to determine the most cost effective HVAC process ventilation system for a specific application. If recirculation is determined to be a viable option, see NPFA-33 and ANSI/AIHA Z9.7 and appendix D in this document for the AFRL on Recirculation and OSHA interpretations which allow for reduction in equipment sizing and re-circulated air flow.

3-5.2.8 Ventilation System Configurations.

3-5.2.8.1 Hangar Bay Air Flow Design.

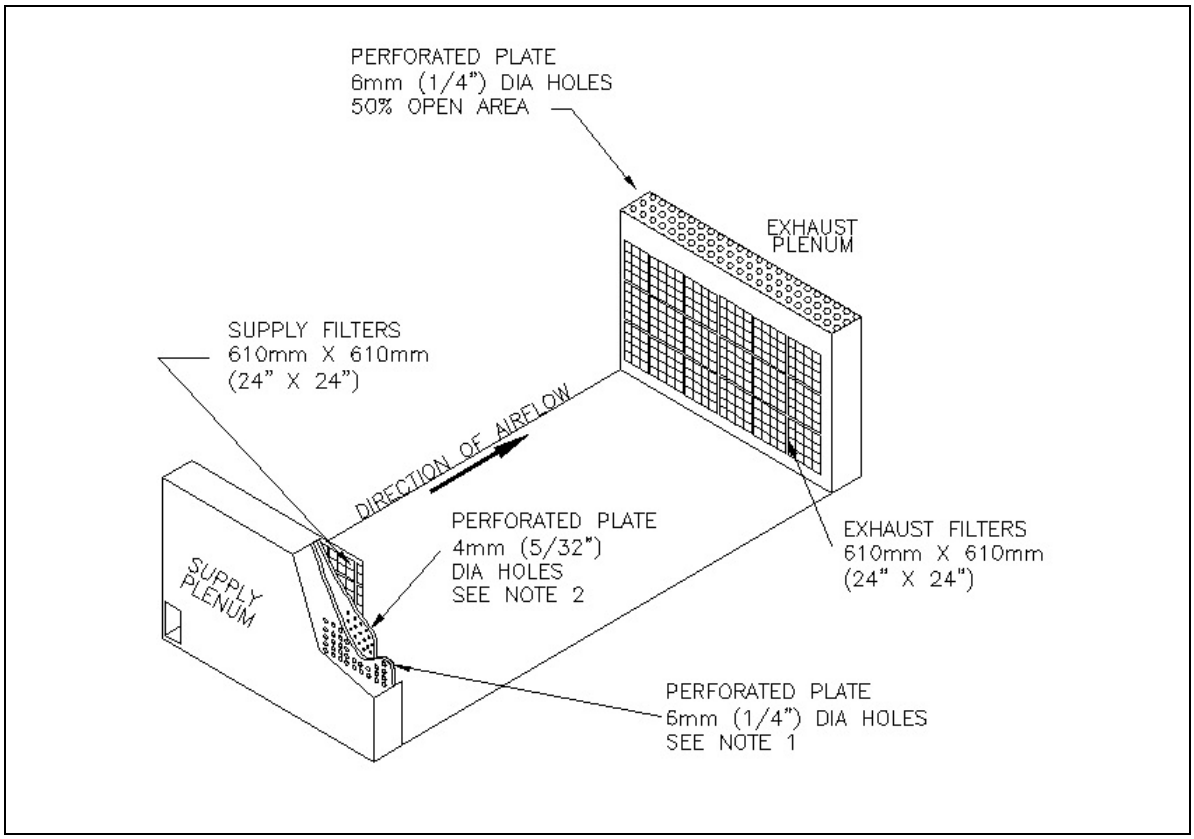
Design or specify the entire supply and exhaust air system using criteria for a horizontal flow hangar configuration with supply air direction from aircraft nose to tail. Figure 3-1 and Figure 3-2 are two methods of designing hangar horizontal airflow distribution. Other configurations must be appropriate for the aircraft mission and approved by the AHJ. Effective capture of the paint overspray and worker safety must be the primary



objective in determining the optimum airflow design. All designs for ventilation systems must introduce the makeup air in a laminar manner and minimize the creation of dead air pockets. This will help to capture the paint overspray and reduce the possible buildup of contaminants.

3-5.2.8.2 Hangar Door Plenums.

Air plenums may be incorporated into the design of the hangar doors as indicated in Figure 3-1. This design may be configured as a swing door as shown (most commonly utilized for fighter or similar sized aircraft), or a double rolling door arrangement where two sets of doors form an air plenum between the inner and outer sides. The double door configuration is generally selected for use with cargo or similar sized aircraft.



The incorporation of an air plenum into a hangar door requires that the air performance characteristics of the plenum remain primary in the Plenum/Door system. The integrity of the air side of the “Plenum Door” must always be maintained and not compromised in favor of space or door function considerations.

FIGURE 3-1. SAMPLE HORIZONTAL FLOW HANGAR CONFIGURATION

NOTES:
1. Size the exhaust plenum for a maximum plenum velocity of 1,000 fpm (5.08 m/s). Size the supply air plenum for a maximum plenum velocity of 500 fpm (2.54 m/s).
2. See Figure 3-2 for hangar doors and exhaust plenum details.
3. Although supply air is shown entering plenum/door from top, the more common supply air path is through door hinges.

FIGURE 3-2. SUPPLY AND EXHAUST PLENUM AIRFLOW CONTROL DETAILS

NOTES:
1. Size open area for an airflow velocity of 2,000 fpm (10.16 m/s) through holes.
2. Size open area for an airflow velocity of between 600 to 700 fpm (3 to 3.5 m/s) through holes.

3-5.2.9 Control of Air Emissions

3-5.2.9.1 Air Emissions Overview.

Emissions of volatile organic compounds (VOC), hazardous air pollutants (HAP) and particulates from surface coating facilities are regulated by USEPA and state environmental agencies via various air pollution regulations, including the National Emission Standard for Hazardous Air Pollutants (NESHAP) for Aerospace Manufacturing and Rework Facilities (40 CFR 63, Subpart GG). Consult the base environmental office and the cognizant Facilities Engineering Command for appropriate requirements for the site. Make every effort to achieve compliance with applicable regulations considering all available pollution prevention alternatives versus the use of VOC/HAP emission controls. Consider recirculation of airflow per NPFA-33 and ANSI/AIHA Z9.7. See appendix D for additional information for OSHA interpretations and the AFRL. Recirculation allows for pollution abatement sizing equipment reduction.

3-5.2.9.2 Aerospace Exhaust Filter Requirements.

A paint spray ventilation system is required to minimize the amount of hazardous air pollutants (HAPs) that are released into the atmosphere. The National Emission Standard for Hazardous Air Pollutants (NESHAP) for the Source Category: Aerospace Manufacturing and Rework Facilities ,commonly called the Aerospace NESHAP requires that particulate filters be installed in the ventilation system to control the inorganic HAP emissions(e.g., chromium, cadmium, lead for example) before they are exhausted to the atmosphere. Filters throughout must be made from noncombustible materials and must meet approval of the fire protection authorities.

Organic HAPS are Volatile Organic Compounds which cannot be captured by the particulate NESHAP filters used on the inorganic HAPS. The hazardous VOCs (or organic HAPs) include 1,1,1-trichloroethane, 1,1,2,2-tetrachloroethane, trichloroethylene, and toluene. VOC (solvent vapor) capture methods such as carbon bed filters must be utilized when hazardous VOC removal or control is required. The requirement to control or capture VOCs is a function of state or local regulations, dependent upon the specific location's classification as an "attainment" or "non-attainment" area per the EPA's designation. The local air quality authorities must be consulted in order to determine requirements for VOC abatement.

Determine the specific type of exhaust filter system required by an analysis of the environmental control regulations at the site of the proposed ACCPF.

3-5.3 HVAC for Ancillary Spaces.

3-5.3.1 Operational Ancillary Spaces.

Provide exhaust ventilation from the floor level for the paint mixing and storage rooms. Refer to *ACGIH Industrial Ventilation* (ACGIH IV)*, A Manual of Recommended Practice*. Also, paint mixing can be done on ventilated benches. Refer to UFC 3-410-04, *Industrial Ventilation*. Provide ventilation systems for paint mixing and paint equipment-cleaning rooms in accordance with *NFPA 33* and the *ACGIH IV*.

3-5.3.2 Administrative and Miscellaneous Support Spaces.

The ventilation design of all spaces adjacent to, in close proximity with, or otherwise possibly affected by the paint spray area operation must provide a positive static pressure relative to the paint spray area in order to prevent the migration of paint vapors into the non-spray areas. Measuring devices must be provided to visually identify the static pressure differential between the paint spray and non-paint spray areas.

3-5.4 Noise and Vibration Control.

Design mechanical systems and equipment to limit noise and vibration in accordance with UFC 3-450-01, *Noise and Vibration Control,* and OSHA Pub 3048, *NPC Hearing: Noise Control – A Guide for Workers and Employees*. Navy projects must also follow NAVFAC P-970, *Planning in the Noise Environment*.

Design hangar bay for maximum 75 dBA space average. Provide sound traps to attenuate fan noise down to this level. Noise levels of 55 dBA in the hangar bay area with the ventilation system operating at maximum airflow have been achieved with careful design attention to fan and duct noise characteristics. Outdoor noise levels must not exceed 75 dBA and must comply with local regulations.

3-6 FIRE PROTECTION AND LIFE SAFETY.

Provide fire protection in accordance with UFC 3-600-01, *Fire Protection Engineering for Facilities* and the following documents:

- Army. ETL 1110-3-485, Fire Protection for Helicopter Hangars, and ETL 1110-3-484, Aircraft Hangar Fire Protection Systems.
- Navy. UFC 4-211-01N, *Aircraft Maintenance Hangars: Type I, Type II and Type III.*
- Air Force. ETL 02-15, Fire Protection Criteria - New Aircraft Facilities, and ETL 98-8, Fire Protection Criteria - Existing Aircraft Facilities.
- NFPA 33, Standard for Spray Application Using Flammable or Combustible Materials;
- NFPA 101, Life Safety Code

Note: Foam Fire Protection is not required for hangars housing aircraft that are defueled and purged or have their fuel cells removed. The requirements in NFPA 409 for unfueled aircraft must be followed for these situations.

3-7 ELECTRICAL.

3-7.1 Electrical Installations.

3-7.1.1 General.

Provide electrical systems in accordance with UFC 3-501-01, *Electrical Engineering* and as follows:

3-7.1.2 Power.

All Areas - Provide separate dedicated panel boards to serve each separate use area.

Hangar Bay - Electrical equipment in the hangar bay must be waterproof or water protected when AFFF and/or deluge water protection is provided to prevent equipment damage in the event of testing or accidental discharge of the deluge system.

Power Service Points:

- Service Points for Ground Service Equipment (GSE), Portable Lighting, or other portable support equipment must meet requirements of the hazard classification of the space.

- Air Force only – The 6-pin “WMJ” receptacle may not be permanently installed in a depot paint/depaint or CCF hangar bay. The “WMJ” receptacle may be installed as a temporary GSE power supply only when non-painting activities are taking place. The “WMJ” receptacles must be removed prior to the initiation of paint/depaint operations.
- External aircraft power provided by the power service points must be within the voltage and frequency tolerances specified for aircraft type. The flexible power cable to the aircraft must be adequately sized to meet the specified aircraft loading (amperage) requirements.
- Three phase, 115/200V, 4-wire, 400 Hz, (kVA ratings as required by aircraft type). Refer to UFC 4-121-10N, *Design: Aircraft Fixed Point Utility Systems* for 400 Hz power requirements and to criteria for hangar bay space power and grounding requirements for aircraft maintenance. Spiral wrapped, six around one, flexible cables, designed specifically for 400-hertz systems must be used. The cable must consist of six power conductors, two per phase, helically laid around one central neutral conductor. The conductor size must be based on the KVA rating of the aircraft type. The cable must also contain a minimum of six control conductors, minimum size # 18 AWG.
- 270 VDC Power, and 28 VDC (interlock power), ratings as required by aircraft type. The 270 VDC power cables must be low inductance, low impedance in order to minimize cross-coupling. The 270 VDC cables must also contain 28 VDC safety interlock wiring. The conductor size must be based on the KVA rating of the aircraft type.
- 28 V direct current (kVA ratings as required by aircraft type) Coordinate with the activity.
- WARNING: Aircraft external power supplies are not rated for the hazard classification of a Paint Spray Bay (Class 1, Division 1). Therefore, all activities requiring the use of external power must be completed, the power cord disconnected from the aircraft and the power to the cord disconnected outside the hangar bay prior to the commencement of spray paint operations.

Emergency Power.-Emergency power must be provided to ensure safe egress from any point within the facility. Emergency power must also serve any component that is required for safe egress from any location on an aircraft in the hangar bay. Availability of breathing air must be included in the emergency egress considerations. Hangar doors must also be operable via emergency power. Coordinate and provide additional emergency power as dictated by the mission. A distinct audible and visual alarm must be initiated whenever the facility experiences a loss of main power

Ancillary Spaces. - Serve shop spaces by distinct panels dedicated to shop and equipment loads only. Do not supply office spaces from shop circuits or panels. Except as specifically noted otherwise, feed loads located in the Shop space from panel boards

located in the Shop space; feed loads located in the Office space from panel boards located in the Office space.

3-7.2 Electrical Hazardous Classifications.

Electrical installations in the following areas must meet the requirements in NFPA 70, *National Electrical Code* for the specific hazardous (classified) location:

- Hangar area,
- Paint and chemical mixing rooms,
- Paint equipment cleaning room,
- Paint storage room.

3-7.3 Grounding.

Provide grounding in accordance with UFC 3-575-01, *Lightning and Static Electricity Protection Systems.*

3-7.4 Lighting.

Provide lighting in accordance with UFC 3-530-01, *Design: Interior and Exterior Lighting and Controls*, and as described below:

- Avoid the use of explosion-proof overhead fixtures by providing sealed, ventilated space above the finished ceiling. Fixtures may then be installed above the classified space.
- Hangar Lighting level – Interior lighting level of 100 FC measured 30 inches from floor must be available for Painting Operations inside the hangar bay. A lesser lighting level may be provided during non-critical operations to be determined by the Operating Group.
- Controllable Hangar Bay Lighting - min. 50 FC up to 100 FC in hangar bay. Provide to the best extent possible a lighting arrangement and control which allows for staged control of fixtures which can provide 50 FC, 75 FC and 100 FC progressively to the hangar floor.
- Vertical aircraft surfaces must be considered and incorporated into the hangar interior lighting design. This lighting may be permanently installed in the side walls, on man lift platforms (if provided), or as portable units. A minimum of 70 FC must be used as the design lighting level for vertical surfaces. Note: Hazard classification must be maintained in all cases.

3-8 EQUIPMENT

3-8.1 Work Platforms.

3-8.1.1 Floor Supported Platforms (FSPs).

Floor supported platforms offer an economical means of accessing elevated aircraft surfaces. Typical FSPs include under wing service decks, vertical scissor lifts, rolling step platforms and telescoping boom lifts. This type of equipment is generally purchased separately from the facility construction budget and not included as part of real property. Consideration of this equipment during the planning phase, however, is essential to ensure sufficient clearance around the aircraft when the lifts are in place, and housing the lifts when not in use.

3-8.1.2 Overhead Telescoping Manlift Platforms (TMPs).

The overhead man-aboard TMPs offer a great deal of flexibility and efficiency of operation for an ACCPF. The TMPs are generally considered when large vertical surfaces such as Vertical Stabilizers or Rudders on large aircraft require access for painting, depainting or repair. The platforms themselves can be designed to carry a painter (or two), his equipment and a technician/spotter (driver).The TMPs become essential for a Depot Facility when timing is critical due to the required aircraft throughput. For a CCF, TMPs offer quick access to virtually any part of an aircraft needing repair or corrosion attention when immediate response is called for in the stated mission. TMPs also provide the advantage of offering access to a variety of aircraft.

TMPs impart a significant load on the structure of the facility and ultimately to the foundations. Therefore, inclusion or exclusion of TMPS must be established early in the planning phase.

As a practical solution, a combination of FSPs and TMPs are generally selected to most efficiently cover an aircraft for a specific corrosion control operation. A full definition and understanding of the mission of the facility is essential in forming the basis for the selection of these systems.

3-8.2 Fall Protection.

Personnel fall protection is required when work platforms are not adequate or practical to reach the upper surfaces of the aircraft or when personnel must walk on aircraft wings or other surfaces during corrosion operations.

3-8.2.1 Personal Fall Arrest System (PFAS).

The PFAS consists of a full body harness, attached to a vertical life line cable or self retracting device which is then connected to a horizontal lifeline (HLL) installed below the ceiling/roof structure.

The PFAS must comply with ANSI/ASSE Z359 Fall Protection Code/Product Standards and 29 CFR 1910. For Navy projects also see UFC 4-211-01N. For Air Force Projects, see AFOSHSTD 91-100, EM 385-1-1 Section 21, and AFOSHSTD 91-501.

3-8.2.2 Flexible Horizontal Lifeline (HLL) Systems.

The HLL system must be constructed of flexible material such as wire rope, fiber or webbing spanned horizontally between two end anchorages and may have intermediate anchorages (singe lor multi span), in-line energy absorber, life line tensioner and turn buckles. HLL system shall be designed and certified by a professional engineer who is qualified in designing HLL systems. The designer must consider the number or workers attached to the system, the sag of the line, clearance requirements and the strength of the end and intermediate anchorages. The design, layout and performance of the flexible HLL shall be traceable to test results and engineering calculations. Calculations that predict the performance of the system shall be validated by tests performed on the system in accordance with the requirements of the ANSI/ASSE Z359 Fall Protection Code/Standards.

3-8.3 Rigid Rail Lifeline Systems

The horizontal rigid rail system (trolly system) shall be constructed of rigid steel track(s), mounted hangers, end stops bumpers, splices and swivel eye trolly. The planner must consider the number or workers attached to the system.

3-8.3.1 Facility design for PFAS.

The most significant fall protection requirement from a facility design perspective is the large load capacity which must be built into the permanent lifeline anchor points attached to the building structure.

Design of anchorages for fall protection is addressed in UFC 3-301-01, *Structural Engineering*. It is imperative that the fall protection system be incorporated early in the planning stage of the facility to allow these loads to be realized and included in the structural design.

3-8.3.2 PFAS Installation.

A Turnkey “furnish & install” PFAS/HLL system by an experienced fall arrest specialist is recommended for best assurance of an ANSI and OSHA compliant system. The manufacturer or installer must provide calculations and drawings to verify that the system meets the design and operational requirements. The manufacturer/installer must also be responsible for testing and certifying the system, providing all verification documentation and training the facility personnel as a requirement for Government acceptance.

3-8.3.3 PFAS and Overhead Crane Coordination.

Hangars with bridge cranes represent a special challenge to the planner/designer in that the Overhead Cranes and PFAS often compete for the same space and the workers attached to their PFAS are at risk of having their life lines struck by the moving crane if both operations happen simultaneously. The first recommendation is to design the two systems so that there is never an overlap or interference. If this is not possible, then it must be mandatory that the two operations can never occur at the same time. If

personnel are within a crane runway area, the cranes must be locked out. Likewise, if the Overhead Cranes are to be operated, the PFAS must be physically relocated out of the path of the crane. It is important for the designers of aircraft hangars to understand the potential conflicts between the two systems and the means by which they can coexist.

3-8.4 Blast and Paint Booths.

See UFC 3-410-04, *Industrial Ventilation*, for Modular "Stand Alone" Paint Spray Booths and Dry Media Blast (DMB) De-paint enclosures. All utilities for the booths must be included in the planning phase of the primary facility. If the booth is to be installed in an interior space, provide sufficient space around the booth to allow for access to maintenance and cleaning.

3-9 SITE WORK.

3-9.1 Aircraft Pavement Design.

Aircraft pavement must be in accordance with UFC 3-260-02.

3-9.2 Site Lighting.

Orient exterior fixtures to minimize glare on ramps and taxi-ways. Refer to UFC 3-260-01, *Airfield and Heliport Planning and Design* for clearance requirements, obstruction lighting requirements, and airfield utility lighting information.

3-10 HEALTH SAFETY AND ENVIRONMENTAL CONTROLS.

3-10.1 Health and Safety

The following Health and Safety standards must be incorporated into the design of all Corrosion Control and Paint Finishing Facilities:

- 29 CFR 1910 Subpart D – *Walking-Working Surfaces*, Sections 1910.21 thru 1910.27
- 29 CFR 1910.94 – *Ventilation*, OSHA
- 29 CFR 1910.106 – *Flammable and Combustible Liquids*
- 29 CFR 1910.107 – *Spray finishing Using Flammable and Combustible Materials*, OSHA
- 29 CFR 1910.169 – *Air Receivers*
- 29 CFR 1910.179 – *Overhead and Gantry Cranes*
- AFOSHSTD 91-501 *Air Force Consolidated Occupational Safety Standard*
- EM 385-1-1 *USACE Safety and Health Requirements Manual*
- OPNAVINST 5100.23 *Series*

3-10.2 Environmental Controls.

The facility must comply with all applicable environmental regulations. The Whole Building Design Guide web site (http://www.wbdg.org/) provides information and links to the various laws and guidance documents pertaining to the environment. For site-specific information, contact the base environmental office and the local Facility Engineering Command.

The type of environmental controls required will depend on the pollution abatement regulations at the site and the type and quantities of paints used. Environmental controls can be a major construction and operating cost item; therefore, an accurate determination of regulations and paints (existing and proposed) is required prior to design. Design must be in accordance with environmental protection regulations per Appendix C.

This Page Intentionally Left Blank

CHAPTER 4 MEDIA BLAST HANGAR DESIGN CRITERIA

4-1 FUNCTION.

The basic function of a Dry Media blasting facility is to remove coatings and/or corrosion from aircraft, aircraft components, ground equipment, or other types of equipment in preparation for the application of surface coatings and corrosion treatment. Plastic Media Blast (PMB) media is the most common type of Dry Media Blast (DMB) abrasive used during depot and field level abrasive blasting operations. Other types of abrasive materials are used so design the facility to accept other abrasives.

During blasting operations, abrasives and the surface coatings on the blasted materials are shattered to varying degrees. This generates dust, which may contain particles of respirable size (0 to 5 micrometer). The composition and toxicity of the dust is often a health or combustion hazard.

A blast cleaning room is defined as an enclosed space where the worker operates the blasting nozzle inside with the component. A blasting cabinet is defined as an enclosure where the operator stands outside and operates the blasting nozzle through an opening or openings in the enclosure of the cabinet. This chapter defines requirements for facilities which are sized to accommodate entire aircraft. For Blast Cleaning Rooms and/or blasting cabinets, see ref. UFC 3-410-04, *Industrial Ventilation*.

4-2 DMB MATERIAL

4-2.1 DMB Material Combustibility

Data sheets for the Plastic Media blast (PMB) material indicate it is non-combustible at the particle size that the material will be initially used at (a PG-1 size which is 5% > 12 mesh, 12 mesh > 80% > 16 mesh and 16 mesh > 15% > 20 mesh). It is typical for many dusts that are not combustible until they reach a particle size of 420 microns or less in diameter (i.e., material passing through a U.S. No. 40 Standard Sieve). The PMB material behaves in this manner, being combustible when particles are small enough; and thereby having the potential to generate a dust explosion when enough of these very small particles are in a uniform fine suspension in air and are heated to a high enough temperature.

4-2.2 DMB Recovery.

Provide a system and equipment to recover, and reclaim the dry media. The media reclamation design must be in accordance with 29 CFR 1910.94. A pneumatic recovery system is recommended instead of mechanical recovery system for dry media (Mechanical systems tend to abrade the media).

Dust collectors must be set up so that the accumulated dust can be emptied and removed without contaminating other working areas or the workers.

4-2.3 DMB Recycling.

In the DMB process for aircraft stripping functions the blast media is recycled when particles are between 12 and 60 mesh. As particle size becomes smaller (i.e. pass through a 60 mesh sieve) the particles become uneconomical for the stripping process and these smaller particles are removed in the stages one and two of the media reclamation process. As particles between 12 and 60 mesh are recycled, some of the media that is returned to the stripping process falls in the particle size range that is combustible (i.e. between 40 and 60 mesh for the plastic media currently in use).

The following system elements are also required:

- Do not integrate the exhaust ventilation system with the media recovery system
- Protect the media recovery system and ductwork from moisture and rainwater intrusion to keep the media from caking and plugging up the system.
- Use a pneumatic recovery system instead of mechanical recovery system for plastic media. (Mechanical systems tend to abrade the media.)

4-2.4 PMB Hangar Cautions.

The premise of the building design is that the system interlocks, media recovery, media recycling, interior space design and housekeeping policies must be such to minimize the amount of small dust particles that may accumulate anywhere in the hangar. The Interior design must emphasize the exclusion of horizontal areas where dust may settle. However, due to the constant generation of this dust, specifically during the depaint process, the space must be rated as hazardous for dust, as absolute control over dust buildup is difficult to achieve. Designers must be aware that PMB materials in a laboratory setting have been shown to form dust clouds that can result in dust explosions. Research reports by US Bureau of Mines have concluded that:

- As delivered PMB material is not hazardous with respect to potential explosion hazard. This refers to material in the 12-16 Mesh size range when delivered, and 12-60 Mesh size range when recycled.
- In PMB media where all material is fine i.e. below 40 Mesh, an explosion is possible under some conditions in an explosive test chamber with a spark igniter.
- In PMB where all material is very fine i.e. all below 140 Mesh, an explosion is likely in an explosive test chamber with a spark igniter.

4-3 WASH RACKS FOR DMB OPERATIONS.

The Aerospace NESHAP requires residual dust resulting from de-painting by DMB be completely removed. In response to this requirement, locate a Wash Rack as close as practical to the Dry Media De-paint Hangar and include this in the planning phase of a new DMB DF. Note that the DMB hangar itself must not be used for the aircraft wash process.

4-4 ARCHITECTURAL AND STRUCTURAL REQUIREMENTS.

Design each hangar for the size and configuration of the specific aircraft to be handled. Determine work-bay dimensions, ceiling heights, and door openings by the aircraft dimensions. Determine the number of work-bays by the workload. In addition to the following specific requirements, design the DMB Depaint hangar using the general architectural criteria set forth in Chapter 3.

4-4.1 Interior Surfaces

In addition to the requirements in Chapter 3, blast bay must be a fully lined and sealed space with hard, light-colored, smooth, surface provided on walls, inside surfaces of doors, and ceilings; all joints sealed, and doors made weather tight to prevent migration of dust into the cavity behind the wall or ceiling. Horizontal surfaces and ledges (Cabinet tops or beam flanges) must be covered with a sloping surface such that the accumulation of dust is mitigated.

4-4.2 Use Group Classifications.

DMB hangar bay area must be classified by the IBC as a Factory and Industrial use group F-1.

4-4.3 Other Architectural Requirements

- Isolate the abrasive blasting operations from other processes, functions, and activities to eliminate contamination.
- Doors on blast bays must be operable from both inside and outside, except that where there is a small operator access door, the large work access door may be closed or opened from the outside only
- An observation window and an access door(s) must be provided in accordance with 29 CFR 1910.94 and AIHA Z9.4. Position the observation window(s) in the hangar bay walls as required to allow for continuous observation of the workers inside the hangar bay from outside the space. Provide the number of doors and windows as appropriate for the size of the hangar bay
- Provide emergency exits on opposing walls. Make sure personnel doors are operable from both inside and outside of the room. Doors must be flanged and tight when closed.

4-5 MECHANICAL REQUIREMENTS.

Design the DMB De-paint Hangar to meet the criteria set forth in Chapter 3, with the following special requirements:

4-5.1 Plumbing.

Industrial waste drainage system must not be installed inside a DMB Depaint hangar bay. No floor drains are to be installed in the hangar floor.

4-5.2 Ventilation for Control of Air Contaminants.

Determine the type of dust hazard and the minimum average air velocity through the blasting enclosure in accordance with 29 CFR 1910.94. The ventilation systems must be specifically designed to remove dust in the combustible particle size range.

Blast-cleaning enclosures must be exhaust ventilated in such a way that a continuous inward flow of air will be maintained at all openings in the enclosure during the blasting operation.

The air exhausted from blast-cleaning equipment must be discharged through dust collecting equipment.

Interlock the ventilation system with the blasting equipment power supply. This will prevent the use of the blasting equipment without proper ventilation controls.

4-5.3 Noise and Vibration Control.

Design mechanical systems and equipment to limit noise and vibration in accordance with UFC 3-450-01. The DMB Depaint operation and the media support equipment generate significant levels of noise by the nature of the process. Special design emphasis therefore must be placed on separating the DMB spaces from the non-DMB occupied spaces to ensure proper sound levels are maintained through out the facility.

4-6 ELECTRICAL REQUIREMENTS.

Design the DMB Depaint Hangar to meet the criteria set forth in Chapter 3 GENERAL DESIGN CRITERIA with the following special requirements:

4-6.1 Hazardous Classification.

Due to the constant presence of dust generated by the DMB depaint process, the potential exists for there to develop an explosive atmosphere in the hangar bay at certain times during the DMB operation, regardless of the emphasis on dust mitigating design and housekeeping diligence. Therefore, the hangar bay must be classified as a Class 2, Division 1 space per NFPA 70.

4-6.2 Grounding.

Provide grounding in accordance with UFC 3-575-01, *Lightning and Static Electricity Protection Systems.*

4-7 FIRE PROTECTION.

DMB Depaint operations are performed only on defueled aircraft. Fire protection requirements for facilities housing only defueled and purged aircraft follow NFPA 409

guidelines which allow the use of sprinkler systems for area protection in the hangar bay. Foam fire protection systems are therefore not necessary for facilities containing aircraft that are defueled and purged or have their fuel cells removed. Aircraft entering sprinkler protected hangar bays must have all fuel tanks defueled and purged. Signs must be installed on all access doors and hangar doors stating “NO FUELED AIRCRAFT” for facilities with sprinkler protection only in the hangar bay.

This Page Intentionally Left Blank

CHAPTER 5 CHEMICAL DEPAINT DESIGN CRITERIA

5-1 GENERAL DESIGN REQUIREMENTS.

ACCPF designed in accordance with Chapter 3 of this document will generally be able to meet the criteria required for chemical depaint operations. Special attention must be given to the interior surfaces (floors, walls, ceilings, trenches, pits) that could come in contact with the paint removal solution due to the inherent corrosive properties of the chemicals. Also, the chemical depaint solution is considered toxic and with the removed paint hazardous waste, requiring specific industrial waste treatment to maintain the mandated zero discharge or meet the input requirements of the Industrial Waste Treatment Plant serving the facility.

5-2 CHEMICAL DEPAINT (ONLY) FACILITIES.

Ventilation air requirements for chemical depaint only facilities may be reduced from a paint finishing facility due to the reduced flammability and toxicity of the current paint removal processes. This evaluation will require 1) exclusion of the depaint facilities from paint spray operations and 2) verification of the reduced flammable properties of the depaint solution and 3) concurrence from the authorities having jurisdiction. The depaint solution will also require evaluation with respect to toxicity for required ventilation and PPE for personnel protection.

5-3 DRAINAGE SYSTEMS FOR CHEMICAL DEPAINT.

The hangar floor drainage system for a chemical depaint facility fully capable of chemical stripping an entire aircraft must incorporate a trench and piping design that has sufficient diameter and slope to carry all paint chips and residue to a collection/holding tank. Trenches in the hangar must be sized with sufficient width to facilitate cleanout on a regular basis. The tank must be sized for a three month projection of activity, assuming that all removed paint will go through the system. The tank must be capable of being emptied of the paint residue manually or automatically. Regardless of the removal means, proper access must be designed into the tank to permit manual clean out and/or inspection.

This Page Intentionally Left Blank

CHAPTER 6 AIRCRAFT WASH RACKS

6-1 INTRODUCTION.

Aircraft Wash Racks are paved areas or facilities provided at all aircraft base facilities for the purpose of cleaning aircraft in conjunction with periodic maintenance and corrosion control activities.

6-2 DESIGN CRITERIA.

Design aircraft wash racks in accordance with UFC 3-260-01, *Airfield and Heliport Planning and Design*.

This Page Intentionally Left Blank

CHAPTER 7 SPECIFIC DESIGN CRITERIA

7-1 INTRODUCTION.

This chapter identifies the specific design needs for the individual spaces. Building design criteria are provided in a standard Functional Data Sheet (FDS) table format that generally follows the Uniformat II/Work Breakdown Structure. The Interior Construction/Built-in Equipment category includes anything physically attached or plumbed to the building such as counters, cabinets, casework, toilet accessories, window treatments, laundry machines, and retractable overhead screens. The Furnishings and Equipment category includes loose/moveable items.

7-2 BUILDING DESIGN CRITERIA.

TABLE 7-1. AIRCRAFT HANGAR BAY(PAINT/WASH/CHEM. DEPAINT)

Description/ Usage	Houses aircraft and equipment anticipated for the mission of Facility. The bay must be sized for the largest aircraft with additional space for anticipated maintenance platforms and equipment. The bay must also include utility connections required for the mission. Utilities will vary for paint application, and chemical depaint versus dry depaint.
Ceiling Ht.	Based on largest aircraft. See required clearances above aircraft.
Windows/Doors	Translucent panels for day lighting in exterior walls; tempered glass windows in hollow metal frames between supervisors' offices and Hangar Bay; supply plenum in hangar doors for cross-flow hangar; heavy duty hollow metal personnel doors and frames with closers, included in hangar doors as required for exiting; factory-finished galvanized steel coiling doors at larger openings; insulated doors between conditioned and unconditioned spaces; openings between Hangar Bay and adjacent spaces protected per code requirements; STC ratings of windows and doors must match that required for walls
Interior Construction/ Built-in Equipment	Interior walls, painted CMU or metal liner panels from floor to 7'-0" (2.1 m) min., rated as required per code; walls between hangar bays rated as required by NFPA 409; cranes and teleplatforms as required by mission requirements
Finishes	**Walls.** Factory finished metal liner panels or painted CMU from floor to 7'-0" (2.1 m) minimum; Block filler must be applied to CMU prior to painting; metal panels above advisable where budget allows or where required for linear air flow **Floor.** Dry shake hardener on concrete is minimum requirement. Coating must provide smooth, easily cleanable surface that will not accumulate dust; verify coating compatibility with chemical strippers and other chemicals that may be present; follow coating manufacturers' recommendations for sealing and bridging concrete joints. **Base.** - **Ceiling.** Exposed construction, painted. Metal panel advisable where budget allows or where required for linear air flow; provide draft curtains as required by NFPA 409
Plumbing	Emergency Showers and Eyewashes, floor drains to IW system
HVAC	See Chapter 3 for requirements as appropriate for paint spray application
Fire Protection and Life Safety	HEF/AFFF for fueled aircraft; Per NFPA 409 for Defueled aircraft
Power	Convenience outlets, dedicated equipment outlets ;aircraft ground power connections Classified area Class1, Div.1, Group C
Ground	Aircraft static grounding system required

TABLE 7-1. AIRCRAFT HANGAR BAY(PAINT/WASH/CHEM. DEPAINT)

Lighting	HID
Communication	**Telephone.** **Data.** **CCTV.** **CATV.** **Public address** – Required, origination in Supervisor's Office **Security.**
Acoustics	Minimum STC 40 assemblies between Hangar Bay and adjacent normally occupied spaces
Furnishings and Equipment	
Special Requirements	Avoid ledges and other horizontal surfaces that are capable of collecting dust.
For use during project execution by the appropriate Service agency	
Occupancy	Staff. Other.
Min. net ft^2 (m^2)	

TABLE 7-2. AIRCRAFT HANGAR BAY (DMB DEPAINT)

Description/ Usage	Houses aircraft and equipment anticipated for the mission of Facility. The bay must be sized for the largest aircraft with additional space for anticipated maintenance platforms and equipment. The bay must be designed for a dusty environment and include strategically placed outlets for Dry Media Blast (DMB) distribution and spent DMB pick up /delivery system for DMB reclamation; with additional utilities specific for the mission.
Ceiling Ht.	Based on largest aircraft. See required clearances above aircraft.
Windows/Doors	Translucent panels for daylighting in exterior walls; tempered glass windows in hollow metal frames between supervisors' offices and Hangar Bay; supply plenum in hangar doors for cross-flow hangar; heavy duty hollow metal personnel doors and frames with closers, included in hangar doors as required for exiting; factory-finished galvanized steel coiling doors at larger openings; insulated doors between conditioned and unconditioned spaces; openings between Hangar Bay and adjacent spaces protected per code requirements; STC ratings of windows and doors must match that required for walls
Interior Construction/ Built-in Equipment	Interior walls, painted CMU from floor to 7'-0" (2.1 m) min., rated as required per code; walls between hangar bays rated as required by NFPA 409; cranes and teleplatforms as required by mission requirements
Finishes	**Walls.** Factory finished metal liner panels or painted CMU from floor to 7'-0" (2.1 m) minimum. Factory finished metal wall panels to ceiling. Block filler must be applied to CMU prior to painting. **Floor.** Dry shake hardener is minimum requirement. Coating must provide smooth, easily cleanable surface that will not accumulate dust **Base.** - **Ceiling.** Factory finished metal liner panels

TABLE 7-2. AIRCRAFT HANGAR BAY (DMB DEPAINT)

Plumbing	Emergency Showers & Eyewashes, no floor drains
HVAC	See Chapter 3 for requirements appropriate for DMB De-paint operation
Fire Protection and Life Safety	Per NFPA 409 for Defueled aircraft
Power	Convenience outlets, dedicated equipment outlets ;Aircraft ground power connections HZD Loc-Class II, Div.1, Group G for dusty environment
Ground	Aircraft static grounding system required
Lighting	HID
Communication	**Telephone.** **Data.** **CCTV.** **CATV.** **Public Address –**Required, origination in Supervisor's Office **Security.**
Acoustics	Minimum STC 40 assemblies between Hangar Bay and adjacent normally occupied spaces
Furnishings and Equipment	
Special Requirements	Avoid ledges and other horizontal surfaces that are capable of collecting dust.
For use during project execution by the appropriate Service agency	
Occupancy	Staff. Other.
Min. net ft^2 (m^2)	

TABLE 7-3. PAINT MIX ROOM

Description/ Usage	Coating mix and paint pot staging; adjacent to paint storage with easy access to paint bay.
Ceiling Ht.	9 ft. (2.7 m) minimum
Windows/Doors	Heavy duty hollow metal doors and frames, rated as required by code
Interior Construction/ Built-in Equipment	Walls and floor-ceiling assemblies rated as required by code
Finishes	**Walls.** Painted CMU. Block filler must be applied to CMU prior to painting. **Floor.** applied to concrete **Base.** - **Ceiling.** Exposed painted structure; paint exposed ductwork, conduit or piping
Plumbing	Emergency Shower and Eye Wash, floor drains to IW system; containment or trenches to IW at doors; compressed air for CA powered paint shakers(optional)
HVAC	Heating, ventilation and cooling required and per NFPA 33
Fire Protection and Life Safety	Required per NFPA 33 and NFPA 101

TABLE 7-3. PAINT MIX ROOM

Power	Convenience outlets; Space classified Class 1 Div 1
Ground	Required - Ground connections for equipment
Lighting	Fluorescent (Hzd Loc-Class 1,div 1)
Communication	**Telephone.** **Data.** **CCTV.** **CATV.** **Public Address -** Speaker **Security.**
Acoustics	Minimum STC 40 assemblies between Paint Mix and adjacent normally occupied spaces
Furnishings and Equipment	Provide built-in counters as required for paint mix equipment
Special Requirements	
For use during project execution by the appropriate Service agency	
Occupancy	Staff. Other.
Min. net ft^2 (m^2)	

TABLE 7-4. PAINT STORAGE ROOM

Description/ Usage	Aircraft coating container storage; adjacent to paint mix, with curbed storage area drained to I.W.; should also have access for deliveries.
Ceiling Ht.	As required to accommodate storage and material handling equipment
Windows/Doors	Heavy duty hollow metal doors and frames, overhead coiling doors, rated as required by code; provide double doors as required to accommodate material movement; provide coiling doors sized to accommodate movement of largest forklift or other material handling equipment
Interior Construction/ Built-in Equipment	Walls and floor-ceiling assemblies rated as required by code; extend and seal walls to floor-ceiling or roof structure above; CMU preferred for walls; metal panels allowed at exterior walls only; provide protection from impact by forklift or other material handling equipment
Finishes	**Walls.** Painted CMU or factory finished metal panels. Block filler must be applied to CMU prior to painting. **Floor.** Sealed concrete **Base.** - **Ceiling.** Exposed painted structure; paint exposed ductwork, conduit or piping
Plumbing	Emergency Shower and Eye Wash, floor drains to IW system; containment or trenches to IW at doors
HVAC	Heating, ventilation and cooling required and per NFPA 33
Fire Protection and Life Safety	Required per NFPA 33 and NFPA 101
Power	Convenience Outlets
Lighting	Fluorescent (Hzd Loc-Class 1,div 2)

TABLE 7-4. PAINT STORAGE ROOM

Communication	**Telephone.** **Data.** **CCTV.** **CATV.** **Security.**
Acoustics	
Furnishings and Equipment	Drum racks, pallet racks and cabinets for storage as requested by facility users
Special Requirements	Provide storage conforming to applicable flammable and combustible liquids codes and standards
For use during project execution by the appropriate Service agency	
Occupancy	Staff. Other.
Min. net ft^2 (m^2)	

TABLE 7-5. TOOL CRIB

Description/ Usage	Special use equipment tools such as pallet jacks, ladders, facility maintenance items.
Ceiling Ht.	9 ft. (2.7 m) minimum
Windows/Doors	Heavy duty hollow metal doors and frames, overhead coiling doors; provide double doors as required to accommodate material movement; provide coiling doors sized to accommodate movement of largest forklift or other equipment; provide tool issue window and counter with rolling service counter door as required by facility users
Interior Construction/ Built-in Equipment	CMU walls or wire mesh partitions as required by facility users, extending to roof or ceiling above
Finishes	**Walls.** Painted CMU or galvanized wire mesh partitions. Block filler must be applied to CMU prior to painting. **Floor.** Sealed concrete as minimum requirement **Base.** - **Ceiling.** Exposed painted structure; paint exposed ductwork, conduit or piping
Plumbing	None required
HVAC	Heating, ventilation and cooling required, positively pressurized in relation to paint spray area
Fire Protection and Life Safety	Required
Power	Convenience outlets
Lighting	Fluorescent
Communication	**Telephone.** **Data.** **CCTV.** **CATV.** **Security.**
Acoustics	

TABLE 7-5. TOOL CRIB

Furnishings and Equipment	Desks and Chairs, bookcases, vertical file cabinets, workbench with stools, aircraft parts shelf, vice, storage cabinets, parts storage bins. Coordinate the quantities of furniture with the users. Other types of furniture may be required based on user and airframe type utilizing the hangar.
Special Requirements	Due to the potentially large pieces of equipment brought into this shop, a rolling service door is recommended in lieu of double doors opening onto the hangar bay. Door must be at least 5 feet (1.52 m) wide and 6'-8" (2.03 m) high. If a 4' (1.22 m) wide opening is adequate, provide a single 4' (1.22 m) wide personnel door in lieu of double doors. Consider using modular rolling storage shelving units for large tool rooms.
For use during project execution by the appropriate Service agency	
Occupancy	Staff. Other.
Min. net ft^2 (m^2)	

TABLE 7-6. EQUIPMENT STORAGE

Description/ Usage	Paint application equipment storage; typically combined with paint equipment cleaning room.
Ceiling Ht.	9 ft. (2.7 m) minimum
Windows/Doors	Heavy duty hollow metal doors and frames, overhead coiling doors; provide double doors as required to accommodate material movement; provide coiling doors sized to accommodate movement of largest equipment
Interior Construction/ Built-in Equipment	CMU walls or wire mesh partitions as required by facility users, extend to roof or floor structure above; if combined with equipment cleaning, may require rated walls and/or electrical classification
Finishes	**Walls.** Painted CMU or galvanized wire mesh partitions. Block filler must be applied to CMU prior to painting. **Floor.** Sealed concrete as minimum requirement; users may require thin film coating such as epoxy **Base.** - **Ceiling.** Exposed painted structure; paint exposed ductwork, conduit or piping
Plumbing	None required
HVAC	Heating, ventilation and cooling required, positively pressurized in relation to paint spray area
Fire Protection and Life Safety	Required
Power	Convenience Outlets
Lighting	Fluorescent
Communication	**Telephone.** **Data.** **CCTV.** **CATV.** **Security.**
Acoustics	
Furnishings and Equipment	Steel shelves and storage cabinets as required by facility users

TABLE 7-6. EQUIPMENT STORAGE

Special Requirements	
For use during project execution by the appropriate Service agency	
Occupancy	Staff. Other.
Min. net ft^2 (m^2)	

TABLE 7-7. EQUIPMENT CLEANING

Description/ Usage	Paint application equipment cleaning; room generally contains small paint booth or other solvent cleaning apparatus for use with paint spray guns and paint pots.
Ceiling Ht.	9 ft. (2.7 m) minimum
Windows/Doors	Heavy duty hollow metal doors and frames, rated as required by code
Interior Construction/ Built-in Equipment	Walls and floor-ceiling assemblies rated as required by code
Finishes	**Walls.** Painted CMU. Block filler must be applied to CMU prior to painting. **Floor.** Sealer or thin film coating applied to concrete as requested by facility users **Base.** - **Ceiling.** Exposed painted structure; paint exposed ductwork, conduit or piping
Plumbing	Emergency Shower and Eye Wash, floor drains to IW system
HVAC	Heating, ventilation and cooling required, positively pressurized in relation to paint spray area
Industrial Ventilation	See UFC 3-410-04, *Industrial Ventilation*, for requirements if small non walk-in paint spray or cleaning booth is present.
Fire Protection and Life Safety	Required
Power	Convenience Outlets; power to optional specialized cleaning booths
Lighting	Fluorescent
Communication	**Telephone.** Required **Data.** **CCTV.** **CATV.** **Security.**
Acoustics	
Furnishings and Equipment	
Special Requirements	Electrical classification may be required in vicinity of solvent cleaning equipment
For use during project execution by the appropriate Service agency	
Occupancy	Staff. Other.
Min. net ft^2 (m^2)	

TABLE 7-8. SOLVENT STORAGE

Description/ Usage	Large container (typ 55 gal) paint solvent storage; requires pallet storage with door openings and aisles suitable for deliveries.
Ceiling Ht.	As required to accommodate storage and material handling equipment
Windows/Doors	Heavy duty hollow metal doors and frames, overhead coiling doors, rated as required by code; provide double doors as required to accommodate material movement; provide coiling doors sized to accommodate movement of largest forklift or other material handling equipment
Interior Construction/ Built-in Equipment	Walls and floor-ceiling assemblies rated as required by code; extend and seal walls to floor-ceiling or roof structure above; CMU preferred for walls; metal panels allowed at exterior walls only; provide protection from impact by forklift or other material handling equipment
Finishes	**Walls.** Painted CMU or factory finished metal panels. Block filler must be applied to CMU prior to painting. **Floor.** Sealed concrete or thin film coating as requested by facility users; coating to be resistant to solvents stored. **Base.** - **Ceiling.** Exposed painted structure; paint exposed ductwork, conduit or piping
Plumbing	Emergency Shower and Eye Wash, floor drains to IW system; containment or trenches to IW at doors
HVAC	Heating and ventilation required and per NFPA 33
Fire Protection and Life Safety	Required per NFPA 33 and NFPA 101
Power	Convenience outlets; Space classified Class II Div 1
Lighting	Required - Ground connections for solvent containers
Communication	**Telephone.** **Data.** **CCTV.** **CATV.** **Security.**
Acoustics	
Furnishings and Equipment	Drum racks, pallet racks and cabinets for storage as requested by facility users
Special Requirements	Provide storage conforming to applicable flammable and combustible liquids codes and standards
For use during project execution by the appropriate Service agency	
Occupancy	Staff. Other.
Min. net ft^2 (m^2)	

TABLE 7-9. CENTRAL ACID STORAGE

Description/ Usage	Central storage for acid cleaner and conversion coating; may include central chemical mix and storage tanks with pumps and piping for distribution to the hangar bay.
Ceiling Ht.	As required to accommodate storage tanks and equipment
Windows/Doors	Heavy duty hollow metal doors and frames, overhead coiling doors, rated as required by code; provide double doors or overhead coiling doors as required to accommodate material and equipment movement
Interior Construction/ Built-in Equipment	Walls and floor-ceiling assemblies rated as required by code; extend and seal walls to floor-ceiling or roof structure above; CMU preferred for walls; metal panels allowed at exterior walls only
Finishes	**Walls.** Painted CMU or factory finished metal panels. Block filler must be applied to CMU prior to painting. **Floor.** Sealed concrete **Base.** - **Ceiling.** Exposed painted structure; paint exposed ductwork, conduit or piping
Plumbing	Emergency Shower and Eye Wash, floor drains to IW system; containment or trenches to IW at doors
HVAC	Heating and ventilation required
Fire Protection and Life Safety	Required
Power	Convenience Outlets
Lighting	Fluorescent
Communication	**Telephone.** **Data.** **CCTV.** **CATV.** **Security.**
Acoustics	
Furnishings and Equipment	Allow space for maintenance, repair and replacement of equipment
Special Requirements	Conform to applicable codes and standards regarding hazardous materials storage
For use during project execution by the appropriate Service agency	
Occupancy	Staff. Other.
Min. net ft^2 (m^2)	

TABLE 7-10. CENTRAL CHEMICAL STORAGE

Description/ Usage	Central storage/distribution for hot soap/water mix and hot and cold water; typically includes bulk storage of concentrated soap, central hot water heater/tank, soap/HW mix tank and associated distribution pumps.
Ceiling Ht.	As required to accommodate storage tanks and equipment
Windows/Doors	Heavy duty hollow metal doors and frames, overhead coiling doors, rated as required by code; provide double doors or overhead coiling doors as required to accommodate material and equipment movement
Interior Construction/ Built-in Equipment	Walls and floor-ceiling assemblies rated as required by code; extend and seal walls to floor-ceiling or roof structure above; CMU preferred for walls; metal panels allowed at exterior walls only
Finishes	**Walls.** Painted CMU or factory finished metal panels. Block filler must be applied to CMU prior to painting. **Floor.** Sealed concrete **Base.** - **Ceiling.** Exposed painted structure; paint exposed ductwork, conduit or piping
Plumbing	Emergency Shower and Eye Wash, floor drains to IW system; containment or trenches to IW at doors
HVAC	Heating and ventilation required
Fire Protection and Life Safety	Required
Power	Convenience Outlets
Lighting	Fluorescent
Communication	**Telephone.** **Data.** **CCTV.** **CATV.** **Security.**
Acoustics	
Furnishings and Equipment	Allow space for maintenance, repair and replacement of equipment
Special Requirements	
For use during project execution by the appropriate Service agency	
Occupancy	Staff. Other.
Min. net ft^2 (m^2)	

TABLE 7-11. MATERIAL STORAGE

Description/ Usage	Secure storage of non-hazardous paint prep materials; typically includes a window for distribution of materials to paint personnel; may also include storage of paint process equipment and parts.
Ceiling Ht.	9 ft. (2.7 m) minimum
Windows/Doors	Heavy duty hollow metal doors and frames, overhead coiling doors; provide double doors as required to accommodate material movement; provide coiling doors sized to accommodate movement of largest forklift or other equipment; provide tool issue window and counter with rolling service counter door as required by facility users
Interior Construction/ Built-in Equipment	CMU walls or wire mesh partitions as required by facility users, extend to roof or floor structure above
Finishes	**Walls.** Painted CMU or galvanized wire mesh partitions. Block filler must be applied to CMU prior to painting. **Floor.** Sealed concrete as minimum requirement **Base.** - **Ceiling.** Exposed painted structure; paint exposed ductwork, conduit or piping.
Plumbing	None required
HVAC	Heating, ventilation and cooling required, positively pressurized in relation to paint spray area
Fire Protection and Life Safety	Required
Power	Convenience Outlets
Lighting	Fluorescent
Communication	**Telephone.** **Data.** **CCTV.** **CATV.** **Security.**
Acoustics	
Furnishings and Equipment	Desks and Chairs, bookcases, vertical file cabinets, workbench with stools, aircraft parts shelf, vice, storage cabinets, parts storage bins. Coordinate the quantities of furniture with the users. Other types of furniture may be required based on user and airframe type utilizing the hangar.
Special Requirements	
For use during project execution by the appropriate Service agency	
Occupancy	Staff. Other.
Min. net ft^2 (m^2)	

TABLE 7-12. PPE STORAGE

Description/ Usage	Room/area designated for secure storage of PPE; storage of PPE is typically combined with PPE cleaning.
Ceiling Ht.	9 ft. (2.7 m) minimum
Windows/Doors	Heavy duty hollow metal doors and frames
Interior Construction/ Built-in Equipment	CMU walls, extend to roof or floor structure above
Finishes	**Walls.** Painted CMU. Block filler must be applied to CMU prior to painting. **Floor.** Sealer or thin film coating applied to concrete as requested by facility users **Base.** - **Ceiling.** Exposed painted structure; paint exposed ductwork, conduit or piping
Plumbing	None required
HVAC	Heating, ventilation and cooling required, positively pressurized in relation to paint spray area
Fire Protection and Life Safety	Required
Power	Convenience Outlets
Lighting	Fluorescent
Communication	**Telephone.** **Data.** **CCTV.** **CATV.** **Security.**
Acoustics	
Furnishings and Equipment	Steel shelves and storage cabinets as required by facility users
Special Requirements	
For use during project execution by the appropriate Service agency	
Occupancy	Staff. Other.
Min. net ft^2 (m^2)	

TABLE 7-13. PPE CLEANING

Description/ Usage	Cleaning of personnel protective equipment; typically includes divided sinks; central washer and drier (optional).
Ceiling Ht.	9 ft. (2.7 m) minimum
Windows/Doors	Heavy duty hollow metal doors and frames
Interior Construction/ Built-in Equipment	CMU walls, extend to roof or floor structure above
Finishes	**Walls.** Painted CMU. Block filler must be applied to CMU prior to painting. **Floor.** Sealer or thin film coating applied to concrete as requested by facility users **Base.** - **Ceiling.** Exposed painted structure; paint exposed ductwork, conduit or piping
Plumbing	Hot and cold water; laundry sink; clothes washer and drier connections; floor drains to IW System
HVAC	Heating, ventilation and cooling required, positively pressurized in relation to paint spray area; clothes drier exhaust to the exterior
Fire Protection and Life Safety	Required
Power	Convenience Outlets; power for Washer and Drier
Lighting	Fluorescent
Communication	**Telephone.** **Data.** **CCTV.** **CATV.** **Security.**
Acoustics	
Furnishings and Equipment	
Special Requirements	
For use during project execution by the appropriate Service agency	
Occupancy	Staff. Other.
Min. net ft^2 (m^2)	

TABLE 7-14. PAINT BOOTH

Description/ Usage	Individual paint spray booth for small parts (may be located inside hangar bay or exterior to building).See UFC 3-410-04 Industrial Ventilation for specifications and facility requirements
Ceiling Ht.	Based on largest part anticipated, with sufficient clearances for movement of personnel and equipment
Windows/Doors	Supply plenum and/or paint filters in doors for cross-flow booth; size doors to accommodate movement of parts; heavy duty hollow metal personnel doors and frames with closers; insulated doors between conditioned and unconditioned spaces;
Interior Construction/ Built-in Equipment	
Finishes	**Walls.** Factory finished metal panels **Floor.** Thin film coating or dry shake hardener is minimum requirement. Coating must provide smooth, easily cleanable surface that will not accumulate dust **Base.** - **Ceiling.** Factory finished metal panels
Plumbing	Drains, if installed must be routed to IW systems for proper treatment. Emergency Shower & Eyewash, floor drains to IW system
Industrial Ventilation	For Paint Booths exhausted to the exterior installed in interior spaces, replacement air must be supplied to the space to maintain an even static pressure. See UFC 3-410-04 Industrial Ventilation for further information on Paint Booth ventilation.
HVAC	See UFC 3-410-04 Industrial Ventilation for information on Paint Booth ventilation.
Fire Protection and Life Safety	See NFPA 33 for Paint Booth Fire Protection requirements
Power	Power receptacles, if required inside the space must be rated Class 1, Div 1 for hazardous spaces.
Lighting	Provide lighting in ceiling and walls as required; light fixtures must be Class I, Division 1 rated; lamps must be capable of replacement either from inside booth or sufficient space and structure must be provided to allow replacement from exterior.
Communication	**Telephone.** **Data.** **CCTV.** **CATV.** **Security.**
Acoustics	
Furnishings and Equipment	
Special Requirements	Provide separate structure, exterior wall panels and roof panels if booth is not located in a hangar or other enclosed building; allow sufficient clearance for movement and maintenance around exterior of booth, but not less than 5 feet (1.5 m)
For use during project execution by the appropriate Service agency	
Occupancy	Staff. Other.
Min. net ft^2 (m^2)	

TABLE 7-15. STENCIL ROOM

Description/ Usage	Houses aircraft stencil equipment; room size should consider size of aircraft stencils as well as equipment.
Ceiling Ht.	9 ft. (2.7 m) minimum
Windows/Doors	Heavy duty hollow metal doors and frames
Interior Construction/ Built-in Equipment	
Finishes	**Walls.** Painted CMU or gyp. bd. on metal studs. Block filler must be applied to CMU prior to painting. **Floor.** Resilient tile or sealed concrete **Base.** Resilient base at gyp. bd. walls **Ceiling.** Acoustical panels
Plumbing	None required
HVAC	Heating, ventilation and cooling required, positively pressurized in relation to paint spray area
Fire Protection and Life Safety	Required
Power	Convenience Outlets; special power for stencil equipment as required.
Lighting	Fluorescent
Communication	**Telephone.** **Data.** **CCTV.** **CATV.** **Security.**
Acoustics	
Furnishings and Equipment	Stools, tables and work benches should be provided as required for layout and trimming of stencils; drawers and shelving should be provided for storage of stencils and tools
Special Requirements	
For use during project execution by the appropriate Service agency	
Occupancy	Staff. Other.
Min. net ft^2 (m^2)	

TABLE 7-16. COMPOSITE ROOM

Description/ Usage	Composite/fiberglass layup/repair room will typically contain work benches with ventilation hoods, and curing ovens for repair of composite parts.
Ceiling Ht.	As required to accommodate movement of largest parts and equipment
Windows/Doors	Heavy duty hollow metal doors and frames,
Interior Construction/ Built-in Equipment	Extend and seal walls to floor-ceiling or roof structure above; CMU preferred for walls; metal panels allowed at exterior walls only
Finishes	**Walls.** Painted CMU. Block filler must be applied to CMU prior to painting. **Floor.** Sealer or thin film coating applied to concrete as requested by facility users **Base.** - **Ceiling.** Exposed painted structure; paint exposed ductwork, conduit or piping
Plumbing	Emergency Shower and Eye Wash, floor drains to IW system
Industrial Ventilation	See UFC 3-410-04, Industrial Ventilation, for requirements.
HVAC	Special temperature and humidity controls may be required based on type of composite.
Fire Protection and Life Safety	Required
Power	
Lighting	
Communication	**Telephone.** **Data.** **CCTV.** **CATV.** **Security.**
Acoustics	
Furnishings and Equipment	
Special Requirements	
For use during project execution by the appropriate Service agency	
Occupancy	Staff. Other.
Min. net ft^2 (m^2)	

TABLE 7-17. WASH RACK

Description/ Usage	Accommodates aircraft cleaning and can be open, covered, enclosed, or integrated into the hangar bay.
Ceiling Ht.	Based on largest aircraft. See required clearances above aircraft.
Windows/Doors	-
Interior Construction/ Built-in Equipment	
Finishes	**Walls.** - **Floor.** - **Base.** - **Ceiling. -**
Plumbing	Safety Shower and Eye Wash(number as appropriate to WR size), floor drains to IW System
HVAC	As appropriate for type of Wash Rack; heating and ventilation required for enclosed spaces
Fire Protection and Life Safety	Fire Protection required for enclosed spaces
Power	Convenience outlets with specialized outlets as required for aux. portable equipment
Lighting	HID or Fluorescent
Communication	**Telephone.** **Data.** **CCTV.** **CATV.** **Security.**
Acoustics	
Furnishings and Equipment	Fall protection requirements are applicable to all Wash Racks, open or covered.
Special Requirements	Facility must have Hot water and Cold Water
For use during project execution by the appropriate Service agency	
Occupancy	Staff. Other.
Min. net ft^2 (m^2)	

TABLE 7-18. SUPERVISOR'S OFFICE

Description/ Usage	Private office located with view of hangar bay
Ceiling Ht.	9 ft.
Windows/Doors	Window to hangar bay protected as required by code; medium duty hollow metal or solid core wood door in hollow metal frame; access via corridor, direct hangar bay access not allowed
Interior Construction/ Built-in Equipment	
Finishes	**Walls.** CMU or gyp. bd., painted; block filler must be applied to CMU prior to painting. **Floor.** Resilient tile, heavy duty carpet tile or sealed concrete. **Base.** Resilient base at gyp. bd. walls **Ceiling.** Acoustical panels
Plumbing	None required
HVAC	Heating, ventilation and cooling required, positively pressurized in relation to paint spray area
Fire Protection and Life Safety	Required
Power	Convenience and work station Outlets
Lighting	Fluorescent
Communication	**Telephone.** Required **Data.** Required **CCTV.** **CATV.** **Security.** **Public Address –** System cabinet with Microphone
Acoustics	
Furnishings and Equipment	Standard office furnishings and equipment
Special Requirements	
For use during project execution by the appropriate Service agency	
Occupancy	Staff. Other.
Min. net ft^2 (m^2)	

TABLE 7-19. OFFICES General

Description/ Usage	Private offices and/or workstations determined by mission requirements
Ceiling Ht.	9 ft. (2.7 m)
Windows/Doors	Window to hangar bay, if provided, protected as required by code; medium duty hollow metal or solid core wood door in hollow metal frame; access via corridor, direct hangar bay access not allowed
Interior Construction/ Built-in Equipment	
Finishes	**Walls.** CMU or gyp. bd., painted; block filler must be applied to CMU prior to painting. **Floor.** Resilient tile or carpet tile **Base.** Resilient base at gyp. bd. walls **Ceiling.** Acoustical panels
Plumbing	None required
HVAC	Heating, ventilation and cooling required, positively pressurized in relation to paint spray area
Fire Protection and Life Safety	Required
Power	Convenience and work station outlets
Lighting	Fluorescent
Communication	**Telephone.** Required **Data.** Required **CCTV.** **CATV.** **Security.**
Acoustics	
Furnishings and Equipment	Standard office furnishings and equipment
Special Requirements	
For use during project execution by the appropriate Service agency	
Occupancy	Staff. Other.
Min. net ft^2 (m^2)	

TABLE 7-20. CONFERENCE ROOM

Description/ Usage	Small assembly with conference table and chairs
Ceiling Ht.	9 ft. (2.7 m)
Windows/Doors	Window to hangar bay, if provided, protected as required by code; medium duty hollow metal or solid core wood doors in hollow metal frame; access via corridor, direct hangar bay access not allowed
Interior Construction/ Built-in Equipment	
Finishes	**Walls.** CMU or gyp. bd., painted; block filler must be applied to CMU prior to painting. **Floor.** Resilient tile or carpet tile **Base.** Resilient base at gyp. bd. walls **Ceiling.** Acoustical panels
Plumbing	None required
HVAC	Heating, ventilation and cooling required, positively pressurized in relation to paint spray area
Fire Protection and Life Safety	Required
Power	Convenience Outlets; Power and Cable connection in Ceiling for projector
Lighting	Fluorescent
Communication	**Telephone.** Required **Data.** Required **CCTV.** Required **CATV.** Required **Security.** **Public Address** Required
Acoustics	
Furnishings and Equipment	Conference table and chairs; white board
Special Requirements	Room should be fitted for Audio/Visual presentations with built in speaker system, projector, and retractable viewing screen or equivalent media presentation equipment.
For use during project execution by the appropriate Service agency	
Occupancy	Staff. Other.
Min. net ft^2 (m^2)	

TABLE 7-21. FAX/COPY

Description/ Usage	Centralized fax/copy room
Ceiling Ht.	9 ft. (2.7 m)
Windows/Doors	Solid core wood door in hollow metal frame (optional)
Interior Construction/ Built-in Equipment	
Finishes	**Walls.** CMU or gyp. bd., painted; block filler must be applied to CMU prior to painting. **Floor.** Resilient tile **Base.** Resilient base at gyp. bd. walls **Ceiling.** Acoustical panels
Plumbing	None required
HVAC	Heating, ventilation and cooling required, positively pressurized in relation to paint spray area; review ventilation requirements for copy equipment, exhaust to exterior may be required
Fire Protection and Life Safety	Required
Power	Convenience Outlets
Lighting	Fluorescent
Communication	**Telephone.** **Data.** **CCTV.** **CATV.** **Security.**
Acoustics	
Furnishings and Equipment	
Special Requirements	Standard reproduction/printing equipment as requested by users; built in cabinets for storage of paper and other supplies
For use during project execution by the appropriate Service agency	
Occupancy	Staff. Other.
Min. net ft^2 (m^2)	

TABLE 7-22. BREAK ROOM

Description/ Usage	Personnel break and assembly room
Ceiling Ht.	9 ft. (2.7 m)
Windows/Doors	Window to hangar bay protected as required by code; heavy duty hollow metal or solid core wood door in hollow metal frame.
Interior Construction/ Built-in Equipment	
Finishes	**Walls.** CMU or gyp. bd., painted; block filler must be applied to CMU prior to painting. **Floor.** Resilient tile **Base.** Resilient base at gyp. bd. walls **Ceiling.** Acoustical panels
Plumbing	Sink, with water supply and drain piping
HVAC	Heating, ventilation and cooling required, positively pressurized in relation to paint spray area
Fire Protection and Life Safety	Required
Power	Convenience Outlets
Lighting	Fluorescent
Communication	**Telephone.** **Data.** **CCTV.** **CATV.** **Security.**
Acoustics	
Furnishings and Equipment	
Special Requirements	
For use during project execution by the appropriate Service agency	
Occupancy	Staff. Other.
Min. net ft^2 (m^2)	

TABLE 7-23. LOCKER ROOMS(CLEAN)

Description/ Usage	Male and female locker/shower/toilet facilities used for storage of operators' personal items
Ceiling Ht.	9 ft. (2.7 m) minimum
Windows/Doors	Heavy duty hollow metal or solid core wood door in hollow metal frame; access via corridor, direct hangar bay access not allowed
Interior Construction/ Built-in Equipment	
Finishes	**Walls.** Glazed ceramic tile on CMU **Floor.** Unglazed ceramic tile **Base.** Ceramic tile **Ceiling.** Suspended acoustical panels with moisture-resistant finish
Plumbing	Flush valve toilets, flush valve urinals, countertop or wall mounted lavatories, showers, floor drains
HVAC	Heating, ventilation and cooling required, positively pressurized in relation to paint spray area
Fire Protection and Life Safety	Required
Power	Convenience Outlets, GFI protected
Lighting	Fluorescent
Communication	**Telephone.** **Data.** **CCTV.** **CATV.** **Security.**
Acoustics	Minimum STC 40 assemblies between Locker Rooms and adjacent normally occupied spaces
Furnishings and Equipment	
Special Requirements	Number of fixtures will be determined by the RFP preparer for design build projects or must provide adequate information for the Design Builder to establish the correct number of fixtures required. Provide 2 tier-1/2 height lockers on concrete base. RFP preparer must determine the number of lockers required. Lockers must be sized based on activity requirements. Provide number of accessible fixtures required
For use during project execution by the appropriate Service agency	
Occupancy	Staff. Other.
Min. net ft^2 (m^2)	

TABLE 7-24. LOCKER ROOMS(DIRTY)

Description/ Usage	Male and female lockers used for disposition contaminated clothing worn by operators during the performance of their corrosion control duties
Ceiling Ht.	9 ft. (2.7 m) minimum
Windows/Doors	Heavy duty hollow metal or solid core wood door in hollow metal frame; access via PPE staging/cleaning area to clean locker room; direct hangar bay or clean corridor access not allowed
Interior Construction/ Built-in Equipment	
Finishes	**Walls.** Glazed ceramic tile on CMU **Floor.** Unglazed ceramic tile **Base.** Ceramic tile **Ceiling.** Suspended acoustical panels with moisture-resistant finish
Plumbing	Hand washing facilities, floor drains
HVAC	Heating, ventilation and cooling required, positively pressurized in relation to paint spray area
Fire Protection and Life Safety	Required
Power	Convenience Outlets, GFI protected
Lighting	Fluorescent
Communication	**Telephone.** **Data.** **CCTV.** **CATV.** **Security.**
Acoustics	Minimum STC 40 assemblies between Locker Rooms and adjacent normally occupied spaces
Furnishings and Equipment	
Special Requirements	Provide 2 tier-1/2 height lockers on concrete base. RFP preparer must determine the number of lockers required. Lockers must be sized based on activity requirements.
For use during project execution by the appropriate Service agency	
Occupancy	Staff. Other.
Min. net ft^2 (m^2)	

TABLE 7-25. TECHNICAL LIBRARY

Description/ Usage	Storage of aircraft technical documents
Ceiling Ht.	9 ft. (2.7 m)
Windows/Doors	Solid core wood door in hollow metal frame
Interior Construction/ Built-in Equipment	
Finishes	**Walls.** CMU or gyp. bd., painted; block filler must be applied to CMU prior to painting. **Floor.** Resilient tile or carpet tile **Base.** Resilient base at gyp. bd. walls **Ceiling.** Acoustical panels
Plumbing	None required
HVAC	Heating, ventilation and cooling required, positively pressurized in relation to paint spray area
Fire Protection and Life Safety	Required
Power	Convenience Outlets
Lighting	Fluorescent
Communication	**Telephone.** Required **Data.** Required **CCTV.** **CATV.** **Security.**
Acoustics	
Furnishings and Equipment	Shelves and cabinets for documents; tables and chairs, as required; computer and telephone
Special Requirements	
For use during project execution by the appropriate Service agency	
Occupancy	Staff. Other.
Min. net ft^2 (m^2)	

TABLE 7-26. MAINTENANCE SHOPS

Description/ Usage	Optional mission-specific maintenance spaces
Ceiling Ht.	As required for the specific maintenance operation
Windows/Doors	Heavy duty hollow metal doors and frames, overhead coiling doors; provide double doors as required to accommodate material movement; provide coiling doors sized to accommodate movement of largest forklift or other equipment
Interior Construction/ Built-in Equipment	CMU walls and/or wire mesh partitions as required by facility users, extend to roof or ceiling above
Finishes	**Walls.** Painted CMU or galvanized wire mesh partitions. Block filler must be applied to CMU prior to painting. **Floor.** Sealed concrete as minimum requirement **Base.** - **Ceiling.** Exposed painted structure; paint exposed ductwork, conduit or piping
Plumbing	As required; Emergency eyewash/showers may be required depending on processes performed and materials used; floor drains to IW
HVAC	Heating, ventilation and cooling required, positively pressurized in relation to paint spray area
Fire Protection and Life Safety	Required
Power	Convenience Outlets
Lighting	Fluorescent
Communication	**Telephone.** **Data.** **CCTV.** **CATV.** **Security.**
Acoustics	
Furnishings and Equipment	To be determined by mission and specified by RFP writer
Special Requirements	
For use during project execution by the appropriate Service agency	
Occupancy	Staff. Other.
Min. net ft^2 (m^2)	

TABLE 7-27. MECHANICAL ROOM(S)

Description/ Usage	HVAC and misc mechanical systems
Ceiling Ht.	As required to accommodate equipment and maintenance activities
Windows/Doors	Heavy duty hollow metal doors and frames, overhead coiling doors; provide double doors or coiling doors sized to accommodate equipment, maintenance, repair and replacement activities
Interior Construction/ Built-in Equipment	CMU or gyp. bd. and metal stud walls, extend to roof or floor structure above
Finishes	**Walls.** Painted CMU or gyp. bd. on metal studs. Block filler must be applied to CMU prior to painting. **Floor.** Sealed concrete **Base.** Resilient base at gyp. bd. walls **Ceiling.** Exposed painted structure; paint exposed ductwork, conduit or piping
Plumbing	Floor drains
HVAC	Heating and ventilation required
Fire Protection and Life Safety	Required
Power	Convenience outlets plus equipment power
Lighting	Fluorescent
Communication	**Telephone.** **Data.** Connection to EMCS as required for energy monitoring. **CCTV.** **CATV.** **Security.**
Acoustics	
Furnishings and Equipment	
Special Requirements	Provide sufficient clearance around equipment for repair and replacement of key components.
For use during project execution by the appropriate Service agency	
Occupancy	Staff. Other.
Min. net ft^2 (m^2)	

TABLE 7-28. COMPRESSOR ROOM

Description/ Usage	Plant air and breathing air compressor systems .Note specific requirements for Breathing Air vs. Plant Air
Ceiling Ht.	As required to accommodate the equipment and maintenance activities
Windows/Doors	Heavy duty hollow metal doors and frames, overhead coiling doors; provide double doors or coiling doors sized to accommodate equipment, maintenance, repair and replacement activities
Interior Construction/ Built-in Equipment	CMU or gyp. bd. and metal stud walls, extend to roof or floor structure above
Finishes	**Walls.** Painted CMU or gyp. bd. on metal studs. Block filler must be applied to CMU prior to painting. **Floor.** Sealed concrete **Base.** Resilient base at gyp. bd. walls **Ceiling.** Exposed painted structure; paint exposed ductwork, conduit or piping
Plumbing	Floor drains
HVAC	Heating and ventilation required
Fire Protection and Life Safety	Required
Power	
Lighting	
Communication	**Telephone.** **Data.** **CCTV.** **CATV.** **Security.**
Acoustics	
Furnishings and Equipment	
Special Requirements	Provide sufficient clearance around equipment for repair and replacement of key components.
For use during project execution by the appropriate Service agency	
Occupancy	Staff. Other.
Min. net ft^2 (m^2)	

TABLE 7-29. CENTRAL PLANT

Description/ Usage	Centralized chilled water and heating hot water supply
Ceiling Ht.	As required to accommodate the equipment and maintenance activities
Windows/Doors	Heavy duty hollow metal doors and frames, overhead coiling doors; provide double doors or coiling doors sized to accommodate equipment, maintenance, repair and replacement activities
Interior Construction/ Built-in Equipment	CMU or gyp. bd. and metal stud walls, extend to roof or floor structure above
Finishes	**Walls.** Painted CMU or gyp.board. on metal studs. Block filler must be applied to CMU prior to painting. **Floor.** Sealed concrete **Base.** Resilient base at gyp. bd. walls **Ceiling.** Exposed painted structure; paint exposed ductwork, conduit or piping
Plumbing	Floor drains
HVAC	Heating and ventilation required
Fire Protection and Life Safety	Required
Power	Convenience outlets plus equipment power
Lighting	Fluorescent
Communication	**Telephone.** **Data.** **CCTV.** **CATV.** **Security.**
Acoustics	
Furnishings and Equipment	
Special Requirements	Provide sufficient clearance around equipment for repair and replacement of key components.
For use during project execution by the appropriate Service agency	
Occupancy	Staff. Other.
Min. net ft^2 (m^2)	

TABLE 7-30. ELECTRICAL ROOM(S)

Description/ Usage	Switchboards, motor control centers, distribution transformers, circuit breaker and lighting panels, VFD equipment
Ceiling Ht.	As required to accommodate equipment and maintenance activities
Windows/Doors	Heavy duty hollow metal doors and frames, overheard coiling doors; provide double doors or coiling doors sized to accommodate equipment, maintenance, repair and replacement activities
Interior Construction/ Built-in Equipment	CMU or gyp. bd. and metal stud walls as required by facility users, extend to roof or floor structure above
Finishes	**Walls.** Painted CMU or gyp. bd. on metal studs. Block filler must be applied to CMU prior to painting. **Floor.** Sealed concrete **Base.** Resilient base at gyp. bd. walls **Ceiling.** Exposed painted structure; paint exposed ductwork, conduit or piping
Plumbing	None required
HVAC	As required for heat load from electrical gear
Fire Protection and Life Safety	Required
Power	Convenience outlets
Lighting	Fluorescent
Communication	**Telephone.** **Data.** **CCTV.** **CATV.** **Security.**
Acoustics	
Furnishings and Equipment	
Special Requirements	
For use during project execution by the appropriate Service agency	
Occupancy	Staff. Other.
Min. net ft^2 (m^2)	

TABLE 7-31. FIRE PROTECTION ROOM

Description/ Usage	Fire water riser, distribution manifold, AFFF or HEF storage tanks
Ceiling Ht.	As required to accommodate tanks, equipment and maintenance activities
Windows/Doors	Heavy duty hollow metal doors and frames, overhead coiling doors; provide double doors or coiling doors sized to accommodate equipment, maintenance, repair and replacement activities
Interior Construction/ Built-in Equipment	CMU or gyp. bd. and metal stud walls, extend to roof or floor structure above
Finishes	**Walls.** Painted CMU or gyp. bd. on metal studs. Block filler must be applied to CMU prior to painting. **Floor.** Sealed concrete **Base.** Resilient base at gyp. bd. walls **Ceiling.** Exposed painted structure; paint exposed ductwork, conduit or piping
Plumbing	Floor drains
HVAC	Heating and ventilation required
Fire Protection and Life Safety	Required
Power	Convenience Outlets
Lighting	Fluorescent
Communication	**Telephone.** **Data.** **CCTV.** **CATV.** **Security.**
Acoustics	
Furnishings and Equipment	
Special Requirements	
For use during project execution by the appropriate Service agency	
Occupancy	Staff. Other.
Min. net ft^2 (m^2)	

TABLE 7-32. COMMUNICATION ROOM

Description/ Usage	Telephone switchboard and misc communications equipment
Ceiling Ht.	9 ft. (2.7 m) minimum
Windows/Doors	Heavy duty hollow metal doors and frames; provide double doors if required to accommodate equipment racks
Interior Construction/ Built-in Equipment	CMU or gyp.board. and metal stud walls, extend to roof or floor structure above
Finishes	**Walls.** Painted CMU or gyp. bd. on metal studs. Block filler must be applied to CMU prior to painting. **Floor.** Sealed concrete **Base.** Resilient base at gyp. bd. walls **Ceiling.** Exposed painted structure; paint exposed ductwork, conduit or piping
Plumbing	None required
HVAC	Heating, ventilation and cooling required, positively pressurized in relation to paint spray area
Fire Protection and Life Safety	Required
Power	Convenience Outlets
Lighting	Fluorescent
Communication	**Telephone.** **Data.** **CCTV.** **CATV.** **Security.**
Acoustics	
Furnishings and Equipment	
Special Requirements	
For use during project execution by the appropriate Service agency	
Occupancy	Staff. Other.
Min. net ft^2 (m^2)	

TABLE 7-33. DRY MEDIA EQUIPMENT ROOM

Description/ Usage	Centralized dry blast media retrieval, processing and distribution equipment
Ceiling Ht.	As required to accommodate equipment and maintenance activities
Windows/Doors	Heavy duty hollow metal doors and frames, overhead coiling doors; provide double doors or coiling doors sized to accommodate equipment, maintenance, repair and replacement activities
Interior Construction/ Built-in Equipment	CMU walls, extend to roof or floor structure above
Finishes	**Walls.** Painted CMU; block filler must be applied to CMU prior to painting. **Floor.** Sealed concrete **Base.** - **Ceiling.** Exposed painted structure; paint exposed ductwork, conduit or piping
Plumbing	None required
HVAC	Heating and ventilation required
Fire Protection and Life Safety	Required
Power	Convenience Outlets; power as required for DMB Depaint Equipment
Lighting	Fluorescent
Communication	**Telephone.** **Data.** **CCTV.** **CATV.** **Security.**
Acoustics	
Furnishings and Equipment	
Special Requirements	
For use during project execution by the appropriate Service agency	
Occupancy	Staff. Other.
Min. net ft^2 (m^2)	

TABLE 7-34. DRY MEDIA STORAGE ROOM

Description/ Usage	Bulk dry media storage (palletized)
Ceiling Ht.	As required to accommodate storage and material handling equipment
Windows/Doors	Heavy duty hollow metal doors and frames, overhead coiling doors; provide double doors as required to accommodate material movement; provide coiling doors sized to accommodate movement of largest forklift or other material handling equipment
Interior Construction/ Built-in Equipment	Extend and seal walls to floor-ceiling or roof structure above; CMU preferred for walls; metal panels allowed at exterior walls only; provide protection from impact by forklift or other material handling equipment
Finishes	**Walls.** Painted CMU or factory finished metal panels. Block filler must be applied to CMU prior to painting. **Floor.** Sealed concrete **Base.** - **Ceiling.** Exposed painted structure; paint exposed ductwork, conduit or piping
Plumbing	None required
HVAC	Heating and ventilation required
Fire Protection and Life Safety	Required
Power	Convenience Outlets
Lighting	Fluorescent
Communication	**Telephone.** **Data.** **CCTV.** **CATV.** **Security.**
Acoustics	
Furnishings and Equipment	
Special Requirements	Include means of media handling, including hopper filling
For use during project execution by the appropriate Service agency	
Occupancy	Staff. Other.
Min. net ft^2 (m^2)	

TABLE 7-35. DRY MEDIA BLAST BOOTH

Description/ Usage	Fully enclosed self contained room specifically designed with the equipment and utilities for the removal of coatings by the DMB method, generally manually performed by a DMB nozzle operator stationed inside the booth. See UFC 3-410-04 Industrial Ventilation for specifications and facility requirements
Ceiling Ht.	Based on largest part anticipated, with sufficient clearances for movement of personnel and equipment
Windows/Doors	Supply plenum and/or dust collection filters in doors for cross-flow booth; size doors to accommodate movement of parts; heavy duty hollow metal personnel doors and frames with closers; insulated doors between conditioned and unconditioned spaces;
Interior Construction/ Built-in Equipment	
Finishes	**Walls.** Factory finished metal panels **Floor.** Thin film coating or dry shake hardener is minimum requirement. Coating must provide smooth, easily cleanable surface that will not accumulate dust **Base.** - **Ceiling.** Factory finished metal panels
Plumbing	Emergency Shower & Eyewash; no floor drains
Industrial Ventilation	See UFC 3-410-04, *Industrial Ventilation*, for requirements
HVAC	Ventilation
Fire Protection and Life Safety	Required
Power	Class 2, Div 1 if provided
Lighting	Provide lighting in ceiling and walls as required; light fixtures must be Class II, Division 1 rated; lamps must be capable of replacement either from inside booth or sufficient space and structure must be provided to allow replacement from exterior
Communication	**Telephone.** **Data.** **CCTV.** **CATV.** **Security.**
Acoustics	
Furnishings and Equipment	
Special Requirements	
For use during project execution by the appropriate Service agency	
Occupancy	Staff. Other.
Min. net ft^2 (m^2)

APPENDIX B BEST PRACTICES

B-1 INTRODUCTION.

The following material identifies background information lessons learned and other current, good design practices. The designer is expected to review and interpret this guidance and apply the information according to the needs of the project.

B-2 RECOMMENDED DESIGN GUIDANCE

B-2.1 Process Ventilation Systems.

Ventilation Fans – General.

Use centrifugal fans with backward curved blades (non-overloading), whenever possible. Centrifugal fans with radial blades are less efficient, but still acceptable. Place the exhaust fan and outlet ductwork outside of the building.

Ventilation during Spray Paint operations.

The ventilation system for an aircraft corrosion control hangar must be designed to prevent fire and explosion. At a minimum, the volumetric airflow rate must keep the concentration of vapors and mists in the exhaust stream of the ventilation system below the 25 percent of the LEL. A well-designed ventilation system will also reduce paint overspray, help control workers' contaminant exposure, and protect the paint finish. Workers must use appropriate respiratory protection irrespective of the airflow rate. On 8 April 1997 and 1 July 1999, OSHA issued interpretations of 29 CFR 1910.94 and 29 CFR 1910.107 for determining the airflow rate required for an aircraft corrosion control hangars. In accordance with OSHA's interpretation letters, see Appendix D, an aircraft corrosion control hangar must minimally comply with the requirements of NFPA 33 and with Subpart Z of 29 CFR 1910 for hazardous substances. Consideration, however, may be given to reduced or recirculated airflow deviating from the velocity levels stated in 29 CFR 1910.94(c)(6)(i)and 29 CFR 1910.107(6)(5)(i).

NOTE 1. Recirculation of exhaust air may be considered provided requirements of ANSI/AIHA Z9.7, NFPA 33, ASHRAE, and OSHA are met and coordinated approval is received from the Facility Project Team.

NOTE 2. Recirculation of exhaust air or reduced air flow during painting may result in a DeMinimus violation from OSHA. See Appendix D, Fig. D-2 – OSHA Interpretation regarding the DeMinimus violation.

Ventilation during Drying (Curing)

Review the paint drying requirements before specifying temperature and humidity ranges. Although the airflow level may be used for drying or curing, a lower ventilation airflow rate is recommended during drying the Drying (Curing) mode to conserve energy. Recirculation of exhaust air can be used if sufficient outside air is provided to

keep the concentration of vapors and mists in the exhaust stream of the ventilation system below the 25 percent of the LEL. Note that the quantity of off gassed vapors is higher early in the drying process, tapering off at the end of the drying cycle. Refer to ANSI/AIHA Z9.7 for exhaust air re-circulation requirement. During the Drying (Curing) process, the hangar must be given the same operational status as the Paint Spray Operation, requiring that all personnel who enter wear the appropriate protective gear for the duration of the Cure cycle. If the ventilation rate is reduced during the Cure cycle, the hangar must be considered unoccupied with restricted access.

Sanding Operations.

Sanding in a space designated for paint spray operations is not recommended. However, if relocating the sanding process is impractical, vacuum exhaust systems must be provided for the sanding tools to minimize the dust generated in the space during sanding operations.

Ventilation Air Flow Study.

A detailed, in-depth analysis must be completed or other historical verification must be provided to prove that the airflow introduced into the paint area will be uniform in distribution and velocity, and that the system can be properly operated for building pressure requirements. Many systems do not perform as anticipated during the design process, due to lack of foresight of real world conditions, the influence of building structure, the air delivery system inlet and outlet conditions, the air exhaust system, the actual aircraft characteristics and surrounding scaffolding and access equipment, among other things. The analysis can be performed by scaled mockup, scaled wind tunnel analysis or Computational Fluid Dynamics (CFD) modeling, among others. The Navy has also specifically endorsed the use of CFD. Refer to OPNAVINST 4790.2. For more extensive information on CFD modeling refer to High Performance Computing Modernization Office (HPCMO), the National Institute for Occupational Safety and Health (NIOSH), the American Society of Heating, Refrigeration and Air Conditioning Engineers (ASHRAE), the American Society of Mechanical Engineers (ASME), the U.S. General Services Administration (GSA) and the U.S. Environmental protection Agency (EPA) for studies using CFD analysis for industrial ventilation requirements. It is suggested to employ a third party consultant to perform these functions.

B-2.2 Program Planning for Determination of Areas for a New ACCPF.

Gross Area Calculations for Corrosion Control and Paint/Depaint Hangars

Note: for clarity of calculations, all dimensions are in English inch-pound units.

1. Introduction
    a. This method is being provided to allow better accuracy in estimating gross areas by programmers and base project managers. This can be used ahead of, or in conjunction with, developing the Requirements Document. It needs only a minimal amount of information to arrive at a reasonable gross area for programming purposes.

b. There are a large number of required and optional rooms/spaces to be accounted for. In the past, most of these rooms were never identified until late in the process - well after the gross area had been fixed. By providing a list of potential spaces, a series of yes/no decisions can be used to quickly determine the area requirement.

c. The following areas are typical CCF spaces and do not necessarily represent all possibilities. The addition of spaces unique to the specific mission should be reviewed and added to the area total as appropriate.

2. Hangar Bay

a. The hangar bay size is set by the size of the largest aircraft anticipated. To meet UFC requirements, a minimum 10 feet clear to structure is added to each side, front and back of the aircraft dimension (an additional 5 feet is added to account for building structure to arrive at gross area). This creates a rectangular hangar bay.

b. (Aircraft width + 30)x(Aircraft Total Fuselage length + 30) = Hangar Bay (Base Amount)

c. Most medium/large aircraft save space by creating a nose or tail pocket. The dimensions of the pocket are determined by the need to keep a minimum of 15 feet from either the leading or trailing edge of the wing to the pocket; and by the need to keep 15 feet clear on either side of the fuselage/tail within the pocket.

d. This space is subtracted for the hangar bay, but is added back as support spaces below.

e. The physical shape of these pockets is difficult to calculate without significant effort. However, the following calculation will identify the gross square footage that can be carved out by the pockets.

f. (Aircraft Width x Aircraft Length[forward or aft of the wing]) = Hangar Bay (Amount to be Subtracted)

g. Finally, the team must determine if and how much user equipment is to be stored/located within the hangar bay. This may include parking for lifts, process tanks for wash/etch/conversion coatings or wing/tail stands. While the exact position of these items will not be known at this time, the following calculation will allow sufficient GSF.

h. (Process Width x Total Fuselage Length) = Hangar Bay (Process Support)

i. B - F + H = Gross Hangar Area

Note: Some facility missions require the flexibility to house different or multiple aircraft in a single facility. This flexibility requires advanced planning, significant design input and will incur impact to the budget. Careful consideration should be given early in the planning stages to the current and possible future missions to provide the most cost effective facility which fulfills its current mission while requiring minimal retrofit as future projected mission changes occur.

3. Supply Air Plenum/Exhaust Air Plenum
    a. These are usually needed to provide laminar flow, but there are some alternatives where they may not be needed.

    b. The supply air plenum requires space for distributing the air across the cross-section of the aircraft. This space needs to be somewhat larger than the exhaust air plenum.

    c. (Aircraft width + 30) x (25 feet) = Supply Air Plenum Space

    d. (Aircraft width + 30) x (15 feet) = Exhaust Air

4. Air Recirculation Fan Rooms
    a. If air recirculation is used, space is required for the recirculating air fans separate from the exhaust fans.

    b. Assuming an average hangar bay velocity of 60 fpm, 80% recirculation would equal 50 fpm.

    c. Since the actual hangar bay geometry is not known, assume a rectangular space based on the aircraft width times aircraft height.

    d. The area needed is directly proportional to the number of fans and the size of the fans.

    e. For allocating space requirements, the calculation of 20,000cfm/fan and 60sf/fan provides a good estimate of the total area needed. This is in spite of the likelihood that on larger (cargo-size) hangar bays, the fans could be as much as 100,000 cfm/fan and 300sf/fan.

    f. If the space is less than 2000 sf, allocate 2000 sf minimum to ensure accessibility, maintainability, clearance to electrical equipment)

    g. (Aircraft width x Aircraft height) x 50fpm ÷ (20,000 cfm/fan) x 60sf/fan

    h. Adjust the total ventilation and recirculation rate (sub.para. b. above) to the actual application in order to most accurately estimate the area of the Air Recirculation Fan Room.

5. Supply Fan Rooms

a. This space includes both outside air and recirculated air supply fans necessary to provide the total air required across the cross-sectional area of the hangar bay. So, this space is needed regardless of the use of air recirculation.

b. Similar to the Recirculation Fan Rooms analysis, the room size is dependent on the size and number of fans.

c. For gross area calculations, use a conservative 75fpm across the cross-section of the hangar.

d. Due to differences in how the fans operate, this calculation uses 25,000cfm as the match to a 60sf fan requirement.

e. As above, a minimum space allocation of 2000sf should be used to ensure adequate space.

f. (Aircraft width x Aircraft height) x 75fpm ÷ (25,000cfm/fan) x 60sf/fan

g. Adjust the total ventilation rate (sub.para c. above) to the actual application in order to most accurately estimate the area of the Supply Fan Room.

6. Paint Storage
    a. Generally, if paint is stored in the facility, sufficient space needs to be provided to allow for two full paint operations (where applicable, this means two full prime and top coat).

    b. A standard 50 sf should be allocated for entry into the room

    c. Include the room's ventilation system which is required but who's size is generally independent of the actual paint stored.

    d. Use 5sf/gallon to determine the room size. This takes into consideration that most paints are 2-component systems and are provided in one- and five-gallon containers with 1-pint to 1-quart for the second component.

    e. (Number of gallons to paint two aircraft) x 5 + 50sf

7. Decontamination
    a. This includes all space associated with the decontamination process. For very minor corrosion control operations in existing hangars, an alternative decontamination process may be permitted locally but this is not recommended.

    b. Size is based on total number of workers since size is mostly determined by the lockers required. Also, one shift is normally 70 - 80% of the total so shower/wash requirements are close to that required for a total number of

workers basis. To ensure adequate space for both male and female workers, this calculation sizes the rooms to accommodate up to 100% male and up to a 50/50 male/female ratio. A lower ratio may be considered, but must be at least double your current female population count.

c. To account for air locks, separation walls or other hidden spaces, include a standard 500sf.

d. Use 40sf/worker to account for clean/dirty lockers, showers, wash basins and the above mix of male/female.

e. (Total number of workers on all shifts) * 40 + 500sf

8. Special Allocation
   a. If you have a large number of workers, the room layout will likely become less efficient.

   b. If the number of workers exceeds 25 per shift, add 200sf.

9. Communications Rooms
   a. If the maximum length inside the facility (corner to corner) is less than 290 feet, a single communications room should be adequate for planning gross area. Even if this assumption is later found to be incorrect for other reasons, the small size of the room is covered by other allowances in these calculations.

   b. Generally, the individual services have their own standard for the primary communications room. Since there are very few phone/data requirements compared to the size of the facility, the minimum size will almost always be sufficient.

   c. Use 100sf for the primary communications room, and 80sf for any secondary communications room, unless your service has a different criterion.

10. Wash Rack Equipment
    a. Where the corrosion control facility has an associated wash rack, space must be provided for that equipment within the facility. Note that dry media paint removal requires, under the Aerospace NESHAP, a wash rack either at the facility or within a short distance of it.

    b. The wash rack itself is not addressed here for gross area calculations. Since this is the most common, an interior wash rack facility area is not addressed.

    c. The wash rack equipment includes hot water, hot soap solution, cold water, concentrated soap, pumps, and storage for hoses. Generally, the

maintenance space requirements outweigh any differences in quantities to be stored.

d. Use 400sf for wash rack equipment if identified.

11. User Equipment Storage (Adjacent to Hangar Bay)
    a. This includes items that are used in the hangar bay by the user, are contaminated or potentially contaminated, but cannot (for various reasons) be left in the hangar bay itself. Typical items are paint carts, dry media hoses, and similar equipment.

    b. The amount of equipment is dependent on production rates and, consequently, the number of workers per shift.

    c. As with other rooms, there is a fixed requirement for room access and ventilation that adds 200 sf to any other actual requirement.

    d. While highly variable in function, a space allocation of 4sf/person will normally provide adequate storage.

    e. (Number of workers on a shift) x 5 +200)

12. Chemical Storage
    a. This space includes rooms for storing detergents, acids and solvents. For fire safety and other reasons, these are usually separate rooms (very small quantities can be stored in flammable cabinets in a single room).

    b. To account for spill containment, egress and circulation space, use a standard 50sf.

    c. Each 55-gal drum requires 5 sf.

    d. (Number of 55-gal drums) * 5 + 50sf

13. Corridors
    a. For corrosion control and paint/depaint hangars, corridors can become a significant space. In many cases, the site constraints will force a less-efficient room layout. In every case, the need to handle material with a fork lift creates the need for much wider corridors and more space.

    b. Since most rooms are accessed from a corridor (either a personal or material handling), the number of individual rooms is the best guide for determining the space needed.

    c. For basic egress routes, allocate 1000sf in addition to all other requirements.

d. Most rooms will run 10 - 20 feet along a corridor. An average corridor width is around 6' (4' for personnel, 8' for material handling), but shared between rooms on both sides. Use 40sf/room.

e. (Number of Rooms) x 40sf/room + 1000sf

14. Electrical Rooms
    a. The single largest load in most corrosion control and paint/depaint hangars is from the fans and hangar lighting. Therefore, the size of the hangar can be used to size the electrical room(s).

    b. Most panelboards will be located in other rooms; this room is primarily for switchgear and similar items.

    c. Due to the higher risk of electrocution, and to meet egress requirements, greater clearances are needed

    d. Use 1% of the hangar bay area, plus a standard allowance of 200sf to cover egress requirements.

    e. The addition of process cooling will increase the size of the electrical room, but for ease of use, that space is calculated within the process cooling room.

    f. (Hangar Floor Area) * 0.01 + 200sf

15. Storage for supply and exhaust filters
    a. If filter replacement is by service contract, this space may still be desirable, but is not critical since the service contractor can be expected to stage the filters ahead of their need.

    b. New facilities need to store supply filters, plus NESHAP-compliant exhaust filters (3-stage). A "filter set" is made up of one 24x24 supply filter, one 24x24 paint arrestor area, one 24x24 second-stage filter, and one 24x24 final filter.

    c. This calculation is for sizing the room as simply as practical - the actual design will be based on more rigorous mechanical engineering analysis. Presuming horizontal air flow, one set of filters (generally 24x24 size, except for paint arrestor blankets that are rolls) is needed for every 400 to 800 cfm (this gives 100-200 feet per minute through the exhaust filters, which optimizes the number of filters while maintaining laminar air flow). Consult the filter manufacturer to verify NESHAP certified airflow for the proposed paint arrestor exhaust filters.

    d. At the least, it is likely that a set of filters will need to be staged within the facility for at least several days to several months.

e. To get a rough idea of the number of filter sets multiply aircraft width by height to get a conservative cross-sectional area and multiply by 50 to get a rough order of magnitude for the air flow cfm. Divide by 150 feet per minute to arrive at the number of square feet of filter area. Divide by 4 sf to get a rough count on the number of filter sets; then divide by the planned stacking density (approx. 3-4 high). Multiply the number of stacks by 2 sf/stack to arrive at the space needed for storing filters, plus allow 100sf for accessibility to deliver and retrieve the filter boxes.

f. Generally, you cannot stack boxes more than 3 - 4 high.

16. Heating System

a. This is space for hot water boilers and steam boilers (for humidification). If direct or indirect fired burners are used within the air handling units, the AHU space should already properly account for that space.

b. As with the electrical room, the size of this equipment (and the room area) are proportional to the hangar floor space.

c. Generally, this room must be isolated with a fire-rated wall separate from all other functions. To account for this, include a base 200sf requirement.

d. Note: this space is sized on the presumption that the coat must cure in 8 hours, which requires a higher temperature and humidity than the application of the coating. If a longer cure time is acceptable, this space can be reduced by 25% or more.

e. Use 1.33% of hangar bay floor area to size this room.

f. <u>(Hangar Floor Area) * 0.0133 + 200sf</u>

17. Process Cooling

a. Note: the cooling equipment is considered required when its purpose is to meet bioenvironmental (heat stress) and paint application requirements.

b. The space is proportional to the hangar dock area.

c. For depot-level (paint/depaint) operations, consideration should be given to the addition of one spare chiller (or space for an additional chiller) which may be required to fulfill the mission of the facility. For Corrosion Control Facilities, the space may not be needed at all. But, if needed, reduce by 25% to account for not needing the spare chiller.

d. To account for pumps, air separators, and access around equipment, include a standard 300 sf.

e. Use 4% of hangar dock floor area to size this room.

f. (Hangar Floor Area) * 0.04 + 300sf

18. Special Allocation
    a. If the combined space for heating and cooling exceeds 4000sf, include an additional 1000sf to account for greater accessibility needs. This will ensure that all pieces of equipment can be replaced at the end of their useful life.

19 Administrative Spaces
    a. For depot-level (paint/depaint) hangars, a new, compliant, efficient, facility tends to draw additional administrative requirements (e.g., second level supervisors).

    b. See other sections of this UFC for the list of administrative spaces. Spaces such as conference rooms, Fax/Copier rooms [ASHRAE Indoor Air Quality Standards generally require a separate room for fax/copiers/printers] T.O. Library Room are fixed generally regardless of the population. To account for all spaces, use a standard 250sf.

    c. Otherwise, admin space can be calculated on a per-person basis without regard to rank/supervisory level.

    d. To account for gross square feet, use 120sf/person.

    e. (# of Admin/Supervisory persons) * 120 + 250sf

20. Break Area
    a This area should be as far from any contamination sources as possible and must be large enough to support the largest number of workers (aircraft and admin) expected. OSHA is paying very close attention to workers being provided the space to eat away from their work.

    b. A standard break area should include space for sinks, counters, microwaves (as many as one for every 10 workers), refrigerators (some organizations are now using commercial refrigerators that may be as large as 3'x6', and may have more than one), vending machines (for space purposes, assume 3 vending machines), ice machine, trash/recycling receptacles, or other storage unit. To account for these items, include a standard 500sf.

    c. The remaining space is for tables, chairs and circulation. The general guidance is to estimate 15sf/person.

    d. (Total Number of Workers in the Facility) * 15 + 500sf

21. Sprinkler Risers
    a. Usually, these are located in other spaces, but this ensures that the required space is considered in the total gross area.

b. Generally, assume one riser per 15,000sf of the otherwise total area.

c. (Entire Calculated Area) / 15,000 * 50sf/riser

22. Fire Pump Room
    a. Most hangars will need fire pumps because of the fire protection water demand, unless the installation has a separate water distribution system designed to support the fire protection systems in the hangars

    . b. Use a standard 1000sf.

23. Blast Media Unload/Storage
    a. Blast media is subject to two primary issues. First, the blast media is broken down by the blast operation and a certain amount of makeup media is needed. Second, it is possible to contaminate a full batch of media in a way that requires replacement of the entire batch.

    b. The quantity of blast media is very dependent on the specific operation and size of aircraft. Depaint hangars may need sufficient media on-hand to completely replace a contaminated batch. For a large aircraft, this could be 50 - 100,000lbs. For a corrosion control operation, it may be only necessary to have a two- to four-week supply based on normal depletion rates.

    c. Material is frequently delivered in 500-lb “super-sacks”. These are usually delivered on a 4x4 pallet so each super-sack will need about 20sf of space.

    d. Delivery paths for forklifts and normal circulation will add a standard 500sf.

    e. (Weight of Media Stored) * 0.04 + 500sf

24. Blast Media Recovery and Feed
    a. Blast Media is recovered using at least three and sometimes four processing steps. These include magnetic separation of iron particles, cyclone separation of media that has become too fine to be useful.

    b. The equipment is fairly large, so even a small operation should allocate 2000sf as a minimum standard area.

    c. The equipment size is, as above, dependent on what the user intends to use the system for. For depaint hangars, assume that the system must hold sufficient clean media for a full strip. In this way, even if the recovery system should fail, one complete aircraft could be stripped.

    d. (Total Weight of Media to Strip one aircraft) * 0.04 + 2000sf

25. Issue Room/Pharmacy

a. Most aircraft operations involve some amount of aircraft preparation (masking, replacement of sealants, small tools and parts, coveralls) In addition, it may be necessary to dispense solvents from an open container, which requires a separate, rated, room. This space covers these items. If the user has a list of material, it is relatively simple to calculate the shelving needed and, from that, the total space.

b. However, since that may not be available, for ease of calculation, use the number of workers per shift.

c. To account for workers assigned to the issue room/pharmacy and basics (desks, issue window, standard circulation), use a standard 500sf.

d. Use 30sf/worker.

e. (Total number of workers per shift) * 30 + 500sf

B-3 PERSONNEL SAFETY ISSUES.

B-3.1 Respiratory Protection.

29 CFR 1910.134(d), *Respiratory Protection*, specifies requirements for respiratory protection. Consult with an industrial hygienist or occupational health specialist to determine the appropriate type of respiratory protection required for each process.

B-4 MAINTENANCE CONTRACTS.

B-4.1 Service Contracts.

The process HVAC system for an ACCPF represents the most significant and critical function essential to fulfill the mission of an aircraft corrosion control facility. Today's controls are designed to operate automatically to maintain proper temperature, humidity, air velocity, hangar bay static pressure with numerous interlocks to ensure personnel safety. The precision of the controls along with the absolute necessity of high performance from the mechanical systems puts the process HVAC systems of an ACCPF into the category of demanding rigorous and specialized preventative maintenance on a regular basis. Because of the uniqueness and complexity of the equipment, these systems generally fall outside of the normal maintenance capabilities. It is therefore recommended that this preventative maintenance function be delegated to a company (or companies) who specialize in such systems on a regular basis through an annual service contract. Consider an annual service contract during the planning phase of a new Project.

The recommended annual tasks to be performed on the system at a minimum would include verification of control functions, test and balance and calibration of all air and water system temperatures and flow volumes. This work would be completed most efficiently in two parts, during the winter season for the heating system, and then in late spring, prior to the summer season for the cooling system. This work must be

accomplished in addition to any other mechanical preventative maintenance (belt adjustment/ replacement, filter changes, greased bearings) that is normally performed on the mechanical equipment.

B-5 LESSONS LEARNED

The purpose of this section is to highlight selected lessons learned during the design, construction, and operation of corrosion control facilities that have been previously built. These lessons can be a good tool for guidance in the design of new and renovated facilities. By not repeating these mistakes, we hope to be able to design better facilities that will meet the needs of the users, state, local, and federal regulatory agencies. Eliminating the need for modifications to new or renovated facilities could potentially save millions of dollars.

The following are lessons learned from existing Air Force corrosion control facilities.

B-5.1 Dimensions of Booth/Bay.

Ensure that all dimensions of the largest aircraft to utilize the facility are taken into consideration during the design phase of the booth. The measurements must include adequate additional space for maintenance stands and work areas.

B-5.2 Incorporating Fall Protection Control Measures.

If fall hazards cannot be eliminated, fall protection and prevention measures must be incorporated or installed in all corrosion control facilities to ensure the safety of all personnel while working on the aircraft. If fall protection are incorporated into the design phase of the project, it will eliminate the need for added cost in rework to later install the system. Attached safety harnesses will allow for proper complete aircraft paints and eliminate the need to paint portions of aircraft outdoors or in unauthorized hangars. AFOSHSTD 91-100, *Aircraft Flight Line – Ground Operations and Activities*, paragraph 8.2.5 states that *"Whenever it becomes necessary to perform required tasks where a worker can fall 4 feet or more, fall protection will be used."* See AFOSHSTD 91-501, Air Force Consolidated Occupational Safety Standard, for more information on fall protection equipment. EM 385-1-1, Section 5 and Section 21, addresses fall protection requirements.

B-5.3 Proper Sizing of Air Compressors.

Research what size compressor will be needed to accommodate all facility requirements based on all workers using tools simultaneously. It is also important to ensure that the building is wired to accommodate the proper size compressor.

B-5.4 Equipment Designation.

For some services and installations, it may make a difference if special equipment is designated as real property. This designation may effect which parties can accomplish repairs and routine maintenance. It may be beneficial to coordinate equipment

purchase with the local installation support offices to ensure support for maintenance and repairs. Also, it is highly recommended that a maintenance contract with the manufacturer be considered.

B-5.5 Airflow Requirements

The objective of an optimum airflow design in a spray paint environment must be to achieve a linear near laminar air flow pattern. 29 CFR 1910.107 (b)(5)(i) states, "*The spraying operations except electrostatic spraying operations shall be so designed, installed and maintained that the average air velocity over the open face of the booth (or booth cross section during spraying operations) shall be not less than 100 linear feet per minute. Electrostatic spraying operations may be conducted with an air velocity over the open face of the booth of not less than 60 linear feet per minute, or more, depending on the volume of the finishing material being applied and its flammability and explosion characteristics. Visible gauges or audible alarm or pressure-activated devices shall be installed to indicate or insure that the required air velocity is maintained. Filter rolls shall be inspected to insure proper replacement of filter media.*"

B-5.6 Air Exhaust

Do not locate exhaust ports below the hangar air intakes, or in any configuration to create a potential for contaminated air to be recirculated through the facility. This may increase the solvent concentrations above the lower LEL limits creating a potential fire hazard. AFOSH Standard 161-2, *Industrial Ventilation*, paragraph 2.b. (6), notes that "*the air supply intake or process exhaust must be located to prevent contaminates being brought back into the facility*." 29 CFR 1910.107 (d)(9) states, "*Air exhaust from spray operations shall not be directed so that it will contaminate makeup air being introduced into the spraying area or other ventilation intakes, nor directed so as to create a nuisance. Air exhausted from spray operations shall not be recirculated*."

B-5.7 Electrical Equipment in Spraying Area

29 CFR 1910.107 (c)(5) states, "*Unless specifically approved for locations containing both deposits of readily ignitable residue and explosive vapors, there shall be no electrical equipment in any spraying area, whereon deposits of combustible residues may readily accumulate, except wiring in rigid conduit or in boxes or fittings containing no taps, splices, or terminal connections.*"

B-5.8 Pressure Differential Devices

Ensure the exhaust ventilation systems for the main aircraft hangar have a pressure differential manometer and/or other devices to ensure the system is operating as designed. 29 CFR 1910.107 (b)(5)(i) states, "*The spraying operations except electrostatic spraying operations shall be so designed, installed and maintained that the average air velocity over the open face of the booth (or booth cross section during spraying operations) shall be not less than 100 linear feet per minute. Electrostatic spraying operations may be conducted with an air velocity over the open face of the booth of not less than 60 linear feet per minute, or more, depending on the volume of*

the finishing material being applied and its flammability and explosion characteristics. Visible gauges or audible alarm or pressure-activated devices shall be installed to indicate or insure that the required air velocity is maintained. Filter rolls shall be inspected to insure proper replacement of filter media."

This Page Intentionally Left Blank

APPENDIX C APPLICABLE ENVIRONMENTAL STANDARDS

C-1 FEDERAL.

Many different federal environmental standards and regulations significantly impact the design of a Corrosion Control Facility. This vast array of requirements exceeds the scope of this guide and will not be covered in significant detail. For more information of environmental standards and regulations, contact your local environmental engineer and bioenvironmental office. During the planning stage of the corrosion facility, planners will complete a General Conformity applicability analysis before completion of the Environmental Impact Analysis Process (EIAP) to allow incorporation of its information into the EIAP. Federal actions must conform to the approved State Implementation Plan (SIP) until the State modifies the SIP or EPA approves the SIP.

C-1.1 Clean Air Act.

The Clean Air Act (CAA) is the major Federal statute (EPA 40 CFR Chapter I) governing the quality of ambient air and permitting releases to the air. There are several programs in the CAA that may have significant impacts or restrictions on the corrosion facility. One main way that the air quality is assured is the new source review (NSR) program. NSR program requires operators of certain types of air pollution-emitting facilities to apply for permission to build in certain areas to prove that the air will not result in worse air quality. These new major sources must not upset the established national ambient air quality standards (NAAQS) and may be required to implement Best Available Control Technology (BACT) to reduce hazardous air pollutants (HAPs) to Lowest Achievable Emission Rates (LAER). There are three types of permits issued under the NSR Program. The permits are Prevention of Significant Deterioration (PSD), nonattainment area NSR, and minor source NSR. The permit is based basically on the threshold values of regulated pollutants.

The National Emission Standards for Hazardous Air Pollutants for Source Categories: Aerospace Manufacturing and Rework Facilities (commonly called the Aerospace NESHAP) EPA 40 CFR Parts 9 & 63 must be applied as applicable in the design of Corrosion Control and Paint Finishing Facilities. This EPA standard applies to facilities that are a “major source” of hazardous air pollutants (HAP) and are involved in the manufacture or rework of commercial, civil, or military aerospace vehicles. (A “major source” of HAPs is defined as a facility or group of aerospace facilities within a contiguous area that emits or has the potential to emit 10 tons per year or more of any listed HAP or 25 tons per year or more of any combination of listed HAP) The local Environmental Management function will use many references, such as a NESHAP flow chart (Figure C-1) to determine if the proposed facility has the potential to be designated as a major source. This important determination will provide key information on whether or not Aerospace NESHAP requirements will apply to the facility, and will have very significant bearing on many design requirements for the facility.

It is important to note that many bases have elected to comply with NESHAP requirements even if they are not currently legally required to do so. Although the

decision to voluntarily elect to comply with NESHAP requirements might initially lead to expensive facility design requirements, it ensures the facility will already be NESHAP compliant if circumstances change at the base and the facility is required to comply with NESHAP requirements at a later date. Reference the National Environmental Policy Act Compliance Guide.

Control of Volatile Organic Compounds.

EPA provides Control Technique Guidelines that States may incorporate into their rules limiting volatile organic compounds for non-major sources of Hazardous Air Pollutants. Reference EPA-453/R-97-004, *Control of Volatile Organic Compound Emissions from Coating Operations at Aerospace Manufacturing and Rework*.

C-1.2 Clean Water Act.

The Clean Water Act (CWA) is the primary Federal statute (EPA 40 CFR Chapter I) governing the quality of the Nation's water. It prohibits the discharge of any pollutant into navigable waters without a permit. Review the National Pollutant Discharge Elimination System Permits (NPDES) permits, the installation of the Spill Prevention, Control and Countermeasures (SPCC) and related documents pertaining to water quality. Also, remember that the Storm Water Pollution Prevention Plan (SWPPP) may need to be reviewed or updated. If the construction disturbs one or more acres, a completed SWPPP and submission of Notice of Intent (NOI) must be timely.

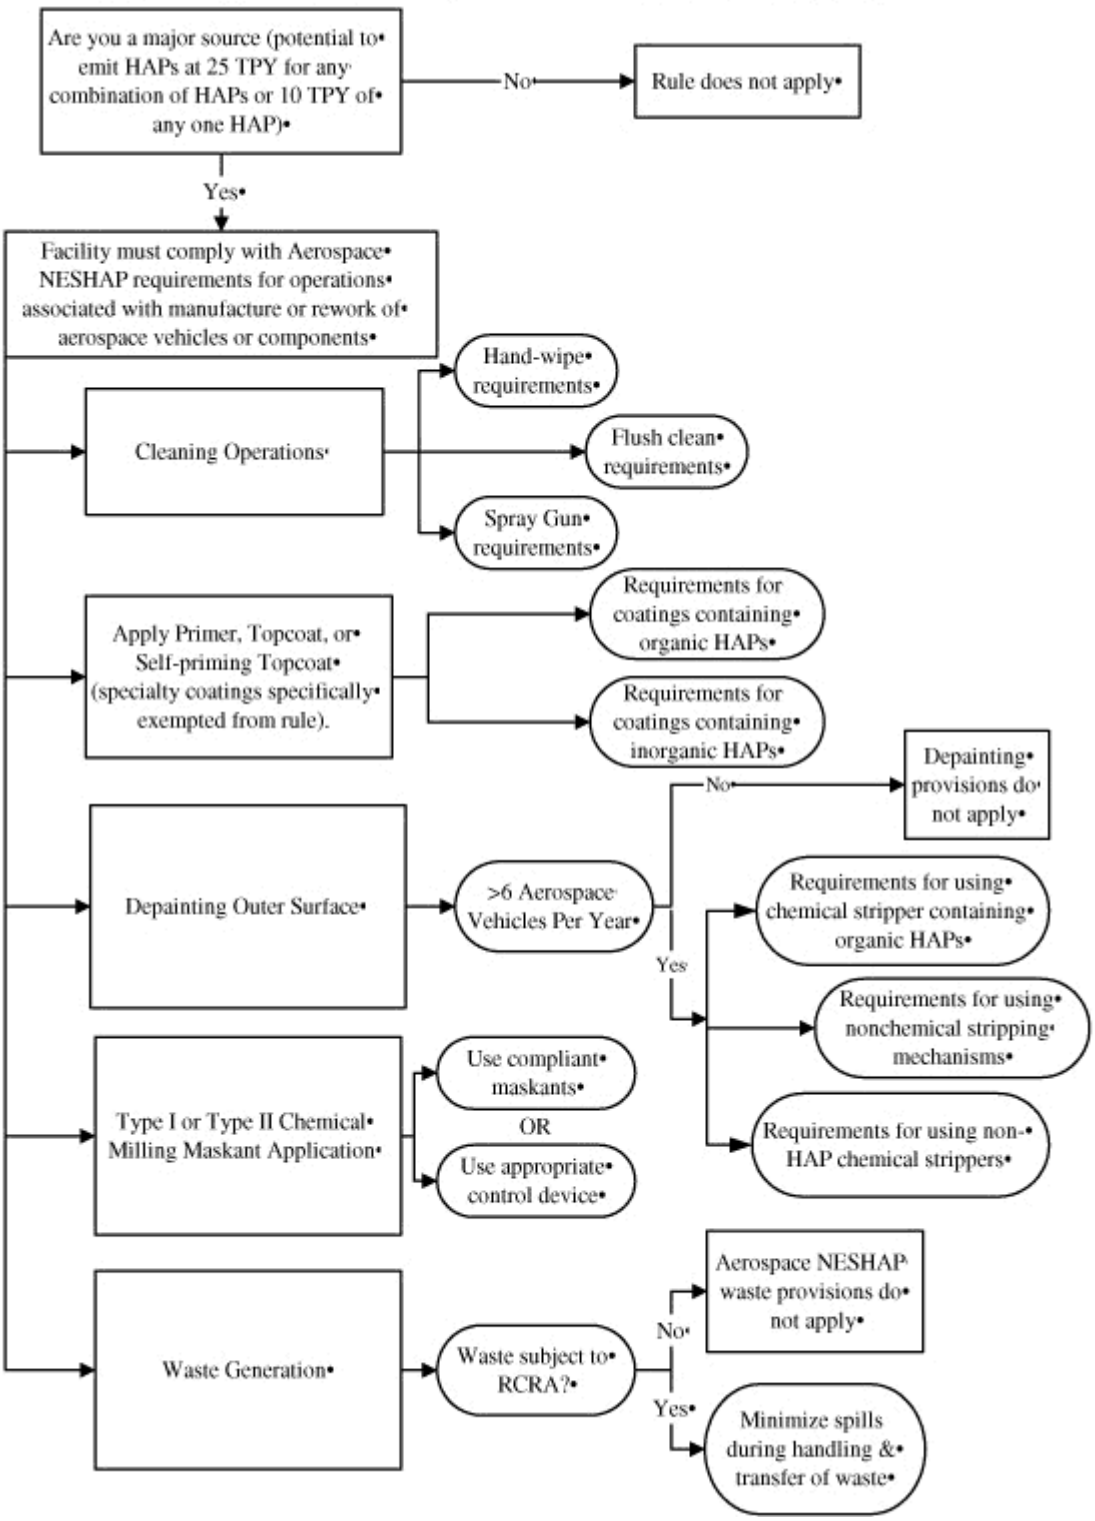
Wastewater discharges from Federally Owned Treatment Works (FOTWs) that is a point source into waters of United States require a NPDES permit. Discharges to Publicly Owned Treatment Works (POTWs) are considered as secondary discharges and are regulated by the POTW authority. POTW authority may have applicable regulations, permits, and agreements.

C-1.3 Resource Conservation and Recovery Act.

The Resource Conservation and Recovery Act (RCRA) is the broadest and widest waste law [40 CFR Chapter I, Subchapter I]. It manages waste included in a variety of other Federal statues such as Toxic Substances Control Act (TSCA), Used Oil Recycling Act, CAA, CWA, and Occupational Safety and Health Act. RCRA regulates solid waste (SW) and hazardous waste (HW) under the concept known as "cradle to grave". Many routine aircraft maintenance operations produce HW because of RCRA's definition. The hazardous waste management plan (HWMP) covers issues such as training, characterization, accumulation, treatment, recycling, inspections, and disposal of HW. One area that might be overlooked is industrial wastewater. Governmental regulations may prohibit discharging such wastewater into domestic wastewater or other non-industrial sewer systems. Pretreatment may not be practical also resulting in the wastewater to be managed under RCRA.

The bulk of what has to be done as RCRA is actually found in the Hazardous and Solid Waste Amendment (HSWA) that was pasted in 1984. Care must be taken with RCRA regulations found in EPA 40 CFR Chapter I, Subchapter I, Parts 260-281. In some

activities, the generator can become the transporter or the treatment, storage, and disposal (TSD) facility based on HW duties and activities. This can have a major impact on training and the HWMP. Be sure to coordinate with local environmental engineers and bioenvironmental personnel for complete RCRA understanding.



C-2 STATE.

In addition to meeting various federal laws, regulations and standards, the facility will also be required to comply with many different requirements mandated by the state the facility is located. Unfortunately, individual state environmental programs sometimes vary greatly. Therefore, it is important for local base agencies assisting in the design process to have access to the most current information. This type of information that is specific to each state can be found at the following website: http://www.rmis.com/db/lawepa.htm.

C-3 LOCAL.

More focus is being placed on the impact of local regulations through the Public Owned Treatment Works (POTW). Local systems are under tighter demands for drinking water, water usage, and sewer treatment. Industry programs many times focus only on the end-of-pipe solutions, which only handles wastewater pollutants. Yet, facilities that work with local regulators can help reduce pollution and waste cost. Ensure that local regulations are reviewed to prevent construction delays and reduce potential construction retrofits.

Figure C-1 Application of Aerospace NESHAP to Various Operations

APPENDIX D OSHA INTERPRETATIONS AND REFERENCES FOR REDUCED AIRFLOW AND RECIRCULATING AIRFLOW

This appendix is included as an aid to the designer for information regarding OSHA requirements for both reduced airflow velocity in the painting zone and allowance of recirculation of exhaust air when proper measures are taken for corrosion control hangars. The U.S. Air Force, which bears the largest share of corrosion control expenses for its fleets of aircraft, have taken a pro-active approach in these matters. Refer to Appendix B, page, B-4, of AFRL-ML-TY-TP-2004-4518, for a detailed analysis, response and requirements of the OSHA interpretations and supporting calculations for the recirculating model. The following is the Abstract from that publication-

"*The text of 29 CFR 1910.107(d)(9), which was imported from the 1969 revision of a fire safety standard, prohibits recirculating ventilation in spray painting facilities. Devices to measure vapor concentrations obsolete this standard almost immediately, but efforts to amend this statement have been frustrated. To accommodate advances in technology, OSHA invoked the designation "de minimis violation" to enable the use of recirculation and other technologies that comply with the most current consensus standards applicable to their operations . . . when the employer's action provides equal or greater employee protection. Whereas industry has adapted to this expedient, Department of Defense agencies have consistently interpreted that if 107(d)(9) is still in print and the alternative is called a violation, however qualified, military installations will not be given permission to employ exhaust recirculation (ER). Individual bases working in isolation have built a few examples of painting hangars using ER, but each of these facilities suffered from one or more serious design faults. Robins Air Force Base (RAFB), near Macon, Georgia, is acquiring a painting hangar to accommodate painting of C-5 aircraft in an ER ventilation system. Because the economics of exhausting 2.5 million cfm of temperature-controlled air is untenable, critical justification for using ER is provided by RAFB's environmental conditions, which require cooling and dehumidifying air used in the ventilation process during four to five months each year. This report identifies documentary precedents for competent designs of future paint facilities and describes the preparation and issuance of a design-and-build contract for construction of this new facility at RAFB*."

…Consistent with the interpretations12, 14, and 16 above, OSHA inspectors did not cite L3 or Air Force facilities using ER ventilation to paint aircraft at Seymour Johnson Air Force Base (SJAFB), N.C., and at Mountain Home AFB (MHAFB), Idaho. SJAFB's facility design placed a vapor control system inside the ER loop, lowering17 both total emissions and the increase in exposure within the workplace. The concept earned a 1994 award by EPA for environmental excellence and has profound implications17 for source reduction strategies."

The OSHA database for available information and interpretations edited as follows:

"*Laws, Regulations and Interpretations provides a comprehensive and easy to use resource for current OSHA standards and enforcement-related information.*

Interpretations, enforcement guides, and other enforcement related information will be interlinked with regulatory requirements using hypertext links. Not all interpretations which have been issued by OSHA are included on "Laws, Regulations and Interpretations page". Ongoing maintenance is designed to provide the most up-to-date OSHA standards and interpretations of employee safety and health issues, while reducing the duplication of information and removing outdated guidance."

Attached is a list of known interpretations attempting to clarify the use of reduced and recirculating airflow by OSHA. Included in the interpretations are those annotated with an "*" are no longer available from the database but are included for supporting clarification, establishing the track record of acceptance by OSHA in industry for various allowances over the last 15-20 years. A copy is included at the end of this appendix or through imbedded file links. Interpretations published on the website may be accessed directly by imbedded hyperlink.(Control-enter key on the subject)

SUBJ: INDUSTRIAL VENTILATION FLOW RATES IN AIRCRAFT HANGARS

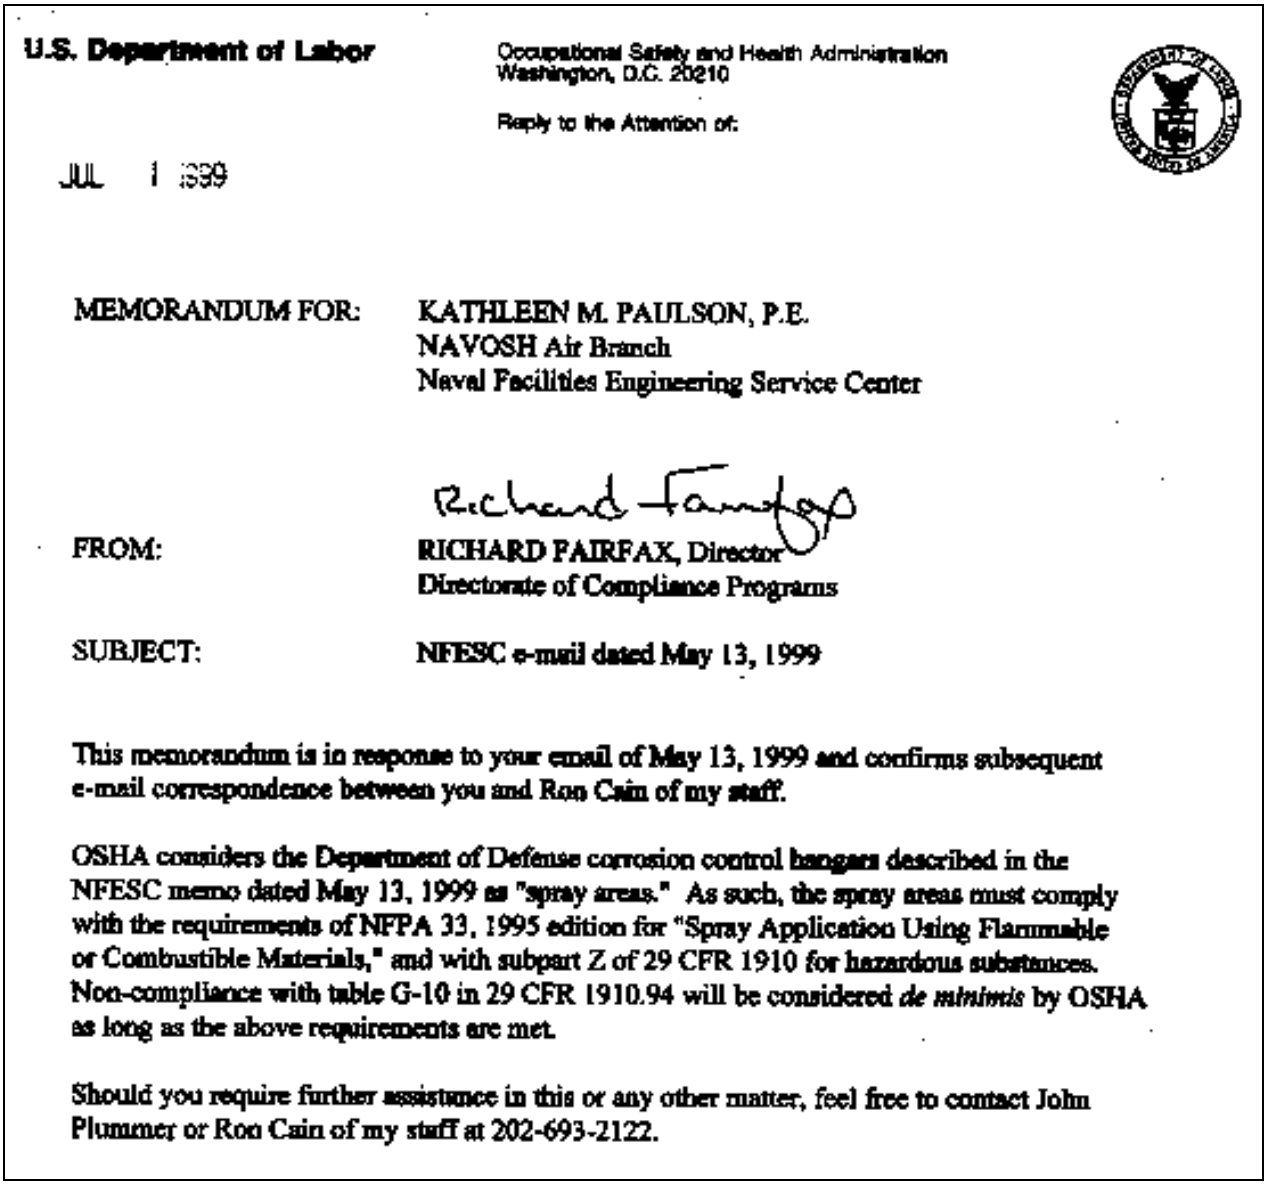
We appreciate your offer to revisit the OSHA standard interpretation you provided to the Department of the Navy, Office if the Assistant Secretary, (Installations and Environment) regarding spray painting in aircraft hangars. See Enclosures (1) and (2). When we tried to apply the interpretation that you provided to us dated April 8, 1997, we discovered discrepancies in our characterization of the processes performed in Navy Final Finish and Corrosion Control Hangars. Enclosure (3) defines the operations performed in each of the various level hangars.

Our questions are:

1. What is your definition of a production spray finishing operation?
2. How do you characterize the five operational levels of hangars discussed in Enclosure 3?
3. What airflow rate criteria is required for each of the five levels?
4. If 100 cubic feet per minute per square foot of cross-sectional area is required for any of the five operational levels, please define the term cross-sectional area. Is it:

    a) Area of the exhaust filter bank?
    b) Area of the exhaust filter bank?
    c) Air envelope around the plane, which excludes the "empty" area where there will be no aircraft parts?
    d) Full opening of the hangar, for instance the approximate side of the hangar door opening plus about 5 feet on the top and sides of the hangar reserved for maneuverability?
    e) Full opening of the hangar including open space for roof trusses?

Naval Facilities Engineering Command (NAVFAC) assigned the NAVOSH Air Branch of NFESC to revise Military Handbook 1003/17, Industrial Ventilation Systems. The handbook defines engineering design criteria for use by all components of the Department of Defense. We are adding a new chapter to the MIL-HDBK discussing the criteria for spray painting in aircraft hangars. We are having difficulties applying the interpretation to our criteria. To add to the urgency,



NAVFAC is also in the process of designing several new aircraft hangars. Reducing the flow rate from 100 cubic feet per minute per square foot of cross-sectional area will provide a significant reduction in equipment first costs and annual operating costs.

Our position is - Aircraft hangars should not be designed for 100 cubic feet per minute per square foot of cross-sectional area due to the size of the space and the dilution effect. Regardless of the flow rate, not all the paint overspray will reach the filters and we acknowledge some will drop to the floor. This is particularly true for the portion of the aircraft farthest from the exhaust filter bank. Paint spray criteria in the ACGIH Industrial Ventilation Manual permits airflow in large spaces as low as 50 cubic feet per minute per square foot of cross-sectional area. Both the NFPA 33 and the ANSI Z9.3 consensus standards require a sufficient ventilation rate to prevent vapor build-up by requiring airflow to keep the vapor less than 25% of the LEL. Airflow calculations based on LEL are typically 10-25% of the rates required for health protection. Enclosure (4) reiterates our understanding of the pertinent regulations.

Our experience shows that even in spray painting operations using flow rates of 100 cubic feet per minute per square foot of cross-sectional area, some employee's occupational exposure exceeds the PEL for certain paints and paint components. Therefore, our employees use respiratory protection when painting in hangars.

Thank you for continuing to consider our concern. Based on our phone conversation today, I understand that you are also working on this issue with the US Air Force. Could you direct us to their point of contact? Our contacts are Kappy Paulson and Trinh Do (805) 982-4984.

Reply to the Attention of:

JUL 1 1999

MEMORANDUM FOR: KATHLEEN M. PAULSON, P.E.
NAVOSH Air Branch
Naval Facilities Engineering Service Center

FROM: RICHARD FAIRFAX, Director
Directorate of Compliance Programs

SUBJECT: NFESC e-mail dated May 13, 1999

This memorandum is in response to your email of May 13, 1999 and confirms subsequent e-mail correspondence between you and Ron Cain of my staff.

OSHA considers the Department of Defense corrosion control hangars described in the NFESC memo dated May 13, 1999 as "spray areas." As such, the spray areas must comply with the requirements of NFPA 33, 1995 edition for "Spray Application Using Flammable or Combustible Materials," and with subpart Z of 29 CFR 1910 for hazardous substances. Non-compliance with table G-10 in 29 CFR 1910.94 will be considered *de minimis* by OSHA as long as the above requirements are met.

Should you require further assistance in this or any other matter, feel free to contact John Plummer or Ron Cain of my staff at 202-693-2122.

NOTE: De Minimis Violations. De minimis violations are violations of standards that have no direct or immediate relationship to safety or health. Whenever de minimis conditions are found during an inspection, they must be documented in the same way as any other violation but would not be included on the citation.

FOREWORD

Facilities Criteria (FC) provide functional requirements (i.e., defined by users and operational needs of a particular facility type) for specific DoD Component(s), and are intended for use with unified technical requirements published in DoD Unified Facilities Criteria (UFC). FC are applicable only to the DoD Component(s) indicated in the title, and do not represent unified DoD requirements. Differences in functional requirements between DoD Components may exist due to differences in policies and operational needs.

All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the most stringent of the FC, the SOFA, the HNFA, and the BIA, as applicable.

Because FC are coordinated with unified DoD technical requirements, they form an element of the DoD UFC system applicable to specific facility types. The UFC system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, applicable to the Military Departments, Defense Agencies, and the DoD Field Activities. The UFC System also includes technical requirements and functional requirements for specific facility types, both published as UFC documents and FC documents.

FC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and the Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office using the following electronic form: Criteria Change Request. The form is also accessible from the Internet site listed below.

FC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide web site http://dod.wbdg.org/.

Refer to UFC 1-200-01, *General Building Requirements*, for implementation of new issuances on projects.

Deputy Director of Civil Engineers
DCS/Logistics, Engineering & Force Protection

FACILITIES CRITERIA (FC)
NEW SUMMARY SHEET

Document: FC 4-211-03F, *Fighter Engine Maintenance Facility*

Superseding: None.

Description: This FC provides requirements for evaluating, planning, programming, and designing fighter engine maintenance facilities. The information in this FC applies to the design of all new construction projects, to include additions, alterations, and renovation projects in the continental United States (CONUS) and outside the continental United States (OCONUS). It also applies to the procurement of design/build services for the above-noted projects. Alteration and renovation projects should update existing facilities to meet the guidance and criteria within budgetary constraints.

Reasons for Document: This FC is the initial release to establish requirements for a fighter engine maintenance facility. It defines the criteria for determining appropriately sized, flexible, cost optimized, durable, quality-designed facilities on a life cycle basis to support the mission.

Impact: This FC will facilitate and standardize the design of fighter engine maintenance facilities throughout the Air Force.

- It will provide more complete and consistent project requirements and will expedite the programming and design of facilities and reduce initial design cost.
- The improved performance-based criteria and coordination with the Air Force request-for-proposal (RFP) template will reduce design-build proposals.

Unification Issues: None.

CHAPTER 1 INTRODUCTION

1-1 GENERAL INFORMATION.

The standard facility prototype design program defines consistent facility requirements across the Air Force enterprise to expedite delivery of a facility. The objective is to deliver appropriately-sized, flexible, cost-optimized, durable, quality-designed facilities on a life cycle basis to support the Air Force mission.

This FC was provides standard facility prototype design criteria to assist Air Force planners in preparing and validating requirements for DD 1391, “FY __ Military Construction Project Data,” and to assist A-E design professionals with the approved project-specific design requirements. It is a source of basic programming and functional information for fighter engine maintenance facilities. This FC is consistent with Air Force Corporate Facility Standards (AFCFS) and UFCs, and complies with Air Force Manual (AFMAN) 32-1084, *Facility Requirements*. Together with the AFCFS, this FC defines Air Force expectations for project programming and A-E design decisions.

A standard facility prototype represents a shift in Air Force facility design philosophy toward maximizing use of open office space and systems furniture. This design approach allows maximum flexibility to reconfigure the building space as mission needs change. Where offices require sound attenuation, or physical or visual separation, evaluate the use of systems furniture or demountable partition walls in lieu of full-height hard wall construction. Maximizing open office space may require more systems furniture; funding must be listed on the 1391 as an FF&E cost. Comply with the latest Air Force policy on centralized procurement of systems and other furniture.

1-2 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01, *General Building Requirement*s. UFC 1-200-01 defines applicability of model building codes and government-unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this FC in addition to UFC 1-200-01 and the UFCs and government criteria referenced herein.

1-3 REFERENCES.

Appendix A contains a list of related documents and references to be used with this FC. The publication date of the code or standard is not included. Use the latest available issuance of the reference.

1-4 INSTRUCTIONS.

The standard facility prototype was developed by determining personnel counts, allowable/authorized space/room sizes, adjacency diagrams between the functional spaces, and the overall facility space requirements. It establishes Air Force criteria for the facility type. Use these criteria together with other Air Force requirement documents such as AFIs and UFCs when programming and designing this facility type.

Supplement this FC with thorough review by individual program managers and operations staff.

1-4.1 Standard Facility Prototype Tools.

This standard facility prototype consists of four parts to be used by programmers and designers:

1. Facilities Criteria for standard prototype (this FC).
2. Interactive programming sheet.
3. Facility Building Information Modeling (BIM) drawings.
4. Supplemental RFP data.

1-4.2 Facilities Criteria.

The facilities criteria consist of three primary components:

- Notional site.
- Composite facility adjacency diagram(s).
- Modules with associated room data sheets.

1-4.2.1 Notional Site.

The notional site plan diagram depicts key site development criteria. It is not a site-specific solution. The information represents the land requirements to construct this facility and includes associated antiterrorism standoff and parking. Use of existing or shared parking is allowable and may reduce the total acreage required for the facility. Adapt the requirements to the specific site and location and comply with the applicable Installation Development Plan (IDP) and Area Development Plan (ADP) for facility siting.

1-4.2.2 Composite Facility Adjacency Diagram(s).

The composite diagram(s) represent ways to conceptually assemble the functional areas (modules) into a cohesive whole. They demonstrate how the various functional components of the facility type can be successfully placed together into layout diagrams. Individual modules are represented by different colors. They are not intended to be definitive building designs.

1-4.2.3 Modules.

Spaces and rooms that are integrally related with a specific functional connection or operational flow are grouped into a module. Modules and the associated room data sheets identify specific criteria and additional detail for each functional area of the facility as outlined in the space program sheets located in Appendix D. Information is provided in a standard presentation and data sheet format. The required space adjacencies and modules are illustrated in figures.

The modules are a grouping of functional spaces and represent “Lego® blocks” to be used in a “kit-of-parts” design approach. Use the fixed modules as pre-assembled pieces of the facility “puzzle.” Assemble them to comply with the required adjacencies indicated in the diagrams and module plans. Arrange modules and create a configuration/composite building layout/plan responding to the constraints and opportunities of the specific site.

The resulting shape of the facility assembled from the standard facility prototype modules must provide construction efficiencies obtained from building proportions and overall configuration. The building footprint shall be organized and well composed. The building design must comply with the installation facility standards (architectural compatibility plan) and the AFCFS.

1-4.2.4 Module Flexibility/Adjustments.

Modules must be used as designed to the greatest extent possible, and must not be deconstructed or altered except as indicated herein. The intent of the standard facility prototype criteria is to avoid manipulation of the composition, functional relationships, adjacencies, and module sizes. Modules contain fixed attributes and must not be changed arbitrarily. Modules may be rotated, flipped, and reversed to accommodate an overall composition or site issue. When the fixed modules cannot be arranged to produce a constructible floor plan due to site constraints, it is permissible to slightly adjust a module proportion to create a constructible plan. Manipulating the module shape must not result in an overall increase in square feet or reduce the functionality of any module or the composite plan.

Some modules are linked to space requirements that increase or decrease in size based on the personnel count and equipment for a particular mission. In these cases, increase or decrease the size of the module to match the revised scope calculation. This may sometimes require minor adjustments in adjacent modules so that they properly fit together to create a constructible facility floor plan. Spaces must comply with any critical dimensions indicated on module plans. Manipulate as few modules as possible to create a constructible facility. The resulting composite plan must respect the established modules’ adjacencies and must not exceed the authorized project scope.

1-4.2.5 Room Data Sheets.

Specific requirements for each room, space, or area are provided on room data sheets that are located following their respective module. Information contained on the data sheets defines the functional and physical requirements for each of the spaces within the facility type.

1-4.3 Programming Sheet(s).

This tool is provided in two formats. The pdf programming sheet cited in Appendix B reflects the baseline standard facility program and is provided primarily as a reference. The additional interactive programming sheet provides a tool for planners and programmers. It allows the input of authorized personnel positions and special purpose spaces. Updated inputs are automatically calculated and provide new required square

footage for each space and the estimated overall facility size. Appendix C contains a link for direct access to the interactive tool.

1-4.4 Facility Drawings – BIM.

This component of the standard facility prototype tool includes both a pdf version and Revit version of the modules and rooms. The spaces, rooms, and modules shown reflect the baseline standard facility program spreadsheet located in Appendix B. Drawings in this FC are exact copies of the larger BIM drawings and comply with the program scope. The BIM drawings provide a starting point for the digitization of building data and a starting point in the design and construction of a facility. BIM and pdf documents are found at the link provided in Appendix C.

1-4.5 Additional and Alterations.

For additions and alterations to existing facilities, use the adjacencies, sizing/scope, and detailed requirements contained in the site diagrams, module drawings, and room data sheets to the maximum extent possible. The functionality and adjacency of the modules are still valid, but may require some manipulation to fit into existing spaces. This standard may be modified slightly to accommodate the existing structure. Move non-structural walls to the greatest extent possible to open up space in the existing facilities to make them more receptive to the placement of the modules. The planner and designer will determine the most efficient means to balance the placement of modules within existing spaces or as a facility addition.

CHAPTER 2 SITE AND OVERALL ADJACENCY

2-1 GENERAL FACILITY OVERVIEW.

A fighter engine maintenance facility is typically a one-story structure. It is a standalone facility that houses fifth-generation fighter engines and maintenance crews based upon four engine work bays – typical for fifth generation fighters. (Note: The F-35 does not require a separate engine maintenance facility). The engine maintenance facility will include the following modules: engine shop bay module, engine shop support module, flight chief/training administration module, break room module, toilet/shower/locker module, and building support module.

2-1.1 AFCFS.

Consult the AFCFS to determine quality standards for this facility group. This standard facility prototype is considered a Group 3 hierarchy.

2-1.2 Facility Users/Occupants.

This facility is operated by active duty, guard, and reserve military personnel, as well as contractor representatives from the selected engine provider. The number of occupants is approximately 25 personnel per shift (typically two shifts) used by both civilian and military personnel throughout the building

2-1.3 Operational Aspects.

Hours of operation for this facility type are user-driven and vary for different engine types. Amount of air traffic on base can also alter the hours of operation. Engines are delivered on flatbed trucks from offsite locations, delivered to engine bay for initial processing, and trailered to and from the flight line. An exterior wash bay is used before and/or after an engine is serviced.

2-2 NOTIONAL SITE.

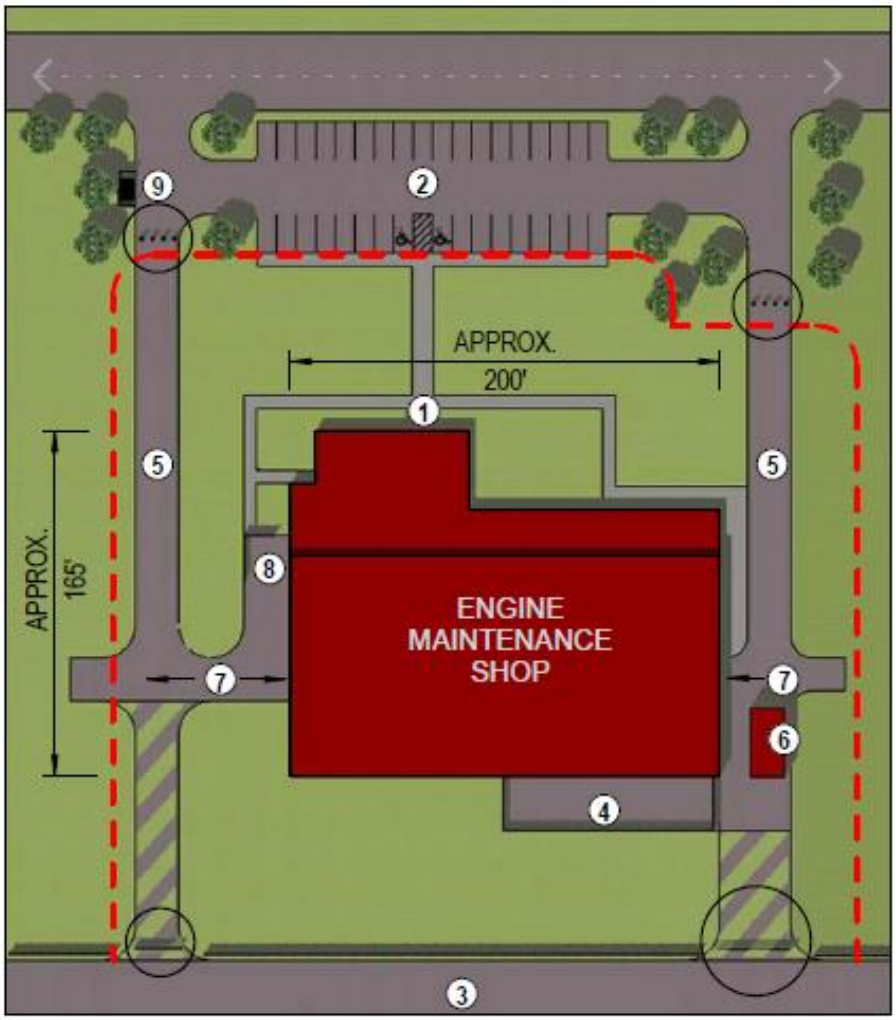
The site diagram represents a notional layout to reflect site development requirements/criteria only. It is not an actual site design. Siting must comply with the Installation Development Plan (IDP) and Area Development Plan (ADP).

2-2.1 Site Location and Orientation.

Several factors must be analyzed to determine the most appropriate and cost-effective location for a facility, such as availability and capacity of required utilities, the mass/scale of the facility relative to adjacent structures, and noise issues. Emphasize operation, function, and safety when siting the facility. The preferred location for a fighter engine maintenance facility is immediately adjacent to the flight line, or in close proximity. Other facilities/functions sited in close proximity may include general purpose maintenance hangars and aircraft sunshades. Analyze and comply with airfield clearances, building setback restrictions, and line-of-sight restrictions from the adjacent flight line.

The preferred orientation allows direct access to flight-line operations and ease of access for flight line vehicles and equipment. The approximate project area required for a four-bay shop is 4.00 acres, which includes antiterrorism standoff and parking.

2-2.2 Vehicular and Pedestrian Circulation.



Ensure convenient, safe vehicular access and circulation for personal vehicles and essential services, including operations, maintenance, deliveries, trash and garbage collection, and emergency services. Provide parking to accommodate the largest shift size plus an additional 40 percent for shift overlap. Separate service drives to the facility from parking circulation areas.

Locate sidewalk networks to provide convenient and safe pedestrian circulation from existing circulation elements of the project site to the new parking areas and doors of the facility.

2-3 COMPOSITE FACILITY ADJACENCY (FIGURE 2-2).

This facility has a mixed use of occupants and many points of entry. A majority of administration and training personnel will enter through the main building entrance. Maintenance groups will be in/out of the engine shop bay throughout the day. If the facility is operational and occupied, spaces are left unlocked and accessible for transitioning engines to/from the flight line. Finalize any additional entrances when siting and orienting the building.

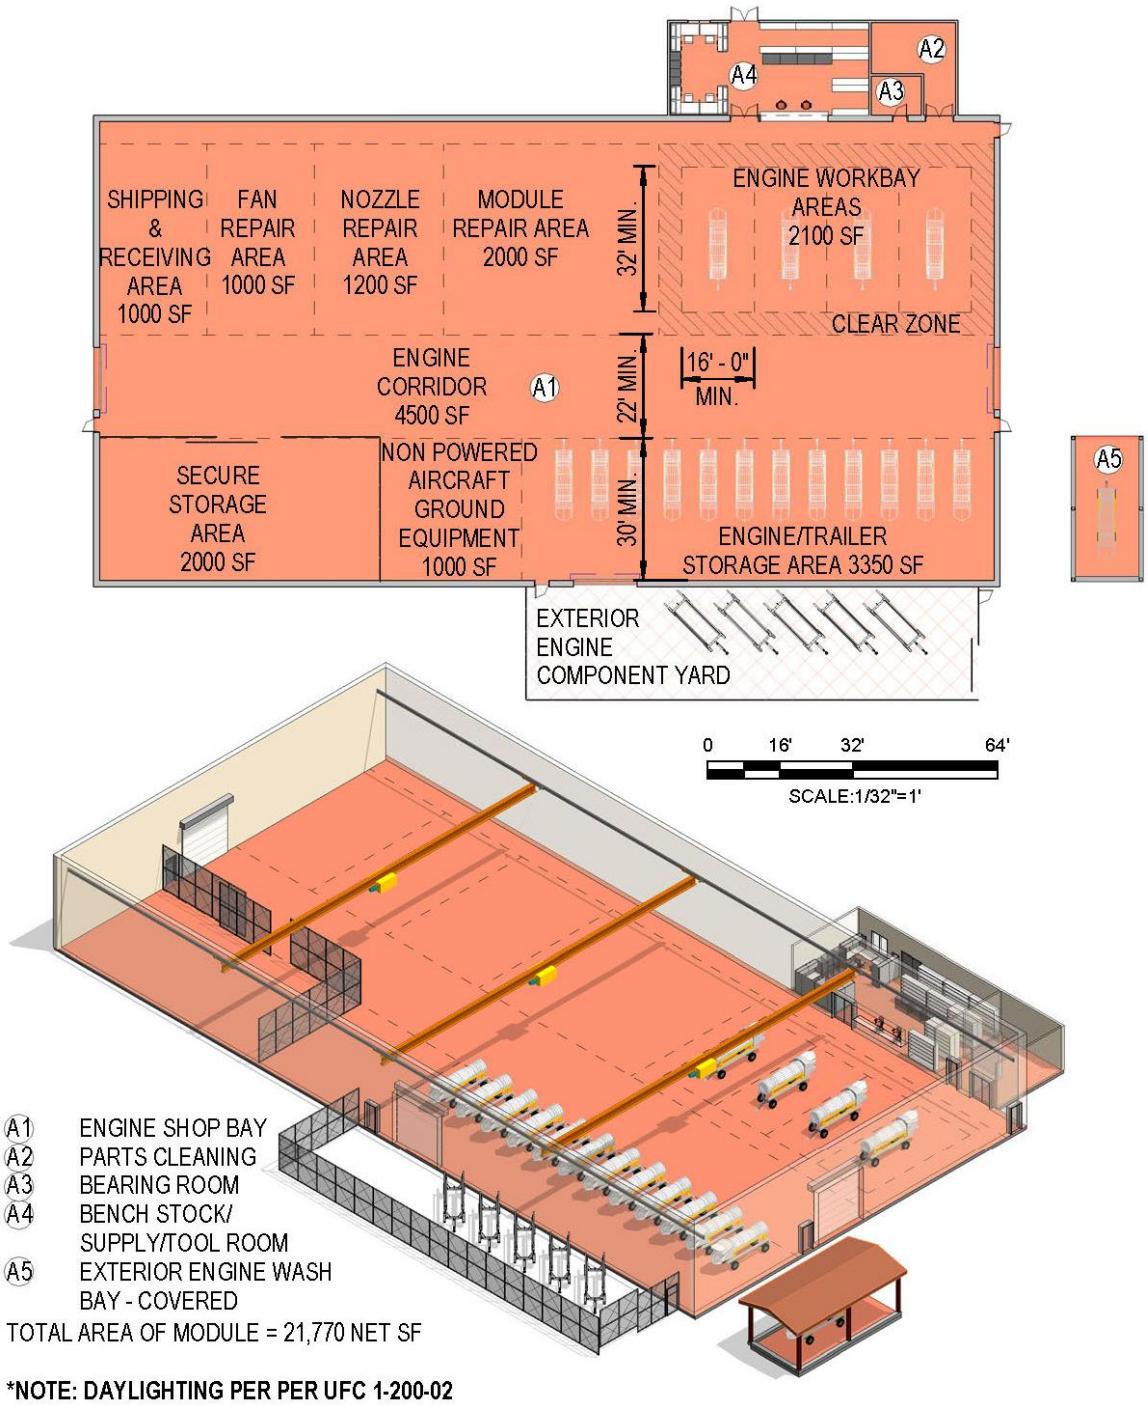
CHAPTER 3 FACILITY REQUIREMENTS AND CRITERIA

3-1 MODULE A - ENGINE SHOP BAY MODULE.

3-1.1 Function and Adjacency.



The engine shop bay supports the primary function of the maintenance facility. It is a high-bay, open-space module, with different sub-areas for different types of engine maintenance. Each area is delineated by paint or separated by an internal fence. Equipment and sub-areas are location- and engine-specific and must be verified for final layout. The engine shop bay must have overhead doors on both sides for shipping and receiving engines. An engine will travel in either direction depending upon its maintenance schedule. Trucks work with the bridge cranes to transition engines to and from the flight line or an off-site location. The width of the bay is determined by critical dimensions shown. The listed sub-areas, or a variation of these, are required. The size of these areas is based on the number of engine work bays, and can range proportionally.

Figure 3-1 Module A Adjacency Diagram

3-1.2 Engine Shop Bay Floor Plan (Figure 3-2).

Figure 3-2 Module A Floor Plan and Axonometric

3-1.3 Data Sheets.

Figure 3-3 A1 Engine Shop Bay Room Data Sheet

Description/Usage		General engine maintenance for F-15, F-16, F-22 aircraft engines. Areas include four engine work bays, secure storage area, non-powered aircraft ground equipment, work aisle, engine trailer storage for 14 trailers with a trailer work area, contractor module repair, nozzle, fan repair, and shipping/receiving.
Ceiling Height		20'-0" minimum or as required for 15' hook height clearance
Windows		Translucent wall panels or glazing for daylighting
Doors	**Type**	Hollow metal, 3'x7' Overhead insulated coiling door, 14'x14' power operated
	Security/ Hardware	Keyed lock set
	View Panels/ Kick Plates	View panels 5"x20" at all exterior doors and bench stock room Kick plates both sides of all doors
Finishes	**Walls**	CMU - painted wainscot to 8', pre-finished metal wall or liner panels above to roof deck
	Floor	Epoxy - Non-slip (fuel resistant) or sealed concrete
	Base	No base
	Ceiling	Exposed structure – painted
Plumbing		No floor drains; eyewash shower/eyewash stations per UFC 3-420-01; compressed air drop every 25 feet; coordinate drop locations with users; hose bib
HVAC		Heated with overhead infrared heaters; ventilation with exhaust fans and intake louvers
Fire Protection		Wet pipe or dry pipe sprinkler system as required by UFC 3-600-01
Power		270Vdc/400hZ aircraft power, 480V RECEPT, and receptacles per UFC 3-520-01
Lighting		Per UFC 3-530-01
Communication	**Tele.**	Determined by operations at location
	Data	NIPR
	CCTV	N/A
	CATV	N/A
	Security	Intrusion Detection System (IDS)
Acoustical		Per UFC 3-450-01 for noise control
Furnishings, Equipment and Casework		Three 5-ton bridge cranes running the full length of the bay – 15' hook height A.F.F.
Special Requirements		Exterior engine component area 25' x 125' of fenced (7'-0" high w/3-strand barbed wire) storage space with concrete surface located adjacent engine shop bay

Figure 3-4 A2 Parts Cleaning Room Data Sheet

Description/Usage		Used to clean engine parts outside of the engine work bay areas. Parts cleaning uses manual solvent parts washers/ cleaners for light to moderate soil levels. Small parts are manually cleaned in the sink and the solvent drains into a 30-gallon reservoir below. Space will have localized exhaust hoods at a parts cleaner station. This space is occupied only by maintenance personnel when cleaning engine parts.
Ceiling Height		No ceiling, 9'-0" minimum clearance
Windows		N/A
Doors	**Type**	Hollow metal, pair 3'x7'
	Security/ Hardware	Keyed lock set Provide door seals for fume containment
	View Panels/ Kick Plates	View panels, 5"x20" at door to engine shop bay Kick plates both sides of each door
Finishes	**Walls**	CMU - painted
	Floor	Epoxy - non-slip or sealed concrete
	Base	No base
	Ceiling	Exposed to structure - painted
Plumbing		Industrial sink, emergency shower/eyewash stations per UFC 3-420-01
HVAC		Air conditioned; heated; localized exhaust over parts cleaning tanks
Fire Protection		Wet pipe sprinkler system
Power		Hazardous location Per UFC 3-520-01 and NEC
Lighting		Hazardous location Per UFC 3-530-01
Communication	**Tele.**	Determined by operations at location
	Data	NIPR
	CCTV	N/A
	CATV	N/A
	Security	IDS
Acoustical		Per UFC 3-450-01 for noise control
Furnishings, Equipment and Casework		Parts cleaning equipment; work bench
Special Requirements		

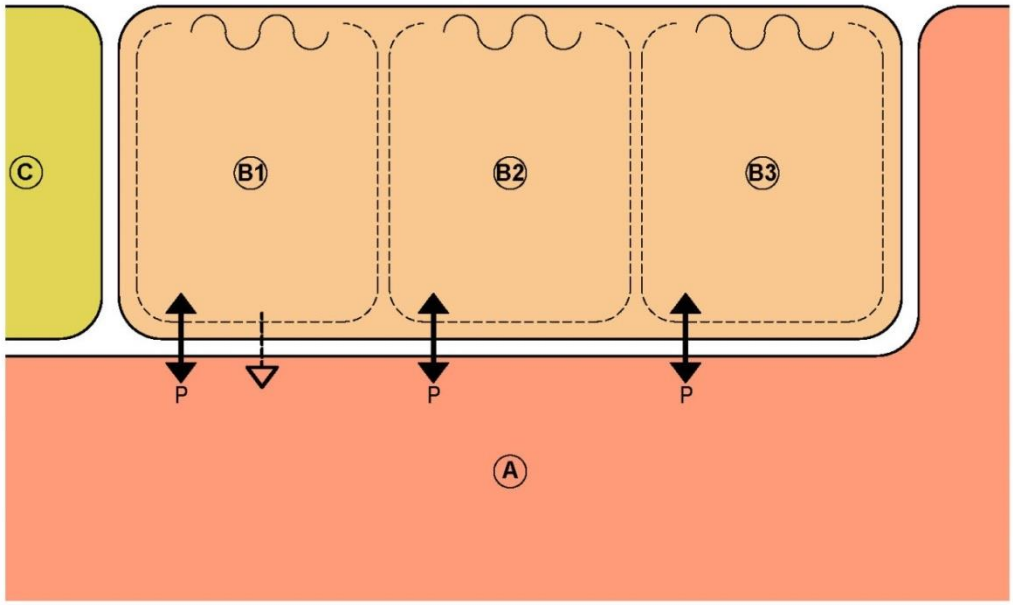
Figure 3-5 A3 Bearing Room Data Sheet

Description/Usage		Used for cleaning, inspection, lubrication, and wrapping of the engine bearings. The room must be a clean, dust free, environmentally controlled area. This space is occupied by maintenance personnel only when accomplishing maintenance on engine bearings.
Ceiling Height		No ceiling, 9'-0" minimum
Windows		N/A
Doors	**Type**	Hollow metal, 4'x7'
	Security/ Hardware	Keyed lock set Provide door seals for fume containment
	View Panels/ Kick Plates	View panels, 5"x20" at door to engine shop bay Kick plates on both sides of door
Finishes	**Walls**	CMU – painted
	Floor	Epoxy – non-slip or sealed concrete
	Base	No base
	Ceiling	Exposed to structure - painted
Plumbing		N/A
HVAC		Air conditioned; heated; ventilation; single zone; localized exhaust
Fire Protection		Wet pipe sprinkler system
Power		Per UFC 3-520-01 and a 30A 240V power outlet. Hazardous areas per T.O. 44B-1-15.
Lighting		Per UFC 3-530-01
Communication	**Tele.**	Determined by operations at location
	Data	NIPR
	CCTV	N/A
	CATV	N/A
	Security	IDS
Acoustical		Per UFC 3-450-01 for noise control
Furnishings, Equipment and Casework		Bearing cleaning vats and equipment, work bench
Special Requirements		Electrical classification of the area around the cleaning vat and ventilation and filtering of the room air must comply with T.O. 44B-1-15. A tacky vinyl blotter/floor mat is required on both sides of the bearing room door entrance.

Figure 3-6 A4 Bench Stock/Supply/Tool Room Data Sheet

Description/Usage		Room for bench stock personnel, tool storage and tool distribution to maintenance personnel
Ceiling Height		9'-0" minimum clearance
Windows		Exterior insulated AT compliant
Doors	**Type**	Hollow metal, pair 3'x7', interior to engine shop bay and exterior 4'x8' coiling manual counter shutter to engine shop bay
	Security/ Hardware	Keyed lock set
	View Panels/ Kick Plates	View panels, 5"x20" at door to engine shop bay Kick plates on both sides of doors
Finishes	**Walls**	CMU or impact resistant gypsum board - painted
	Floor	Epoxy – non-slip or sealed concrete
	Base	Resilient
	Ceiling	Exposed to structure - painted or acoustical ceiling tile
Plumbing		N/A
HVAC		Air conditioned; heated; ventilation; single zone
Fire Protection		Wet pipe sprinkler system
Power		Per UFC 3-520-01
Lighting		Per UFC 3-530-01
Communication	**Tele.**	Determined by operations at location
	Data	NIPR
	CCTV	N/A
	CATV	N/A
	Security	IDS
Acoustical		N/A
Furnishings, Equipment and Casework		Four workstations in open office setting; storage racks; counter with coiling manual counter shutter from tool delivery area to engine shop bay
Special Requirements		

Figure 3-7 A5 Exterior Engine Wash Bay - Covered Room Data Sheet



Description/Usage		An open wash bay to clean engines before or after being transported. Engines are backed in on trailers.
Ceiling Height		12’ minimum clear height to structure
Windows		N/A
Doors	**Type**	N/A
	Security/ Hardware	N/A
	View Panels/ Kick-Plates	N/A
Finishes	**Walls**	N/A
	Floor	Concrete or asphalt
	Base	N/A
	Ceiling	Exposed structure - painted
Plumbing		Freeze-proof hose stations; localized area drains
HVAC		N/A
Fire Protection		N/A
Power		N/A
Lighting		Flood lighting; per UFC 3-530-01
Communication	**Tele.**	N/A
	Data	N/A
	CCTV	N/A
	CATV	N/A
	Security	N/A
Acoustical		N/A
Furnishings, Equipment and Casework		N/A
Special Requirements		Provide hose stations in close proximity 16’ (w) x 32’(L) x 12’(H) clear of all obstructions; canopy sun shade for engines as required by mission and base constraints

3-2 MODULE B – ENGINE SHOP SUPPORT MODULE.

3-2.1 Function and Adjacency (Figure 3-8).

The engine shop support module is comprised of administration spaces that directly support the engine shop bay and is the only administration module placed directly adjacent to the engine shop bay. It is used by maintenance crews or personnel working directly with maintenance crews. Space requirements for personnel is the driving force in determining the net square footage needed in this module. These spaces can be separated by demountable partitions, systems furniture, or metal stud/gypsum board wall construction.

Special Requirements		

3-3 MODULE C – BREAK ROOM MODULE.

3-3.1 Function and Adjacency (Figure 3-13).

The break room module is a stand-alone module, sized to accommodate 16-20 personnel. It will include a counter with sink and cabinets above, and areas for a microwave, refrigerator, and vending machines. This module supports the maintenance crews in the engine shop bay, as well as the administration personnel. It also functions as a team room for meetings. This module is centrally located for easy access from both groups.

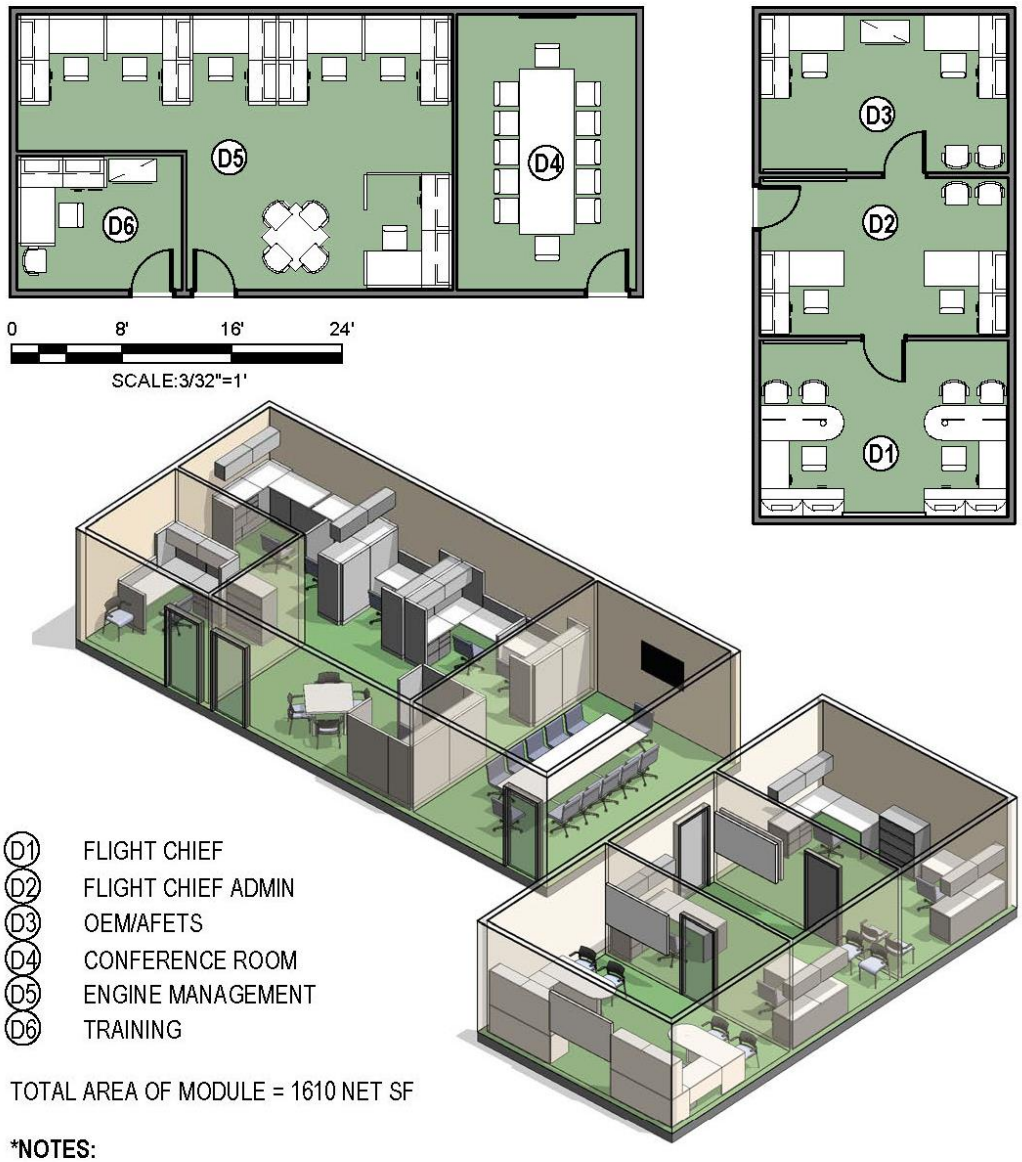
Acoustical Requirements		Per UFC 3-450-01 for noise control
Furnishings, Equipment and Casework		Seating for 16-20 people; refrigerator, microwave, dishwasher, double sink with disposal; vending machines; wall-mounted video monitor and bulletin board.
Special Requirements		

3-4 MODULE D – FLIGHT CHIEF/TRAINING ADMINISTRATION MODULE.

3-4.1 Function and Adjacency (Figure 3-16).



The Flight/Chief training administrative module comprises the following spaces: the Flight Chief office, with two workstation desks for the two Flight Chiefs; a Flight Chief administration area with two workstations, adjacent to the Flight Chief's office; an OEM/AFETS office with two workstations, located near the Flight Chief administration area; a conference room sized for 12 persons, centrally located near the Flight Chief's office; an engine management office with five open workstations and one small conference table; and a training office with one workstation. Locate this module directly adjacent to the building's main corridor, near the toilets/showers/lockers module and break room module. Interior spaces can be separated by demountable partitions, systems furniture, and/or gypsum board permanent construction.

	CCTV	N/A
	CATV	N/A
	Security	N/A
Acoustical Requirements		Per UFC 3-450-01 for noise control
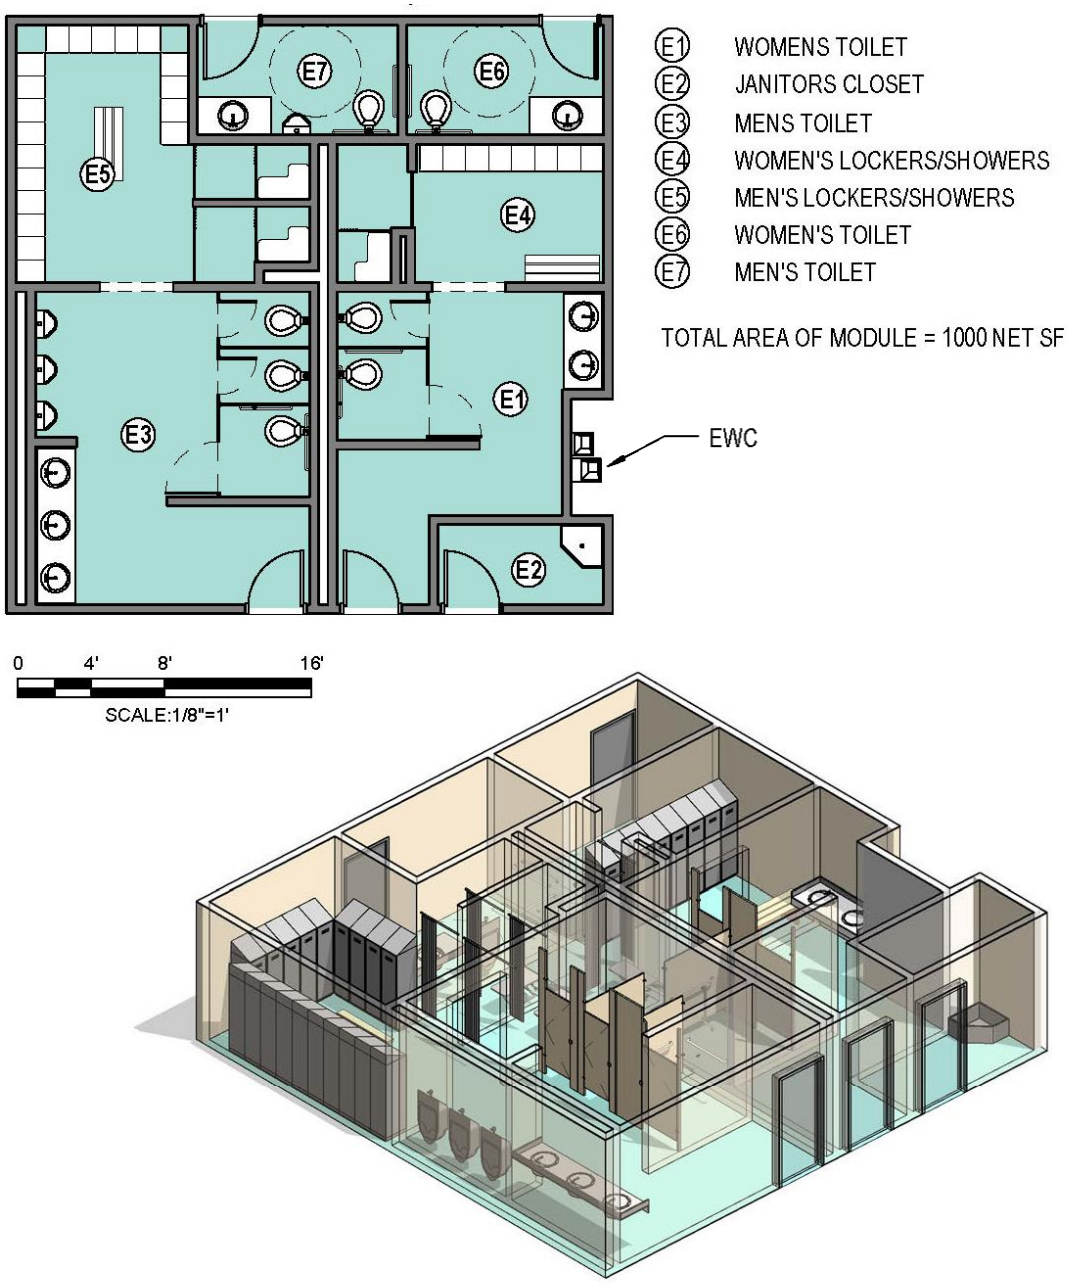
Furnishings, Equipment and Casework		One workspace with space for visitors; lateral storage; whiteboard for instructional use.
Special Requirements		

3-5 MODULE E – TOILETS/SHOWERS/LOCKERS MODULE.

3-5.1 Function and Adjacency.



The toilets/showers/lockers module consists of men's and women's toilet/shower/locker rooms (sized for 25 total per shift, 75/25 male/female ratio) and a janitor's closet. It will be centrally located, with direct access to the engine shop bay area. The locker room module will have full-height lockers for two shifts (25-30 lockers). It will contain a single male toilet room and a single female toilet room, each with one water closet and an adjacent lavatory, and with access to the administrative module.

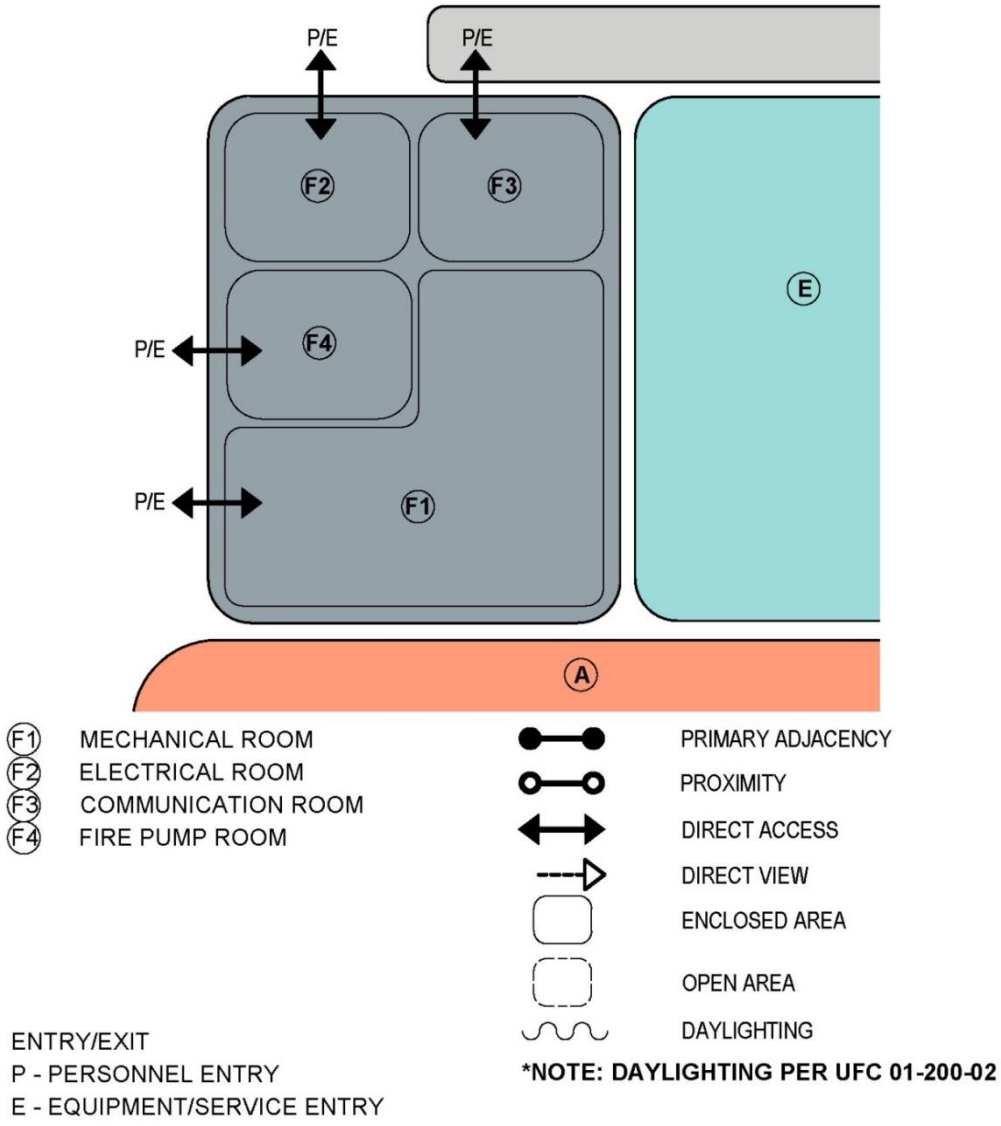
Figure 3-24 Module E Adjacency Diagram

3-5.2 Toilets/Showers/Lockers Floor Plan (Figure 3-25).

Figure 3-25 Module E Floor Plan and Axonometric

3-5.3 Data Sheet.

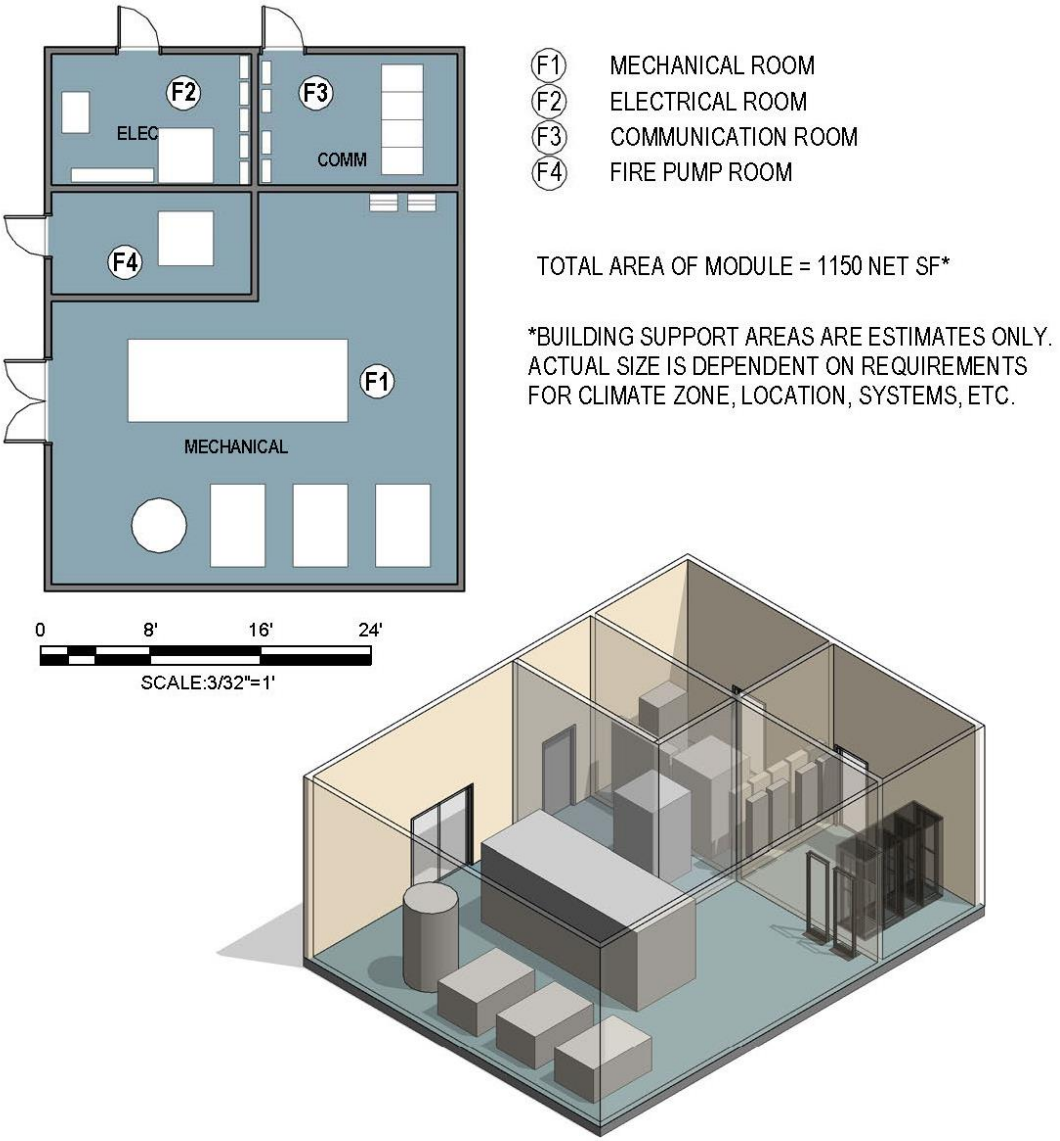
Figure 3-26 E1-E7 Toilets/Showers/Lockers Room Data Sheet



Description/Usage		Toilets/showers/showers serve all personnel in the facility. Toilet for maintenance crew use must be available from the engine shop bay.
Ceiling Height		9'-0" minimum
Windows		N/A
Doors	**Type**	Hollow metal, 3'x7'
	Security/ Hardware	Push-pull
	View Panels/ Kick Plates	No panels Kick plates both sides of doors
Finishes	**Walls**	Ceramic tile full height at wet walls, showers, gypsum board - painted
	Floor	Porcelain tile or quartz epoxy
	Base	Porcelain tile or quartz epoxy
	Ceiling	Gypsum board - painted
Plumbing		Sinks; toilets; urinals; floor drains in restroom areas, shower and locker areas; mop sink; EWC
HVAC		Air conditioned and heated restrooms, showers, lockers; ventilation; exhaust from restrooms, locker rooms, janitor's closet
Fire Protection		Wet pipe sprinkler system
Power		Per UFC 3-520-01
Lighting		Per UFC 3-530-01
Communication	**Tele.**	N/A
	Data	N/A
	CCTV	N/A
	CATV	N/A
	Security	N/A
Acoustical Requirements		Per UFC 3-450-01 for noise control
Furnishings, Equipment and Casework		Determine fixture count by number of building occupants at maximum load; wall hung urinals; lavatories in counter tops.
Special Requirements		Water-resistant gypsum board throughout. See RFP for accessories requirements.

3-6 MODULE F – BUILDING SUPPORT MODULE.

3-6.1 Function and Adjacency.



The building support module consists of a mechanical room, an electrical room, and a telecommunications room (fire protection room if not in mechanical room). All rooms must have exterior access (with exception of the communication room, which may have interior access). Building support modules must be located on an exterior wall adjacent to the utility courtyard and accessible for maintenance.

Figure 3-27 Module F Adjacency Diagram

3-6.2 Building Support Floor Plan (Figure 3-28).

Figure 3-28 Module F Floor Plan & Axonometric

3-6.3 Data Sheets.

COMMENTS:

1	Programming Matrix is based upon 4 engine workbays - typical for 5th Gen. Fighters (Note F-35 does not require a seperate engine maintenance facility)
2	Break Room also serves as Classroom, sized per Table 6.3 Break Rooms and Table 6.4 Classroom of Air Force Manual 32-1084 (Break Room 16% of 50 occupants mulitplied by 18 sf per occupant plus Classroom of 20 persons multiplied by 25 sf per person)
3	Reference Tables in Chapter 6 of Air Force Manual 32-1084 for additional information.
4	Includes all areas listed in Air Force Manual 32-1084, Chapter 1 and Chapter 6
5	Per AFM 32-1084 Chapter 1, net-to-gross multiplier of up to 25%, used 15% as large portion of area is in Engine Shop Bay.
6	Building Support areas are estimates only and actual size is dependent on requirements for climate zone, location, system, etc.
7	Administration Areas include circulation factor of 10% per Chapter 1 Air Force Manual 32-1084
8	Male/Female ratio of 75/25
9	Exterior Engine Component Yard is uncovered exterior space
10	Engine Management room has small Mini Conference area for up to 6 persons @ 15 sf per person
11	Waiting area in Flight Chief Admin. per AFM 32-1084 Table 6.3 - 20 sf per person, 2 people

Federal Requirements for High Performance and Sustainable Buildings (HPSB) & UFC 1-200-02

HPSB I: Employ Integrated Design Principles (UFC 1-200-02 para 2-2)

Total Points	2		Possible Points	2
Yes	HPSB I.1	Integrated Design		1
Yes	HPSB I.2	Commissioning		1

UFC 1-200-02 para 2-3. Promote Sustainable Location and Site Development

Total Points	1		Possible Points (HPSB only)	1
Yes	UFC para 2-3.1	Site selection		1
Yes	UFC para 2-3.2	Mitigation of Heat Island Effect		1
Yes	UFC para 2-3.3	Reduction of Light Pollution		1
Yes	HPSB III.3-4	Stormwater Management		1

Air Force MILCON Sustainability Requirements Scoresheet

version LEED® 2009 (Updated September 2013)

* required entry

HPSB II: Optimize Energy Performance (UFC 1-200-02 para 2-4)				
Total Points	4		Possible Points	4
Yes	HPSB II.1	**Energy Efficiency**		1
		Yes	Reduce energy use 30% below ANSI/ASHRAE/IESNA Standard 90.1-2010 or if not - achieve maximum energy efficiency that is lifecycle cost effective	
		30.0%	Insert percentage below ANSI/ASHRAE/IESNA Standard 90.1-2010 in terms of energy use (e.g. 32)	
		0	Insert building energy intensity (kBtu/yr-sqft) calculated IAW 10 CFR 433	
Yes	HPSB II.2	**On-site Renewable Energy - Solar Hot Water Heater System**		1
		Yes	Installed solar hot water heater system or found installation not lifecycle cost effective	
		0.0	Insert generation capacity (MMBtu/yr)	
		0.0%	Insert percentage of demand	
Yes	HPSB II.3	**On-site Renewable Energy**		1
		Yes	Installed renewable energy elements or projects were not lifecycle cost effective	
		0	Renewable energy types (check below)	
		☐ Solar PV ☐ Geothermal ☐ Hydro ☐ Waste to Energy ☐ Solar CP ☐ GSHP ☐ Wind ☑ Renewables were not ☐ Solar Thermal Electric		
		0.0	Insert generation capacity (kW)	
		0.0%	Insert percentage of total building	
Yes	HPSB II.4	**Measurement and Verification**		1
		Yes	Water Metering: Select N/A if no service	
		Yes	Electric Metering: Select N/A if no service	
		Yes	Natural Gas Metering: Select N/A if no service	
		N/A	Steam Metering: Select N/A if no service	
HPSB III: Protect and Conserve Water (UFC 1-200-02 para 2-5)				
Total Points	3		Possible Points	3
Yes	HPSB III.1	**Indoor Water**		1
Yes	HPSB III.2	**Outdoor Water**		1
Yes	HPSB III.4	**Water used for heating and cooling**		1
		Yes	Water efficient measures were implemented with heating and cooling equipment when life cycle effective	
HPSB IV: Enhance Indoor Environmental Quality (UFC 1-200-02 para 2-6)				
Total Points	6		Possible Points	6
Yes	HPSB IV.1	**Thermal Comfort**		1
Yes	HPSB IV.2	**Ventilation**		1
Yes	HPSB IV.3	**Moisture Control**		1
Yes	HPSB IV.4	**Daylighting**		1
Yes	HPSB IV.5	**Low Emitting Materials**		1
Yes	HPSB IV.6	**Protect Indoor Air Quality during Construction**		1
Yes	HPSB IV.7	**Environmental Tobacco Smoke**		
HPSB V: Reduce Environmental Impact of Materials (UFC 1-200-02 para 2-6)				
Total Points	6		Possible Points	6
Yes	HPSB V.1	**Recycled Content**		1
Yes	HPSB V.2	**Biologically-based Products**		1
Yes	HPSB V.3	**Environmentally Preferable Products**		1
Yes	HPSB V.4	**Waste and Materials Management - Recycling**		1
Yes	HPSB V.5	**Waste and Materials Management - Divert 50% from Disposal**		1
		50.0%	Insert percentage diverted from landfill	
			Data element is not applicable	
Yes	HPSB V.6	**Ozone Depleting Substances**		1
HPSB Totals			Possible Points	22
22	Federal Requirements - Yes or N/A			
0	Federal Requirements - Maybe			
0	Federal Requirements - No			
100%	Percentage of Federal Requirements Met

LEED® 2009 Checklist

LEED® Credits and/or Prerequisites that meet HPSB/UFC Requirements
LEED® Credits and/or Prerequisites that align closely with HPSB/UFC Requirements
LEED® Credits that meet USAF Energy & Water Criteria (may depend on technologies & strategies)

Sustainable Sites				
Achievable Points	11	Sustainable Sites	Possible Points	26
Yes	Prereq 1	Construction Activity Pollution Prevention (HPSB GP3)		Required
Yes	Credit 1	Site Selection		1
Maybe	Credit 2	Development Density & Community Connectivity		5
Maybe	Credit 3	Brownfield Redevelopment		1
Maybe	Credit 4.1	Alternative Transportation - Public Transportation Access		6
Maybe	Credit 4.2	Alternative Transportation - Bicycle Storage & Changing Rooms		1
Yes	Credit 4.3	Alternative Transportation - Low-Emitting & Fuel Efficient Vehicles		3
Yes	Credit 4.4	Alternative Transportation - Parking Capacity		2
Maybe	Credit 5.1	Site Development - Protect or Restore Habitat		1
Maybe	Credit 5.2	Site Development - Maximize Open Space		1
Yes	Credit 6.1	Stormwater Design - Quantity Control (HPSB GP3)		1
Yes	Credit 6.2	Stormwater Design - Quality Control (HPSB GP3)		1
Yes	Credit 7.1	Heat Island Effect - Non-Roof (UFC)		1
Yes	Credit 7.2	Heat Island Effect - Roof (UFC)		1
Yes	Credit 8	Light Pollution Reduction		1
		Option 1	Select which LEED® Interior Lighting Option was used	

Water Efficiency				
Achievable Points	7		Possible Points	10
Yes	Prereq 1	Water Use Reduction - 20% Reduction (HPSB GP3)		Required
4	Credit 1	Water Efficient Landscaping (HPSB GP3)		2 to 4
		2	Reduce Potable Water Use by 50% (HPSB GP3)	2
		4	No Potable Use or Irrigation (HPSB GP3)	2
Maybe	Credit 2	Innovative Wastewater Technologies		2
3	Credit 3	Water Use Reduction (HPSB GP3)		2 to 4
		2	30% Reduction (HPSB GP3)	2
		3	35% Reduction (HPSB GP3)	1
		4	40% Reduction (HPSB GP3)	1

Energy & Atmosphere				
Achievable Points	17		Possible Points	35
Yes	Prereq 1	Fundamental Commissioning of the Building Energy Systems (HPSB GP1)		Required
Yes	Prereq 2	Minimum Energy Performance (HPSB GP2)		Required
Yes	Prereq 3	Fundamental Refrigerant Management (HPSB GP5)		Required
15	Credit 1	Optimize Energy Performance (HPSB GP2)		1 to 19
		1	12% for New Buildings/8% for Existing Building Renovations	1
		2	14% for New Buildings/10% for Existing Building Renovations	1
		3	16% for New Buildings/12% for Existing Building Renovations	1
		4	18% for New Buildings/14% for Existing Building Renovations	1
		5	20% for New Buildings/16% for Existing Building Renovations	1
		6	22% for New Buildings/18% for Existing Building Renovations	1
		7	24% for New Buildings/20% for Existing Building Renovations	1
		8	26% for New Buildings/22% for Existing Building Renovations	1
		9	28% for New Buildings/24% for Existing Building Renovations	1
		10	30% for New Buildings/26% for Existing Building Renovations	1
		11	32% for New Buildings/28% for Existing Building Renovations	1
		12	34% for New Buildings/30% for Existing Building Renovations	1
		13	36% for New Buildings/32% for Existing Building Renovations	1
		14	38% for New Buildings/34% for Existing Building Renovations	1
		15	40% for New Buildings/36% for Existing Building Renovations	1
		16	42% for New Buildings/38% for Existing Building Renovations	1
		17	44% for New Buildings/40% for Existing Building Renovations	1
		18	46% for New Buildings/42% for Existing Building Renovations	1
		19	48%+ for New Buildings/44%+ for Existing Building Renovations	1
0	Credit 2	On-Site Renewable Energy (HPSB GP2)		1 to 7
		1	On-site 1%	1
		2	On-site 3%	1
		3	On-site 5%	1
		4	On-site 7%	1
		5	On-site 9%	1
		6	On-site 11%	1
		7	On-site 13%	1
Yes	Credit 3	Enhanced Commissioning (HPSB GP1)		2
Maybe	Credit 4	Enhanced Refrigerant Management (HPSB GP5)		2
No	Credit 5	Measurement & Verification (HPSB GP2)		3
No	Credit 6	Green Power		2

Materials & Resources				
Achievable Points	7		Possible Points	14
Yes	Prereq 1	Storage & Collection of Recyclables (HPSB GP5)		Required
0	Credit 1.1	Building Reuse - Maintain Existing Walls Floors & Roof		1 to 3
		1	Maintain 55% of Existing Walls Floors & Roof	1
		2	Maintain 75% of Existing Walls Floors & Roof	1
		3	Maintain 95% of Existing Walls Floors & Roof	1
Maybe	Credit 1.2	Building Reuse - Maintain 50% of Interior Non-Structural Elements		1
2	Credit 2	Construction Waste Management (HPSB GP5)		1 to 2
		1	50% Recycled or Salvaged	1
		2	75% Recycled or Salvaged	1
0	Credit 3	Materials Reuse		1 to 2
		1	5% of value of material reused content	1
		2	10% of value of material reused content	1
2	Credit 4	Recycled Content (HPSB GP5)		1 to 2
		1	10% of value of material recycled content	1
		2	20% of value of material reused content	1
2	Credit 5	Regional Materials		1 to 2
		1	10% Extracted, Processed & Manufactured	1
		2	20% Extracted, Processed & Manufactured	1
Maybe	Credit 6	Rapidly Renewable Materials (HPSB GP5)		1
Yes	Credit 7	Certified Wood (HPSB GP5)		1
Indoor Environmental Quality				
Achievable Points	10		Possible Points	15
Yes	Prereq 1	Minimum IAQ Performance (HPSB GP4)		Required
Yes	Prereq 2	Environmental Tobacco Smoke (ETS) Control (HPSB GP4)		Required
Yes	Credit 1	Outside Air Delivery Monitoring		1
Maybe	Credit 2	Increased Ventilation		1
Yes	Credit 3.1	Construction IAQ Management Plan, During Construction (HPSB GP4)		1
Yes	Credit 3.2	Construction IAQ Management Plan, Before Occupancy (HPSB GP4)		1
Yes	Credit 4.1	Low Emitting Materials, Adhesives & Sealants (HPSB GP4)		1
Yes	Credit 4.2	Low Emitting Materials, Paints & Coatings (HPSB GP4)		1
Yes	Credit 4.3	Low Emitting Materials, Flooring Systems (HPSB GP4)		1
Yes	Credit 4.4	Low Emitting Materials, Composite Wood & Agrifiber Products (HPSB GP4)		1
Yes	Credit 5	Indoor Chemical & Pollutant Source Control		1
Yes	Credit 6.1	Controllability of Systems, Lighting (HPSB GP4)		1
Maybe	Credit 6.2	Controllability of Systems, Thermal Comfort		1
Yes	Credit 7.1	Thermal Comfort, Design (HPSB GP4)		1
Maybe	Credit 7.2	Thermal Comfort, Verification		1
Maybe	Credit 8.1	Daylight & Views - Daylight 75% of Spaces (HPSB GP4)		1
Maybe	Credit 8.2	Daylight & Views - Views for 90% of Spaces		1
Innovation & Design Process				
Achievable Points	4		Possible Points	6
Yes	Credit 1.1	Innovation in Design 1.1		1
			Select if ID 1.1 was for energy and/or water	
Yes	Credit 1.2	Innovation in Design 1.2		1
			Select if ID 1.2 was for energy and/or water	
Yes	Credit 1.3	Innovation in Design 1.3		1
			Select if ID 1.3 was for energy and/or water	
Maybe	Credit 1.4	Innovation in Design 1.4		1

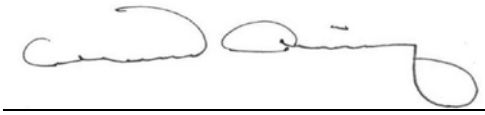
Change No.	Date	Location

This UFC supersedes UFC 4-213-10 Change 1, dated September 2012

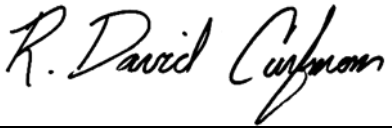
FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD-3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA). Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.



UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale may be sent to the respective DoD working group by submitting a Criteria Change Request (CCR) via the Internet site listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:



- Whole Building Design Guide web site https://www.wbdg.org/ffc/dod.

Refer to UFC 1-200-01, *DoD Building Code*, for implementation of new issuances on projects.

UNIFIED FACILITIES CRITERIA (UFC)
REVISION SUMMARY SHEET

Document: UFC 4-213-10, *Graving Dry Docks*

Superseding: UFC 4-213-10, *Design: Graving Dry Docks*, 1 September 2012, with Change 1

Description: This revised UFC serves as a specific guidance for planners, designers, contractors and maintenance technicians involved in the planning, designing, construction and maintenance of graving dry docks. The document is organized into chapters that address the various phases beneficial to the personnel involved in working with a dry dock. The document provides a unified approach to the formatting and content of Unified Facilities Criteria**.**

Reasons for Document:

- This UFC provides revised information that adheres to the format and content of the criteria documents.
- Revisions capture current changes in shipyard requirements and anticipated requirements of the Shipyard Industrial Optimization Program (SIOP). Revisions include: dry dock dimensions for new submarine classes, dry dock production needs, changes in flood elevation, fire safety standards, etc.

Impact:

- This revision does not have any cost impacts.

Unification Issues:

- This revision does not have any unification issues.

TABLE OF CONTENTS

CHAPTER 1 INTRODUCTION 1
1-1 PURPOSE AND SCOPE. 1
1-2 APPLICABILITY. 1
1-3 GENERAL BUILDING REQUIREMENTS. 1
1-3.1 Anti-Terrorism and Security. 1
1-4 CYBERSECURITY. 1
1-5 GLOSSARY. 1
1-6 REFERENCES. 2
CHAPTER 2 SHIPYARD LAYOUT 3
2-1 SHOP FACILITIES. 3
2-2 LAYDOWN SPACE. 3
2-3 POWER AND UTILITIES. 3
2-4 CRANE AND CRANE TRACKS. 3
2-5 SHIP APPROACHES. 3
2-5.1 Turning Basins. 3
2-5.2 Dry Dock Orientation Effect. 4
2-6 FITTING OUT/REPAIR PIERS. 4
2-6.1 Existing Piers. 4
2-6.2 New Piers. 4
2-7 SILTING AND SCOURING. 4

CHAPTER 1 INTRODUCTION

1-1 PURPOSE AND SCOPE.

The purpose of UFC 4-213-10 is to provide a uniform guidance for the planning, design, construction, renovation and maintenance of graving dry docks. This document has undergone many iterations over the decades. Much of the specific recommendations have been lifted from existing facility designs that have proven valuable.

Any dry dock construction or other work must be performed in concert with the NAVSEA Dry Dock Certification program, namely the requirements of MIL-STD-1625 and Naval Ship's Technical Manual (NSTM), Chapter 997, must be met.

1-2 APPLICABILITY.

UFC 4-213-10 applies to all facility planners, designers, contractors, and maintenance technicians involved in the planning, design, construction, and maintenance of Graving Dry Docks. It is assumed that the general vicinity, such as specific shipyard, has been selected, that the size of ship to be accommodated has been determined, and that the dry dock function, shipbuilding or repair has been decided. Consideration must be given to strategic site selection to meet present or future naval requirements, ease of defense, and general accessibility to and from the sea.

1-3 GENERAL BUILDING REQUIREMENTS.

Comply with UFC 1-200-01, *DoD Building Code*. UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

1-3.1 Anti-Terrorism and Security.

In some locations, consideration should be given to protective construction for the upper part of the pumpwell and the service tunnels. For waterfront security criteria, refer to UFC 4-025-01, *Waterfront Security Design*.

1-4 CYBERSECURITY.

All control systems (including systems separate from an energy management control system) must be planned, designed, acquired, executed, and maintained in accordance with UFC 4-010-06, and as required by individual Service Implementation Policy.

1-5 GLOSSARY.

APPENDIX B contains acronyms, abbreviations, and terms.

1-6 REFERENCES.

APPENDIX C contains a list of references used in this document. The publication date of the code or standard is not included in this document. Unless otherwise specified, the most recent edition of the referenced publication applies.

CHAPTER 2 SHIPYARD LAYOUT

2-1 SHOP FACILITIES.

Locate a dry dock near yard supporting industrial shops, or vice versa, from which material requiring fabrication or manufacture may be obtained.

2-2 LAYDOWN SPACE.

Provide ample space on both sides of a dry dock. If there are no restrictions, furnish a strip at least 250 ft (76.2 m) wide on each side of the dry dock coping and at the head end.

2-3 POWER AND UTILITIES.

Proximity to sources of power and utilities is desirable but seldom a determining factor. Electricity, fresh water, saltwater fire protection, compressed air, steam, oxygen, acetylene, and sewers are usually required as described in CHAPTER 8.

2-4 CRANE AND CRANE TRACKS.

Captive cranes should not be used if it can be avoided. Trackage should be interconnected for portal crane utilization elsewhere in the same yard.

2-5 SHIP APPROACHES.

Maneuvering a ship into a dry dock necessitates careful attention to the shape of the approach body of water, locations of ship channels, prevailing winds, currents, and relationship to other waterfront structures.

2-5.1 Turning Basins.

A ship must parallel the long axis of a dry dock before it enters; therefore, provide a turning basin of appropriate width, length, and depth of water outboard of a dry dock entrance. The length and depth of a dry dock are indicative of the maximum ship to be accommodated. The turning basin should have a width outboard of the dry dock at least two times the dock length and properly shaped for turning. The depth of water in the turning basin should be no less than that at the entrance sill of the dry dock. Where piers or other structures extend into a waterway and flank the approach to a dry dock entrance, the turning basin should be large enough to allow a ship to be turned before coming abreast of such flanking structures. A dry dock must not be located where flanking structures are too close to the path of a ship entering or leaving the dry dock. Leave room for tugs to operate beside a ship until it is clear of the dry dock entrance. The distance between such structures and the side of the ship path should not be less than 150 ft (45.7 m).

2-5.2 Dry Dock Orientation Effect.

In some cases, through necessity or choice, a dry dock may be oriented with the axis at an acute angle to the general shoreline.

This orientation is advantageous where, like a river, there is a current parallel to the shoreline, in which case the slanted position precludes the necessity of having a ship abreast of the current flow when entering or leaving the dry dock. Turning basin layouts are modified by such positioning, but the guidance for clearance of structures flanking the entrance must be observed.

2-6 FITTING OUT/REPAIR PIERS.

Fitting out or repair piers should be provided adjacent to dry docks.

2-6.1 Existing Piers.

In planning dry docks for existing shipyards, it may be that existing piers can serve this purpose for ships to be built or overhauled in the dock. The locations of such piers might influence positioning new dry docks reasonably near the piers, but the importance of this is not great since it involves only a single transfer of the ship after undocking.

2-6.2 New Piers.

When fitting out/repair pier capacity does not exist, new piers or wharves must be included in the project as essential support for dry docks. Refer to UFC 4-152-01, *Piers and Wharves*, for pier and wharf design.

2-7 SILTING AND SCOURING.

Ascertain the stability of the access waterway with regard to silting or scouring. A prospective site should be reconsidered if the possibilities of silting or scouring indicate excessive future dredging maintenance. Study historical characteristics of the waterway and possible effects on current flow due to planned new work or anticipated future structures.

2-8 TOPOGRAPHY, HYDROLOGY, AND METEOROLOGY.

2-8.1 Site Conditions.

Prior to the design of a dry dock, certain minimum information is required about conditions at the proposed site. Dry dock construction methods used are usually closely related to site conditions and to the type and shape of a dry dock.

2-8.2 Yard Grades.

The coping of a new dry dock must be compatible with general grades in a yard, or at least the grades in the vicinity of the dry dock and supporting facilities serviced by dry

dock cranes. Also, the elevation of the top of a dry dock must provide a certain minimum freeboard dependent on the highest anticipated tides, waves, and storm surge with consideration for sea level change.

2-8.3 Tide Range.

Ascertain the tidal range. Use this information as a basis to determine the final height of a dry dock, and also the height and strength of cofferdams or other temporary structures possibly involved in the dry dock construction. For predictions, which may be peculiar to the specific site, refer to records and predictions of *National Oceanic and Atmospheric Administration (NOAA)*, and to the local historical records.

2-8.4 Storm Potentialities.

Ascertain potentialities of a site. These data have a bearing on the determination of the freeboard height of a dry dock, and on the design of temporary construction work. Design for at least 1-percent annual exceedance probability storm event (100-year return period). In some areas, 0.2-percent annual exceedance probability storms (500-year-return period) and tides should be considered.

2-8.4.1 Wind Effects.

Include a study of prevailing winds and their velocities, fetch of water involved, and the length and height of waves. When these data are combined with tide records, they indicate the expected probable high-water conditions. The wind effects may influence the design of fenders or moorings contiguous to a dry dock. Refer to NOAA wind records for areas of the United States and possessions.

2-8.5 Water and Air Temperatures.

Approach body of water temperature ranges are important in designing heating and ventilating systems, coolers, cathodic protection systems, and any systems utilizing the water. Air temperature data are required for similar reasons. Obtain water and air temperature in the vicinity from NOAA and the local historical records.

2-8.6 Water Chemical Content.

The chemical content of water is subject to pollution when a dry dock is located on a river. When water is supplied by wells or well points from soil layers permeated by other than seawater, the chemical content is not known. The corrosiveness of the water must be determined for design of pipes, coolers, any equipment utilizing the water, pumping equipment, and dry dock pressure relief systems. Refer to UFC 3-230-01, *Water Storage and Distribution.*

2-9 FOUNDATION CONDITIONS.

2-9.1 Features.

Dry docks generally have diverse and varied types of foundation designs, which encompass the whole gamut of soil and foundation engineering. Designs are found in the complete range of such engineering, from the simplest spread footing to a complex elastic mat. Consequently, site specific soil investigations must be especially thorough and complete in the determination of a great variety of soil properties.

2-9.2 Borings.

Examine all available records of borings in the vicinity of a proposed site. The scope of previous borings will help determine the program extent for additional borings. For soil investigation procedures, refer to UFC 3-220-01, *Geotechnical Engineering*.

2-9.2.1 Depths of Borings.

Overall or mean soil pressures under dry docks are not great; therefore, for areas under the main body of a dock, borings need not be as deep as for other structures where load concentrations are severe. Where a dry dock is likely to be the relieved type, the depths of borings should be sufficient to allow proper analyses of percolation problems. Where piles, either the bearing or hold-down types, might be used, boring depths should adequately indicate the soils to be penetrated.

2-9.2.2 Usage.

Borings determine soil properties and ground water levels for establishing tip elevations for piles supporting special structures. Borings can also be used for conducting permeability and pumping tests, if necessary. Refer to UFC 3-220-01 for criteria for pumping and permeability field tests and laboratory permeability tests.

2-9.3 Pile Driving Records.

Consult previous pile driving records for applicable information. Supplement these records, if necessary, by new test pile data, especially in areas where appurtenant foundation structures may be used for track supports, capstan foundations, and similar facilities. Pile driving information and equipment is discussed in UFC 3-220-01.

2-9.4 Laboratory Tests and Soil Analyses.

Laboratory tests applicable to soils are generally necessary. For application and interpretation of such tests refer to UFC 3-220-01.

2-9.5 Bearing Capacities of Soils.

Make tests for bearing capacity appropriate to the types of applied loading in accordance with provisions of UFC 3-220-01. For designs of dry dock cross-sections,

especially those with thin floors, the soil modulus of subgrade reaction under a floor is important.

2-9.6 Foundation Materials.

Many types of foundation materials may be encountered in a site, and almost all may be utilized for supporting a dry dock. This material variability, however, results in a number of structural types from which a selection must be made. For selection of structural types affected by foundation conditions, refer to CHAPTER 4. Seismicity of the area should be considered.

2-9.6.1 Soils.

Types of soil which may be encountered, and upon which dry docks may be founded, include soft and hard rock, hardpans and shales, sand and/or gravel, soft and hard clay, marl, soft and hard mud, and certain types of coral. Extremely cavernous coral, through which water flows in quantities that precludes even grouting, cannot be used as a site support.

This Page Intentionally Left Blank

CHAPTER 3 DETERMINATION OF GRAVING DOCK DIMENSIONS

3-1 MINIMUM DIMENSIONS.

This chapter presents design criteria on graving dock dimensions with particular reference to minimum inside length, width, depth, and configuration. The minimum inside dimensions of a graving dock depends on the classes of ships to be accommodated. However, the exact configuration of the inside of the walls and the resulting shape of the inside cross section will represent a compromise between several conflicting factors, the dominating one being the structural type that is finally selected. For designation of dry dock features, see Figure 3-1.

It is important to remember that all areas of the dry dock must be accessible for inspection. This includes all tunnels, chambers and ballast tanks. Inspection is performed by humans on a regular basis. Therefore, making tunnels tall enough to walk through and openings that allow for ladders is important for the design.

3-2 REPAIR AND SHIPBUILDING DRY DOCKS.

This type of double function dry dock is the only type constructed in naval shipyards. Ships needing routine maintenance and repair, or those coming into dry dock in a damaged condition, require a deeper dock than ships under construction that are generally removed to a fitting-out pier for completion. A damaged ship may have a severe list and/or trim requiring additional dry dock depth.

3-2.1 Basic Dimensions.

Lay out dry dock plans according to the applicable type of ship as shown in Table 3-1. The values listed in Table 3-1 are recommended for new dry dock layout and may not be applicable for existing dry docks. Guidance for minimum dimensional allowances to ease ship positioning and provide industrial space for shipbuilding or repair work are:

- Normal keel block height: 6 ft (1.8 m). Other size blocks are available and acceptable. Minimum recommended height of blocking is 4 ft (1.2 m). Consider taller blocking ships with sonar domes.
- Ships keel clearance over blocks: 2 ft (0.6 m). NSTM CH 997 requires 1 ft (0.31 m) clearance from hull or appendage during docking evolution.
- Ship to head end clearance: 10 ft (3.0 m)
- Ship to caisson end clearance: 40 ft (12.2 m)
- Ship to wall clearance, each side: 15 ft (4.6 m)

Figure 3-1 Designation of Dry Dock Features

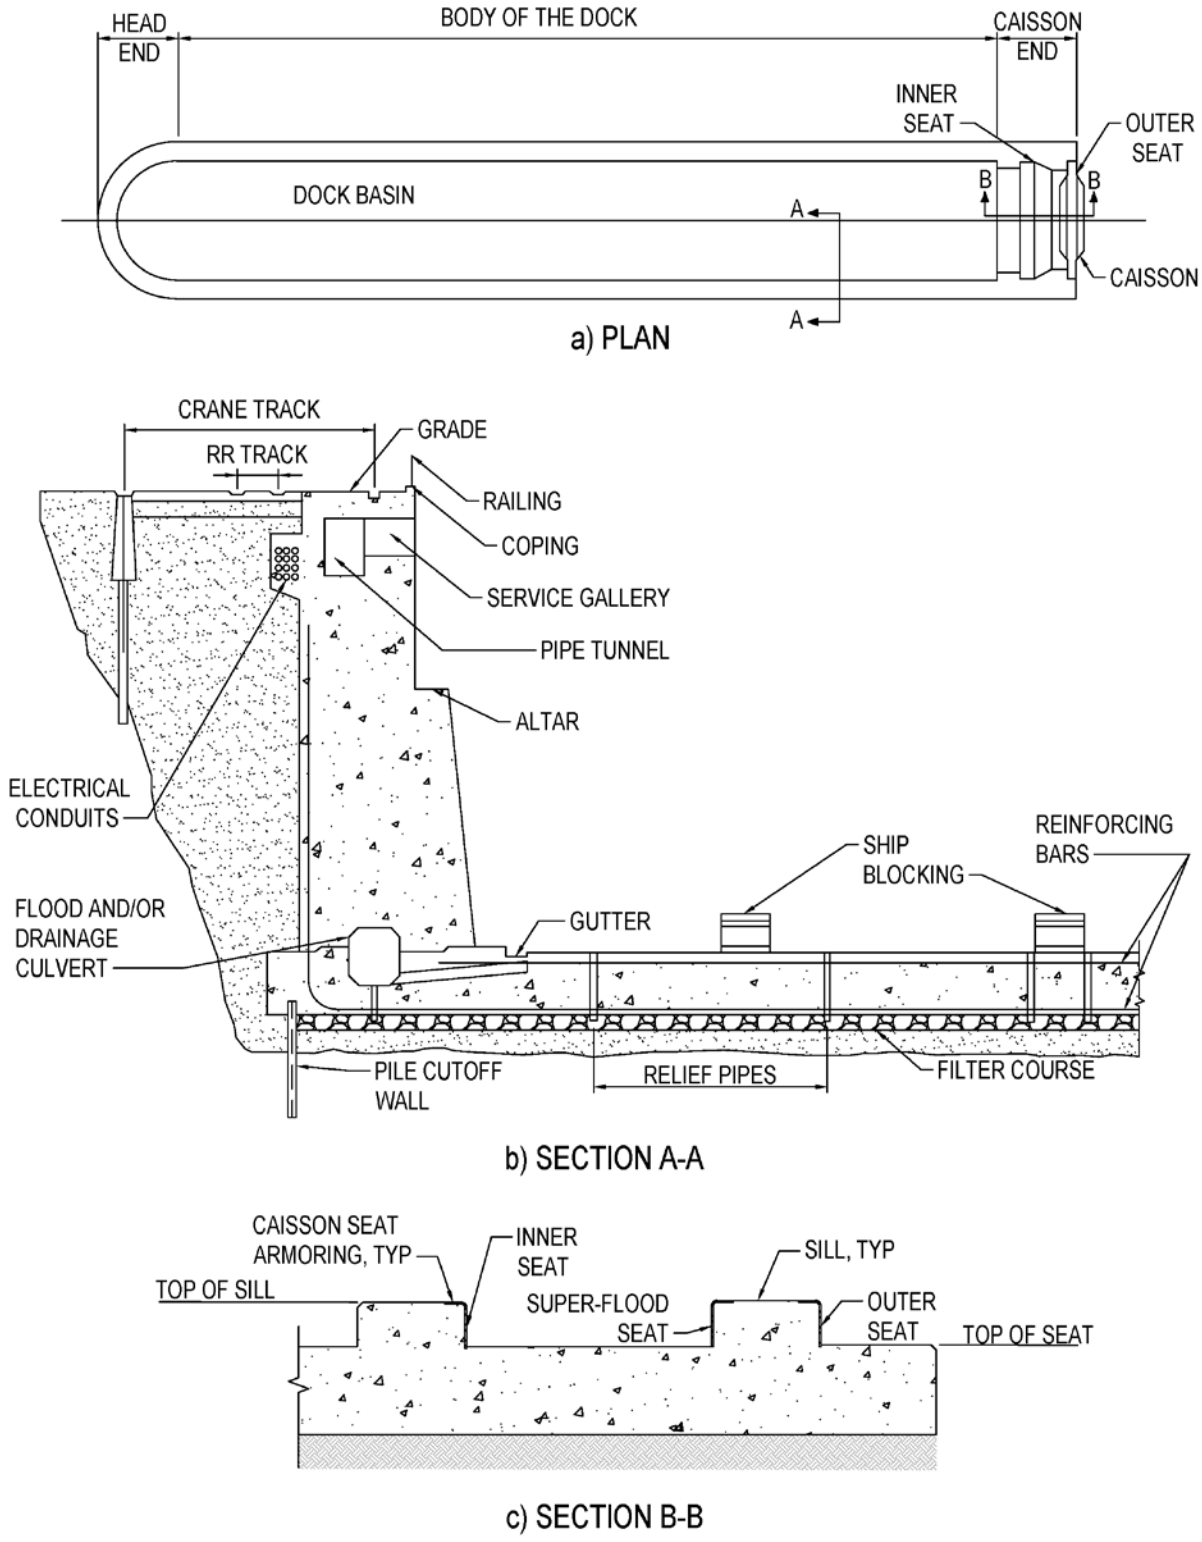

Table 3-1 Basic Dry Dock Dimensions [a]

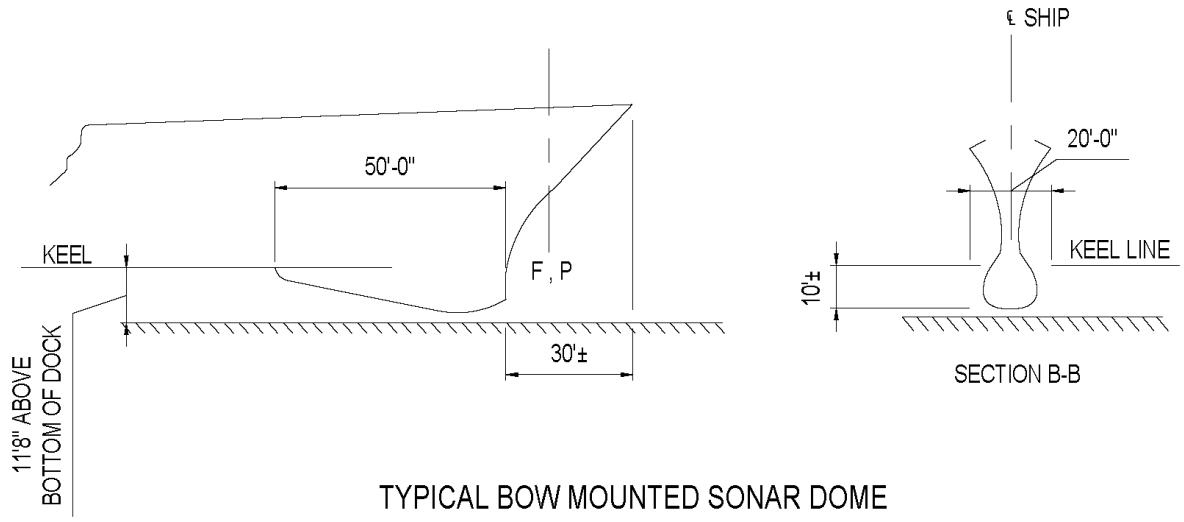
Ship Type [b]	Width, Clear Inside Body ft (m)	Length, at coping from Head to Outer Caisson Seat ft (m)	Depth, from MHW to Dry Dock Floor ft (m)
SSN Submarine	90 (27.4)	630 (192.0) [c]	43 (13.1)
SSBN or SSGN	130 (39.6)	800 (243.8) [c, d]	48 (14.6)
Destroyer or Frigate	90 (27.4)	650 (198.1)	42 (12.8) [e]
Cruiser	115 (35.1)	800 (243.8)	38 (11.6)
Auxiliary	130 (39.6)	850 (259.1)	45 (13.7)
Carrier	Floor 210 (64.1) Coping 190 (58.0)	1,250 (381.0)	55 (16.8) [f]



Note:

[a] Dimensions listed are basic planning guidance. Ship class, site-specific conditions, and anticipated industrial work to be performed will dictate final design dimensions.
[b] Refer to the following website for ship characteristics: https://www.nvr.navy.mil/SHIPS.html
[c] Allowance for shaft and dome removal included.
[d] Minimum floor work area. Does not include Caisson End shown in Figure 3-1 (a).
[e] Allowance for sonar domes below keel line included.
[f] Damaged condition.

3-2.2 Allowance for Sonar Domes.

Sonar domes are ordinarily located on the fore part of the ship keel. For a new dock to accommodate vessels so equipped, use the height of blocking required for removing domes with a sonar dolly. Sonar equipment is of various configurations and no set rules can be given (see Figure 3-2). Specific criteria must be outlined in project requirements. Sonar dome pits have been installed in some dry docks to reduce the required height of blocks.

Figure 3-2 Sonar Dome

3-2.3 Caisson Seats.

Provide an inner and an outer caisson seat at the entrance to graving docks. The outer seat is required to permit repairs to be made on the inner seat. For seat dimensions, refer to CHAPTER 9. A double-faced seat is required if a super-flooding feature is installed. For new construction, the inclusion of the superflood seat is negligible design and construction cost, therefore always provide an inner, outer and superflood caisson seats.

3-3 DRY DOCKS FOR SHIPBUILDING ONLY.

These dry docks, although sometimes built under the auspices of the Navy, are generally built in private shipyards and usually for a particular class or classes of ships. This type of dry dock is usually semi-permanent for economic reasons. The overall design, layout, pumping systems and utilities will be similar to repair dry docks. However main dewatering pump capacity can be reduced considerably as dewatering is only necessary prior to start of construction and not for docking existing ships.

Other considerations may be made to reduce cost if the life span of the dry dock will be 20 years or less. Determination of the dock lifespan and compromises weighed should be carefully considered. Experience has shown that docks built as semi-permanent have now been reclassified, and the associated life-extension project costs and risk have been considerable.

3-3.1 Height of Floor.

The draft at the time of undocking is predicated on the degree of vessel completion to be attained in the dry dock before removal to fitting-out pier. The weight and displacement will determine the elevation of the floor below mean high water.

3-3.2 Width.

Shipbuilding docks may be made narrower than repair dry docks for the same class of ships. Provide sufficient clearance to accommodate the required construction equipment between the hull and walls.

3-4 INSIDE CONFIGURATION.

3-4.1 Head End Shape.

The head end of the dry dock may be square, semicircular, trapezoidal, or ship shape as shown in Figure 3-3. One shape may best fit the pattern of adjacent structures. Additionally, there are other advantages and disadvantages which are directly associated with the construction and operation of the dry dock itself. A tabulation of these for each shape of head end is shown in Table 3-2, and is to be used as follows:

3-4.1.1 Square.

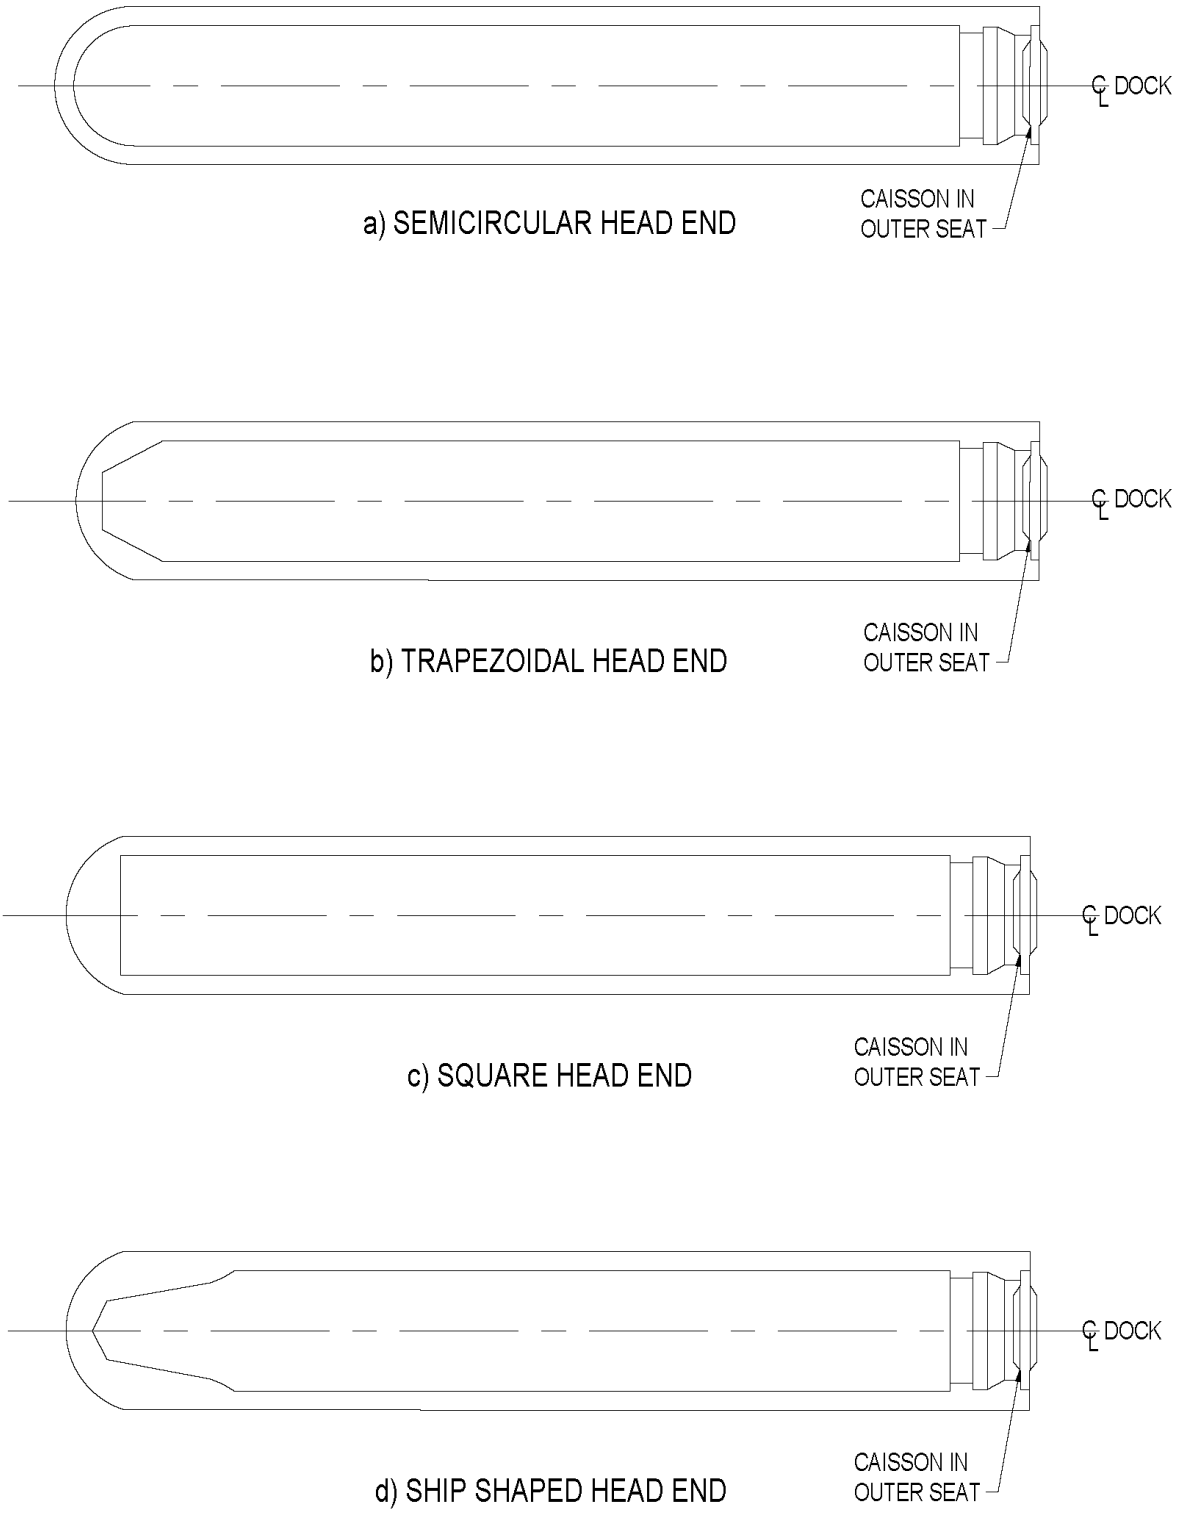
Use the square end for multiple docking, or for docks that are likely to have future extensions.

3-4.1.2 Semicircle.

Use the semicircular end for medium sized docks that cannot readily be lengthened at the head end.

3-4.1.3 Trapezoid.

Use the trapezoidal shape for small docks that are not likely to be lengthened at the head end.



3-4.1.4 Ship Shaped.

Ship shaped dry docks are not versatile and are obsolete.

Table 3-2 Design Considerations for Various Head End Shapes

Design Considerations	Square	Semicircle	Trapezoid
Economy of formwork	Poor	Fair	Best
Economy of concrete	Poor	Best	Good
Simplicity of crane tracks	Poor	Best	Good
Simplicity of installation of service facilities	Best	Poor	Good
Fit into yard	Poor	Good	Good
Adaptability for future extensions	Best	Poor	Fair
Providing access to dock floor:			
for Carriers	Best	Fair	Poor
for Other Ships	Good	Good	Good
Suitability for multiple docking	Best	Fair	Poor

Figure 3-3 Head End Shapes

3-4.2 Entrance End.

At the entrance end of a dock, the walls may be vertical or sloped outward. Refer to CHAPTER 9 for caisson dimensioning and details of the seats.

3-4.2.1 Clearances.

Ship clearances are not as large at the entrance as in the body of the dock where working space is necessary. For docks having vertical walls, allow 5 ft (1.5 m) minimum clearance from the ship hull on each side.

3-4.2.2 Roadway.

Where an entrance caisson is to be used as a roadway for vehicular traffic, the dock coping in the way of the caisson must be designed and detailed to suit.

3-4.3 Cross Section.

The most important influence of the inside as well as the outside shape of a dry dock cross section is the structural type (and construction methods) adopted. For relation of shape to these factors, refer to CHAPTER 4.

3-4.3.1 Floor and Wall Coping Elevation.

Design the coping of the dry dock wall high enough so that it will not be overtopped by severe waves which could possibly occur at extreme high water (storm surge) level, or at the grade of the surrounding yard, whichever is higher. See Section 3-5. Establish floor elevation per Section 3-2; Floors should provide drainage to prevent standing water via crown, slope or trenches.

3-4.3.2 Service Tunnels and Galleries.

In order to bring utilities and services from the shipyard to the docked ship it is convenient to have either service tunnels, galleries or both along the top of the dry dock wall. Attention should be paid to the location of these wall features and the anticipated water level in a flooded dock. Flooding service tunnels and galleries is not desired.

3-4.3.2.1 Service Tunnels.

Service tunnels are located in and near the top of walls. The tunnel is utilized to route large size salt and fresh water piping from the yard to the dry dock. Smaller piping such as for compressed gases, electrical and data cabling can also be run in these tunnels. The tunnel must be designed for intermittent human occupancy. Openings from the service tunnel to galleries allow service to pass through. Service tunnels and galleries should be designed and constructed such that they are always kept dry. Sump pumps, isolation valves and tunnel drains should be installed if necessary. Tunnels should be wide enough to accommodate all the required piping plus clearance for people to walk and to effect repairs. The height should provide 6.5 ft (2 m) headroom even where pipe

crossovers exist. Refer to Section 3-4.3.5 entitled “Crane Rails” for the relation of shape and location of tunnels to crane tracks.

3-4.3.2.2 Galleries.

Galleries can be set into the wall or cantilevered out from the wall surface. Their design should consider ship clearances during docking evolutions. The purpose of the gallery is to allow that final length of hose connection from the services in the tunnel to the ship. Gallery size should use the same parameters as service tunnels.

3-4.3.3 Steps or Altars.

The number of setbacks or altar platforms in the inboard faces of the dock walls should be kept to a minimum. Modern reinforced concrete design practically eliminates the necessity of any altars.

For full hydrostatic dry docks, gravity walls, a single step back may be made, part way up on the inboard face, to reduce concrete thickness in the upper part of the wall and to improve the stability of the wall.

3-4.3.4 Flooding and Drainage Tunnels.

Flooding and drainage tunnels are usually provided in the walls of dry docks. In order to create the most favorable stress conditions- See CHAPTER 6 and CHAPTER 7 for design considerations for these systems. Any tunnel should be designed for periodic human inspection but made as small as is compatible with hydraulic requirements. Large tunnels should never be less than 6 ft (1.8 m) high. Except for pure gravity walls, drainage tunnels present structural problems and result in increased cost.

3-4.3.5 Crane Rails.

Place one crane rail on top of the wall as close to the centerline of the dry dock as possible and compatible with other wall and tunnel design considerations. Never place the inboard rail nearer than 5 ft (1.5 m) to the edge of the coping. Rails should be set with the top flush with the concrete surface. The companion rail is generally located off the wall structure and supported independently. For additional criteria regarding location of crane rails, refer to CHAPTER 8.

3-5 FLOOD ELEVATION AND SEA LEVEL CHANGE.

A design flood elevation (DFE) must be determined in order to set the coping elevation, protect a dry dock and supporting infrastructure from flooding, and calculate the buoyancy factor of safety (FS). DFE is based on expected flood levels, additional water levels from extreme events, and future sea levels. Integrating shipyard and supporting infrastructure at new and retrofitting existing dry docks is both cost and time prohibitive. Therefore, a risk-based, adaptive approach is recommended in order to design for future extreme water events. Unless other guidance superseding this UFC is released, the following methodology is recommended.

1) First, calculate a design flood elevation using each of the three methods described below.
2) Second, rank the three elevations from lowest to highest. Begin a design that meets all structural requirements for the lowest elevation and formulate strategies to adapt to the higher elevations.
3) Finally, perform an analysis of alternatives (AOA) for future adaptive mitigations. This can be done by assigning relative cost and risk values to each of the three elevations relative to buoyancy FS, over-toping the dock, and the shipyard flood mitigation plans.

3-5.1 Flood Elevation Determination Methods.

3-5.1.1 UFC 3-201-01 Method.

This method follows UFC 3-201-01 using Table 2-1 for ASCE Flood Design Class 4. The coping is set to the minimum Design Flood Elevation (DFE) using the Base Flood Elevation (BFE). The BFE is the elevation of flooding, including wave height, having a 1% chance of being equal or exceeded in any given year.

Equation 3-1 Computation of Flooding Rate

$$DFE = BFE + 3\ ft\ (0.91\ m)$$

3-5.1.2 Extreme Event Method.

Compute the Extreme Flood Elevation (EFE) by using the FEMA value for elevation of flooding, including wave height, having a 0.2% chance of being equal or exceeded in any given year + 1 foot to coping.

Equation 3-2 Computation of Flooding Rate

$$EFE = FEMA\ 0.2\% + 1\ ft\ (0.31\ m)$$

3-5.1.3 Sea Level Change Approach.

Sea Level Change (SLC) affects the future storm surge and extreme tides. Global and local SLC shall be considered on any new construction or major dry dock renovation project. The science of SLC and application to design is an area under rapid development. All SLC values shall use the projections for at least the year 2100. Compute the extreme sea level elevations (ELSE) by:

Equation 3-3 Computation of Flooding Rate

$$ESLE = Local\ SLC + MHHW\ + Extreme\ Water\ Level$$

Where:

Local SLC = Global Scenario + Site Specific Adjustments

3-5.2 Minimum Values for New Construction.

The coping elevation shall be at or above the ELSE when using the medium global scenario and compared to the high and highest scenario for purposes of the AoA. Buoyancy FS shall be satisfied at ELSE for at least the high global scenario. If the FS is below 1.0, iterate on the design by adding mass or additional hold down elements. Check and report the FS for the highest global scenario.

3-5.3 Adaptive Strategies for Existing Docks.

For existing docks, the prediction and analysis should follow the same methodology minimum values. The mitigation for buoyancy is limited to adding hold down elements via tension piles through the floor to engage the rock or earth below the dry dock. Mitigating the potential for high water events that over-top the dry dock coping and caisson weather deck include permanent or semi-permanent floodwalls, adding a weir to the caisson, and raising the elevation of the immediate surrounding area. For any approach, the increased hydrostatic loads and resilience must be analyzed.

3-5.4 Shipyard Area Planning.

Recognizing that the dry dock does not stand alone and its mission requires the resources of the entire shipyard. Mitigating strategies for flooding the surrounding shipyard can only be addressed at the installation level. Dry Dock construction projects shall consult the area development plan and the Shipyard Infrastructure Optimization Planning (SIOP) office PMS 555 in order to maximize the dock’s operational days per year.

This Page Intentionally Left Blank.

CHAPTER 4 STRUCTURAL TYPES OF DRY DOCKS

4-1 DESIGN AND CONSTRUCTION.

This section deals with the influence of foundation requirements on shape and the reasoning leading up to specific type selection.

4-1.1 Basis of Type Designation.

Type designations are determined by the structural requirements necessary to neutralize the pressure of the water that surrounds it.

4-1.1.1 Hydraulic Pressure.

Hydraulic pressure can be resisted by the employment of sufficient weight and strength to resist the full pressure potential or can be diminished by absorbing the flow so as to lower the hydraulic gradient under the dry dock. The degree to which the water pressure is relieved determines the type terminology: (1) full hydrostatic; (2) fully relieved; and (3) partially relieved.

4-1.1.2 Piles.

Each of the three types of dry docks may be built with or without piles. For the full hydrostatic type, piles may be used to engage soil beneath the dry dock to contribute to the hold-down weight. For the fully and partially relieved types, piles may be used to improve the elastic modulus of the foundation or to reinforce the soil at locations of excessive soil pressure; for example, beneath the toes of walls or under ship blocking.

4-1.2 Methods of Construction.

Since a dry dock is constructed on the shore or extending into water, there is always the problem of excluding water from the construction site. To define completely the structural type of a dry dock, it is generally necessary to state its method of construction.

4-1.2.1 Water Exclusion.

On sites where water exclusion is feasible, a cofferdam, should be used. Since it must be deeper and wider than the finished dry dock, a cofferdam often presents technical and engineering problems more difficult than for the structural design of a dry dock itself. The structural type and shape of the dry dock may be influenced by the method used to solve the cofferdam problem. On sites where water exclusion is not feasible, a dry dock must be constructed by underwater methods, in which case the method used also influences the structural type and shape.

4-2 TYPES DICTATED BY FOUNDATION CONDITIONS.

4-2.1 Full Hydrostatic.

A dry dock is classed as full hydrostatic unless there is a relief drainage system that lowers the natural hydraulic head on the walls or floor. No material, even rock, can be considered impervious in the sense that it will prevent or decrease the hydraulic pressure on the structure. The full buoyancy of the dry dock must be resisted by one or more of the following factors: (1) weight of concrete; (2) weight of soil below the dock engaged by hold-down devices; or, (3) weight of earth resting on a ledge formed by the projection of the floor slab beyond the sidewalls or friction of the earth on the sidewalls.

4-2.1.1 Selection of Type.

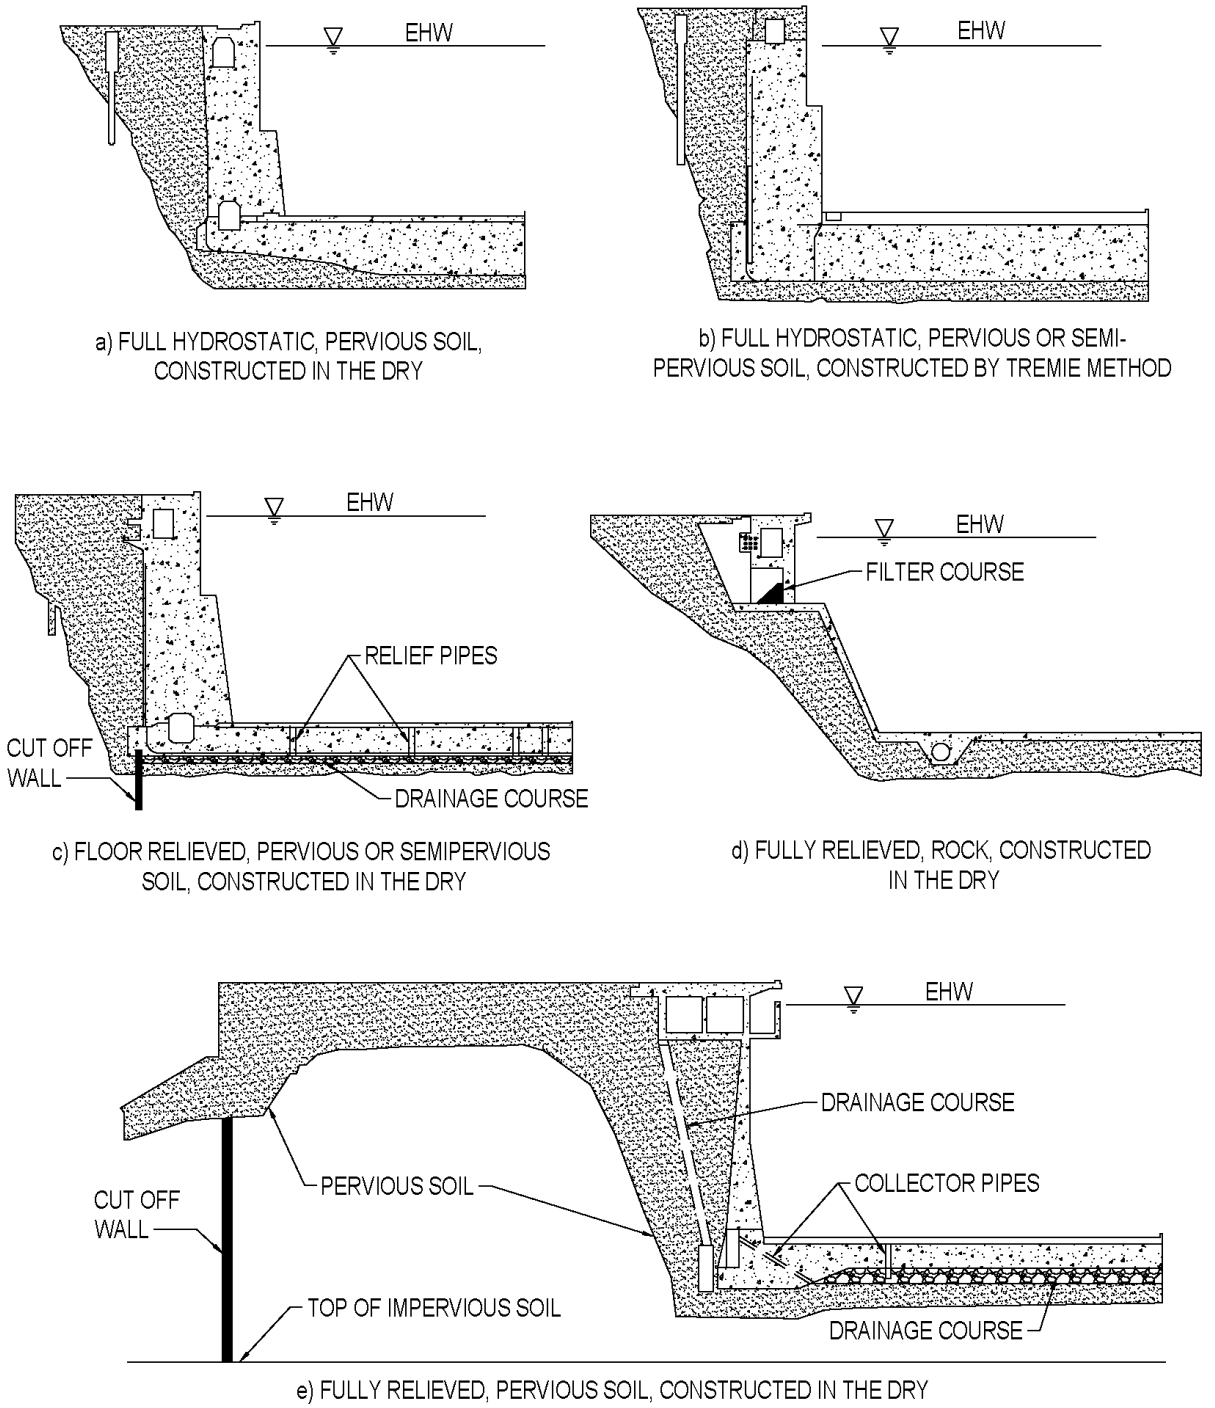
Theoretically, a full hydrostatic dry dock can be built under almost any site or foundation condition. However, for large and deep docks, where the pressure on the floor and sidewalls is great, and especially where it is not feasible to secure a satisfactory hold-down system to the material beneath the dock, economic considerations may force the choice of another type.

4-2.1.1.1 Dry.

A full hydrostatic type of dock does not require relief pumping and, therefore, has the least cost of power and maintenance. If possible and where all other local conditions are suitable, it should be constructed in the dry.

4-2.1.1.2 Wet.

All dry docks constructed in the wet are of the full hydrostatic type because conditions preclude installing reliable relief systems underwater. Docks of this type can be constructed with or without pile hold-downs. See (a.) of Figure 4-1 for the cross section of a full hydrostatic dock constructed in the dry and (b.) of Figure 4-1 for a dock constructed by tremie methods.



4-2.2 Fully Relieved.

A fully relieved dry dock requires a drainage system to eliminate or reduce the pressure on the floor and walls so that these elements may be of minimum size. Lower original cost will be offset to some degree by higher pumping costs throughout the life of the structure. The pressure relief type may be built for all types of foundation conditions if the flow of water is naturally cut off by not too pervious soil, or by natural or manmade means. The exception is for dry docks constructed in the wet.

4-2.2.1 Dry Dock in Rock.

For this type, it is necessary to line the rock excavation with concrete and provide weep holes through the floor and sidewall concrete lining. For an example of this type, see (d.) of Figure 4-1.

Figure 4-1 Graving Dock Sections by Structural Type and Construction Method

4-2.2.2 Dry Dock in Impervious Soil.

Where the soil is impervious, or nearly so, and the volume of seepage water to be handled is small, provide for this water to be drawn off through drainage courses placed under the floor and against the walls. This drainage course may or may not be supplemented by a pipe system to carry the seepage water into the dry dock chamber for disposal by pumping. The volume of seepage water that must be pumped during the life of a dry dock will depend on the degree of perviousness of the soil.

4-2.2.3 Dry Dock in Pervious Soil.

For a fully relieved dry dock to be built in pervious surrounding soil, provide a suitable cutoff outside the dry dock to stop the greater part of the general flow.

4-2.2.3.1 Sheet Pile Cutoff.

A dry dock may have an immediate surrounding of granular material underlain by an impervious stratum. A sheet pile cutoff, perhaps originally a part of the construction cofferdam and located at a distance from the dry dock, when driven to the impervious layer, can provide the necessary obstruction for cutting off the large volume of seepage flow which would otherwise reach the dry dock. For an example of this type, see (e.) of Figure 4-1.

4-2.2.3.2 Granular Material Filter.

Granular materials generally found at these dry dock sites must be excluded from the relief system flow. This requires the use of carefully designed filter courses and a system of drainage pipes adjacent to the walls and under the floor. The amount of pumping for this type will depend on the efficiency of the cutoff and the permeability of the soil.

4-2.3 Partially Relieved.

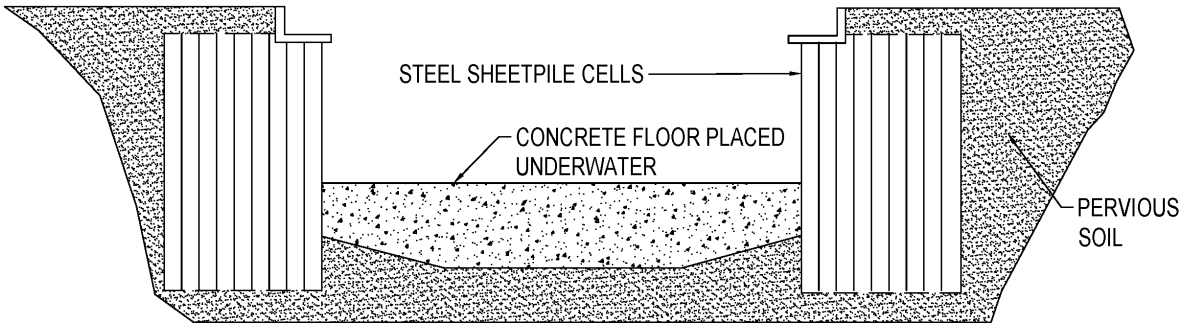
A partially relieved dry dock has relief provided for the floor only. Its use reduces the amount of floor concrete and minimizes difficulty in construction of the cofferdam. Provide the following:

4-2.3.1 Cutoff Wall.

Generally, a cutoff wall to surround the floor area only.

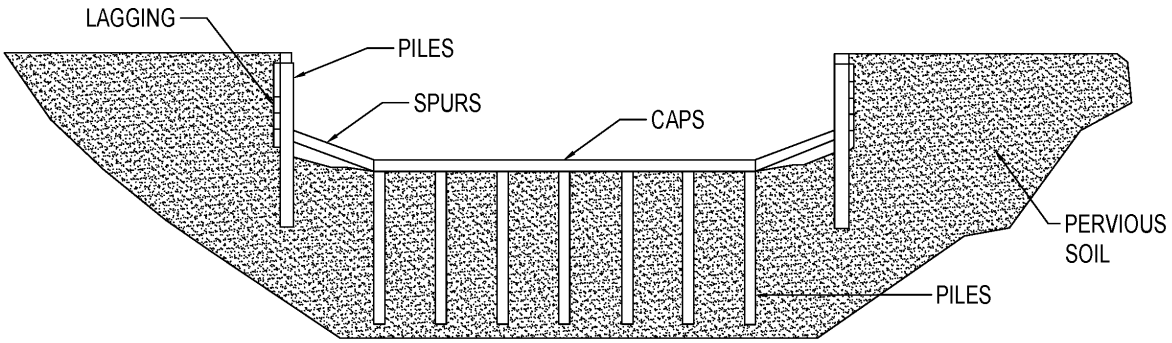
4-2.3.2 Filter Course.

A filter course under the floor. A system of collector pipes in the filter course may be used to carry the seepage water into the dry dock collecting tunnel.



4-2.3.3 Alternate.

As an alternative to a collector system, provide holes through the floor for the seepage water to flow into the dry dock chamber then through trenches and scuppers to the collecting tunnel. See (c.) of Figure 4-1.



4-2.4 Miscellaneous Types.

For dry docks of temporary or semi-permanent nature, a great variety of types may be used. These types are so much different in general character from the conventional naval dry dock that classification in accordance with the method of solving the water pressure problem is not entirely definitive. These dry docks are generally for shipbuilding or for building other types of floating structures and take a great variety of shapes and forms (see Figure 4-2). For these dry docks, provide the simplest drainage systems. Either the floor or walls, or both, may not be watertight, and the water may seep through them into the dock chamber and run off the floor into trenches or pump sumps for disposal by pumping.

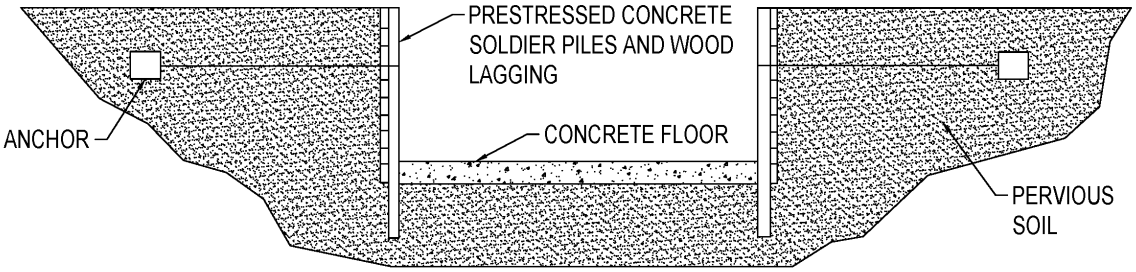


Figure 4-2 Miscellaneous Types of Dry Docks

CHAPTER 5 STRUCTURAL DESIGN

5-1 SCOPE.

This section presents criteria on structural design of dry docks, with particular reference to dead loads, hydrostatic pressure, earth pressure, live loads, special conditions of loading, materials and design stresses, and methods of analysis.

5-1.1 Design Life.

Half the graving dry docks in the Navy's inventory are over 100 years old. It is incumbent on the design agent and end user to consider both the current mission and the future environment.

5-2 DEAD LOADS.

Dead loads are of special significance because the deadweight of the structure, including all mobilized earth weight plus friction and tension piles, must be greater than the maximum buoyancy.

5-2.1 Weight of Concrete Structure.

For design purposes, compute the weight of reinforced concrete structures on the basis of 150 lb/ft^3 (23.56 kN/m^3) weight in air. For plain or mildly reinforced concrete, assume it to be 145 lb/ft^3 (22.78 kN/m^3), unless higher value is justified by testing.

5-2.2 Weight of Earth.

In computing the total resistance to uplift, include the weight of earth engaged by any extension of the slab beyond the outside of the wall. Earth below the dry dock floor, when engaged by hold-down piles or other devices, is included in the computation of the total weight.

5-2.2.1 Weight of Earth on Floor Slab Projections.

5-2.2.1.1 Specific Weights.

Unless special, lightweight soils are encountered, use 60 lb/ft^3 (9.42 kN/m^3) for submerged soils and 100 lb/ft^3 (15.71 kN/m^3) for soils above water levels. The use of alternate values estimated based on geotechnical testing, is permitted.

5-2.2.1.2 Computation of Volume.

To compute volume with a dock empty and with mean high water, use the soil weight above the slab projection between a vertical plane at the outer edge of the projection and the back of the wall. With a dock empty and extreme high water, add the weight of earth wedge between the vertical plane and an intersecting plane sloping 15 degrees outward from the vertical plane.

5-2.2.2 Weight of Earth Engaged by Floor Slab Hold-downs.

5-2.2.2.1 Specific Weights.

This earth is always submerged. For ordinary soils, use 60 lb/ft^3 (9.5 kN/m^3). Since this weight is usually very important, determine the correct weight by geotechnical testing if there is any indication that the soil may be of a greater or lesser weight.

5-2.2.2.2 Computation of Total Weight.

The hold-down capacity of individual piles may be computed by methods given in UFC 3-220-01. The total hold-down capacity is not necessarily the sum of the individual capacities of a pile group.

- Weight: In computing the weight of this block, assume its plan dimensions to extend beyond the outer rows of piles by one-half the typical pile spacing.
- Depth: For the depth of block, assume the block bottom is above the pile tips by a distance of one-half the typical pile spacing. Where spacings are different in each direction, use the larger of the spacings.

5-3 HYDROSTATIC PRESSURE.

5-3.1 Weight of Water.

In computing pressures, use 64 lb/ft^3 (10.05 kN/m^3) for seawater and 62.4 lb/ft^3 (9.80 kN/m^3) for fresh water. For brackish water, the specific weight should be adjusted based on the water salinity content.

5-3.2 Buoyancy Computations.

Minimum factor of safety (FS) for buoyancy is 1.0 under all conditions and at all stages of the dry dock's life. This includes construction and through the end of the dry dock's expected operational life. Make all buoyancy computations for four water levels, as follows:

5-3.2.1 Extreme High Water (EHW).

To check safety against uplift with the maximum (15-degree) earth wedge mobilized. A FS shall be no less than 1.1 for this condition.

5-3.2.2 Mean High Water (MHW).

To check safety against uplift with the minimum earth block and friction mobilized. Refer to Section 5-2 entitled "Dead Loads" and Section 5-4 entitled "Earth Pressure".

5-3.2.3 Extreme Low Water (ELW).

With a ship in dock to determine maximum downward load on foundation soil or piles.

5-3.2.4 Flood Elevation.

Current and future flood elevations must be considered. After determining the design flood elevation (DFE), see Section 3-5, check the dry dock stability at this extreme event. For dry docks with a safety wall or flooding barrier the water above the yard grade may provide additional mass to counter act this increased buoyant force.

5-4 EARTH PRESSURE.

5-4.1 Variations.

Acting against a dock structure, the resultant outside earth pressure will vary considerably according to pressure and weight conditions inside the dock. Resultant earth pressures will be different when a dock is full of water, when a dock is dry but contains a vessel, and when a dock is empty. See UFC 3-220-01 for determination of earth pressures.

5-4.2 Water or Ship in Dock.

Active pressure is to be used because the rotation of the wall with respect to the floor is negligible. Do not use surcharge for computing pressure on dry dock walls except where railroad rails on ballast are near the wall.

5-4.3 Dock Empty.

Assume partial passive pressure to be operative where there is structural continuity at the juncture between sidewalls and floor because, with the dock empty, sidewalls of full hydrostatic docks tend to rotate outward against the backfill. The amount of passive resistance must be determined by assuming a uniform increase in resistance to occur throughout the sidewall height, starting from zero value at the top to an ascertained maximum bottom value. The rate of increase is based on the condition that the total internal work of the bending stresses throughout the dock cross section has a minimum value.

5-4.3.1 Inconsistency in Partial Passive Pressure Assumption.

The earth pressure at floor level should be no greater than active pressure, because the horizontal displacement of sidewalls is zero at about floor level, which is the approximate center of rotation for the sidewalls. Nevertheless, the method of approximating the total passive resistance for the condition of dock empty, as described previously, has proved satisfactory for existing structures so designed.

5-4.3.2 Upward Pressure.

5-4.3.2.1 Full Hydrostatic Dock.

The distribution of upward pressure beneath a dock designed to resist full hydrostatic pressure is known when the dock is empty, because the dock weight is nearly equal to total buoyancy.

5-4.3.2.2 Relieved Floors.

For relieved floors, earth pressures are not uniform because they are dependent on slab deflections induced by concentrated ship loads and moments at the wall bases. For the solution of elastic foundation problems and associated soil pressures, refer to any of the industry accepted foundation analysis books.

5-4.3.2.3 Friction on Sides.

In addition to the dock deadweight, friction piles, and earth weight over projections, the frictional resistance between backfill and sidewalls also is effective in preventing uplift.

- Mean High Water (MHW): To determine the frictional resistance for an empty dock at mean high water, the lateral force acting against the sidewalls (that is, the force corresponding to the active pressure of submerged earth) is multiplied by the coefficient of friction for the earth material on the sidewall material.
- Extreme High Water (EHW): Stability against uplift at extreme high water is computed using a deadweight of the earth wedges as described in Section 5-2 entitled “Dead Loads”, instead of frictional resistance.

5-5 LIVE LOADS.

For design purposes, conditions comprising live loads are:

- Shiploads applied to dock floors through blocking.
- Wheel loads from crane wheels, railroad tracks, and trucks applied to local beam and slab supports.
- Local static and moving loads on roofs and floors or pumpwells.
- Railroad track loadings, as a surcharge of earth pressure, from tracks carried on ties and ballast adjacent to sidewalls of docks and walls of pumpwells.
- An impact allowance of 15-percent is made for moving loads for structural members forming the primary support for the moving loads.

5-5.1 Shiploads.

Determine shiploads on the floor for the specific class ship. Shiploads on the floor must be determined in accordance with the guidance provided in MIL-STD-1625, and NSTM Chapter 997.

5-5.1.1 Thin Floors.

For thin floors, investigate the effect of these extra heavy loads, and reinforce the floor locally as necessary.

5-5.1.2 Positioning.

Base the blocking arrangement for design of the floor on any likely positioning of ships in the dock. Larger ships may be docked only on the centerline of the graving dock. For docks wide enough to permit multiple docking of ships abreast, or long enough to permit various placement fore and aft, apply the load pattern for such smaller ships multiple docked in odd positions to the floor as well as the load pattern of larger ships docked on the centerline.

5-5.2 Wheel Loads.

The typical wheel loadings for a 40 ST (36.3 t) locomotive crane, 25 ST (22.6 t), 35 ST (31.7 t), and 50 ST (45.4 t) portal cranes are given in UFC 4-152-01.

5-5.2.1 Full Hydrostatic Graving Docks.

Crane wheel loads do not normally influence the design of the main wall of graving docks designed to resist full hydrostatic pressure, because of the extensive longitudinal distribution of the wheel loads by the walls. Wheel loads from cranes operating around full hydrostatic graving docks, therefore, usually are significant only in the design of local beam supports under rails crossing the overhead of service tunnels, pumpwells, and other auxiliary structures.

5-5.2.2 Relieved and Partially Relieved Graving Docks.

For relieved and partially relieved graving docks, crane wheel load may influence the design of main dock walls as well as the design of local beam supports.

5-5.2.3 Mobile Crane Loads.

Mobile cranes are to some extent replacing locomotive cranes. Use truck crane wheel loads as given in UFC 4-152-01 or the crane manufacturers wheel load specifications (covering many of the larger ~ 220 ST (199.6 t) mobile cranes used by PWDs/Shipyards/Private Contractors) for beams, slabs, and the overhead structure of the pumpwell, where crane track loading does not govern.

5-5.3 Loads on Pumpwell Overhead and Floors.

Pumpwell overhead should be designed for a uniform load of 600 lb/ft^2 (28.8 kN/m^2) and for truck crane wheel loading when it is at ground level. The critical load for floors supporting main pumps usually corresponds to the maximum upward pressure. Use a uniform load of 300 lb/ft^2 (14.4 kN/m^2) for floors not subject to upward hydrostatic pressure; also these floors are to sustain loads from operating machinery placed thereon either in a permanent operating position or in a temporary overhaul position. Include vibrations induced by reciprocating and rotating equipment in the design.

5-5.4 Anti-Terrorism, Bomb and Blast Resistance and Security.

Dry docks are not usually designed to resist bombing or blast effects because of the massive size of the structure involved. In some locations, consideration should be given to protective construction for the upper part of the pumpwell and the service tunnels. For waterfront security and anti-terrorism/force protection criteria, refer to UFC 4-025-01, *Waterfront Security Design*.

5-6 EARTHQUAKE LOADS.

Seismic analysis of the dry dock must be performed in accordance with MIL-STD-1625. Seismic forces should be considered as an “extreme” load and are to be combined with the additional forces that are present during regular operations, with appropriate load factors in accordance with UFC 4-152-01. Site specific geotechnical studies must address seismic and soil-structure interaction based on the hazard levels addressed in MIL-STD-1625, consider Chapter 4 of ASCE 61.

5-7 SPECIAL CONDITIONS OF LOADING.

5-7.1 Full Hydrostatic Dry Docks.

Although there are many special loading conditions to be considered in the design of a graving dock (for example, nonsymmetrical loads, wave action on exposed walls, earthquake, and unusual water differentials), the design of full hydrostatic pressure docks generally is concerned with four especially critical conditions.

- **Case I**. Dock under construction.
- **Case II**. Dock empty. Maximum hydrostatic uplift.
- **Case III**. Maximum ship load. Minimum hydrostatic uplift.
- **Case IV**. Dock full of water. Include superflooding, if applicable.

5-7.2 Partially and Fully Relieved Dry Docks.

Critical conditions for partially and fully relieved designs are similar to those for full hydrostatic dry docks, except for appropriate allowance for decreased upward and lateral water pressures in accordance with the degree of lowering of hydraulic gradients.

5-7.3 Dry Docks Built by Underwater Methods.

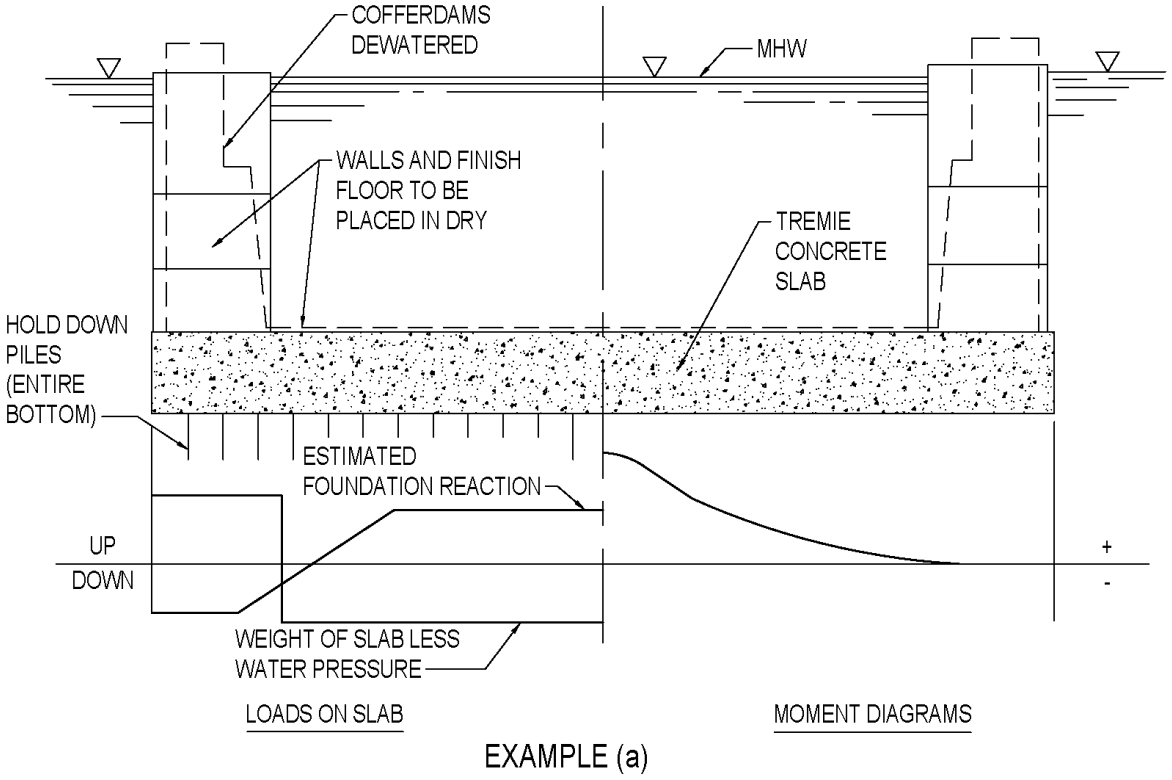
When completed, these dry docks are always of the full hydrostatic type. In some cases, however, this method of construction involves loadings not encountered with construction in the dry. These cases occur when walls are built entirely in the dry in cofferdams set on slabs previously constructed underwater. Under these conditions, when wall cofferdams are dewatered, the partially completed structure does not have the benefits of wall and finish floor slab weight to overcome the buoyancy of the cofferdams, or the full sidewall thrust to overcome the tension in the slab. For examples of two such conditions, see Figure 5-1.

These dry docks are frequently associated with the use of hold-down piles, necessary if the weight of the floor slab is insufficient to overcome the total buoyancy including that of the empty cofferdam or cofferdams. Note in (a.) of Figure 5-1 there is a tendency to develop tension in the slab bottom without benefit of axial compression from a sidewall thrust. In (b.) of Figure 5-1, there is a tendency to develop tension in the slab top with a side thrust that is much smaller than will be developed against the walls of the completed dock.

5-8 MATERIALS AND DESIGN.

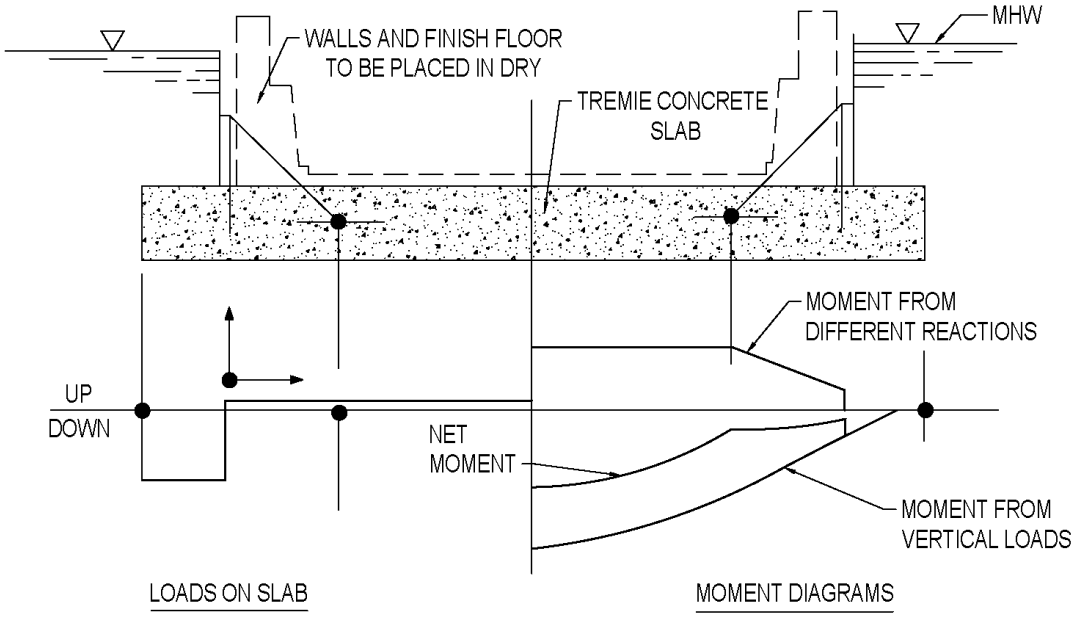
This section contains special provisions applying to concrete for dry dock walls, floors, and general cross section.

5-8.1 Concrete.



5-8.1.1 Classes of Concrete.

Recommend using concrete as specified in UFGS 03 31 29 or UFGS 03 31 30 *Marine Concrete* as appropriate. Use minimum 3,500 psi (24.12 MPa) estimated 28 days compressive strength cast-in-place concrete for the main body of the dock. Classes of greater strength may be used in accordance with structural requirements. Do not specify mortar intrusion concrete (see APPENDIX B, Glossary) for permanent dry docks.



5-8.1.2 Admixtures.

Admixtures may be used to produce air entrainment, higher strength, greater durability and better workability, up to maximum percentages detailed in the project specifications.

Figure 5-1 Dry Docks with Slabs Constructed Underwater, Walls and Finish Floor Constructed in Dry

EXAMPLE (a)

EXAMPLE (b)

5-8.1.3 Mass Concrete.

The designer must follow the guidance in UFGS 03 31 29, UFGS 03 31 30, ACI 207.1R, ACI 207.2R, and ACI 207.4R to prevent undesirable cracking in mass concrete used to construct the dry dock. A thermal study must be conducted as a part of the design effort when mass concrete will be used in construction of the dry dock. The designer must specify the methods of crack control to be used including mix design, pour size and sequencing, and temperature control during placement and curing. Consideration must be given to the following during design to minimize cracking:

- Maximizing aggregate size.
- Limiting monolith widths to 50 ft (15.5 m).
- Increasing temperature and shrinkage reinforcement above the minimum requirements of ACI 318 up #9 (#29) bars at 12 in. (305 mm) in each face.
- Requiring the contractor to conduct a mass concrete simulation test (mock up) prior to construction to validate the adequacy of crack control measures.
- Mass concrete temperature control plans.

5-8.2 Reinforcing Steel.

5-8.2.1 Cover.

Minimum concrete protection for reinforcement is as follows:

- 6 in. (152 mm) where face of concrete will be in contact with soil, and surfaces subject to cavitation or abrasion erosion.
- 3 in. (76 mm) for formed or finished surfaces not in contact with soil.
- 2 in. (51 mm) over bearing pile butts.
- At piles intended as tension piles and having a considerable length of embedment in the concrete, place the reinforcement as in the first bullet above.

5-8.2.2 Reinforcing Bars.

Reinforcement should have a minimum yield strength of 60,000 psi (413.7 MPa), and conform to either of ASTM A706/A706M, *Standard Specification for Deformed and Plain Low-Alloy Steel Bars for Concrete Reinforcement* or ASTM A615/A615M*, Standard Specification for Deformed and Plain Carbon Steel Bars for Concrete Reinforcement*, Grade 60. High strength or special large size reinforcement should conform to Grade 75 or Grade 80. Consider use of galvanized, coated or corrosion resistant reinforcement such as fusion bonded or purple bar coating. To control cracking, the maximum center-to-center spacing should not exceed 12 in.

5-8.3 Foundations.

Evaluate safe soil bearing capacity by methods set forth in UFC 3-220-01. Where the safe capacity of the soil is exceeded, provide structural support. Types of structural supports applicable to the foundation of dry dock proper and to supplemental structures are: timber piles, concrete piles, steel H-piles, pipe piles with open or closed ends, and caissons. For pile capacities, analytical treatment, information on range of capacities for various types of piles, and capacity of caissons, refer to UFC 3-220-01.

5-8.4 Cellular Cofferdam Wall.

The dock wall consisting of cellular sheet pile structure should be designed based on USACE EM 1110-2-2503 *Design of Sheet Pile Cellular Structures Cofferdams and Retaining Structures.*

5-8.5 Design.

5-8.5.1 Reinforced Concrete.

5-8.5.1.1 Load and Strength Reduction Factors.

In design of reinforced concrete structures, proportion members for adequate strength in accordance with provisions of the latest edition of ACI 318, *Building Code Requirements for Reinforced Concrete*, using load factors and strength reduction factors (Φ) specified.

5-8.5.1.2 Service Load Stresses.

Alternatively, non-prestressed reinforced concrete members may be designed using service loads and permissible service load stresses in accordance with provisions of ACI 318-99, Appendix A, Alternate Design Method.

5-8.5.1.3 Buoyant Condition Increases.

For a buoyant condition of a continuous U cross section, which might be produced in a relieved or partially relieved dock resulting from failure of the pressure relief system, or for construction stages, the ordinary working design criteria may be increased 50 percent.

5-8.5.2 Steel and Other Materials.

For appurtenant structures of concrete, steel, wood, and other structural materials, design must be in accordance with UFC 1-200-01.

5-8.5.2.1 Allowance for Corrosion of Steel Structures.

Steel structures must be designed with a corrosion allowance such that allowable stresses will not be exceeded when corrosion has reduced structural component cross sectional areas by the amount of the corrosion allowance. Corrosion allowances should be tailored to suit the environment of each steel structure. All pressure or flooding boundaries must be considered. This includes such examples as the caisson hull, watertight hatches and sluice gate thimble plates.

5-9 METHODS OF ANALYSIS.

5-9.1 Full Hydrostatic.

For analysis of four basic conditions of loading, refer to *American Civil Engineering Practice, Volume II*.

5-9.2 Fully or Partially Relieved.

Where these dry docks have relatively thin floors, concentrated ship blocking loads and wall reaction produce deflections resulting in variations in foundation pressures and requiring methods of elastic foundation analysis. The problem is to be treated as two-dimensional. The elastic foundation method may be used to assist in estimating foundation pressures for the special loading conditions discussed in Section 5-6 entitled “Special Conditions of Loading”.

5-9.3 Seismic Analysis.

Simple method of analysis such as Seismic Coefficient Method and Equivalent Lateral Method should be implemented in the initial stage of analysis and later progressing to increasing complexity by implementing linear elastic response spectrum, time-history modal-analysis and non-linear time history-direct integration procedure, if necessary. Refer to EM 1110-2-6053, Earthquake Design and Evaluation of Concrete Hydraulic Structures for general approach for the seismic analysis.

5-9.4 Computer Analysis.

The dock structure may be analyzed using structural finite element analysis (FEA) and/ or soil-structure interaction (SSI) analysis codes, depending on the complexity of the structure and loading. The analysis may initially be performed on two-dimensional (2D) sections and later progressing to three dimensional (3D) analysis, if necessary.

5-10 SAFETY CONSIDERATIONS.

5-10.1 Basic Safety Standards.

For general safety standards see OSHA Part 1915, *Occupational Safety and Health Standards for Shipyard Employment*, and Part 1910.29 *Fall protection systems and falling object protection-criteria and practices*. Local shipyard safety instructions or

other current U.S. Navy safety requirements may take precedence. Consult representatives from the local safety office and the appropriate subject matter experts before finalizing the design of safety features.

5-10.2 Safety Features Peculiar to Dry Docks.

Observe the safety features described in the sections below.

5-10.2.1 Coping Railing.

It is necessary for coping railings to be removable to avoid fouling lines when docking and undocking ships. The removal and replacement must be accomplished with as little hazard as possible because of the seriousness of the accident should a person fall into an empty dock. Chain rail with removable stanchions were used in the past, but maintaining adequate chain tension is a common problem. Solid metal pipe or fiberglass railing, provided in 6 to 10 ft (1.8 to 3 m) sections for ease of removal/reinstallation, is preferred. The design and locations of the top rail, mid rail, and toeboard must meet fall protection requirements. Refer to the shipyard safety office or current U.S. Navy safety guidelines for specific requirements.

5-10.2.2 Stairways.

Use open mesh treads on all framed stairways. Use non-slip treads for concrete stairways. At the top of steep, infrequently used stairways provide a guard. Closing chains may be used however; self-closing gates are preferred because they do not rely upon personnel to reattach the chains after each use. Open stairways must have top rail and mid-rail. If the top rail is used to guard an opening then the top of the rail as measured from the stair nosing is between 36 in. and 38 in. (914 mm and 965 mm).

5-10.2.3 Toeboards.

Provide toeboards in accordance with fall protection requirements at all rails where falling object protection is required. At the coping edge, a curb may serve as a toeboard.

5-10.2.4 Obstructions to Mooring Lines.

Keep the top of coping clear between the edge of the coping and the line of capstans and bollards.

5-10.2.5 Stepdowns in Tunnels and Culverts.

Avoid unprotected stepdowns in all unlighted tunnels and culverts. Use guardrails, or an arrangement of rails and gratings, to protect personnel while still retaining the water carrying capabilities of the tunnel or culvert.

5-10.2.6 Spillways.

Provide replaceable corrosion resistant (type 316 Stainless Steel or Composite) ladder rungs or guardrails, depending on steepness, up flooding and discharge spillways, to aid in access for inspection of sluice gates and stoplogs.

5-10.2.7 Dock Floor Irregularities.

Graving dock floors should present an unbroken surface. Cover drainage conduits with gratings that do not protrude above the floor level. Run service pipes near the sidewalls and bridge them at stairways. Floor finish should be sufficiently rough to prevent slipping, but not so rough as to injure blocks.

5-10.2.8 Painting.

Paint obstructions with a striped pattern composed on contrasting colors as outlined in UFC 3-190-06.

- Service pipes are customarily painted according to established color codes, but those below headroom or otherwise forming obstructions should be painted with contrasting colors in stripes.
- Channel pedestrian traffic through safety zones by marking the borders of pedestrian passageways with traffic zone paint.

This Page Intentionally Left Blank

CHAPTER 6 FLOODING

6-1 DESIGN FACTORS.

This chapter contains criteria and information on flooding of dry docks, particularly methods of flooding and the design of hydraulic structures.

6-1.1 Requirements.

Flooding of dry docks is done entirely by gravity; superflooding feature installations require a pumping system to raise the water inside basin to water levels to higher elevations than the tide range allows. Design and arrange all flooding systems to operate with a minimum of disturbance to ship blocking, no intake of silt or floating objects, a minimum of required special gate control, and no vacuum or cavitation effects in the water channels. Gates and gate operating mechanisms must be reliable and durable.

6-1.2 Flooding Periods.

The average time for flooding Navy Dry Docks of the five types may be used as a design guide. Flood times are for empty docks. Actual flood time will depend on many factors. New docks or renovations shall set flooding time requirements based upon operational, environmental and functional needs of the shipyard. The times for flooding the docks should be, for the main classifications:

- SSN Submarine and destroyer docks, 90 minutes.
- Cruiser docks, 135 minutes.
- Carrier and Auxiliary docks, 135 minutes.

6-2 FLOODING METHODS.

There are three general methods used for flooding graving dock basins.

1. From flooding intakes on one or both sides of the entrance through culverts built into the lower parts of sidewalls and connected to floor openings spaced along the dock length at the floor.
2. From flooding intakes on one or both sides of the entrance through culverts passing transversely under the floor near the entrance with openings leading upward into the floor.
3. Through ducts or tubes in the caisson or entrance closure gate. This is referred to as a flood through caisson.

6-2.1 Common Intake Features.

Except under special conditions, place one intake opening on each side of an entrance. For very large docks requiring large culverts, two openings on each side may be used to reduce sluice gate sizes. Opening edges should be rounded to reduce eddying and contraction of the stream.

6-2.1.1 Opening Elevations.

No standardization can be established for opening elevations since these depend on tidal ranges, stem rises of gate valves, and proximity and character of entrance approach bottoms. In general, depths below mean low water, where opening soffits are placed, should not be less than opening heights. When an entrance approach bottom is near the invert or openings, protect the bottom area in front of and adjacent to the openings from erosion by heavy rip-rap or other means.

6-2.1.2 Trash Racks.

Place trash racks over openings to prevent intake of solid matter. Trash racks must be removable for maintenance and replacement.

6-2.1.3 Stoplogs.

Between trash racks and sluice gates, provide vertical slots in culvert sides to accommodate stoplogs furnished to shut off the water for sluice gate maintenance with double valve protection.

6-2.1.4 Sluice Gates.

Control graving dock flooding with sluice gates. Provide two sluice gates per flooding opening or a sluice gate plus a stoplog to assure “double valve protection” against inadvertent flooding as required by MIL-STD-1625.

6-2.1.4.1 Minimum Design.

When under heavy hydrostatic pressures occurring during high tide levels with wave action, design must be adequate to prevent operating and maintenance troubles caused by distortion, warping, and excessive friction.

6-2.1.4.2 Maximum Design.

Design maximum sluice gate sizes to allow flooding a dock within the specified time.

6-2.1.4.3 Design for Two-Way Pressure.

When sluice gates are subjected to two-way pressure, they must be specifically designed for such service.

6-2.1.4.4 Specific Requirements.

- Minimum design life of 30 years.
- Maximum leakage of 0.05 gpm/ft (0.6 lpm/m) of the seal perimeter at the design seating and unseating head.
- Limit the largest dimension to 96 in. (2.44 m).
- Provide local mechanical gate position indicators at gate stands, and remote electrically operated indicators at pumpwell control boards.
- Design structural supports for gate lifting mechanisms to carry a load two times the manufacturer rated lifting force (Factor of Safety = 2.0).
- Sluice gates used in dock flooding, dewatering, or drainage systems must be oriented such that the greatest pressure they will experience will seat the gate leaf against the gate frame. Sluice gates that will experience pressure from both sides (dock flooding gates for superflooding docks, gates in interconnecting tunnels between dry docks, etc.) must be specifically designed to accommodate expected unseating heads.
- Suitable corrosion resistant thimbles should be embedded in concrete for attachment of sluice gate frames.
- For all wedges and seating surfaces where sliding occurs, the use of a metal sliding against a metal of the same alloy composition may create galling problems. Use metals of different alloy composition or the same metals with different hardness and anchor these seating surfaces with dovetail grooves. For specific wearing problems, consult a metallurgist.

6-2.1.5 Draft Boards and Dock Marks.

Draft Boards or water level indicators must be placed on dry dock walls near the entrance on each side and on dry dock walls near the head end on each side. The indicators must be clearly visible from the opposite side at the top of a dry dock. Mark gauges with numerals 6 in. (152 mm) high, 3 in. (76.2 mm) clear space above and below and with the bottoms of numerals corresponding to multiples of 1 ft (305 mm) of draft.

The gauges may be cast as recesses in wall concrete and painted, colored tile cemented into a wall, noncorrosive metal anchored into the wall or plastic composite also anchored to the wall. The zero level may be referenced to the dock floor elevation, sill height or the top of the standard docking blocks used. Refer to NSTM Chapter 997, and MIL-STD-1625 for additional requirements.

Dock marks are longitudinal markings along the dock length. They are helpful in referencing utility locations, work orders for maintenance requests and progress during dock evolutions. They should be placed along the upper wall or top-level coping facing inward so that they are visible from the opposite sides of the dock and from the floor

when the dock is empty. Zero should be the inner caisson seat face. Maximum increments must not exceed 100 ft (31 m) center to center.

6-2.1.6 Vents.

Vents must be provided behind each gate, leading from water duct soffits to the free atmosphere on the coping where the vent openings must be covered by grating. A vent must be located at the highest point of a soffit before it curves down into the flooding culverts proper.

6-2.2 Flooding Culverts.

One of the two following types of culverts may be used to conduct flooding water from entrance works into a dry dock chamber.

6-2.2.1 Sidewall Type.

Sidewall culverts are located in the lower parts of sidewalls, connected to the sea through the entrance works. Floor openings and one or two large sidewall openings are connected to them.

6-2.2.1.1 Advantages.

This arrangement achieves filling without dangerous currents. A flooding culvert often serves in part as a drainage and/or dewatering culvert. The use of floor openings for filling provides a blanket of water to cushion the force of water from the outlets and also flushes the floor drains.

6-2.2.1.2 Flooding Design.

In a flooding culvert, maximum velocity occurs during early flooding stages and is gradually reduced by loss of head resulting from the rising water level inside a dock. The flooding time is greatly affected by the flow rate at reduced heads when a dock is nearly full. Therefore, large culverts and openings are desirable. It is important to reduce friction, eddy currents, and turbulence, by making interior surfaces of culverts smooth and all changes of direction by means of gradual curves.

6-2.2.1.3 Tunnels.

This system is efficient if hydraulic requirements do not result in tunnels of such size as to produce complex and high stress concentrations in the walls. This is especially true of thin walls with stressed reinforcing steel and less true in gravity walls. Even for the latter case, formwork is expensive. Long stretches of tunnel increase cleaning and maintenance work. From experience long stretches of tunnels that wrap around the dock floor or deliver water to the head end of dock are unnecessary. For existing docks, these tunnels should be filled, after checking for structural concerns, during renovations of the dock.

6-2.2.2 Transverse Floor Type.

Transverse floor culverts comprise a number of openings, spaced across a dock floor above a wide culvert located parallel to, and from 10 to 18 ft (3.1 to 5.6 m) inboard of, the inner caisson seat; the inboard distance depending on the dock size. The culvert ends rise in the sidewalls and terminate in the entrance works.

6-2.2.2.1 Flooding Factor.

In operation, the method of flooding through openings of transverse culverts necessitates partial opening of the sluice gates for a sufficient time to attain adequate water depth on the floor, so the flow velocity toward the head end will not dislodge or damage the blocking.

6-2.2.2.2 Cost Factor.

A properly designed system of this type will comply with specified flooding times at lesser cost than the system of flooding through sidewall culverts.

6-2.3 Flood Through Caisson.

Dry docks can be flooded through ducts or tubes in an entrance closure caisson or gate. This method for flooding the dry dock can be used exclusively, or it can be used in combination with flooding intakes in the dock walls. This is the preferred method because it provides greater redundancy and is more cost effective than the other two methods for both initial construction costs and O&M costs. Conversion of existing docks from using culverts to caisson flood through tubes is recommended when repair of flooding sources is studied.

For this method of dry dock flooding, multiple round tubes or ducts penetrate the caisson shell plating through the caisson ballast tank. Tube diameter is normally 30 in. (762 mm) and should not be larger than 36 in. (914.4 mm). The number of flooding tubes is dictated by the desired flooding time and hydraulic characteristics. However, utilize at least two flooding tubes for redundancy if the dock is to be flooded exclusively through the caisson. Each flooding tube must meet the requirements of double valve protection per MIL-STD-1625. This can be accomplished by having two valves installed in series or with one valve and flanges on the exterior of the caisson for steel blanks. Additional requirements are contained in CHAPTER 9.

6-2.4 Super-flooding.

Super-flooding is a system to raise the inside water levels to higher elevation than that of the normal tides. A super-flooding system has been used in several graving dry docks with inadequate water depth to enable them to dry dock sonar equipped ships and ships of newer deep draft design. Ideally a dry dock would be designed without the need for such a system. However, increased ship docking capability may be obtained by installing a super-flooding system that lifts ships by flotation. The operation consists of off-center vessel entry into the dock chamber, placing entrance caisson in seat,

pumping water into the dock chamber thus raising the ship, breasting the ship over preset keel blocks, and then dewatering the dock chamber.

It also requires that the dry dock have an inboard faced caisson seat or securing devices for the entrance closure to resist the outward hydrostatic pressures caused by the raised interior water level. Super-flooding is most cost effectively accomplished by installing the super flooding pumps in the caisson. At least two super flooding pumps should be used. The system should be piped to allow suction to be taken from the outside face of the caisson and discharged into the dry dock. Super-flooding can also be accomplished by using the main dewatering pumps thorough a specifically designed arrangement of sluice gate and dewatering valves. This design requires that the main dewatering pumps take suction from the flooding source and discharging into the dock.

6-3 HYDRAULIC DESIGN.

6-3.1 Overall Factors.

In hydraulic design of flooding systems, consider the factors of waterheads, required flooding times, optimum configuration of culverts, permissible flow velocities, and limiting sizes of sluice gates.

6-3.1.1 Heads.

Hydrostatic head causing flow varies from a maximum when a dock chamber is empty, to zero when a dock chamber is full. Mean high water (MHW) or mean higher high water (MHHW) is used as the reference elevation for determining maximum head.

6-3.1.2 Required Flooding Time.

Refer to Section 6-1 entitled “Design Factors”.

6-3.1.3 Flow Velocities.

The maximum desired flooding flow velocity should be 25 ft/s (7.6 m/s). This velocity may not conform to an available head that could produce higher velocities. In such cases, either provide built-in head losses in the system or reduce the intake area by sluice gate throttling.

6-3.2 Evaluation of Flooding Time.

The many factors affecting flow in flooding systems make it practically impossible to compute accurately the time required for the flooding. Such factors include:

- Variations in Hydrostatic Head. These conditions exist because of water rise in the dock, and the difference in actual tidal conditions from those assumed in the design.
- Transitions in culvert cross sections in many cases are necessarily abrupt; for example, at dock floor openings.

- Changes in elevation and direction of the main culvert alignment.
- Head losses in trash racks and gratings.
- Roughness condition of culvert walls.
- Entrance and discharge head losses.
- Size of ship in dock.

6-3.3 Computation of Flooding Time.

Because of the difficulty in combining the various factors influencing flow, the entire system is treated as an entity with a single overall flooding coefficient applied in the basic formulas as in Equation 6-1.

Equation 6-1 Computation of Flooding Rate

$$Q = aC_f\sqrt{2gh}$$

Where:

Q = *flooding rate, ft³/s (m³/s)*

C_f = *overall flooding coefficient (dimensionless)*

a = *cross section area of main culvert, ft² (m²)*

g = *acceleration of gravity, ft/s² (m/s²)*

h = *difference in elevation between water in dry dock and outside water, ft (m)*

To determine the relationship between a varying head, as the water rises in the dry dock, and an interval of elapsed time, take the expression in Equation 6-2.

Equation 6-2 Computation of Flooding Velocity

$$\frac{Q}{A} = -\frac{dh}{dt}$$

Where:

A = *average plan area of the water pond in a dry dock, ft² (m²)*

t = *interval of elapsed time, sec*

Then substituting the value of Q from Equation 6-1,

Equation 6-3 Time Rate of Change

$$dt = \frac{-Adh}{a \cdot C_f\sqrt{2 \cdot g \cdot h}}$$

Or for definite time intervals (integrating Equation 6-3 between limits h_2 and h_1)

Equation 6-4 Time rate of change for definite interval

$$t_2 - t_1 = \frac{2 \cdot A \cdot \left(\sqrt{h_1} - \sqrt{h_2}\right)}{a \cdot C_f \sqrt{2 \cdot g}}$$

The total time T, for the dock to reach the outside water level (h_2 = 0) with an initial difference h_1:

Equation 6-5 Total flooding time

$$T = \frac{2 \cdot A \sqrt{h_1}}{a \cdot C_f \sqrt{2 \cdot g}}$$

The value of C_f may be obtained from tests on dry docks or other structures such as ship locks with comparable flooding systems. For proposed flooding systems of unusual character, or for dry docks of unprecedented size, model tests should be considered.

CHAPTER 7 DEWATERING

7-1 DEWATERING SYSTEMS.

This section deals with criteria, data, and information on dewatering, with particular attention to basic components, basic requirements, and pumping systems.

7-1.1 Main Dewatering System.

This system is used to remove water from the dry dock basin during docking operations. Large grating covered culverts in the dry dock floor adjacent to the main pump suction chamber are normally used to facilitate flow into this system.

7-1.2 Drainage System.

A drainage system collects the last few inches (centimeters) of water blanketing the graving dock floor, as well as rainwater, flushing water. The floor should be sloped or crowned so that water will make its way to longitudinal floor trenches that lead to culvert adjacent to the main pump suction chamber. The trenches should be covered by securely anchored strong gratings.

7-1.3 Environmental Systems.

Environmental requirements in most locations now require that potentially contaminated water be treated prior to discharge. If potentially contaminated and uncontaminated waters are allowed to mix, the mixture must be handled as contaminated water. For this reason, it is usually necessary to segregate potentially contaminated water sources in the dry dock from uncontaminated sources that can be pumped directly into the harbor. Potentially contaminated sources can include water that contacts the dry dock floor where industrial activities are occurring. Uncontaminated sources include water pumped from the dry dock during docking/undocking operations, water that leaks past the caisson seat, ship’s cooling water, and water that leaks through dock walls or enters the dock through pressure relief pipes. Segregation is typically done by designating a location just beyond the sill beyond which all water is handled by the environmental discharge systems, and any water between this location and the caisson is discharged by the drainage system.

Design environmental systems so that system failure does not result in flooding of the dry dock floor. Environmental systems should overflow into the normal floor drainage system before the water reaches dry dock floor level.

Environmental system requirements vary by location and can be subjective. For this reason it is critical that environmental system planning and design be closely coordinated with the regulatory authorities to ensure compliance with environmental requirements.

7-2 DEWATERING SYSTEM COMPONENTS.

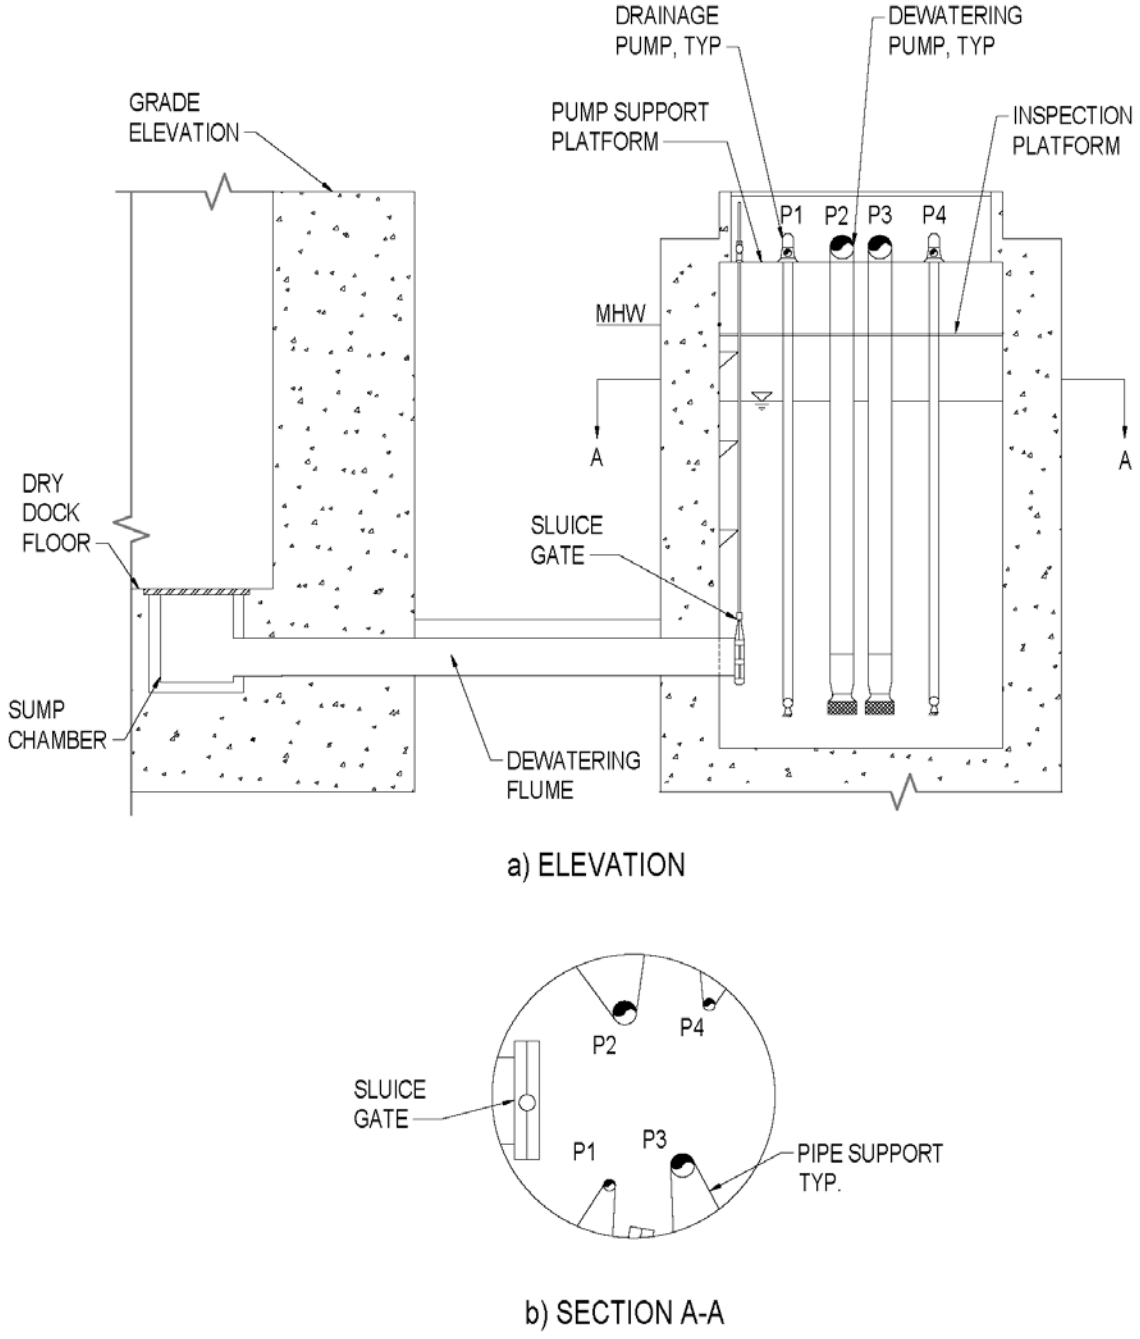
7-2.1 Floor Trenches.

The floor trench should be narrow and short grating covered leading to the pump suction chamber, collector channel, a wide, deep, grating covered open culvert leading to the pump suction chamber, handles the greater portion of water pumped out of the flooded graving dock by the main dewatering system.

7-2.2 Sand Sumps.

Abrasive materials harmful to pumps and pump fittings are continuously washed off a graving dock floor in sufficient quantities to justify the installation of a settling basin. Provide settling basins to retain most of these harmful suspended particles. Locate these basins in an accessible part of the collector channel to permit easy removal of collected sediment and sand. Other methods of containing this material may be used as an alternate, such as floor barriers around the ship.

7-2.3 Suction Chamber.



Provide a suction chamber (large enclosed space) for the suction bells of the dewatering pumps next to or in dock sidewalls, preferably near the dock entrance. Specific design requirements are:

- Locate the chamber floor below the graving dock floor approximately 10 ft (3.1 m); shape it to conform to flow lines of water entering pump suction bells, if necessary.
- Provide access to the main suction chamber from the dock floor culvert.

7-2.4 Pumpwell or Pumphouse.

Provide a pumpwell or pumphouses of reinforced concrete for housing the pumps, motors, valves, gates, controls, and other equipment. Pump suction chambers constitute the lower part of a pumpwell. A design, known as a wetwell (see Figure 7-1), can significantly reduce the amount of mechanical equipment and flooding risk compared to traditional Navy dry dock pumpwells. This design combines the suction chamber and pumpwell areas with an open, flooded center that equalizes with the dock. Wetwells also make use of more commercial off the shelf equipment vice custom manufacturing. Contact the NAVFAC EXWC Dry Dock SME for more information.

Figure 7-1 Elevation View of Wetwell Operations Level

7-2.4.1 Pumps and Motors.

Several functional types of pumps with motors may be housed in a pumpwell; main dewatering units predominate. Other pump and motor units are:

- Drainage pumps.
- Sump pumps.
- Sewage pumps.
- Salt water pumps (fire protection and flushing).
- Vacuum pumps (if required for priming).

7-2.4.2 Valves and Gates.

Include the following valves and sluice gates in a pumping plant:

- Gate valves in discharge line from each main pump.
- Check valves in discharge line from each main pump.
- Miscellaneous valves and sluice gates for operation of the drainage system.
- As an alternative, dewatering systems may discharge above sea level or be looped above sea level (with a suitable siphon breaker). In this case discharge gate valves and check valves are not required. The system must be designed to prevent back-flooding into the dry dock with outside water levels up to the caisson overtopping level if the valves will be omitted.

7-2.4.3 Double Valve Protection.

Dry docks must be protected from sources of potential flooding through normal flooding and dewatering sources. Therefore, dewatering and drainage systems must have two valves or a valve and a stoplog. In situation where an adjacent dock shares a pumphouse or suction chamber, each dock must be isolated. Combinations of valves and sluice gates may be used.

7-2.4.4 Amenities within Pumphouse.

Depending on the occupancy category and expected duration of docking evolutions, the pumphouse may require facilities to be provided for the staff. This may include one or more toilets, lockers, kitchenettes, even offices and tool rooms. With modern remote operations, communication equipment and more efficient equipment, the trend has been to reduce the size of pumphouses and suction chambers. Therefore, less space will be necessary for staff to continually occupy these areas.

7-2.4.5 Heating and Ventilating.

Refer to UFC 3-410-01 for heating and ventilating criteria for pumping stations.

7-2.5 Pump Discharge Tunnel.

Design the pump discharge tunnel in the form of a variable section header, or header tunnel, connecting the various pump discharge lines to carry water into the discharge tunnel outer portions. The tunnel should be designed for occasional human inspection.

7-2.5.1 Auxiliaries.

Install gate valves and check valves in all pump discharge lines, except in unusual cases where discharge is above high water.

7-2.5.2 Discharge Stoplog.

Provide a stoplog or hinged stoplog in the discharge tunnel to allow inspection and maintenance of discharge valves.

7-2.6 Gratings.

Gratings must have small openings to prevent small tools and other objects from going through the pumps. During work around a docked vessel, some dock floor drainage grates may be temporarily removed. As an added precaution to prevent damage to the pumps, it may be advisable to place a grating over pump suction boots or bells.

7-2.7 Salt Water Intake Screen.

Where salt water is to be pumped for fire protection or other purposes, provide a screen at the intake to catch solids of sizes that would interfere with pump operation. If large quantities of salt water are to be handled, moving mechanical screens may be required. Refer to UFC 3-230-01 for screen design.

7-2.8 High Water Sensing Systems.

Provide two independent water level sensing systems. The primary sensing system, which must operate from station power, must be designed to activate both the pumps and the alarm. A backup or secondary sensing system must have an independent power source and operate the alarm only. Both systems must announce locally and at a central location that is continuously manned. Refer to MIL-STD-1625 for additional system performance requirements.

7-3 BASIC REQUIREMENTS OF DESIGN FACTORS.

Three basic design factors enter into the design of a pumping system: (1) desired pumping time, (2) initial cost of pumps, motors, pumpwell structure, and appurtenances,

and (3) power supply. Also consider the relatively small percent of time that pumps are in operation.

7-3.1 Pumping Time.

The average time for dewatering Navy Dry Docks of the five types may be used as a design guide. Pumping times are for empty docks. Actual dewatering time may depend on many factors. New docks or renovations shall set dewatering time requirements based upon operational, environmental and functional needs of the shipyard.

- Submarine docks, 135 minutes.
- Destroyer docks, 150 minutes.
- Cruiser and Auxiliary docks, 165 minutes.
- Carrier docks, 240 minutes.

7-3.2 Initial Cost of Installation.

For comparative studies, obtain the cost of various sizes of pumps, motors, controls, and other mechanical accessories from manufacturers. The cost of pumpwell and discharge structures increases with the sizes of pumps. This is especially true with regard to pumpwell foundations that are usually the deepest part of the entire dry dock foundation and lead to special construction problems.

7-3.3 Power Considerations.

Dewatering pumps of all naval dry docks should be driven by electric motors. These main pumping units require a considerable amount of electrical energy for brief periods of time and at infrequent intervals. If electrical current is purchased for this purpose, it involves a large demand or service charge. If current is furnished by the station, this results in a relatively heavy station demand, necessitating installation of additional power capacity for generating equipment.

7-3.3.1 Power Demands.

Keep the maximum power requirements as low as practicable, consistent with the required capacity. Keep power demands as constant as possible through the whole pumping head range. Although the initial cost of high-speed standard motors is relatively low, their operating characteristics are not suitable for driving dewatering pump units. Therefore, the design of the motor driven, direct connected pumping unit for dry docks involves an adjustment and compromise of the conditions of: varying hydraulic head, minimum range of required power, lower unit speeds, and relatively good efficiency. These conditions often necessitate a sacrifice in efficiency. High efficiency, however, is not of prime importance in equipment that is operated so small a percentage of the time.

7-4 PUMPING SYSTEMS.

7-4.1 Components.

The main dewatering system of a dry dock usually includes:

- The suction inlet located within the dock chamber
- The suction passage and/or culvert
- Pump suction chamber
- Pump suction bells
- Pumps
- Discharge check and gate valves
- Discharge culvert including backwash trash rack
- Hinged stop gate, sliding stoplog, or discharge sluice gate.

Where pumping plants may be designed to remove water from more than one dock, additional suction sluice gates are required to permit independent pumping of the docks. The pumphouse only has the operations level and the wet sump below the floor elevation. The discharge from the pumphouse should be as close to or above the tide level to reduce flood risk through the dewatering system. See Figure 7-1 for elevation view of pumphouse operations level.

7-4.2 Elevation of Discharge.

The most desirable operational pumping arrangement is a system in which the discharge invert is directly overboard above the level of the caisson weather deck, and in which no discharge check and gate valves, trash racks, or stop gates are required. Operation is simplified as there is no large power driven valves with electrical controls to be operated and maintained.

7-4.2.1 Design.

The design outlined above allows elimination of a large portion of the pump room substructure, with an accompanying reduction in pumping plant initial cost. The additional elevation required in delivering water overboard above the level of the caisson weather deck increases the total static pumping head. This increase, however, may be more than offset by reduction in friction owing to elimination of the pump check and discharge valves. The designer should consider the installation of a loop in the discharge piping to carry the water above the level of the caisson weather deck and then back down to discharge below sea level. The loop should have a siphon breaker installed at the top of the loop. The looped system may prove to be more efficient than one discharging at a higher level.

7-4.3 Pumping Head.

The pumping head of the main dewatering pumps is the sum of the maximum hydrostatic head and hydraulic system losses. See Figure 7-2. Maximum hydraulic system losses exist when maximum flow occurs, which is the time of minimum static head.

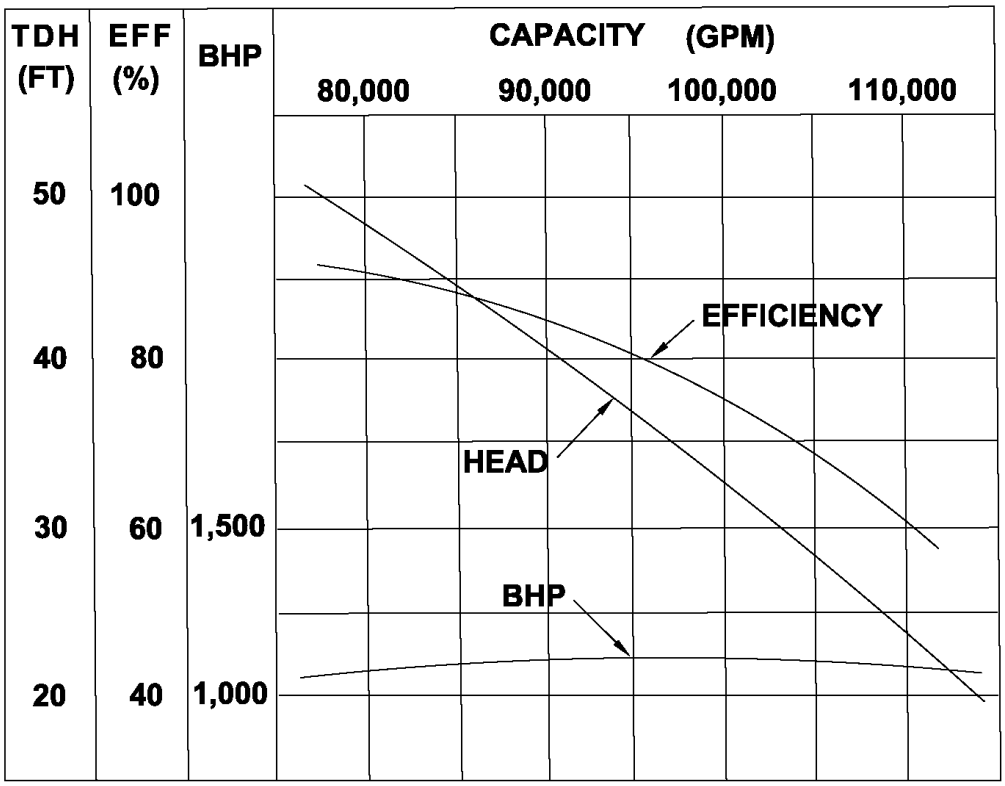
7-4.4 Pump Suction.

With reference to design and satisfactory functioning, the most critical portion of a hydraulic system is the suction portion extending from dock chamber to dewatering pump suction bell. This portion consists of the suction inlet, suction pit below the inlet, and conduits leading from the pit to individual pumps or to a pump suction chamber common to all pumps, and the pump suction bells. If the conduits are separate for each pump suction, sluice gates may be installed in each conduit to permit working on a pump without impairing the use of other pumps.

7-4.4.1 Periphery of Pit Opening.

In dewatering a dry dock, one or more of the main pumps may be shut down as the water level approaches the dock floor, in order to prevent loss of pump suction. As the water level continues to recede it generally becomes necessary to throttle the discharge of the last operating pump. This condition occurs when the pump capacity exceeds the quantity of water flow reaching the pump suction from the dock chamber through the pump suction pit and conduits. The elevation of the pumps with reference to the dock floor does not contribute to this condition. To delay the time of shutdown and throttling, design the dock floor suction inlet to have as large a perimeter as practicable.

7-4.4.2 Area of Pit Opening.



The suction pit opening (free area) should be of sufficient size to result in a flow velocity in the range of 3.5 to 4.5 ft/s (1.1 to 1.4 m/s). Base the flow on the pumping rate when the water level is 2 ft (0.6 m) above the dock floor and discharging against mean high tide. The suction condition may be greatly improved by providing openings on the opposite side of the dock chamber connected by conduits under the dock floor.

7-4.4.3 Use of Sidewall Culverts.

Where a sidewall culvert drainage system is used to facilitate removal of low-level water from the dock floor, it should drain to and terminate in the main dewatering pump suction chamber.

Figure 7-2 Characteristic Curves for 54 in. Mixed Flow Pump

TIME	TOTAL DYNAMIC HEAD (FEET)			CAPACITY (GALLONS)	NET STATIC HEAD (FEET)
	DISCH	SUCTION	NET		
12:10	116.5	92.5	24.0	109,000	0.8
12:33	113.8	87.5	26.0	105,000	5.5
1:06	109.6	76.8	32.8	100,000	13.1
1:37	106.8	72.0	34.5	95,000	20.3
2:08	104.6	64.3	40.3	90,000	26.7
2:40	102.7	58.0	44.7	85,000	33.3
3:06	101.4	53.0	48.4	80,000	38.3

7-4.4.4 Shape of Pump Suction Works.

Design the configuration of a pump suction pit and the conduit leading to the pump suction chamber, or suction bell, so that the flow will have a constant or uniformly accelerated velocity. The surface of the passages should be smooth and of such shape as not to produce eddies. There should be no sharp turns or abrupt changes in a conduit section. It may be necessary to install stream guide vanes in the suction chamber to effect good distribution and flow to the pump suction bells.

7-4.4.5 Arrangement of Suction Bells.

7-4.4.5.1 Design for Velocity.

Where several pump suction bells draw from a common chamber, the flow in the region of the bellmouth should be free from high velocities and changes in direction that tend to cause vortices.

In addition:

- The velocity of approach should be in the range of 2 to 3 ft/s (0.6 to 0.9 m/s).
- The designed bellmouth velocity should be in the range of 4 to 5 ft/s (1.2 to 1.5 m/s).
- The water depth below the bellmouth should be approximately one-half the bellmouth diameter.
- Laterally there should be no obstruction to flow within one diameter of the centerline of the bell.

7-4.4.5.2 Design for Vortex Action.

The system design should give such hydraulic characteristics as will preclude vortex action at the suction inlet and at the suction bell.

7-4.5 Pump Discharge.

The design of the pump discharge line is less critical than that of the suction line. The discharge conduit surfaces should be smooth, and sharp angles that tend to produce eddy currents must be avoided. The conduit should be such that the streams from individual pumps converge in as near a parallel direction as practicable. Changes in conduit sectional areas should be gradual and should not produce fluctuating velocities.

7-4.5.1 Allowable Velocities in Discharge Works.

At discharge of individual pumps, use 20 ft/s (6.1 m/s) maximum. In cross section of combining discharge culvert, use 14 ft/s (4.3 m/s) maximum.

7-4.5.2 Head Losses.

Head loss computations exclude losses through the pumping unit. These are included in the manufacturer rating. Total loss should not exceed 10 to 12 ft. (3.1 to 3.7 m). Suction loss should be not more than 2 to 3 percent of total loss.

7-4.5.3 Valves.

Where the discharge terminations are submerged, both gate and check valves are required. Where the discharge is above water, only a low resistance discharge flap valve is required. Gate valves should be the outside stem and yoke type suitable for throttling operation, and should be motor driven with push-button control. Check valves should be the low resistance, horizontal, nonslam, or dashpot control type. Check valves must be designed to shut automatically upon a power outage.

7-4.6 Pump Capacity.

Base the capacity of the main dewatering pumps on the desired dewatering time, volume to be removed, type of graving dock construction, and characteristics of the hydraulic system. As the water level in the dock recedes, the pump discharge volume falls off accordingly. The unit pump rating in gallons per minute should be taken as the average discharge volume. This average is based on the pump discharge when the hydrostatic suction head ranges from that of mean high water down to the head existing when the water level in the dock is 2 ft (0.6 m) above the dock floor.

7-4.7 Pump Efficiency.

Rate dewatering pumps in accordance with average overall efficiency instead of efficiency at a fixed capacity rating. Average overall efficiency is based on the range of head stated above, and is defined as the ratio of the total work done to the total power input to the motor. The total work is determined by multiplying the amount of water pumped in each interval between water level readings, by the average head in the same interval.

7-4.8 Pumps.

In the design and operation of pumping units, provision must be made for certain relationships between the suction lift and/or head, discharge head, capacity, and speed. This design factor is necessary to obtain rated capacity and efficiency, and to avoid outage and high maintenance from vibration and cavitation.

7-4.8.1 Main Dewatering Pumps.

At least two main dewatering pumps are required to meet the dewatering time requirement and to have redundancy. Limit the size to 54 in. (1.4 m).

7-4.8.1.1 Classes of Pumps.

The three general classes of pumps suitable for moving large volumes of water at relatively low heads are as follows:

- Axial flow. For static head pumping up to 25 ft (7.8 m), axial flow units (propeller) may be the most desirable.
- Mixed flow. Mixed flow units give good results on heads up to approximately 75 ft. (23.3 m).
- Centrifugal. Centrifugal pumps are more suitable for the higher heads.

7-4.8.1.2 Design Problems.

Dry dock dewatering presents unusual water pumping problems because of the extreme variations in both suction and discharge heads. See Figure 7-2 for typical operating characteristics of a 54 in. (1.4 m) mixed flow impeller pump operating under graving dock hydraulic conditions.

7-4.8.2 Drainage Pumps.

Provide drainage pumps to remove seepage, precipitation, caisson and valve leakage, and wash water, and to clear the dewatering pump suction chamber and drainage system. Because of sandblasting operations, the drainage pumps (and sump pumps discussed below) must be capable of handling a certain amount of sand and sandblasting products in suspension without excessive wear on casings of impellers. Also, ready access should be provided to pump suction chambers through manholes or other openings located so as to facilitate easy cleanout of these chambers.

7-4.8.2.1 Pump Capacity.

Estimate the total capacity required for relieved docks from an evaluation of the foundation permeability. For gravity docks, where only two units are required, the capacity of each unit should be:

- Submarine or destroyer docks: 2,500 gpm (568 m^3/h).
- Cruiser docks: 5,000 gpm (1,135 m^3/h).
- Carrier and Auxiliary docks: 7,500 gpm (1,703 m^3/h).

7-4.8.2.2 Types.

Drainage pumps should be vertical shaft, direct connected, motor driven; they may be of the wet or dry pit type:

- Wet pit pumps may be similar to main dewatering pumps of the axial discharge type.

- Dry pit pumps may be a mixed flow or centrifugal unit.
- Axial discharge pumps are the least expensive in that no suction piping and only a relatively small amount of discharge piping is required.

7-4.8.2.3 Head and Motor.

The required pumping head of drainage pumps is higher than that for the main dewatering pumps and is not so variable. Motors are generally located on the dewatering pump motor drive floor.

7-4.8.2.4 Environmental Requirements.

Local regulatory authorities may have specific requirements for drainage pumping discharges. Refer to local regulations.

7-4.8.3 Sump Pumps.

Sump pumps, vertical drive wet pit (submerged) centrifugal type, should have a capacity of 75 gpm (~280 l/min) each, and should be installed in duplicate.

7-4.9 Pump Drives.

Use vertical motors directly connected by line shafts to pump impellers. Main dewatering pumps generally are of the dry pit type. Install the motors and electrical switchgear on a floor only sufficiently below the top of the dock to allow for equipment and operating headroom. Place drainage pump motors and the drive mechanism for control of the main valves on the motor drive room floor. Drainage pump motors may be at a lower elevation to shorten the shafts, as long as they are above the possibility of being flooded due to a flooding pumpwell, or are submersible.

7-4.9.1 Speed.

Speeds of dewatering pump motors are dictated by the specific speed of the pump impellers; generally, low speed motors are required.

7-4.10 Driving Shaft.

The entire weight of revolving parts of the vertical pumping unit should be carried by a thrust bearing in the base of the motor at the top of the shaft. Specific requirements include the following:

7-4.10.1 Thrust Bearings.

Use self-aligning thrust bearings.

7-4.10.2 Guide Bearings.

Guide bearings must be of sufficient strength and adequate design to prevent vibration for lateral deflection of the vertical shaft. Use self-aligning and adjustable; the bearing surfaces may be of bronze or babbitt.

7-4.10.3 Lubrication.

Provide adequate lubrication. Generally, use water for this purpose where the bearings are submerged in the pump discharge stream. Provide clean, cold, fresh water of ample volume and pressure.

7-4.11 Elevation of Pumps.

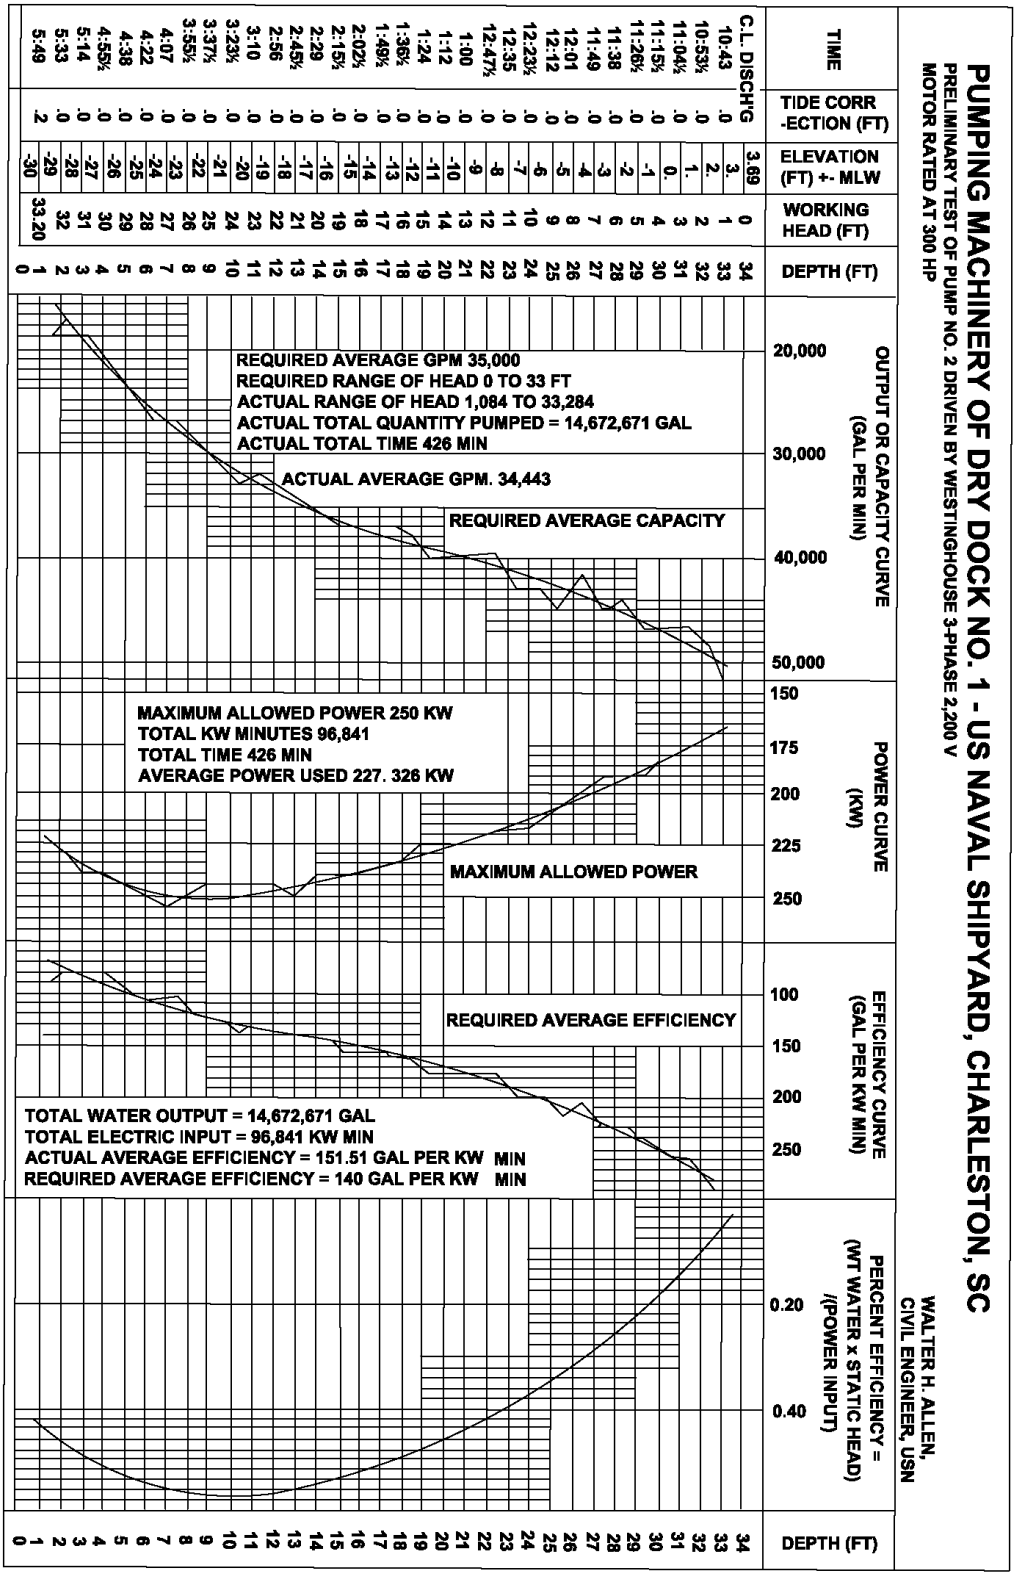
Determine pump elevation by the vertical position of the dewatering pump impeller centerline. For vertical type centrifugal or mixed flow dewatering pumps, refer to the centerline of the pump discharge. For vertical mixed flow main pumps, the pump elevations must be about 3 ft (0.9 m) below the dry dock floor.

7-4.12 Priming.

All graving dock pumps not set at an elevation at which the impeller is submerged at all times must be equipped for priming. Priming consists of flooding the pump suction piping and the pump casing surrounding the impeller by removing air by means of a vacuum pump.

7-4.13 Heating and Ventilating.

Provide heating and ventilation in the pump room, as required to prevent damage by moisture condensation and freezing, and for the comfort of the operating personnel.



7-5 FIELD TESTING OF DEWATERING SYSTEM.

In order to check the operating characteristics with design requirements, it is necessary to field test the dewatering pumps, including the hydraulic system as installed. These tests cover pump capacity, power consumption, and evaluation of efficiency. For the results of an actual field test, see Figure 7-3.

7-5.1 Determination of Capacity.

Prepare a volumetric curve on which the volume of water in the graving dock, in cubic feet, is plotted against elevations referred to the datum plane, or to some other fixed elevation such as the graving dock floor or coping. When appreciable leakage occurs, a leakage curve is prepared by recording the rate at which water in the dock rises at various elevations.

Figure 7-3 Curves from Field Tests

7-5.1.1 Curve Construction.

During pumping tests, the water elevations in the dock are usually taken at intervals of 10 minutes. To the amounts of water pumped, as determined from these observations, add the appropriate amount of leakage taken from the leakage curves. The average capacity is the total amount of water pumped, divided by the pumping time. Take water level readings in the dock with great accuracy, preferably at two or more points simultaneously, and average. Use specially constructed gauges for obtaining accurate readings, unaffected by waves. To eliminate inaccuracies in observations, plot all readings to large scale, draw a smooth curve, and make any necessary corrections.

7-5.2 Power Input.

Take readings, simultaneously with those for capacity, of the power input to motors, as determined by calibrated wattmeters placed in the circuit as near as practicable to the main switchboard panels. In computing results, make corrections for ratio, scale, and phase-angle error. Determine frequency from speeds taken on a synchronous motor feeding from the same source of supply as the pump motors. Read pump speeds with a speed counter and stop watch directly from the motor shaft.

7-5.3 Determination of Head.

Efficiency requirements may be based on total dynamic head as determined by calibrated gauges in the suction and discharge of each pump, but variable results are obtained by this method. Tests based on static heads between the levels of the water in the dock and the sea are more reliable than gauge tests, and give a more practical indication of the performance of the plant as a whole. The objection to this method is that a pump manufacturer, in order to furnish guarantees of efficiency, must estimate all friction losses in the system.

7-5.4 Tide Effect.

Generally, tests to determine capacity and efficiency are so timed that the end of the test will occur when the elevation of the tide is at approximately mean high water or mean higher high water. Although it is necessary that the pumps be capable of dewatering docks at any tide stage, the average condition of the tide for graving dock pumping is probably nearer half tide than high water. At locations where tide range is considerable, it may be more reasonable to base capacity and efficiency requirements and tests on half tide conditions.

CHAPTER 8 FITTINGS, BLOCKING, SHIP SERVICES

8-1 FITTINGS.

Major fittings, and fittings peculiar to graving docks, are covered in this section; other fittings are merely mentioned. All fittings must be made of corrosion resistant materials and installed in a way that will minimize maintenance. Ferrous metal fittings must be zinc coated; small fittings may be cadmium plated.

8-1.1 Capstans.

Capstans are used at graving docks for pulling vessels into the dock chamber, and entrance caissons into seat or stowed position.

8-1.1.1 Location.

Locate one capstan on the centerline of the dock at the head end; one at each side of the caisson seats at the entrance end; and others on the sides of the graving dock, spaced not more than 300 ft (93 m) apart. Set capstans shoreward of the outermost crane rail of the track nearest to the centerline of the dock.

8-1.1.2 Requirements.

Typical capstan designs use the reversing gypsy-head type consisting of a barrel mounted on a vertical shaft and driven by an electric motor through reduction gearing. For electric control typically 460 volts nominal, three-phase 60 Hertz current, a magnetic reversing controller, including transformer and relay cabinet, push-button station having flexible cord, with a variable frequency drive (VFD) to provide infinite speed control with accurate current and thermal overload control. Arrange the completed equipment to operate with a minimum of noise and vibration.

Horizontal drum, winch type capstans are also acceptable. It is important to solicit and receive input from the shipyard rigging shop when deciding on capstan requirements.

Arrange all parts subject to wear so that they may be accessible for inspection, lubrication, and cleaning. Secure all fastenings that are likely to become loosened by vibration by locknuts or other suitable devices. Use material commonly used for the service required and marine environment. The entire capstan unit should be designed and furnished by the same fabricator. Templates should be furnished for setting anchor rods.

8-1.1.3 Capacity and Speed.

Capstans must be capable of pulling up to 30,000 lbs (13,500 kg) at a line speed of 30 fpm (0.15 m/s) and up to 15,000 lbs (6,750 kg) at 60 fpm (0.30 m/s) with slack speed of 90 fpm (0.46 m/s). Design capstans to also be used as bollards with a line pull of 100,000 lbs (45,000 kg) applied at the center of the barrel and directed upward at an

angle of 30 degrees with the horizontal. Any required variations in the above indicated line pulls and speeds will be specified in project requirements.

8-1.1.4 Capstan Pits.

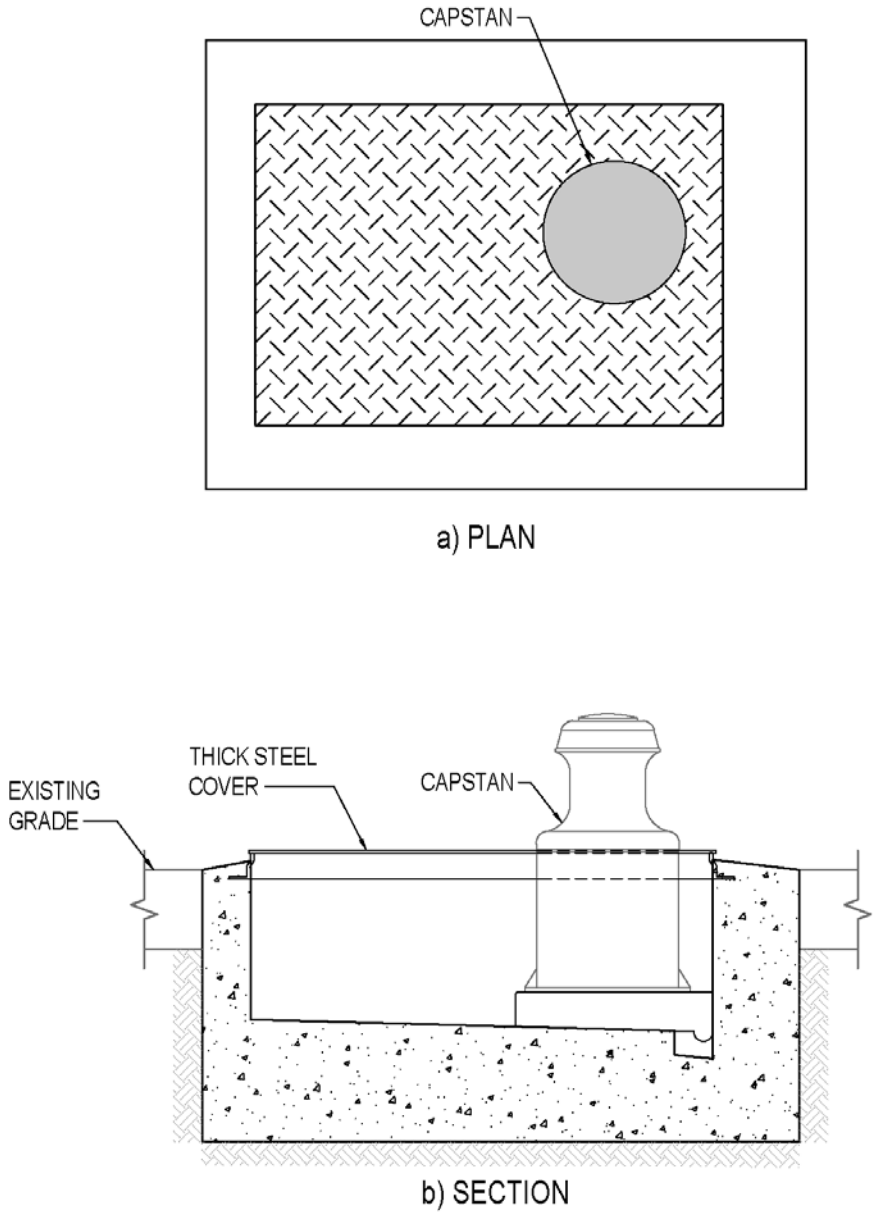
Typically, capstan driving mechanisms and foundations are located below coping elevation in pits generally consisting of concrete chambers founded on heavily reinforced concrete slabs firmly anchored and supported by batter and vertical piles. To avoid interference with lines, expose only the capstan barrel and the watertight cover of the capstan pit. See Figure 8-1.

- Secure machinery with anchor bolts embedded in chamber foundations. Provide watertight manholes for limited ready access to machinery, and an overall pit cover made in sections to permit removal of machinery.
- Provide capstan pits with drainage systems large enough to drain off normal precipitation as well as possible heavy leakage.
- Capstan pits, subject to humidity that might interfere with electric motor operation, may require portable blowers to dry out the pit before operation. For drawing of capstan and pit for dry dock application, refer to American Civil Engineering Practice, Volume II.

When replacing or renovating capstans consider removable or portable capstan units. These units would consist of a palletized self-contained capstan or winch, motor, controller. The capstan unit would be brought in via crane lift or fork truck only for the evolution, then removed and stored off site during the ship availability. In this design the capstan unit would not have a pit but a pad at the coping elevation and secured to permanently installed anchors in the coping concrete similar in design to aircraft runup pads.

8-1.1.5 Controls.

Install electric power capstan controls in machinery pits. Provide topside controls and locate them so that they allow the operator an unobstructed view, clear of lines and working parties. Topside controls should be portable so they may be stowed when not in use. Install controls in watertight enclosures.



8-1.2 Bollards.

Bollards are iron or steel castings, upright (concrete filled) secured to foundations by steel bolts. Refer to UFC 4-152-01 and UFC 4-159-03 for description of bollards.

8-1.2.1 Location.

Set bollards in line with the capstans at approximately 50 ft (15.5 m) on centers between capstans.

Figure 8-1 Capstan Pits

8-1.2.2 Pull.

At a minimum, provide large bollard with horn per Table 6-11 of UFC 4-159-03 (nominal load 35 ST (31.8 t)).

8-1.2.3 Shape.

Bollards must include at least one horn and be shaped so that lines will not slip, jam, or ride off the top.

8-1.2.4 Foundations.

A bollard foundation may be a concrete substructure adequately supported by piles arranged to resist large overturning moments. Construction economy may be affected by tying bollard foundations to outer crane rail or dry dock foundations. Refer to UFC 4-159-03 for description of bollards.

8-1.3 Cleats.

Install 20 ST (18.1 t) cleats spaced at about 60 ft (18.6 m) centers on the coping for securing mooring lines. Refer to UFC 4-152-01 and UFC 4-159-03 for description of cleats. Consider aligning cleats on both sides of the dock at the coping level.

8-1.4 Stairways.

Stairways in the dry dock may be cast as part of the wall concrete or may be constructed of structural steel with open mesh treads bolted to the walls. Stairways can be damaged by falling objects, fouled lines, and swinging crane loads. Semi-permanent prefabricated stairways bolted to walls facilitate repair and allow for relocation. Stairs must comply with NFPA 101, dimensional criteria for new stairs.

The number and location of stairways must meet the following parameters:

- One stairway from coping to dry dock floor on each side of the dock at the head end.
- One stairway from coping to dry dock floor on each side of the dock at the caisson end.
- Spacing between stairways along each side of the dock must not exceed 300 ft (91 m).
- Pumpwells must have at least two stairway exits from pump room floor.

Alternatively, a life safety analysis or evacuation plan developed by a qualified fire protection engineer in consultation with the DFPE, both as defined in UFC 3-600-01, *Fire Protection Engineering for Facilities*, may be performed to optimize the number and location of pumpwell and dry dock floor stairways. The analysis must account for the actual work performed in pumpwell and on the dry dock floor with a ship in dock, and

the number of individuals accessing the dock during typical shifts. Obstructions such as docking blocks, fork trucks, scaffolding, CONEX boxes and other equipment will impact evacuation. The pumpwell analysis must account for the mechanical equipment in the pumpwell that would impede movement. The life safety analysis must include those impacts when evaluating evacuation routes. In all cases, at least two stairways from the coping to the dock floor must be provided, with one located at the caisson end and one at the head end.

8-1.5 Ladders.

Provide ladders only where the available space is insufficient for stairways, or where traffic is too light to warrant stairway construction. Place ladders in pumpwells as leads to access hatches and large manholes. Refer to 29 CFR 1910.23 for ladder requirements. Also consult local safety regulations as to the maximum allowed ladder length without fall protection.

8-1.5.1 Steel Shapes.

Fabricate ladders of steel shapes. Plug weld rungs into rails. Install ladders so that the distance from the center of the rungs to the finished wall surface will not be less than 7 in. (178 mm). Secure ladders to the adjacent construction with heavy clip angles, welded to the rails and secured to masonry, concrete, or stud framing with not less than two 3/4 in. (19 mm) diameter bolts. Intermediate clip angles must be provided not over 5 ft (1.6 m) on centers. Provide brackets as required for securing of ladders welded or bolted to structural steel and built into the masonry or concrete. In no case should ends of ladders rest upon finished roof or floor. Ladders and supports must be galvanized after fabrication unless a corrosion resistant material is used. Bar steel rungs are installed 12 in. (305 mm) apart, vertically below manholes, and at other locations where frequent access is not generally necessary.

8-1.5.2 Stainless Steel.

Low carbon stainless steel (UNS S31600/ S31603) rungs and ladders should be considered for alternating wet-dry, high corrosion areas.

8-1.6 Safety Railing.

Provide railing (guard rail system) around fixed installations (such as machinery), around open shafts, along dock walls at altars or setbacks, and along the top edge of retaining walls in accordance with 29 CFR 1910.29. Removable solid railing sections may be installed where access is required around permanent openings and installations. Incorporate fall protection requirements where removable railings are installed. Install fall protection tie off points in areas that require inspection when railings are removed (fall protection may not be required during docking/ undocking).

8-1.6.1 On Coping.

Provide a removable railing with toeboards unless the coping wall serves as a fall protection barrier. Chain railing was used in the past but maintaining adequate chain tension was a common problem. Solid metal pipe or fiberglass railing, provided in 8 to 12 ft (2.5 to 3.7 m) sections for ease of removal/reinstallation, is preferred. Solid railing sections should fit securely into sleeves fastened to the coping and are open on the bottom to prevent debris accumulation.

8-1.6.2 On Stairways.

Provide rigid pipe rails of two parallel pipes approximately 2 in. (51 mm) diameter and running between fixed pipe stanchions on all stairways. These may be a removable type, if necessary. The top rail is not less than 36 in. (914 mm) and not more than 38 in. (965 mm) as measured from the leading edge of the stair tread to the top surface of the rail, the midrail is midway between the leading edge of the stair tread, and the top rail.

8-1.7 Marking Plates.

Provide plates in dock structures marked with their exact stationing in the dock to facilitate setting of keel and side blocking.

8-1.7.1 Composition and Marking.

Marking plates should be bronze or stainless steel metal plates approximately 8 in. (203 mm) long by 4 in. (102 mm) wide set flush with end anchored into the embedding concrete. Each plate must be marked appropriately with centerlines, and with respective distances to the graving dock centerline and abutment. Figures should be 2 in. (51 mm) high and permanent.

8-1.7.2 Location.

Marking plates must be laid out accurately. Set marking plates at the following points:

- One on each coping at the dry dock entrance.
- In both copings at approximately 50 ft (15.5 m) intervals from the dry dock entrance toward head end.
- One near the coping edge on the graving dock centerline, at the head end.
- One several feet back from the coping edge on the dock centerline, at the head end.
- One in the dock floor, several feet to one side of the dock centerline, sufficient to clear keel blocks, and at approximately 50 ft (15.5 m) intervals from the dry dock entrance coordinated with b) above.

8-1.8 Fenders and Chafing Strips.

To protect masonry structures at a dock entrance, or a caisson berth, provide fenders and/or chafing strips as required. Use fenders as necessary to protect equipment (such as stairways, ladders, floodlights, and service outlets) from being fouled by a vessel entering or leaving a dock. Generally, treated timbers anchored by bolts are used as chafing strips, but suitable, rotatable, pneumatic and rubber fenders may also be used. Refer to UFC 4-152-01 for design of fenders, and UFGS 35 59 13.14 20 for polymeric piles.

8-2 SHIP BLOCKING.

Responsibilities for design and material specification of ship blocking rests with the Naval Sea Systems Command (NAVSEA). The information herein is basic guidance; Consult NAVSEA for criteria beyond the planning stage.

8-2.1 Ship Supports.

Provide means to keep a docked vessel far enough above the floor to permit work on its keel, giving allowance for removal or installation of sonar domes, rudders, propellers, and similar parts. Blocking arrangements are laid out in the dock in accordance with the docking plan for each individual vessel.

8-2.2 Dog and Side Shores.

Long overhangs of vessels are frequently supported by shores. Shores are wedged against the ship bottom and/or its sides, either against dock wall altars or against the dock floor.

8-2.3 Keel Blocks.

Keel blocks are placed under the longitudinal centerline keel of the vessel. The exact location of the blocks depends on a vessel's docking plan. All keel block are interchangeable; therefore, each is designed for the maximum ship load likely to be imposed upon it at any location. Compression is the primary stress, but provision must be made to resist uplift, overturning, and horizontal movements induced by eccentric loads, earthquakes, or accidental impacts. Reinforced concrete stresses are not critical in design; grade of concrete and amount of reinforcement steel are selected to resist rough handling and temperature variations. Standard composite keel blocks (see Figure 8-2) were historically rated at 25 LT/sf (274 t/m^2), based on an allowable stress for wet timber in compression perpendicular to the grain taken at 250 psi (1.7 MPa) for soft caps. This allowed a reasonable safety factor. For the standard 6 ft (1.9 m) center-to-center keel block spacing, that rating represented a 37.5 LT/ft (125 t/m) ship load. Now, the safe allowable timber compressive stress for distributed loading, taken as the fiber stress at the proportional limit of Douglas Fir, is 370 psi (2.6 MPa). This assumes a uniform pressure over the entire 42 by 48 in. (1,067 by 1,219 mm) top of a docking block, resulting in a total load of about 330 LT (335.2 t). Most ships have narrower skegs and the allowable block loading is decreased accordingly. For allowable block

loadings for this condition, refer to NSTM Chapter 997, Docking Instructions and Routine Work in dry dock.

8-2.4 Bilge or Side Blocks.

Bilge or side blocks are composite or timber, built up, shaped, and located according to dimensions indicated in the table of offsets of docking plan of the vessel. These are designed for 250 psi (1.72 MPa) load applied uniformly over the effective bearing area in contact with the hull of the ship. Batten each block adequately for stability, and the resultant load reaction should fall within the middle one-third of the base dimension of the block on the dock floor.

8-2.5 Type of Construction.

Build composite blocks with wood top and bottom layers, and concrete sandwiched in between. Use sufficient concrete to make the blocks non-buoyant. Secure the wood layers to the concrete with steel bolts embedded in the concrete. U-bolts embedded in the sides of the concrete may be provided for lifting, or pipe holes may be provided through the blocks to insert pipes for lifting by forklift or crane rigging. All hardware (except dogs) should be zinc coated or cadmium plated. For a typical block, see Figure 8-2. For heavy loads, these blocks may be used double as indicated in Figure 8-2.

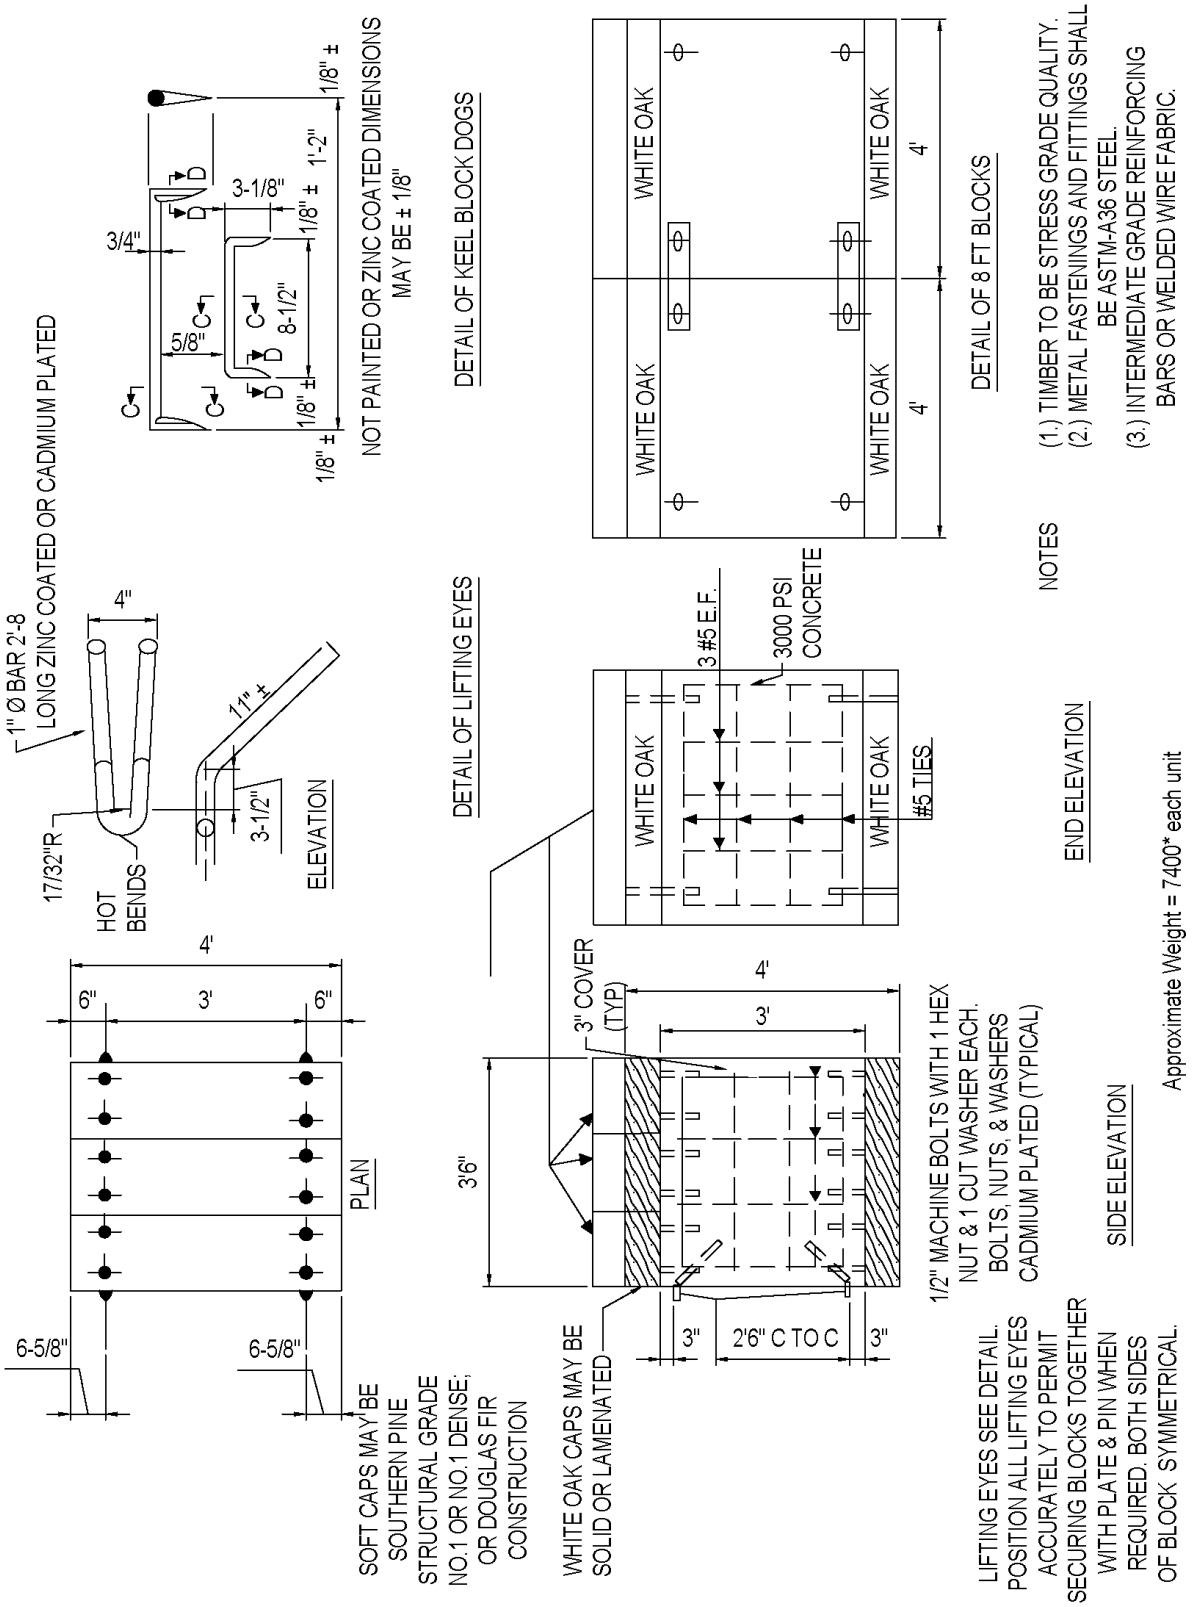
8-3 SUPPORTING FACILITIES.

8-3.1 Industrial Shop Facilities.

Shipbuilding graving docks and graving docks used for extensive repair, alteration, and the rebuilding of vessels must be supported by industrial shop facilities capable of manufacturing or otherwise supplying, installing, and testing the large number of items required.

8-3.2 Transportation Facilities.

A graving dock must be serviced by the following transportation facilities.



8-3.2.1 Paved Road Network.

This network provides access to the entire dock area and should be capable of carrying trailer trucks, flatbed trucks, mobile track cranes, truck cranes, and other heavy traffic.

8-3.2.2 Parking Facilities.

Provide parking as space permits clear of the graving dock operating areas.

Figure 8-2 Ship Blocks

8-3.2.3 Standard Gauge Railroad Track.

Where material for the graving dock operations are delivered to the yard by rail, a standard gauge track may be provided on either side of the dock. At the dock, locate this track between the portal crane rails nearest to the dock. This standard gauge track may also be used for the operation of locomotive cranes. At some yards, materials may be handled by heavy truck cranes instead of locomotive cranes, and railroad tracks may not be required. Use UFC 4-152-01 for track support design.

8-3.2.4 Portal Crane Track.

8-3.2.4.1 Location.

To minimize the required reach of dry dock cranes over a graving dock, locate crane rails as close to the edge of the coping as possible, but not nearer than about 5 ft (1.6 m). Because they must withstand high weight concentrations and shock loads, crane rails, unless supported directly on the dock walls, are usually supported by concrete beams on closely spaced piles, or by continuous spread footings generally tied in at intervals with the graving dock sidewalls. There are some locations where trackage may be supported by ties and ballast. Portal cranes may be designed to operate on either a two-rail track or a four-rail track. Space tracks far enough apart to allow passage of railroad and truck traffic between outer rails of pairs of rails.

8-3.2.4.2 Interchangeability.

To obtain maximum operational efficiency and economy, portal cranes should be interchangeable among the various yard facilities they might serve. As far as possible, incorporate the following features into a yard crane track layout:

- All portal crane tracks should have the same gauge as other yard crane tracks.
- When track consists of two pairs of rails, lay each pair at standard railroad gauge.
- Interconnect the various crane tracks.
- Provide spur track turnouts for repairing cranes.
- Provide a sufficient number of switches and passing tracks to permit individual cranes and other rolling stock to travel without interrupting the operation of other cranes.
- Refer to NAVFAC 11230.1 for track inspection, certification, and alignment procedure.

8-3.3 Weight and Materials Handling Equipment.

Small capacity locomotive or motor truck cranes are assigned to graving dock activities to supplement portal cranes. The locomotive cranes operate on the standard gauge railroad track.

8-3.3.1 Portal Cranes.

These cranes are constructed on portal frame bases that travel on wide gauge (20 to 30 ft (6.2 to 9.3 m)) tracks. Capacities and reach should be as specified for each individual project.

8-3.3.1.1 Clearances.

Clearances must be such as to permit complete rotation (360 degrees) without interference with the ship in dry dock, buildings, or other structures. Cranes and track layout must be carefully studied to ensure adequate clearances in the way of overhanging deck structures of aircraft carriers. For carrier docks, provide two sets of tracks on each side of the dock, one of conventional arrangement with rail near the edge of the coping, and one outboard at a distance sufficient for the crane to clear the flight deck of the carrier.

8-3.3.1.2 Power Drive.

Portal cranes may be powered by self-contained diesel electric drive or all electric.

8-3.4 Personnel Facilities.

Provide facilities such as lavatories, showers, and lunchrooms near the graving dock.

8-3.4.1 Lavatories.

Provide lavatories fairly close to the graving dock. They should contain toilets, urinals, washbowls, showers, first aid equipment, and perhaps equipment lockers. They should be large enough to accommodate the normal complement of the yard crew working in or around the graving dock, and the crew of any docked vessels. When the sanitary facilities of a docked vessel are being worked on, they are very often unavailable for use; therefore, separate dockside facilities are often reserved for use by the vessels officers and crewmembers on duty.

8-3.4.2 Lunchrooms.

Provide an appropriate type lunchroom near the graving dock.

8-3.4.3 Quarters for Ship’s Crew.

When extensive repairs or alterations are performed on a vessel in active service, work is often carried on around the clock. The accompanying noise and construction activities

may prohibit habitation on the vessel. Under these conditions, provide quarters ashore, or berthing barges for the use of the officers and crew of the ship.

8-3.5 Storage Facilities.

Provide storage space to house the infrequently used dock gear, such as hawsers, cables, rafts, floats, fenders, portable communication equipment, and portable floodlights.

8-4 MECHANICAL SERVICES.

Ships in graving docks are unable to fill their own requirements for mechanical services essential for work, habitation, comfort, and protection. These services, and those required for repairs and cleaning associated with the docking operations, must be supplied from dockside facilities. Such services include steam, compressed air, water, Wheeler system, oxygen, acetylene, and sewage disposal. Utility requirements for specific ship classes is provided in UFC 4-150-02.

8-4.1 Pipe Galleries and Tunnels.

Carry service pipes, in tunnels, utilidors, or in galleries at the top of the dock sides. The open type gallery is desirable and should be used unless prohibited by some compelling reason or when steel is attached to the wall.

8-4.1.1 Design.

Design the gallery to be approximately 7 ft (2.2 m) high, and recessed 4 ft (1.2 m) or more into the dock wall. Provide a wall on the dock side approximately (2-1/2 ft (0.8 m) high, topped by a low railing for safety of personnel in the gallery (3-1/2 ft (1.1m) fall protection barriers).

8-4.1.2 Service Line Location.

Mount service lines on the walls and ceiling of this galleries and pipe tunnels.

8-4.1.3 Advantages.

Open type galleries have the following desirable features:

- Safer to work in than on an altar
- Better lighting
- Ample working space
- Ample room for addition of services
- Accessibility to all outlets along the dock.

8-4.1.4 Outlets.

Locate service outlets in accordance with criteria in UFC 4-150-02.

8-4.1.5 Looped Pipelines.

Sectionalize and valve all liquid, steam, and gas lines to provide service with a minimum of interruption of work should a break occur along any line.

8-4.2 Fresh Water.

For industrial use, and with an abundant supply, it may be used to fill fire protection, flushing and cooling requirements. In cold climates, waterlines must be protected from freezing. Provide meters to record water consumption. All fresh water outlets must have a backflow preventive device, and be painted as specified in UFC 4-150-02, for services on piers.

8-4.2.1 Potable Water.

Provide one 2-1/2 in. (63.5 mm) valved outlet at each service gallery, and size the mains to adequately provide the required quantity of distilled or potable water at a residual pressure of 40 to 80 psi (276 to 551 kPa) at any outlet. The quantity of water required by dry docks is contained in UFC 4-150-02.

8-4.2.2 Flushing and Cooling.

Flushing/cooling systems are to be part of the fire protection systems where high pressure fire protection systems are provided, including the following:

- If a graving dock is provided with fire hydrants only outside the dock, as fire protection, install the flushing/cooling systems separately.
- Provide one 2-1/2 in. (63.5 mm) valved outlet in each service gallery.
- Supply the quantity of water required for flushing and cooling to the most remote flushing/cooling outlets at not less than 40 psi (276 kPa) residual pressure. Connect systems either to station pumps or to separate graving dock pumps having a minimum discharge pressure of 150 psi (1034 kPa). The required quantities for combined flushing, cooling and fire protection are contained in contained in UFC 4-150-02.

8-4.3 Salt or Non-potable Water Supply.

When fresh water is not abundant, use salt or non-potable water system for flushing, cooling and fire protection.

Provide salt or non-potable water service to the dry dock to meet cooling, flushing, auxiliary seawater and fire protection requirements. Flow rates and pressures are

governed by other documents. Refer to UFC 4-150-02, MIL-STD-1625 and NAVSEA 8010.

8-4.3.1 Station System Connection.

Where a graving dock fire protection system is connected to station fire protection and flushing/cooling systems, make connection through a valved check valve and a valved pressure reducing valve in a bypass permitting the station system to supply flushing/cooling water to the dock system. This arrangement also permits the graving dock fire protection pumps to augment the station system in emergencies.

8-4.3.1.1 Alternative Arrangement.

If this arrangement is not possible, install flushing/cooling pumps with minimum discharge pressures of 150 psi (1034 kPa) at most remote outlet. Arrange graving dock fire pumps in parallel operation for flushing and cooling, and arrange series operation for standby fire protection.

8-4.3.1.2 Fire Pumps.

Redundancy must be provided such that the required flow rate and pressure can still be provided after the loss of any single fire pump and/or the loss of the normal system power supply. Standby diesel fire pumps are normally provided to meet this requirement. Fire pump installations must conform to the provisions of NFPA 20, *Standard for the Installation of Stationary Pumps for Fire Protection*.

8-4.3.2 Type of Piping.

All piping for graving dock fire protection systems must be cement lined AWWA ductile iron pipe, class to suit required fire pressures, with lugged and rodded joints and fittings (except the pipes in pumpwells and service galleries should be flanged). Any joint of equal strength may be used, subject to the approval of the cognizant Service.

8-4.3.3 Pipe Sizes.

Where station systems are connected to dry dock systems, pipe sizes from station pumphouse to docks should be generous enough to provide pressures for dry dock flushing and cooling requirements.

8-4.4 Wastewater Collection.

Segregation of sanitary sewage, industrial wastewater and hydrostatic leakage water is required. Dry dock and ship sewage will be collected and discharged into the station sewerage system. Hydrostatic leakage not mixed with industrial waste is not polluted, therefore can be pumped into receiving waters, except at locations where local environmental regulations forbid it. Refer to local regulations.

8-4.4.1 Sanitary Sewer System.

All sewage and hotel wastes from ships in dry dock must be collected and transported to a treatment plant. Preferably, locate a sewer main on each side of the dock. Discharge of all sewage to a main on only one side of the graving dock should be considered if local circumstances dictate. Provide receiving manifolds located along the coping of the graving dock and connect to the main sewer through laterals. Transport sewage from the ship to the manifold receiving connection by way of a hose. Design the sewer system to meet peak flow rates from the largest ship class for which the dry dock is designed. These are contained in UFC 4-150-02. For additional design criteria refer to UFC 3-240-01, *Wastewater Collection and Treatment*.

8-4.4.1.1 Receiving Hose Connections.

Space the receiving hose connections approximately 300 ft (93 m) centers. The spacing may be varied to suit docking conditions in a specific dry dock. Locate the hose connections between the edge (coping) of the graving dock and the crane track to eliminate any interference with the operation of the cranes. Make each connection 4 in. (102 mm) diameter and install an in-line check valve to prevent backflow.

8-4.4.1.2 Laterals.

Laterals between the receiving hose connections and the main sewer must have a diameter of 4 in. (102 mm). Where possible, the laterals should be located in the dry dock service and pipe galleries to minimize installation costs and to facilitate maintenance. Pitch laterals to drain to the main sewer. Consider local conditions for the optimum location of the laterals.

8-4.4.1.3 Main Sewers.

Size main sewers to receive ship discharges plus any other flow entering into the collection system. Main sewers should be located in the pipe galleries or beyond the structural concrete of the graving dock. Consider local conditions for the optimum location of the main sewers. Main sewers should be gravity sewers and slope toward the inboard end of the dock and connect to the station sewer system or to a pump lift station. Use a force main where it is impracticable to install a gravity sewer. Locate sewer cleanouts in the main sewers at a maximum spacing of 300 ft (93 m).

8-4.4.1.4 Ship-to-Dock Transfer System.

Ships outfitted with CHT systems discharge sewage under pressure on the lowest weather deck. Ships not outfitted with CHT systems will discharge through existing outlets in the hull. For ships not outfitted with CHT systems, a temporary system for collecting sewage from multiple outlets must be installed.

- Auxiliary Pumping: Gravity dry dock sewer systems may require auxiliary pumping when the ship’s discharge point is below the level of the top of dry dock wall. The facilities required for auxiliary pumping include hose,

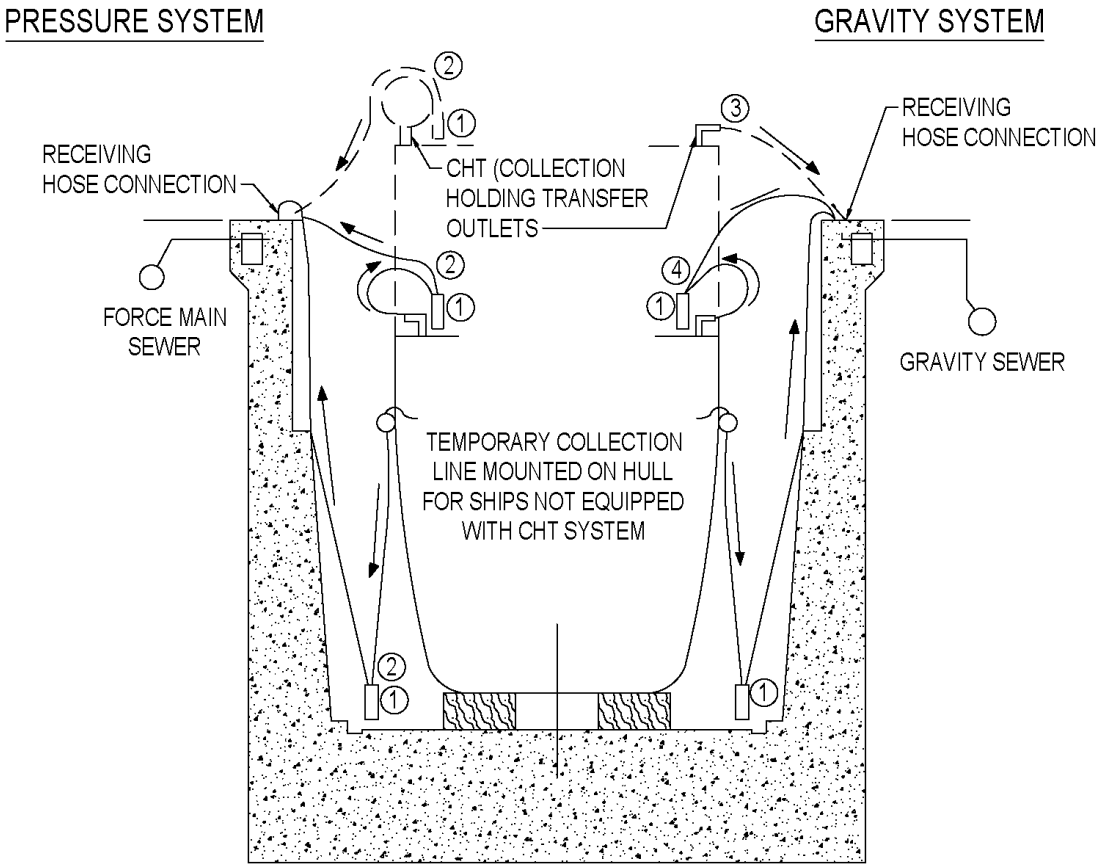
portable wet well, and pump. Use a 4 in. (102 mm) sewage hose to transfer sewage from the ship or portable pumping unit to the dry dock sewer system. Refer to Figure 8-3.

- Collection System and Components: The temporary collection system for ships not outfitted with CHT system, and the auxiliary pumping system components, are collateral equipment to be furnished by the shipyard.

8-4.4.2 Industrial Wastewater Collection.

Collect and treat industrial wastewater, including runoff and hydrostatic leakage that come in contact with industrial waste, such as sand blasting grit and organotin paint chips, as necessary, prior to discharge. Refer to UFC 3-240-01.

8-4.5 Steam.



Steam may be required in a graving dock for heating, cleaning equipment and tanks, and ship use. In northern latitudes, provision must be made for heating those areas in which personnel must remain for lengthy periods, such as pump rooms, motor rooms, caissons, toilets, and shower rooms. Use steam for deicing and for keeping necessarily exposed fresh waterlines from freezing. Freezing may sometimes be prevented by running a parallel steam line.

8-4.5.1 Quantity.

Exact quantities of steam to be furnished to the ship are difficult to determine. Changes in ship designs, variations in ships of the same class, and differences in repair operations make close estimation of steam demand loads purely academic. On the other hand, providing sufficient steam to take care of the total maximum demand load that could occur under the worst conditions would result in a grossly over-designed and expensive system. UFC 4-150-02 gives the design steam demand for various ships.

Use engineering judgment to determine actual working values depending on the concurrency or nonconcurrency of other steam loads for the dry dock complex, frequency of docking of maximum ship, and effect of multiple docking. High-pressure steam for test operations is usually provided from portable generators. Consider planning for temporary portable steam generators that would utilize shipyard local power and potable water as supply.

Figure 8-3 Schematic of Conditions for Portable Sewage Pumping Systems in Graving Docks

① INDICATES PORTABLE WET WITH SUBMERSIBLE PUMP

② PUMPING MAY BE REQUIRED FOR ENTRY INTO PRESSURIZED SYSTEM

③ NO PUMPING REQUIRED WHEN CHT DISCHARGE IS ABOVE RECEIVING CONNECTION

④ PUMPING MAY BE REQUIRED WHEN CHT DISCHARGE IS BELOW CONNECTION

NOTE: THE TEMPORARY COLLECTION SYSTEM, HOSE, PUMP AND WET WELL ARE COLLATERAL EQUIPMENT TO BE FURNISHED BY THE SHIPYARD

8-4.5.2 Steam Mains.

If steam service is required, provide graving docks with steam mains on at least one side of the dock. Size the pipe supplying the mains to provide a carrying capacity equivalent to that of the two dock mains. For example, a 6 in. (152.4 mm) mains. Base the determination of equal carrying capacities on a table of equalization of pipes. Refer to UFC 3-430-09. The number and location of steam branch outlets vary from three to six per side, depending on the size of dry dock. Provide a suitable flanged valve provided with a blind flange for each branch outlet. Size mains and branch outlets for steam service, unless specifically directed otherwise, in accordance with the following:

8-4.5.2.1 Submarine and Destroyer Docks.

For both single and double width docks, use 4 in. (102 mm) main and 2-1/2 in. (63.5 mm) outlets.

8-4.5.2.2 Cruiser, Auxiliary, and Carrier Docks.

Size mains according to quantity of steam carried and the permissible pressure drop. Outlets should be 2-1/2 in. (63.5 mm). Provide carrier docks with an additional 4 in. (102 mm) outlet, located at the center group of service outlets on each side of the dock, for feeding ships with 4 in. (102 mm) steam shore connections.

8-4.5.2.3 Piping.

Steam piping must be in accordance with the provisions of UFC 3-430-09 concerning steam distribution systems. Condensate return piping usually is not required, but should be provided when recovery of the condensate is economically desirable or when dictated by special project requirements.

8-4.5.3 Insulation.

Steam lines must be thoroughly insulated from source to outlets.

8-4.6 Compressed Air.

Compressed air is required in a graving dock for tools and sandblasting.

8-4.6.1 Quantity.

Determination of required quantities is dependent on the operations to be performed and ranges from 3,500 to 8,000 ft^3/min (1.7 to 3.8 m^3/s) for small and large docks, respectively.

8-4.6.2 Mains.

All classes of graving docks should have mains on both sides of dock.

8-4.6.3 Outlets.

Base number and location of outlets on service air requirements for hull maintenance. Provide a suitable flanged valve provided with a blind flange for each branch outlet. Do not use plug valves

8-4.6.4 Size of Main and Outlets.

Size of mains and outlets as shown in Table 8-1 must be as follows:

Table 8-1 Size of Main and Outlet

Dock	Main inch (mm)	Outlet inch (mm)
Submarine and Destroyer	4 (102)	2.5 (63.5)
Cruiser	6 (152)	2.5 (63.5)
Auxiliary	6 (152)	2.5 (63.5)
Carrier	6 (152)	3 (76.2)

8-4.6.5 Piping and Fittings.

Piping and fittings must conform to the requirements of UFC 3-430-09.

8-4.6.6 Air Pressure.

Air pressure at branch outlets should be 100 psi (689 kPa) unless otherwise specified in project criteria. High-pressure air for testing 3,000 to 4,500 psi (2067 to 3101 kPa) should be described in project requirements and may be portable equipment.

8-4.7 Oxygen and Acetylene.

Oxygen and acetylene are required for cutting metals, brazing, heating, and welding operations. Graving docks are, for the most part, not equipped with a central oxygen and acetylene distribution system, and consequently are supplied from individual portable tanks (bottles or cylinders). The provision of a central distribution system should be considered in a new dock construction and in existing docks where large quantities of these gases are required. If distribution systems are planned, use the criteria below.

8-4.7.1 Location of Piping.

Never run mains for these gases in a pipe tunnel or an enclosed or partly enclosed service gallery, because of the extreme hazard involved. Locate both mains and outlets above extreme high water to prevent contact with oil floating on the water surface during flooding of the dock. Mains are best located in a special open slot formed as an integral

part of the coping curb, or placed on the wall of the dock below the coping elevation, and protected from damage by a heavy fender member.

Place service outlets under open protective hoods above the coping level or on the inner faces of the coping line. Temporary connections to the dock floor may be made after each dewatering if distribution to the floor level is required.

8-4.7.2 Oxygen.

For oxygen piping, use standard weight, black steel, seamless tubing with beveled ends for welding. Pipe should be factory washed.

8-4.7.2.1 Sizes.

Provide these ranges of sizes, unless required otherwise:

- main from supply to side of dock, 2 to 3 in. (50.8 to 76.2 mm)
- distribution piping around the dock, 1-3/4 to 2-1/2 in. (44.5 to 63.5 mm)
- extensions to outlets 3/4 to 1 in. (19.1 to 25.4 mm).

It is standard practice to reduce the pipe size serving the more remote outlets in accordance with the reduction in volume of gas to be delivered.

8-4.7.2.2 Valves.

Use globe type shutoff valves, 400 psi (2,756 kPa), cold, non-shock gas working pressure. Prefabricate valve assemblies in the shop to minimize the possibility of leakage after fabrication.

8-4.7.2.3 Joints.

Use tinned threaded joints, made up with litharge and glycerin.

8-4.7.2.4 Testing.

Before outlets are attached, subject each section of line to a pressure air test at least 1.5 times the working pressure.

8-4.7.2.5 Identification.

Paint oxygen piping green and mark outlet valves “FOR OXYGEN.”

8-4.7.3 Acetylene.

For acetylene piping, use standard weight, black steel with beveled ends for welding.

8-4.7.3.1 Sizes.

Generally, provide these ranges of sizes:

- main from supply to side of deck, 1-1/2 to 2-1/2 in. (38 to 63.5 mm)
- distribution piping around the dock, 1 to 2 in. (25.4 to 51 mm)
- extensions to outlets, 3/4 to 1 in. (19 to 25.4 mm).

8-4.7.3.2 Valves.

Use forged or cast steel of the lubricated plug type cutoff valves.

8-4.7.3.3 Testing.

After fabrication, but before attaching outlet equipment, pressure test each section of line to at least 1.5 times the working pressure.

8-4.7.3.4 Identification.

Paint acetylene piping yellow and mark the outlet valves “FOR ACETYLENE.”

8-4.7.4 Supply.

If not supplied in portable tanks, the required supply of oxygen and acetylene may come from an existing yard system or be produced by stationary generators.

8-4.7.4.1 Alternate System.

If an existing system is not available, the choice between installation of stationary generators or banks of tanks will depend on the volume of gases required, estimated on both daily and weekly consumption rate. Where an appreciable volume of gas is required per week, it may be produced by stationary generators more economically than if supplied by tanks.

8-4.7.4.2 Building Design.

Buildings housing either tanks or generators should be of light steel construction and located at least 50 ft (15.5 m) from any adjacent structure or operation.

8-5 ELECTRICAL SERVICES.

8-5.1 Electrical Conduits.

Keep electrical circuits separate from service piping. They may be placed in concrete encased ducts behind the dock wall or, for large dry docks, in a separate tunnel shoreward from the pipe tunnel or gallery. Secondary electric power distribution lines are sometimes placed in supplementary utility tunnels, separate from immediate dry dock outlet system.

8-5.1.1 Support.

Wherever electric cables in underground installations are mounted on wall racks, support the cables away from the wall to allow leakage water to pass by.

8-5.2 Substations.

One or more electrical substations are required per UFC 4-150-02 to provide for conversion and distribution of electricity at the required voltages and capacities for ship services, and for operation of dock supporting facilities. Use mobile or portable transformer units to supply occasional high demand loads, and for testing nuclear vessels. Provide suitable protected primary feeder terminations at appropriate locations for portable design guidance.

Two feeders should be run to the pumphouse, in the event that the main feeder goes down. They should be fed from two separate power sources.

Install a back-up stand-by diesel power generator near each pumphouse to run at least the drainage pumps and alarms in the event all electrical power is lost. Consider sea level change and EHW for elevation of substations and generators.

8-5.2.1 Design.

A single substation may be incorporated into the pumpwell machinery room or, for a large dry dock, one may be required on each side of the dry dock, and not necessarily in the pumpwell machinery room.

8-5.2.2 Power Service Outlets.

Power must be conducted from the substation to dockside capstans, lights, and other necessary outlets, through cables in ducts run from manhole to manhole. The outlets should be weathertight and above mean high water. Make provisions for draining this secondary underground electric distribution system. Refer to UFC 4-150-02 criteria for outlets for ship services and portable equipment, and recommended design of electrical distribution systems.

8-5.3 Power Uses.

Electric power is required for the following:

- Pumps (see paragraphs 8-5.7.1, and 8-5.7.2)
- Sluice gates and valves (see paragraph 8-5.7.3)
- Capstans and winches (see paragraph 8-1.1.2)
- Lighting (dry dock, laydown area and pumphouse) (see paragraphs 8-5.7.8, 8-5.8.2.1, and 8-5.8.4)
- Ship services (see paragraph 8-5.8.1)

- Permanent Loads and Industrial Power (see paragraph 8-5.8.2)
- Telephones (see paragraph 8-5.7.9)
- Alarm systems (see paragraphs 7-2.8, 8-5.2, 8-5.8.3, 9-3.5.3, and 9-3.5.4)
- Control systems (see paragraphs 8-5.7.6, 8-5.7.7, 9-3.5.1, and 9-3.5.2)
- Welding machines (see paragraph 8-5.8.2.2)
- Battery charging (for some submarine requirements, see UFC 4-150-02.
- Heating, ventilating fans and air conditioning (see paragraph 7-4.13)
- Caisson (see paragraph 9-3.5.2)
- Elevators (as required by operations).

8-5.4 Methods of Installation.

Install outlets for servicing the vessels in the galleries on the sides of the dock, with other services. Carefully place outlets to facilitate connecting ships to the shore cables. All outlets, if subject to flooding, must be the watertight receptacle type. Provide a grounding system with connections in each service gallery.

8-5.5 Power Requirements.

Estimation of total power requirement calls for a careful analysis of the occurrence of simultaneous power uses listed in Section 8-5.3 entitled “Power Uses”.

8-5.5.1 Individual Requirements.

Correlate individual requirements by preparing a schedule of probability of usage. For assistance in formulating a schedule, refer to UFC 4-150-02 that shows ship service power and welding requirements for the various classes of vessels. These values are only indicative of range, and may be influenced by special requirements peculiar to any given installation. Meet the direct current welding requirement with portable converters rather than a fixed direct current bus system.

8-5.5.2 Special Requirements.

The project scope will specify any special power requirements. The total requirements for the electrically supplied supporting facilities must be estimated from the final design capacity of various installations.

8-5.6 Pumping Plant.

All electrical equipment in pumping plants must be a type suitable for installation in damp, humid atmospheres. Provide electrical heaters in large motors and switchgear to minimize condensation. The power distribution equipment should be a coordinated assembly of switchgear. Assemble the controls for all pumps, gates and valves, and the valve position indicators in a suitable panel or benchboard unit.

8-5.7 Power Demand Range.

The following tabulation presents probable range of electrical power demand for pumping the several classes of graving docks and is shown in Table 8-2. These figures may be used for preliminary purposes of study and/or design but are only indicative of the ranges to be expected.

Table 8-2 Range of Power Demand for Graving Docks

Class of Dock	Range of Power demand hp (kW)
Submarine	1,005 to 1,675 (750 to 1,250)
Destroyer or Frigate	1,273 to 1,742 (950 to 1,300)
Cruiser	1,742 to 4,020 (1,300 to 3,000)
Carrier & Auxiliary	4,690 to 6,700 (3,500 to 5,000)

8-5.7.1 Main Pump Motors.

Main pump motors should generally be of the wound rotor induction type, with starting resistance steps provided in the secondary windings, except where variable pitch impeller type pumps are used. In this latter case, use synchronous motors with reduced voltage starting where required. In general, operate these motors on a minimum of 2,400 volts, and at greater voltage where economically sound. Use drip-proof construction, and provide space heaters to heat the windings to approximately 5 °F (3 °C) above the ambient room temperature whenever the motor is disconnected from its voltage supply.

8-5.7.2 Drainage Pump Motors.

Drainage pump motors should be of the squirrel cage induction type, operated at 480 volts and at higher voltage where economically sound. Provide reduced voltage starting when required by design conditions. Provide drip proof construction and space heaters for the windings of the pump motors.

8-5.7.3 Other Motors.

Provide sump pumps, sluice gates, gate valves, sewage pumps, and ventilation fans operating at 460 volts. Motors should be drip proof or totally enclosed.

8-5.7.4 Switchgear.

Install high voltage protection and distribution equipment in a steel-enclosed, dead front assembly of switchgear. Carefully coordinate interrupting ratings of the gear with the systems to which connection is to be made. Construction should be drip proof, and space heaters should be provided to maintain the compartments of the switchgear approximately 5 °F (3 °C) above the ambient room temperature when the pumping plant is not in use.

8-5.7.5 Grounding.

Provide grounding systems for all electrical equipment frames, enclosures, and conduit systems.

8-5.7.6 Control Voltage.

Control voltage for all electrical equipment should be either 115 or 230 volts.

8-5.7.7 Control Panel.

Assemble pushbuttons and indicating lights for all pumps, gates, and valves (in addition to the synchronous position indicator for each valve and the dry dock water level indicator) on a steel control panel or benchboard type structure. Provide motor control on or adjacent to the starting equipment for each motor.

8-5.7.8 Lighting.

Provide vaporproof LED fixtures. Provide receptacle outlets at strategic locations for use during repair and inspection.

8-5.7.9 Telephone.

Provide telephone outlets at or near the control panels. Consider systems to support data, cybersecurity, and cell phone signal in pumpwell.

8-5.7.10 Installation.

All electrical installation should be in accordance with the requirements of NFPA 70, National Electrical Code. Use rigid steel type conduit. Plastic coated rigid steel conduit should be used where the conduit is exposed and subjected to flooding. Galvanized, rigid steel conduit should be used where the conduit is exposed but not subjected to flooding. Concrete encased conduit should be Schedule 40 PVC. Use cables in accordance with the latest revisions of the Uniform Facilities Guide Specifications (UFGS) Division 26, *Electrical*.

8-5.8 Dock Services.

Services are required as described in the sections below, as specified.

8-5.8.1 Ship Services (Hotel).

Power for ship services is supplied to provide the living requirements of the ship's crew, and includes loads such as lighting, cooking, pumps, fans, and other equipment. Current characteristics of the system must be the same as that of the ship supplied. Power is taken to the ship with portable cables, and connected to its electrical system through a connection box at one or more ship service outlets, which are located as indicated for each ship class in UFC 4-150-02.

8-5.8.2 Permanent Loads and Industrial Power.

Other electrical equipment such as dock lighting, receptacles, weight handling equipment ,and industrial power should be supplied from dedicated 480Y/277 Volt transformers.

8-5.8.2.1 Temporary Lighting and Power.

Design temporary lighting and power systems to supply 120-volt, 1-phase power for portable tools, lights, blowers, and other equipment used aboard the ship for repair.

8-5.8.2.2 Welding.

Provide welding service by both single- and multi-operator welding sets. The multi-operator sets are generally placed on shore, and single operator sets are placed on board ship or, if space permits, on shore. Large size welding sets are motor driven. The small sizes are either motor generator or static types. All types should be 480-volt operated. The base welding power should provide 75 percent of the total demand, and the single operator placed either aboard ship or on shore should supply 25 percent of the total demand.

8-5.8.2.3 Welding Power.

Provide power for welding equipment should from the Industrial power Cam-lok receptacles.

8-5.8.2.4 Electric Lines.

On small docks, electric lines are placed in ducts encased in concrete on the land side of the walls. For large docks, where the electrical requirements are great, place lines in a separate concrete electrical tunnel on the land side.

8-5.8.3 Fire Alarm Service.

For fire alarm system design and installation, refer to UFC 3-600-01.

8-5.8.4 Lighting.

All lights in the dry dock should be centrally controlled and the lighting intensity on the work surface should be not less than 10 foot-candles (107.6 lux).

8-5.8.4.1 Temporary Lighting.

Consider the minimum lighting requirements in 29 CFR 1915.82(a)(2) and supplementation lighting requirements in 29 CFR 1915.82(a)(4) for minimum foot candle lighting levels.

8-5.8.4.2 Night Lighting.

Provide adequate lighting on the walls of the dry dock for night work and, for daylight work, in high sidewall dry docks where daylight lighting is often impaired.

8-5.8.4.3 Types.

These lights may be of the submersible or non-submersible type. If the latter, they must be kept above the dock flooding level. If of the former type, they may be placed at a lower level, and sometimes at two levels for deeper docks.

8-5.8.4.4 Location.

Place lights on mounts to permit training and elevating, and locate at suitable intervals horizontally. They must be placed in niches or protected by cages.

8-5.8.4.5 Floodlighting.

Fabrication and material storage areas around the dock generally are lighted by banks of floodlights mounted on portable or fixed towers, or on sides of buildings. The lighting intensity for these areas should be about 10 foot-candles (107.6 lux). Portable towers should be connected to Industrial power receptacles.

8-5.8.4.6 Emergency Lighting.

Provide emergency lighting in accordance with in 29 CFR 1915.82(c)(1) and 1915.82(c)(2).

This Page Intentionally Left Blank

CHAPTER 9 ENTRANCE CLOSURES

9-1 SELECTION.

This chapter contains basic data for criteria to design and construct entrance closures, including various types of gates and caissons. Advantages and disadvantages of each type are discussed.

9-1.1 Requirements.

Basic requirements in the choice of entrance closure are reasonable initial costs, ease and rapidity of control, low maintenance, and feasibility of traffic movements across the top.

9-1.2 Types.

A review of available types reveals why floating caissons have been adopted as standard for Navy dry docks. Other types may be suitable for smaller, temporary, nonmilitary dry docks.

9-1.2.1 Miter Gates.

Miter gates were probably the first satisfactory mechanical gates. Each closure consists of a pair of gate leaves, hinged at the dock walls, swinging horizontally so when closed the free ends meet in fitted contact. Gates are moved by means of a hawser to a nearby power capstan. The sides and bottoms bear against seats in the dry dock walls and floor. This type of gate is suitable for timber construction and steel; however, they are now no longer commonly used.

9-1.2.2 Hinged Gates.

A flap gate is a rigid, one-piece gate hinged at its bottom, and swinging downward and outward. It is a compartmented structure with means for varying its buoyancy for raising and lowering. Although this type of gate does not impose such severe loads on the hinges as the miter gates, it has similar disadvantages except those of recesses. Means must be provided to support a gate when down in open position.

9-1.2.2.1 Foster Hinged Gate.

This type of gate was a commercial device developed by C. J. Foster, Inc. It was a structure that could be folded, and that did not require transverse girders between the sidewalls of the dock. It was designed for unlimited widths and depths to suit dock conditions. Reaction due to water pressure on the gate was distributed to the floor slab of the dock. Massive abutments were not required to support the ends of the gate.

9-1.2.3 Set-in-Place Gates.

Set-in-place gates are in various forms and may be built in one piece or multiple sections. They are of beam and plate construction, with reactions carried to the walls by girders and to the floor by beams. Since their placement and removal must be done by weight handling equipment, the sizes of cranes required for naval dry dock closures makes this type of closure unpractical.

9-1.2.4 Sliding and Rolling Caissons.

These types are built-in box shapes, mounted on hardwood sliding surfaces or metal rollers that move them into or out of place. They may be equipped with air chambers for buoyancy which reduce the work of moving. They have some advantages of a floating caisson but require expensive recesses in dock walls for stowage. Cleaning and maintenance of the roller or slide paths are difficult.

9-1.2.5 Floating Caissons.

Floating caissons are watertight structures with flooding and dewatering systems for operation. For design of hull, floating stability, and all operational purposes, they are symmetrical both transversely and longitudinally. See Figure 9-1 and Figure 9-2 for typical design and hull elements of a floating caisson with flood through capability.

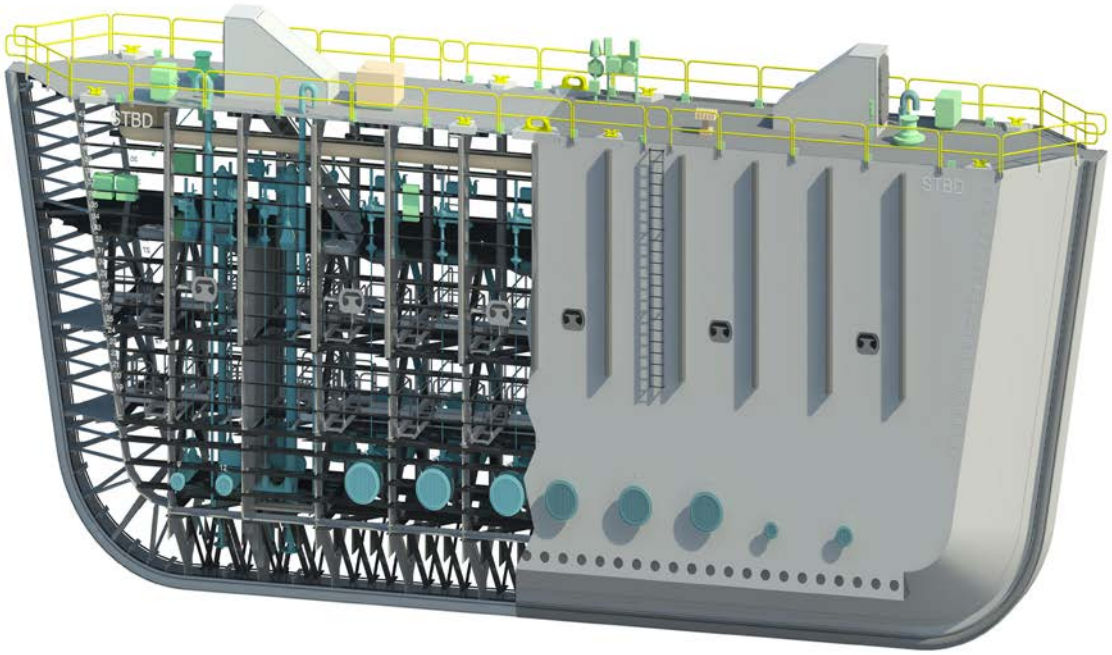
9-1.2.5.1 Advantages.

- The cost is reasonable, since practically all of the hull elements function structurally.
- A caisson may be handled easily and is seaworthy for towing to other sites (to another dry dock for repair) or from its construction site to point of use.
- It may be used at more than one seat in the same dry dock or other dry docks.
- Its symmetrical form allows reversibility with either side toward the dock chamber, permitting maintenance and repair on exposed side.

9-1.2.5.2 Disadvantages.

- The time for closing and opening the dock entrance is slower than for other types of closures.
- Because of shore service connections (electric and sometimes air), it is not operative too far from the caisson seat.

Figure 9-1 3D Perspective View of Caisson



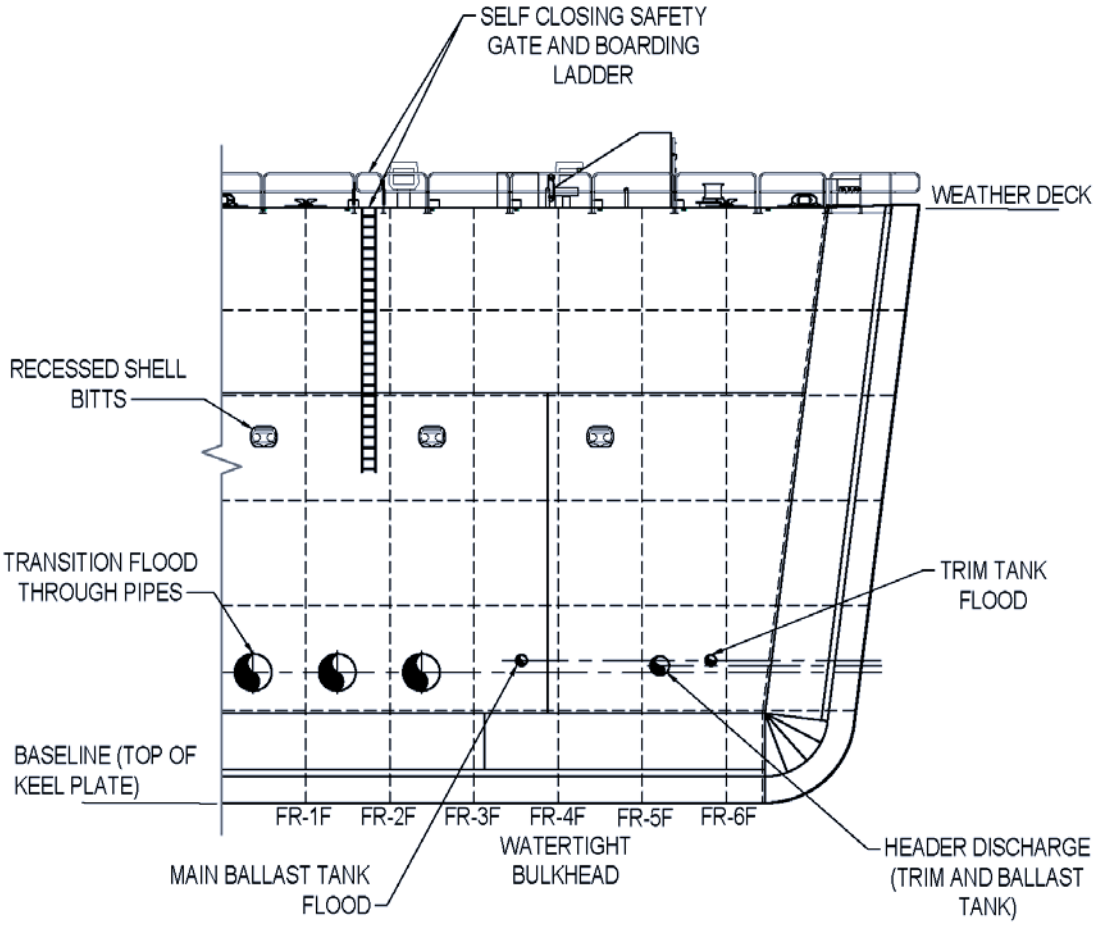


Figure 9-2 Hull Elements

9-2 DESIGN OF FLOATING CAISSONS.

9-2.1 Application.

The following paragraphs describe types of floating caissons, their operation, and materials of construction.

9-2.2 Requirements.

Caissons must allow reasonably rapid opening and closing of the dock entrance at any tide stage, be stable transversely and longitudinally at any draft, have strength and other characteristics to resist water pressure, and provide watertight seal when seated.

9-2.3 Types.

Floating caissons are usually one of the four types described below.

9-2.3.1 Ship Type Caisson.

This type has a faired shape similar to the lines of a ship. The required curvatures for frames and plates make the construction uneconomical, and it is now outmoded.

9-2.3.2 Hydrometer Type.

This type has a narrow width over as much of the height as possible between its waterline at extreme light draft when afloat and its waterline at mean high water when seated. This reduces the amount of adjusted water ballast during lowering and raising for seating and unseating operations.

9-2.3.3 Box Type.

This type is constructed in the shape of a box, with vertical or sloped ends to suit the seat shape. The girder ends project from the box to bear against the seats built in the dock side walls.

9-2.3.4 Rectangular Type.

This type is similar to the box type. It has simplified internal and external welded construction. All body girders and breasthooks are completely enclosed by the plating. All modern designs have been of this type.

9-2.4 Ballast Control.

The draft of caissons is adjusted for seating, unseating, and towing by flooding or pumping out water ballast. (Refer to Section 9-2.7 entitled “Machinery” for ballast control).

9-2.5 Operation.

Operation is functional as applied to the design objectives. Detailed operational instructions must be supplied for each installation but are, in general, as described in the two sections below: “Opening the Entrance” and “Closing the Entrance”.

9-2.5.1 Opening the Entrance.

To open the entrance, the procedure is as follows:

- In preparation for lifting the caisson from its seat, the water level inside the graving dock must be raised to the water level outboard the caisson, by flooding the dock basin.
- Caisson dewatering pumps are started; then with the discharge valves open and sufficient water ballast removed, the caisson floats off the seat. Pumping is continued until desired draft is obtained. The caisson in operation is very rarely pumped up to light draft.
- After the discharge valves are closed and secured, and the machinery is shut down, the caisson is warped out of the graving dock entrance channel limits by capstans and/or tugs. The caisson weather deck is fitted with chocks, bitts, and cleats for line attachment.

9-2.5.2 Closing the Entrance.

To close the entrance, the opening operation is reversed, except that ballast tanks are filled by opening flooding valves to let in water. During submergence, the caisson must be positioned correctly with respect to seats, and must have negligible list or trim.

9-2.6 Materials of Construction.

Modern caissons are built of welded steel.

9-2.7 Machinery.

The main machinery of a floating caisson consists of dewatering pumps and flooding, dewatering, and equalizing valves to control the water ballast. Design the ballast control system so that complete control of trim may be maintained during submerging and raising operations. The pumps are driven by electric motors powered through cables attached to shore connections located near the caisson seat at coping. Compressed air, when used, is also obtained from shore connections, through air hose.

9-2.7.1 Auxiliary Machinery.

Auxiliary machinery may include electric fans, motorized dry dock flooding valves, and an air compressor. When a dry dock is flooded through the caisson, two valves in each flooding tube are required for double valve protection.

9-3 DESIGN OF RECTANGULAR TYPE FLOATING CAISSONS.

9-3.1 Shape.

Since construction of caissons is not sufficiently repetitive, definitive drawings have not been prepared.

9-3.1.1 Elevation.

In elevation, the shape of a caisson must conform to the shape of the seats in the dry dock walls, which have been dimensioned to provide the required ship clearances.

9-3.1.2 Height.

The elevation of the caisson weather deck is normally the same as the dry dock coping. However, the elevation of the weather deck need not be any higher than required to prevent overtopping at the maximum possible outside water level (storm surge or extreme high water (EHW) level with consideration for sea level change). If there is a significant difference between the level of the dry dock coping and the maximum possible outside water level, then consider a lower weather deck elevation.

9-3.1.3 Cross Section.

For a typical caisson cross section, see Figure 9-3. Determine beam by strength and stability requirements. Slope the bottom and sides from the stems and keel at an angle of approximately 45 degrees, to meet the beam width. Slope the sides slightly inward at the top but maintain requirements for roadway and deck layout.

9-3.1.4 Plan.

Make the structure symmetrical about both axes. See Figure 9-4.

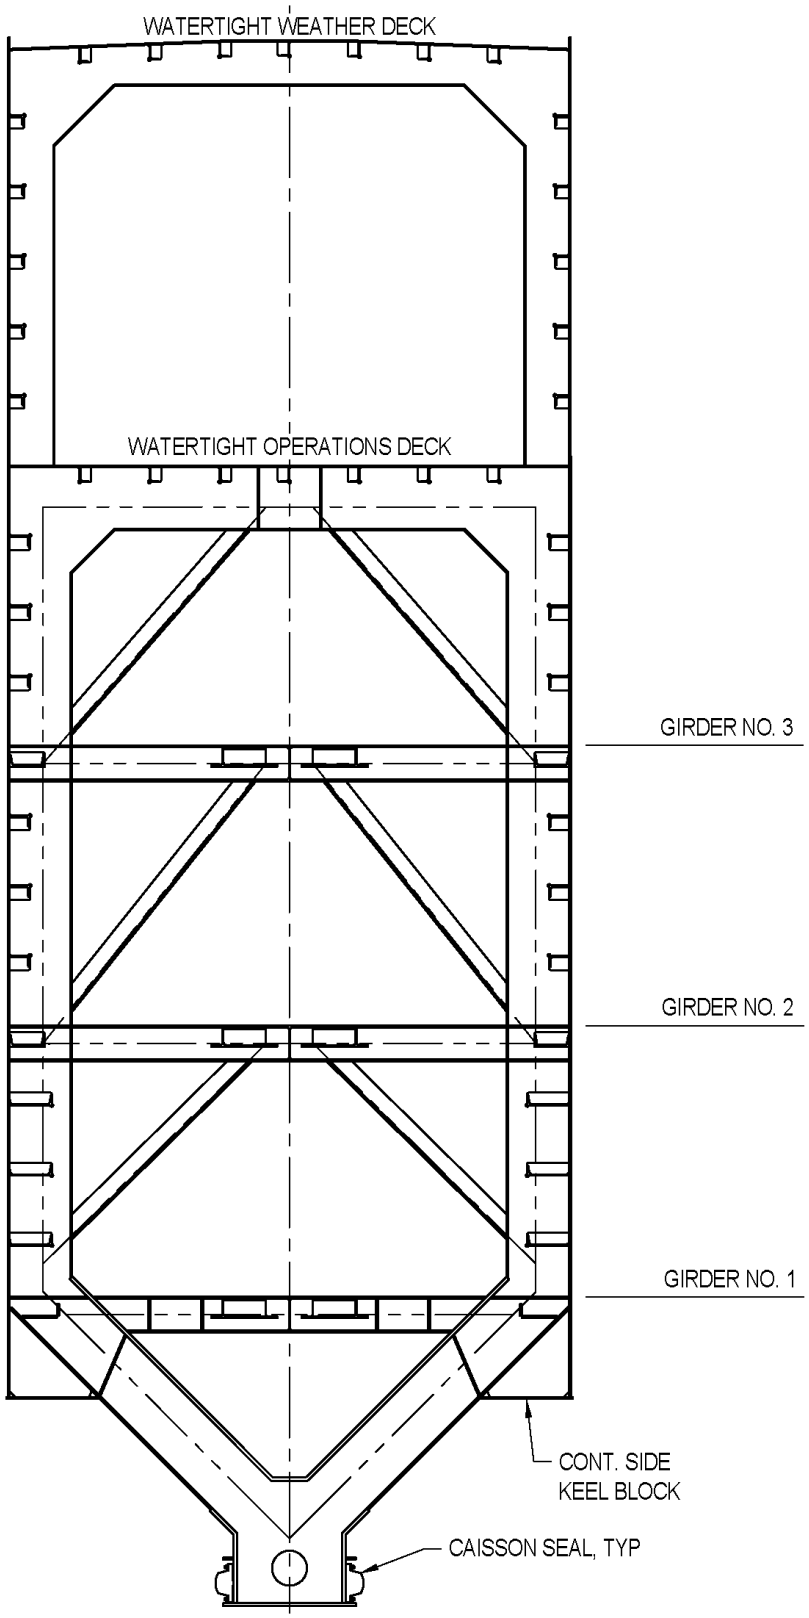
9-3.1.5 Stability Afloat.

Caisson stability afloat must meet the requirements of the current edition of The ABS Rules for Building and Classing Steel Vessels Under 90 Meters. The stability analysis will consider all ballasting conditions (tanks empty, partially full, full), towing loads, windage loads, mooring loads, live loads on weather deck and machinery deck (safety deck), and free surface effects.

9-3.2 Tanks.

Ballast is used to control the caisson draft and stability.

Figure 9-3 Cross Section and Typical Framing Arrangement of Welded Caisson



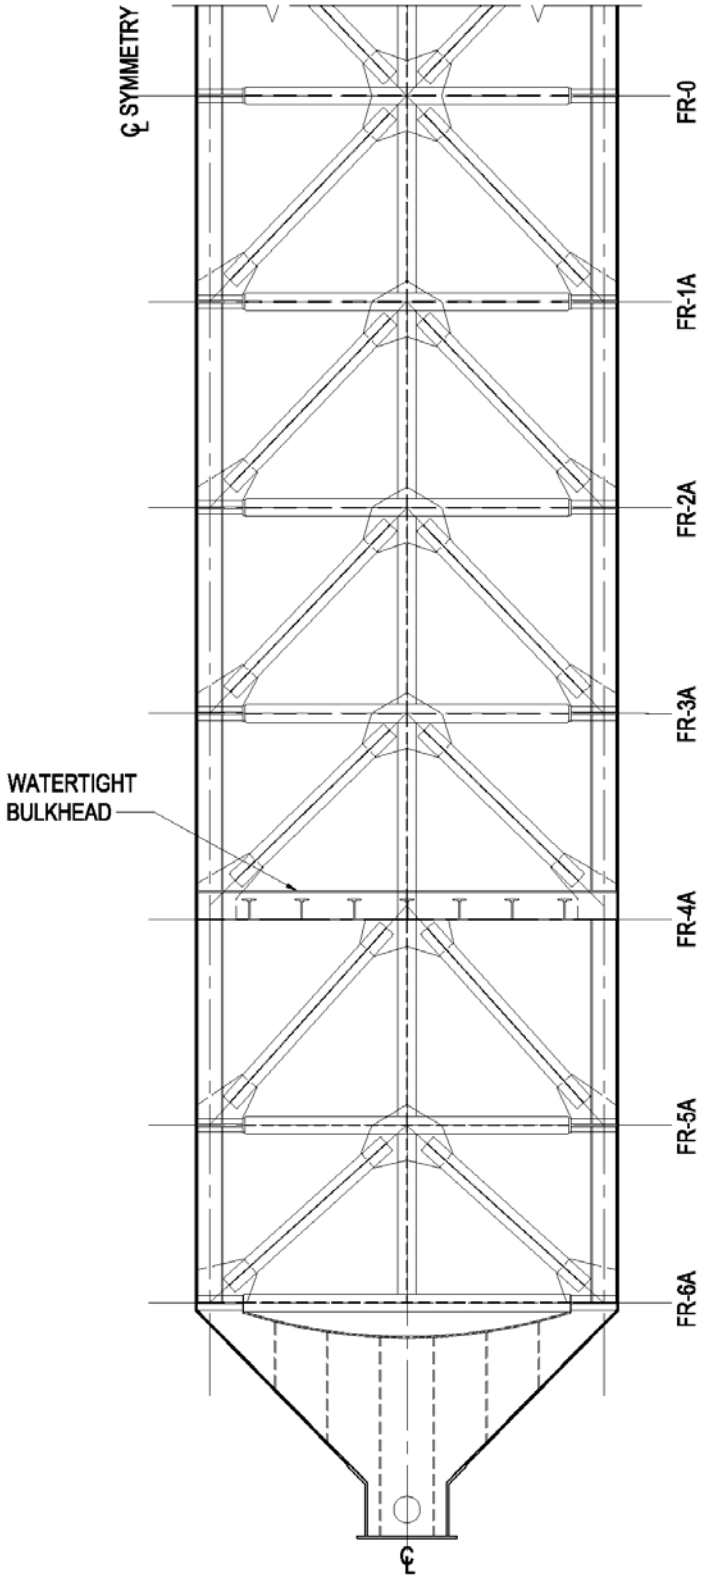


Figure 9-4 Typical Horizontal Girder for Welded Caisson

9-3.2.1 Fixed Ballast.

Fixed ballast is required to insure stability under all operating conditions. Fixed ballast at the bottom of a caisson is concrete. Quantity of fixed ballast is determined by the minimum draft and stability requirements. The minimum draft of a floating caisson must be such that it can be raised from the sill or seated at mean lower low water.

9-3.2.2 Water Ballast.

The maximum draft of a caisson normally occurs while the caisson is being seated at extreme high water. As a general rule, caissons are designed to allow for seating at mean high water, and the machinery deck (safety deck) is located, and dip pipes proportioned, to suit this condition.

If the dock can be superflooded, adequate water ballast must be provided so the total weight of the caisson (light weight plus water ballast) exceeds the amount of water displaced with the water level outside the dock at mean high water and the water level inside the dock at the maximum superflood level.

If the dry dock is located in an area where there is a significant possibility that the water level will rise above the overtopping level (coping or floodwall level) and flood the dock during destructive weather, then the caisson should be designed such that when floating and fully ballasted it has a freeboard of between 1 ft (0.31 m) and 2 ft (0.62 m) below the weather deck level. This will allow the caisson to be safely removed from its seat when the water level approaches the top of the caisson.

9-3.2.3 Ballast Tank Design.

9-3.2.3.1 Tank Layout.

Ballast tanks should be configured so the caisson can be trimmed, if necessary, by adjusting water ballast. This is normally accomplished by either using a single main ballast tank with trim tanks on either end of the caisson, or by using two ballast tanks with a watertight bulkhead on the caisson’s centerline.

9-3.2.3.2 Tank Sizing.

It is desirable to be able to dewater ballast and trim tanks one at a time with the caisson in its seat and the dock dry to facilitate inspections and maintenance. If tanks are to be dewatered individually for inspections and maintenance, then they must be sized such that the caisson’s weight (light weight plus water ballast) always exceeds the caisson’s buoyant force, and there must never be an unseating moment on one end of the caisson. This calculation is done with the outside water level at MHW to allow tank inspection and maintenance under all normal operating conditions.

9-3.2.3.3 Machinery Deck (Safety Deck) Location.

The locations of machinery decks (safety decks) depend on necessary water ballast, adaptability to framing arrangements, and required headroom for machinery. There are advantages to raising the machinery deck (safety deck) higher over the end trim tanks than over the center tanks of the caisson because it allows use of shorter pump shafts and valve stems. Locate machinery decks (safety decks) at elevations higher than those indicated by computations.

9-3.2.3.4 Dip Pipes.

Provide dip pipes in each water ballast compartment to limit ballast water to design level and to keep water from wetting the underside of the machinery deck (safety deck). Dip pipes serve as vents until ballast water reaches the pipe ends. Once the dip pipes are immersed, the air remaining in the ballast tank is compressed until it limits the water level in the tank to the maximum design level. This provides a safety feature if there is a failure in the ballast tank's flooding or dewatering systems. These pipes are installed extra long, and cut off to the elevation determined by submergence tests. Steel dip pipes corrode quickly since their interiors are inaccessible and protective coatings can't be maintained. For this reason, dip pipes should be constructed from type 316L stainless steel.

9-3.3 Watertight Integrity.

The caisson hull structure must be watertight below the weather deck level. Main ballast and trim tank vent/dip pipes, caisson power supply, etc. must penetrate the weather deck and not the side shell plating. Windows and/or portlights must not be installed in the side shell plating.

Provisions to ensure the watertight integrity of the weather deck must be provided including watertight hatches for personnel access to the machinery deck (safety deck) level and trim tanks (if applicable). Weather deck penetrations for utilities, tank vents, machinery level ventilation, etc. must be watertight to at least 6" above the level of the weather deck.

Provisions to ensure the watertight integrity of machinery spaces must be provided. Watertight hatches must be provided in the machinery deck (safety deck) and bulkheads (if applicable) for access to the main ballast tank and trim tanks. All machinery deck (safety deck) penetrations including pump and valve shafts, lubrication lines, electrical wiring, etc. must be watertight.

The caisson must be designed to ensure that it will remain afloat in a satisfactory condition of equilibrium with the uncontrolled flooding of any one compartment (main ballast or trim tank) except the machinery space.

9-3.4 Analysis and Design.

Analyze and design caissons for all applicable loading conditions such as dead and live loads, hydrostatic pressure, and seismic. Refer to Figure 9-5 and Figure 9-6 for some example loading scenarios. Structural steel design may be in accordance with either AISC Steel Construction Manual or ABS Rules for Building and Classing Steel Vessels Under 90 Meters.

9-3.4.1 Approximate Analysis.

To resist external water pressure when a caisson is seated and the dock is empty, consider the caisson closure as a rectangular slab supported at side and bottom edges with free top edge. For approximate determinations of principal moments, shears, and reactions, assume the design length as a mean of the top and keel lengths and apply elastic theory for a rectangular plate supported on three sides. Determine also the distribution of shears and moments in individual frames and girders, stiffeners, and plating.

9-3.4.2 Framing.

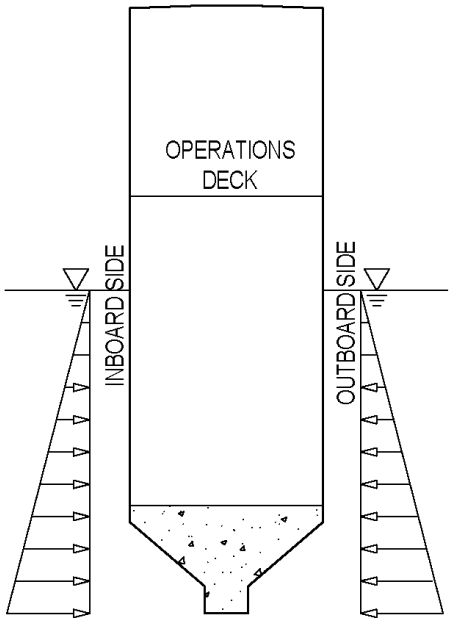
Main framing should consist of a series of vertical trusses or frames attached to horizontal girders or frames at panel points. Make a bulkhead frame near each end watertight for trim tanks. Only the machinery/safety and weather deck horizontal girders are made watertight. Space vertical frames about 8 ft (2.5 m) on centers, with spacing of horizontal girders preferably not exceeding 10 ft (3.1 m). Place short intermediate horizontal girders, usually called breasthooks, in the upper half near the caisson ends, for better distribution of shears and end reactions.

9-3.4.2.1 Vertical Frames.

For construction details, see Figure 9-3.

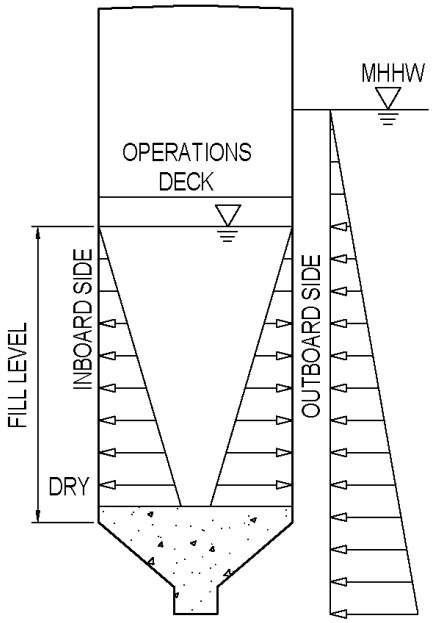
Design as follows:

- Design vertical frames to resist caisson shears and bending moments in vertical directions and local bending between girders. The part of the total vertical caisson bending moment applicable to a frame is determined from the approximate analysis (refer to Section 9-3.4 above entitled “Design Analysis”). Chord stresses are determined by beam analysis.
- Local bending moments between girders on the outboard side result from water pressure loads brought to the vertical frames by hull plating and stringers.
- Web member stresses are found by assuming the distributed vertical pressure loadings to be concentrated at panel points and computing the consequent shears.



- Diagonal web members should preferably be tee sections; horizontal strut members angle sections; and chord members wide angle sections formed by bent plates or a web plate with a welded flange.
- Web member connections should be fillet welded.

9-3.4.2.2 Horizontal Girders.



See Figure 9-4 for details of a typical girder. Design as follows:

- Design horizontal girders similarly to vertical frames. In general, they are the same type of construction.
- Girder flanges should be combination tee and wide-angle sections and, for computing stresses from girder action, include all adjacent hull plating.
- Members of safety and top decks must resist local loads introduced by secondary framing and deck plating at those locations.
- Webs at the girder ends are longitudinally stiffened plating for required shear resistance.
- Weather decks should be cambered to provide drainage and designed for specified uniform live loadings and concentrated vehicular loads normal to the girder plane.
- Design machinery decks (safety decks) for water pressures and machinery loads.
- Horizontal members in ballast and trim tanks should be designed such that air will not be trapped beneath the members as the tanks are flooded, and water will not be trapped above the members as the tanks are dewatered. Steel in air pockets will not be protected by the cathodic protection system when the tanks are flooded. Pooled water will hinder inspection and maintenance when the tanks are dewatered. Install vent/drain holes in unstressed areas of horizontal members, as required, to prevent these problems.

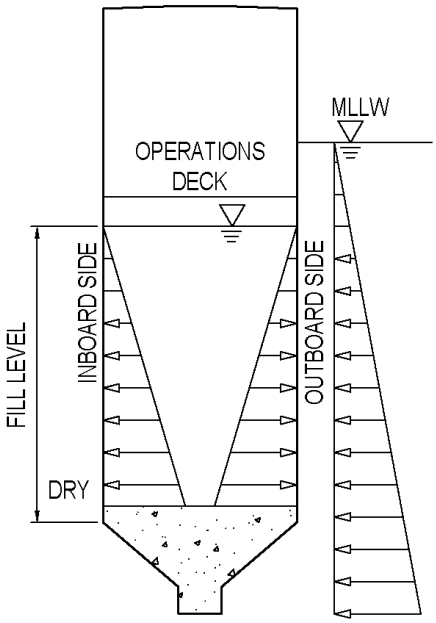


Figure 9-5 Example Load Cases for Caisson – 1 of 2

9-3.4.2.1 Secondary Framing.

Make shell plate stringers of flat bars, structural tees (ST or MT), bulb flats or angles running horizontally. At keel, provide web plate stiffeners in a vertical direction, spaced about 2 ft (0.6 m) on centers, between vertical frames. Design stringers as continuous beams to resist local water pressure transmitted by plating. Stringers for both weather and machinery decks (safety decks) should run in the long direction of the caisson. Design them as continuous beams.

9-3.4.2.2 Plating.

Stresses in shell plating are biaxial, due to bending in two directions. Determine maximum stresses in plating by combining stresses from overall bending and twisting of the caisson and bending stresses from local water pressure loading. Assume twisting moments resisted only by shearing stresses in the plating. Determine principal stresses by combining shear resulting from twisting, stresses produced by bending in both vertical and horizontal directions, and stresses due to local bending.

9-3.4.2.3 Stems and Keels.

Stems and keels distribute hydrostatic pressures on caissons to the masonry of dry dock seats. Keels are to be filled solid with concrete ballast, and stiffened with diaphragm plates.

9-3.4.2.4 Allowance for Corrosion of Steel Structure.

Steel caisson structure must be designed with a corrosion allowance such that allowable stresses will not be exceeded when corrosion has reduced structural component cross sectional areas by the amount of the corrosion allowance. Steel caisson structures will corrode during use regardless of coating systems and cathodic protection systems used. The use of a corrosion allowance (addition) during design should allow many years of use before costly structural repairs are required. The minimum corrosion allowance is listed in ABS Rules for Building and Classing Steel Vessels Under 90 meters 3-2-6/1.6.4(b).

9-3.4.2.5 Welding.

All caisson welded connections must be continuous to develop maximum strength and to facilitate cleaning and coating for corrosion protection. Skip welding must not be used in ballast and trim tanks or on the caisson exterior.

9-3.4.2.6 Maintainability.

The caisson must be designed and constructed such that all structural steel surfaces are readily accessible for maintenance and repair of protective coatings.

9-3.4.3 Gaskets and Seats.

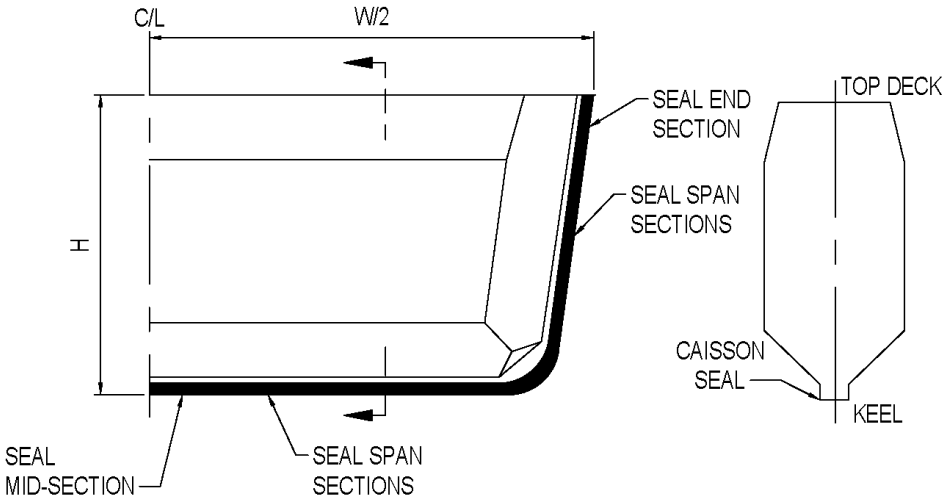
The bearing of caisson ends and keel is taken through special molded, steel reinforced, rubber seals set on both faces of caisson keel and stem. Contact NAVFAC EXWC for details. See Figure 9-7.

9-3.4.3.1 Graving Dry Dock Seats.

For cruiser, auxiliary, and carrier docks, build recesses into the dry dock entrance floor 2 ft (0.6 m) and into the dry dock entrance side walls 2-1/2 ft (0.8 m), to form docking seats. For destroyer and submarine docks, these depths may be decreased respectively 6 in. (152 mm). Protect the bearing surface with either type 316 or monel armor plating.

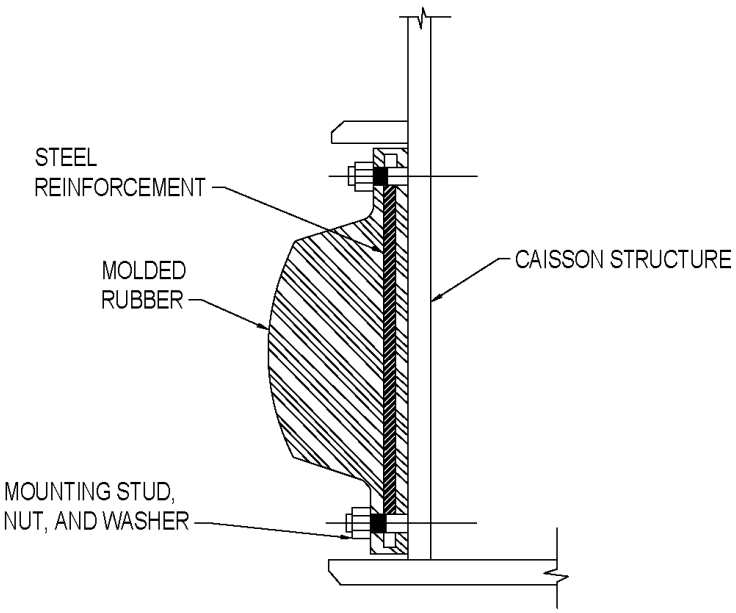
9-3.4.3.2 Super-flooding Feature.

For dry dock designs including the super-flooding feature, face the dry dock seat recesses inboard and outboard to provide bearing reaction from either direction (refer to CHAPTER 6).



9-3.4.4 Side Docking Keels.

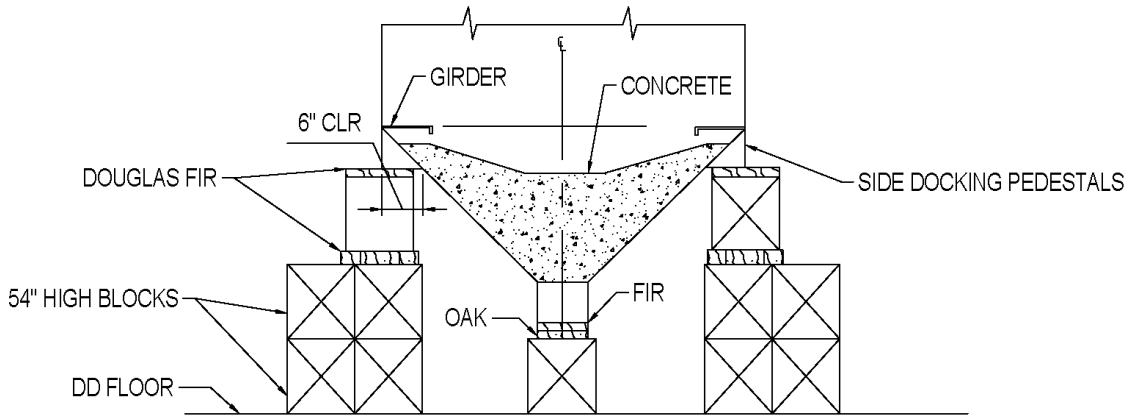
The caisson design must include side docking keels located approximately at the turn of the bilge on both sides of the caisson. The side docking keels provide a horizontal bearing surface for bilge blocks when the caisson is drydocked for maintenance or repair. See Figure 9-8. Side docking keels must be designed to accommodate two blocking plans such that the portion of the caisson that bears on the bilge blocks in the first docking plan is fully exposed to facilitate maintenance when the caisson is docked in the second docking plan. Design analysis must ensure adequate caisson stability while drydocked per NSTM Chapter 997, Docking Instructions and Routine Work in Dock.



9-3.5 Equipment.

Mechanical and electrical equipment must conform to the same specifications as the corresponding equipment in the dry dock pumpwell.

Figure 9-7 Detail of Gasket for Caisson



a) CAISSON SEAL LOCATIONS

b) SEAL ASSEMBLY

Figure 9-8 Caisson Side Docking Keels

9-3.5.1 Major Equipment.

Provide the following major items of equipment. Each system (caisson tank flooding, caisson tank dewatering, dry dock flooding, etc.) must consist of at least two parallel and independent systems for redundancy:

- Vertical shaft pumping units as required. Control by start-stop pushbutton mounted on or near the floor stand and/or at the control console.
- Gate valves or butterfly valves as required for water control. Use motor operated, except for small valves which may be hand operated. Provide sea connection with screens and gratings.
- Check valves in discharge pipes of main pump units.
- Inclinometers of suitable type to show both list and trim.
- Gauges for indicating the water level in each ballast compartment and draft.
- Heating and ventilating systems to suit climatic conditions.
- Dock flooding via piping through the caisson and 36 in. (76.2 mm) valves with controls. Two valves are required in each pipe. Use valves suitable for pressure from both sides to accommodate rotation of the caisson. Locate pipes high enough to avoid sucking mud and debris on the harbor bottom into the pipes. Consideration should be given to angling the ends of pipes down to prevent the movement of ship blocking. Install flanges on

the caisson shell on both sides of the caisson to facilitate the installation of blanks over the pipes. Refer to CHAPTER 6.

- Pumps and piping systems must be designed such that individual system components can be removed for repair and replaced without cutting and welding.

9-3.5.2 Electrical Equipment.

Supply 480 volts nominal, 3-phase, 60 Hertz per second electric current from the dry dock system to shore connection receptacles on the caisson. Operate main motors at 460 volts. Operate heater and fan motors on 120 volts, obtained from a transformer provided in each starter. Operate lights and convenience receptacles on 120 volts, obtained from 460/120-volt transformers. Provide controls, circuit breakers, and similar items, as necessary.

9-3.5.3 Ballast Tank Alarms.

Provide high and low water alarms for the main ballast tanks. Both alarms must annunciate locally and at the shipyard operations center.

9-3.5.4 Miscellaneous Fittings.

The following miscellaneous fittings are required:

- Companionway ladder or ladders with railings
- Vertical fenders to ballast compartments
- Timber composite or rubber fenders both sides of hull.
- Cast steel chocks and cleats on the weather deck. If the elevation of the weather deck is significantly higher than the pier elevation when the caisson ballast tanks are empty, consider also installing mooring fittings in the caisson shell at the appropriate elevation. The use of these fittings when mooring the caisson pier side for extended periods will eliminate problems with extreme vertical angles on mooring lines
- Non-skid surfacing on weather deck. Do not use a bituminous surface.
- Hinged or portable ramps (where required) for providing pedestrian access or vehicular access to roadway on caisson.
- Curb lights
- Hand railing (galvanized or other corrosion resistance)
- Access manholes and machinery hatches. Machinery hatches in the weather deck and machinery deck (safety deck) must be sized and located to facilitate the removal and reinstallation of all pumps and valves

- Capstan installations for line handling and warping out of and into dry dock seat or to mooring location, if necessary
- Visible and audible water alarm on weather deck.

9-3.5.5 Cathodic Protection.

All metal surfaces of the caisson that are normally immersed in sea water including the exterior shell plating, main ballast tank(s), and trim tanks should be protected from corrosion by a sacrificial anode type cathodic protection system. UFC 3-570-01, Cathodic Protection, provides guidance on system design. Consider using aluminum anodes for caisson cathodic protection rather than the commonly used zinc anodes. Aluminum anodes are both more efficient (three times as many amps-hours per pound consumed) and provide more protection (better protective potential for longer time) than conventional zinc anodes. Zinc is an environmental contaminant of concern in seawater, and the use of zinc anodes may cause problems with environmental regulators. Aluminum is not a contaminant of concern in seawater, so utilizing aluminum anodes instead of zinc anodes should eliminate this issue. However, some aluminum anodes contain mercury,so be sure to specify aluminum anodes that contain no mercury.

9-3.5.6 Protective Coatings.

Epoxy protective coatings meeting either MIL-DTL-24441D or MIL-PRF-23236D must be used to protect all caisson steel.

This page intentionally left blank.

CHAPTER 10 CONSTRUCTION

10-1 CRITERIA.

This chapter presents data and information as criteria for the construction of a dry dock body, the entrance closure, supporting facilities and accessories, and mechanical and electrical equipment.

10-1.1 Approach.

Criteria for the dry dock body are intended to guide the designer by indicating basic construction problems encountered, depending on the type of dry dock chosen. They are also intended to assist in the preparation of construction specifications as well as design drawings. References to construction of the dry dock body are based on the use of concrete. Phases of construction are presented in chronological order of the work.

10-2 DRY DOCK BODY.

10-2.1 Clearing and Demolition.

A site must be cleared of all interfering structures above and below water. Dispose of removed material according to contract requirements. Remove all objects that will interfere with excavation.

10-2.2 Rerouting Utility Lines.

Essential mechanical and electrical services that will be interrupted by construction work must be rerouted before demolition. Possible extensions of the services to the new dry dock, when completed, must be considered in rerouting.

10-2.3 Excavation.

Excavation is the first major step in the construction of a dry dock. It is necessary to make room for construction of the dry dock body, and often the removal of unsuitable foundation materials is required. Excavation may be done by dredging or in the dry, depending on the type of material, method of dewatering, or intention to construct the dry dock by underwater methods. Dredging is generally the most economical method.

10-2.3.1 Dredging.

A Department of the Army, Corps of Engineers permit must be obtained for dredging work in navigable waters and material disposal. Dredging may be done by hydraulic methods, or mechanical methods such as clamshell bucket or dragline. If soil is removed by hydraulic dredging, it may be piped to approved disposal areas, to yard locations for fill, or to stockpiles for future use. If dredging is done by clamshell or dragline, the removed soil must be barged to a disposal point.

Hydraulic dredging is not feasible for certain soils such as stiff clays or those containing boulders or rock. Blasting may be necessary for very hard materials, after which a clamshell or dragline is used for its removal. For additional information on dredging operations, refer to UFC 4-150-06, *Military Harbors and Coastal Facilities*.

10-2.3.2 Water Removal.

If water can be removed and kept excluded from a site with reasonable effort, construct dry docks in the dry. This method affords the greatest economies in material and the best quality of completed construction. The method of handling water percolation depends on the type of enclosure and on the nature of surrounding and underlying soils. For dry docks constructed in the dry, continued exclusion of water is most important. (Refer to the Section 10-2.4 entitled “Cofferdams”.)

10-2.3.3 Dry Excavation.

For hard materials, dry excavation is preferred. Where dewatering a site must be done by tiers of well points, excavation in the dry is initiated after the water table in the bank has been lowered. Excavation in the dry may be done by power shovels, draglines, clamshells, bulldozers, tractor drawn pans, or combinations of these methods.

10-2.3.4 Fine Grading.

Fine grading is done by hand tools, bulldozers, and scrapers. Replace over-excavation by well-consolidated material or lean concrete.

10-2.4 Cofferdams.

Cofferdams usually consist of sheet pile or earth structures, or both combined. The function of a cofferdam is to surround a site and to cut off, or minimize, water inflow. Portions of a cofferdam may become permanent parts of the finished dry dock. At the dry dock entrance end, a cofferdam must be removable to allow access for vessels when the dry dock is in operation. There are several types of cofferdams, four of which are described in the sections below.

10-2.4.1 Excavated Pit Cofferdam.

Where most of a dry dock is on land, and the soil in the area is sufficiently impervious and mostly of granular character, a hole may be dug and dewatered by means of well points or deep wells, or a combination of both.

10-2.4.1.1 Entrance Closure.

The entrance closure may be an earth-dike, with or without a line of sheet pile cutoff, or it may consist of a line of earth filled sheet pile cells.

10-2.4.1.2 Clay and Rock Foundations.

The open pit method is generally not suitable for clays. Dry docks built in rock fall into this category, except that water influx is usually small and can be collected in sumps to be pumped out by conventional pumps, see (d.) of Figure 4-1.

10-2.4.2 Earth Dike Cofferdam.

If suitable foundation and borrow material is available, a simple earth dike may suffice to exclude water from a site, even where dry docks will be located well out in the water. Usually, however, a sheet pile cutoff is provided as a dike core. Where sheet pile cutoffs can penetrate to impervious material, earth dikes are ideal. Where earth dikes are used, also provide for lowering the water table by well points and/or deep wells. For an example of a dry dock constructed with this type of cofferdam, see (e.) of Figure 4-1.

10-2.4.3 Cellular Sheet Pile Cofferdam.

For particularly unfavorable soil conditions (for example, where embankment material in place, or available, is very pervious or otherwise unsuitable), a continuous wall of cellular sheet piles may be used to enclose an entire dry dock site. Normally, do not choose this type of construction because the cost is relatively high. This method may prove feasible for shipbuilding docks of semi-permanent character where sheet pile cells become incorporated into the dock structure. See (a.) of Figure 4-2.

10-2.4.4 Internally Braced Sheet Pile Cofferdam.

The use of this type depends on special foundation conditions. The bottom must be relatively impervious and must have the strength to resist a blow. One example of this type of bottom is firm clay into which sheet piles can be driven to a substantial depth for cutoff. The clay must be firm enough so that the depth of material surrounded by the sheet piles has sufficient strength to resist uplift. Design as follows:

- Sheet piles of the Z-type are usually used because of the high ratio of rigidity to weight.
- Internal bracing must be placed in two directions and in vertical tiers spaced to accommodate the strength of sheet piles. Wales and struts may be of wood or steel or a combination of both. Steel is usually required below the top tier.

10-2.5 Foundation Piles.

Piles may be required to help support dry dock structures constructed on weak soil types. They may also be used to help hold down a dry dock floor slab against uplift pressures. Piles may be needed for track and capstan supports.

10-2.5.1 Types.

Piles may be of wood, steel, or concrete. Wood piles that are not completely covered must be treated.

10-2.5.2 Driving.

Piles may be driven either in the dry or underwater. Steel piles placed underwater are usually driven to a predetermined top elevation. Timber piles driven underwater may be cut to a predetermined top elevation by an underwater saw operated by a barge mounted motor and guide frame.

10-2.5.3 Length.

Because piles will vary in length at any given location, the lengths ordered must be sufficient to allow for possible variations. Piles may or may not penetrate into a structural foundation slab, depending on design anchorage requirements.

10-2.5.4 Locations.

The accurate positioning of each pile is important to maintain the validity of design assumptions and make possible the installation of prefabricated items.

10-2.5.5 Precautions in Driving and Handling.

Be sure that piles are undamaged by handling prior to driving, and substitute sound piles for those damaged in driving. Creosoted timber piles and precast concrete piles are particularly susceptible to handling and driving damage.

10-2.6 Foundation Course.

To stabilize soft bottom material, place a foundation course consisting of a layer of gravel or crushed rock several feet thick. For dry docks with relieved floors, grade the foundation course material to function as a filter. Where drainage pipes are used in conjunction with the filter course, the material around the pipes must be carefully placed and carefully compacted, to preclude damage to the pipes.

10-2.7 Foundation Slabs.

Foundation slabs may be poured either by the tremie method or in the dry.

10-2.7.1 Tremie Method.

For the tremie method, divide the floor slab into reasonable size placements by forms placed underwater. Place as follows:

- Each placement must be placed through multiple pipes to minimize the distance of concrete flow after emerging from the tremie pipe end. Pipes should be no more than 12 ft (3.7 m) apart.
- Water must be excluded from tremie pipes before they are filled with concrete. Water may be kept out by special foot valves or expelled by various go-devil devices that separate water from the concrete columns in the pipes as the columns build up with introduced concrete.
- Tremie concrete must be brought to within 1.5 to 2 ft (0.46 to 0.61 m) (nominally) of the top of the finished slab. Pour the remainder of the finished slab in the dry. This procedure allows cleaning the top of the tremie concrete after dewatering, embedment of various floor fixtures, and a final accurate floor finish and elevation.

10-2.7.2 In the Dry Method.

When docks are constructed in the dry, the floor is placed to full thickness in one operation, and contains the embedded items.

10-2.7.3 Field Verification of Weight.

For full hydrostatic docks, verify the actual weight of concrete and reinforcing steel being placed during construction, in order to ascertain the possible necessity for additional weight for conformity with design computations.

10-2.8 Sidewalls and Abutments.

Construct all abutments and sidewalls in the dry. For walls constructed on tremie placed slabs, the walls must be built within dewatered cofferdams placed on top of the tremie slabs. See Figure 5-1 for examples of cofferdams on tremie slabs.

10-2.9 Miscellaneous Items.

Other structures built in connection with a graving dock (such as capstan, bollard, and crane rail foundations) present no unusual problems and may be constructed in accordance with accepted practice. Care must be taken to ensure accurate positioning of items to be embedded in concrete, and watertightness of such structures as capstan pits, pumpwells, and service galleries. All holes left by removal of items (such as from ties) should be patched, because such unevenness in concrete surfaces accelerates deterioration and may cause leakage.

10-2.10 Backfill.

Backfill may be placed in the water or in the dry next to sidewalls and abutments. For tremie docks, it may be expeditious to place backfill in the wet. In the dry, backfill should be placed in shallow layers and each layer thoroughly compacted. Backfills comprise foundations for roadways, laydown area, and other structures built directly on them, and must have sufficient strength to support such loads.

10-3 ENTRANCE CLOSURES.

10-3.1 Construction and Use.

Entrance closures (caissons) are usually built of welded steel construction, but may also be built of reinforced concrete. Construction may be by a naval shipyard, but is usually done by a private contractor. Being adaptable for towing, a caisson may be built some distance away, in a yard particularly suited to economical prefabrication, and subsequently towed to the graving dock site.

10-3.2 Dimensions.

It is important to accurately check dry dock seat dimensions against those of the proposed closure, particularly for clearances. This is essential in the case of new caissons for existing docks. Contract documents for caisson construction should require that as-built caisson dimensions be within 1/4 in. (6.3 mm) of molded dimensions. Seal bearing surfaces should be within 1/8 in. (3.2 mm) of a vertical plane (or the designed shape if the seat is not planar). Measurements should be made during construction to verify that the as-built dimensions are within tolerance.

10-3.3 Ballast.

Permanent ballast necessary for proper operation and stability of a caisson is usually provided prior to an inclining test, and additional ballast, if necessary, is added at testing time.

10-3.4 Launching.

Caissons may be constructed in a graving or floating dry dock or on shipbuilding ways. Some small caissons can be built on piers and placed, by crane, in the water.

10-3.5 Steel Caissons.

Methods and operations used in prefabrication, assembly, and launching of steel caissons are very similar to those of other welded steel floating vessels.

10-3.6 Concrete Caissons.

Several prototype concrete caissons were built using practices developed for construction of concrete vessels and ships. These practices differ from standard concrete construction methods in the unusual care needed to achieve a watertight, durable, and structurally sound caisson. The service record of concrete caissons should be evaluated prior to proceeding with new designs. The concrete caisson may be placed in the outer seat while the steel caisson is being overhauled.

10-3.7 Closure Tests.

Five types of tests are required as described in the sections below.

10-3.7.1 Watertightness Test.

Watertightness must be made prior to launching, either by filling a caisson with water or by use of low pressure air.

10-3.7.2 Seating Test.

After launching, caissons must be seated and then raised several times with both faces toward the dock, to validate caisson operational performance. Tests should include the operation of all equipment (pumps, valves, capstans, etc.) and the dock should be pumped dry to validate performance of the rubber seals. If the dock is equipped for superflooding, it should be superflooded to the maximum design level with both caisson faces toward the dock.

10-3.7.3 Deflection Test.

Deflections at various points of a caisson under full load (high tide with a graving dock empty) must be determined in comparison with no-load positions, and then checked against original design data. For a convenient reference line, use a wire stretched along the caisson centerline and fastened at the caisson ends.

10-3.7.4 Inclination Test.

Inclination tests are used to determine the stability of a caisson under light conditions. The tests are on a caisson equipped and ready for operation, by moving known weights off center and recording the resulting caisson inclination angles. Angles are indicated by plumb bob pendulums, and obtained at light drafts only. Occasionally, a change in the amount of permanent ballast may be necessary because of such tests.

10-3.7.5 Submergence Test.

In a submergence test the caisson ballast and trim tanks are fully flooded. This test validates the airtight and watertight integrity of the machinery deck (safety deck) and ensures that the ballast tank dip pipes are cut to the proper length. This test also ensures that the caisson can sink deep enough to be seated at mean high water, and that the caisson weather deck will be above sea level when the tanks are fully flooded.

10-4 SUPPORTING FACILITIES AND ACCESSORIES.

10-4.1 Crane Rails.

Provide complete crane foundations, anchor bolts, and rails for portal cranes. Rails must be factory bent to required curvatures. Thermite weld or weld rail joints in accordance with alternate methods subject to NAVFAC approval. Refer to typical installation details in UFC 4-152-01.

10-4.2 Cranes.

Dry dock cranes are usually obtained by separate contracts with firms specializing in this type of equipment. Because of size, cranes are assembled at sites by manufacturers, from prefabricated sections. Performance tests are required after assembly.

10-4.3 Railroad Tracks.

Installation of ballasted dockside railroad tracks should follow standard railroad construction practice. Other railroad tracks are supported by a dock wall or special foundations, such as piles.

10-4.4 Bollards and Bitts.

An important construction problem in the installation of accessory anchorages is that of correct positioning of anchor bolts during concrete placements. Since changing positions of embedded bolts after the concrete has set causes difficulties and expense, and is undesirable structurally, every possible precaution should be taken against disturbing such bolts during placement.

Accessories subject to corrosion must have basic corrosion resistant shop coats of paint after manufacture, with finish coats on installation prior to acceptance.

10-4.4.1 Bollards and Cleats.

Space bollards and cleats to suit classes of vessels using the docks. Bollard foundations consist of large blocks of solid concrete, which generally rest on piles or are anchored directly to dock structures or crane track foundations. Embed anchor bolts in the concrete. Set bollard castings by crane on layers of mortar placed on the concrete foundations.

10-4.5 Ladders.

Use replaceable corrosion resistant ladders, and anchor ladders with 0.75 in. (19 mm) diameter Type 316 anchors to walls. Refer to 29 CFR 1910.23 for ladder requirements.

10-4.6 Manhole Steps.

Manhole steps may be built into either concrete or brick masonry. If the spacing and stagger pattern of steps is constant, it is usually economical to fabricate special stepholding forms as reusable standard wall panels.

10-4.7 Draft Boards.

Do not install ceramic tile draft boards at the same time a concrete wall is placed, but form the concrete to allow for subsequent tile installation. Set individual tiles flush with

the wall in a bed of mortar. The gauge zero usually coincides with the elevation of the blocking 4 to 6 ft (1.2 to 1.9 m) above floor level.

10-4.8 Marking Plates.

Where marking plates already have centerlines, it is practically impossible to set them accurately at the time concrete is placed. Therefore, either form the concrete for subsequent plate installation or set plates in the placement and stamp on the centerlines afterwards.

10-4.9 Fenders and Chafing Strips.

Fenders, chafing strips, and other fittings used for protective purposes (such as timber or metal guards around stairways, floodlights, and similar items) are customarily furnished and installed by contractors. Individual guard units should be preassembled, as completely as possible, and then fastened by anchor bolts embedded in concrete. Because of exposed positions and repeated submergence, treat all timber and coat all metal with corrosion resistant material.

10-5 MECHANICAL AND ELECTRICAL EQUIPMENT.

10-5.1 Installation.

Mechanical and electrical equipment for graving docks is manufactured, and to a large extent assembled, at manufacturers' plants. Installation of such equipment may be done under the direction of manufacturer superintendents, general contractor, subcontractor, or yard forces. Installation of mechanical and electrical equipment is generally in accordance with standard building practices. Only those installation features peculiar to graving docks are considered below.

10-5.2 Capstans.

Placement of heavy capstan machinery usually should be done with truck or locomotive cranes. To maintain an even bearing, place a layer of grout between machinery foundations and concrete bases containing the anchor bolts.

10-5.3 Pumping Machinery.

Pumping machinery is usually installed by the manufacturer. Because of the complexity of running performance tests on main pumps, detailed tests are made at the factory. Usually, only one main pump is tested in sufficient detail to obtain all necessary data for plotting suitable performance curves.

10-5.3.1 Shaft Alignment.

It is extremely important to install pumps, pump motors, connecting shafts, and shaft support bearings so the shafts are correctly aligned with no unbalanced stresses imposed on the bearings.

10-5.3.2 Running Test.

After installation, perform a thorough running test on the entire pumping plant. Fire pumps should be tested in accordance with NFPA 20, Standard for the Installation of Stationary Pumps for Fire Protection.

10-5.4 Piping and Flow Control Equipment.

Piping and flow control equipment should be purchased, installed, and tested by a separate contractor under the general contractor. Valves larger than 6” should be motor operated. All motor operated valves and sluice gates should have a handwheel that allows manual operation in the event of a power failure. All valve and sluice gate manual handwheels should operate such that turning the handwheel in the clockwise direction when viewed from in front or above closes the valve or sluice gate.

10-5.4.1 Installation Practice.

Large diameter piping is supported above the floor by small concrete piers. Small diameter piping is generally hung from ceilings or walls by a variety of suitable pipe hangers or brackets. An alternate method of installing small diameter piping is to run the pipes along racks that are attached to masonry walls by expansion bolts or structural steel. In areas subject to earthquakes, the brackets and connections must be capable of resisting seismic forces.

10-5.4.2 Installation Timing.

Because of the character of mechanical or piping installation, and general lack of sufficient working space to improve efficiency, the mechanical work should be done after the structural work has been nearly completed. This phase is particularly applicable when separate contracts are let for structural and mechanical work.

B-3 DEFINITION OF TERMS.

Bilge: The curve of a ship's hull joining the side and the bottom.

Bitts: A pair of vertical wooden/iron posts mounted either aboard a ship or on a wharf, pier or quay.

Bollard: A short vertical post used on a ship or a quay for mooring.

Bulkhead: A dividing wall or barrier between compartments in a ship.

Capstan: A revolving cylinder with a vertical axis powered by a motor used to supply force to ropes and cables.

Captive Crane: A traveling crane limited to use at one facility because of the absence of track connections to other facilities.

Cavitation: The formation of cavities in a fluid flow due to low pressures attending high velocities in the fluid.

Chafing Strip: Strips of wood or other material placed on sides of waterfront structures, fittings, or vessels to protect against chafing from contact with other structures, ropes, or chains.

Cleat: A T-shaped piece of metal or wood on a pier or vessel to which ropes are attached.

Cribbing: A framework, usually of timber, designed to distribute concentrated ship loads and to provide longitudinal stability to the keel blocks.

Elastic Mat: Structural slab on ground (usually of concrete) supporting separated vertical loads. The elastic deflections of the mat are correlated with resulting nonuniform soil reaction in computing stresses in the mat and the earth pressures.

Fairlead: A fitting through which a line may be led so as to preserve or change its direction without inducing excessive friction.

Go-Devil: A tight plug in a pipe, utilized to clear a pipe of liquid or debris.

Gypsy Head: A small auxiliary drum at the side or top of a winch.

Keel: The principal bottom structural element of a ship extending along the centerline for the full length of the ship.

Mortar Intrusion Concrete: Concrete made by injecting cement or sand-cement mortar into the interstices of previously placed aggregate (it can be placed in the dry or underwater).

Skeg: Vertical projection extending below the hull of a vessel to reduce yawing.

Sonar Dome: A bulge or appendage on the keel of a ship, usually forward, for housing sonar equipment.

Stoplog: A dam consisting of a piece or pieces in slots in the sides of a waterway to shut off flow.

Trash Rack: A grille, usually of vertical metal bars, used to screen out debris from the entrance to a waterway.

Tremie Concrete: Concrete placed underwater in such a manner that there is no free drop of the concrete through the water. This can be accomplished by pouring through a pipe or placing with special bottom-dump bucket. See Tremie Pipe.

Tremie Pipe: A vertical pipe through which concrete is placed underwater. In operation, water must be expelled from the pipe (so as not to mix with the concrete) by a go-devil (see above) placed ahead of the concrete, or the pipe must be freed of water before placing concrete and kept dry by means of a special flap valve at the bottom. During concrete placing, the bottom end of the pipe is kept buried in the concrete mass being placed to prevent backflow of water into the pipe.

Weep Hole: Opening provided in a wall or bulkhead to facilitate drainage of water. It usually serves to reduce hydrostatic pressure behind the structure.

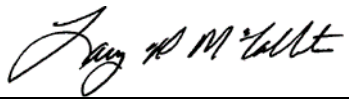
Change No.	Date	Location

This UFC supersedes UFC 4-214-03, dated JAN 2004 and TM 5-814-9, dated FEB 1992.

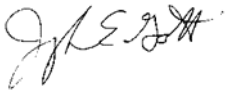
FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with USD (AT&L) Memorandum dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA.) Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.



UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Services' responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Command (NAVFAC), and Air Force \2\ Civil Engineer Center (AFCEC) /2/ are responsible for administration of the UFC system. Defense agencies should contact the preparing service for document interpretation and improvements. Technical content of UFC is the responsibility of the cognizant DoD working group. Recommended changes with supporting rationale should be sent to the respective service proponent office by the following electronic form: Criteria Change Request. The form is also accessible from the Internet sites listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:



- Whole Building Design Guide web site http://dod.wbdg.org/.

Hard copies of UFC printed from electronic media should be checked against the current electronic version prior to use to ensure that they are current.

Document: UFC 4-214-03, *Central Vehicle Wash Facility*

Superseding: TM 5-814-9

Description: This criteria is a comprehensive reference for scoping, design, and construction of vehicle wash facilities and their appurtenant structures.

Reasons for Document:

- Criteria formatting was updated to conform to UFC 1-300-01.
- Criteria was updated to include sustainable design features, namely Net-Zero water usage considerations for scoping, design, and construction.
- Criteria was updated to reflect current codes and methodology.

Impact:

- The update to this criteria will provide a path to more sustainable designs by means of water use reduction.

CHAPTER 1 INTRODUCTION

1-1 PURPOSE AND SCOPE.

This manual provides a comprehensive reference source for planning, and designing a central vehicle wash facility (CVWF) and decentralized, net zero wash facilities. The CVWF provides a rapid, economical method for washing tracked and wheeled tactical vehicles. The design elements provide for water pollution control, solid waste disposal, and conservation of manpower and water. This manual is limited to wash facilities and wastewater treatment for cleaning vehicle exteriors only; this design information does not pertain to facilities for treating wastewater from maintenance cleaning activities.

The Original Technical Manual (TM) 5-814-9 was adopted in 1992 to provide for large operational and rapid washing of tracked and wheeled tactical vehicles. The Technical Manual was converted to the current UFC 4-214-03 in 2004 utilizing the same concepts for washing tactical vehicles. The detailed requirements for washing these type vehicles are based on large lay-down areas and large quantities of water with introduction of new water as necessary. This update incorporates Chapter 8 which introduces new Net Zero design capabilities for Installations to meet the current needs for saving water and utilizing smaller lay-down areas for washing tactical vehicles. Installations are encouraged to review this alternative method of washing tactical vehicles in combination with the modernization of the type of wheeled vehicles necessary for rapid deployments. The Net Zero Concept is especially pertinent for changing climate and for smaller installations with large Reserve Components.

1-2 APPLICABILITY.

Information in this manual applies central vehicle wash facilities and decentralized, net zero wash facilities on all installations that maintain a fleet of tactical vehicles for which there is a consistent washing requirement demanding cost-effective, on- post facilities.

1-3 GENERAL BUILDING REQUIREMENTS.

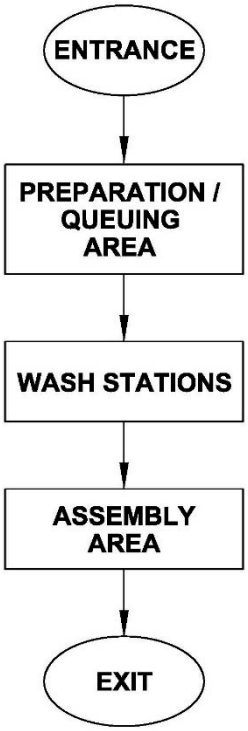
Comply with UFC 1-200-01, General Building Requirements. UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein. All applicable codes and criteria should be followed, including, but not limited to the International Building Code (IBC) and UFC 3-600-01 Fire Protection.

1-4 BACKGROUND.

The Department of Defense has unique vehicle cleaning requirements in terms of numbers, types of vehicles, washing time, and degree to which washing is critical. Civilian technologies for cleaning off-road tactical vehicles and treating the wastewater created by this washing are not recommended. However, civilian technology may apply to facilities for washing vehicles in a transportation motor pool (TMP), most of which are the wheeled, on-road type such as sedans and buses. Figure 1-1 shows the

recommended washing sequence for tactical vehicles. For installations where specific conditions require that a prewash be constructed, the washing procedure is shown in Figure 1-2. The central vehicle wash facility is designed to provide expedient, cost-effective vehicle cleaning for tactical vehicles. The concept incorporates water conservation including recycle techniques and pollution control.

Figure 1-1 Standard Sequence for Tactical Vehicles



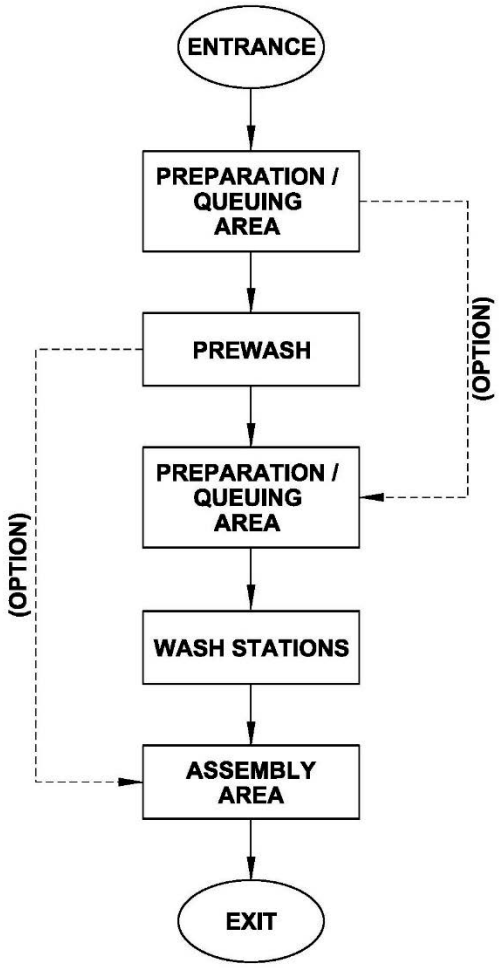


Figure 1-2 Washing Procedure with Optional Prewash

1-5 REFERENCES.

Appendix A contains a list of references used in this document. The publication date of the code or standard is not included in this document. In general, the latest available issuance of the reference is used.

1-6 GLOSSARY.

Appendix C contains acronyms, abbreviations, and terms.

CHAPTER 2 CVWF DESIGN CONCEPT

2-1 OVERVIEW.

The standard CVWF consists of a vehicle preparation area, wash stations, and vehicle assembly area Figure 2-1 Standard Central Vehicle Wash Facility Plan. However, the layout of a facility will be site-specific, based on the installation's mission and needs. Information on siting and master planning is found in Chapter 3. A design example is provided in Appendix B.

2-2 PREWASH (OPTIONAL).

At installations with heavy soiling conditions, high demands for washing, and/or limited washing times, a prewash system is recommended. There are several options for prewash systems which have been constructed for use in tactical vehicle washing: bath, air spray, water spray stand, and automatic washer. The vehicle bath is the most effective prewash system for tactical vehicles. Figure 2-2 shows a typical CVWF plan with the CONUS approved bath prewash system for tactical vehicles. Commercial type, such as those in a TMP, would utilize commercial automatic washers and not facilities described for the CVWF.

2-3 WASTEWATER TREATMENT.

A system for conveying and treating wastewater is included in the CVWF design, since water used to wash the vehicles will become contaminated with dirt, debris, and products related to vehicle operation such as oil, fuels, hydraulic fluid, and grease. All wastewater must receive primary treatment to remove settleable and floating materials. Following primary treatment, the wastewater is either released to a collection system or further treated onsite and stored for reuse during future washing operations. The water used to wash vehicles should be recycled whenever possible and feasible. However, even in a total recycle system, some of the wastewater may need to be released to a discharge system before or after receiving secondary treatment. This discharge is done to ensure that water quality and water balance are maintained. Measured makeup water is added to the recycle system to compensate for the volume of water carried off on the wet vehicles, released, and loss due to evaporation.

2-3.1 Primary Treatment.

All wastewater must receive primary treatment. A sediment basin that provides primary treatment is required to allow most of the suspended solids to settle and to allow the free grease, oils, and other pollutants to separate from the wastewater.

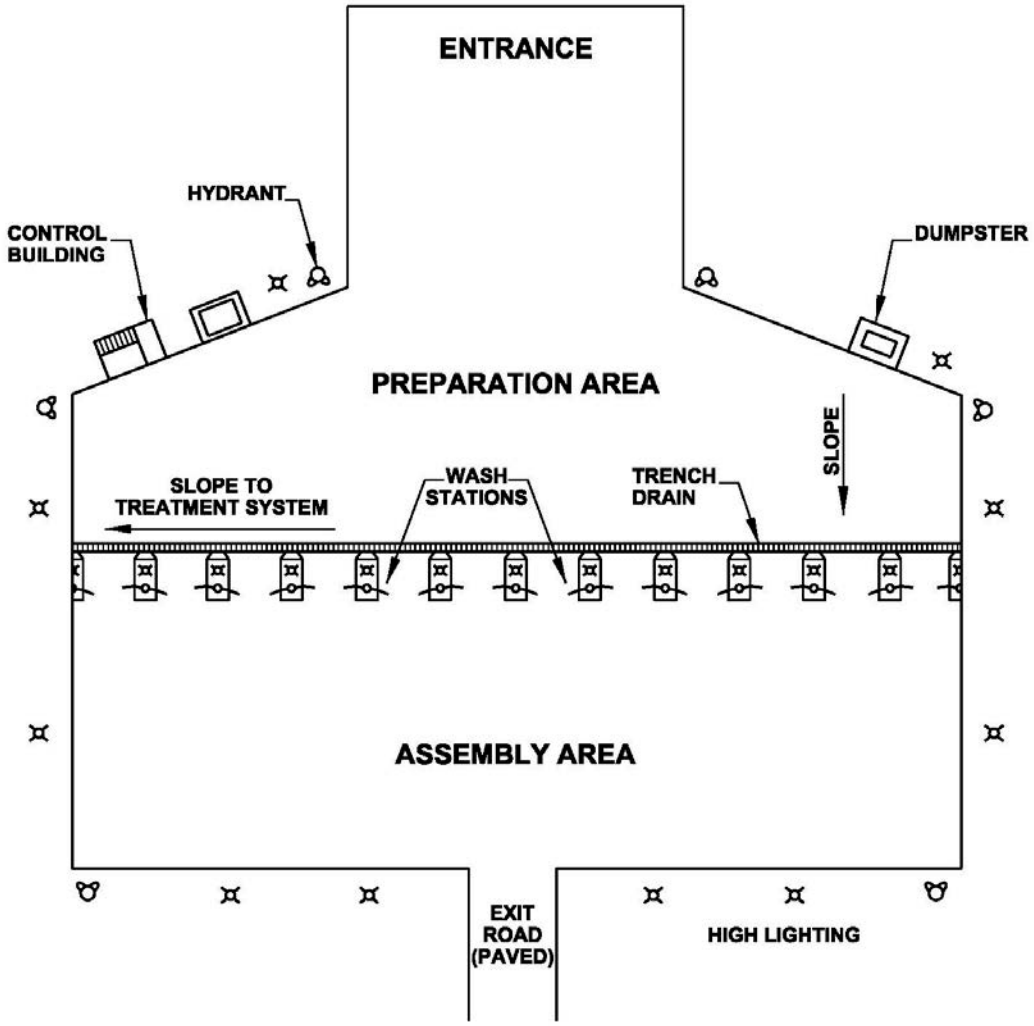
2-3.2 Secondary Treatment.

For the purposes of this manual, secondary treatment refers to intermittent sand filters, lagoons, or discharges to sanitary sewage systems. Two systems of onsite secondary treatment are used following primary treatment if the water is to be recycled. These methods include intermittent sand filters and lagoons. Lagoons are not the standard system but are included because they have been used as a wastewater treatment

method for CVWFs. Lagoons are not allowed in certain states for secondary treatment. Consult with state regulations. The third system of handling wastewater, discharge to sanitary sewer, may be available at an installation, but this method is not used in conjunction with a recycle system.

For Air Force projects, before discharging to an existing sanitary or stormwater system approval by the base or regional environmental section must be granted prior to discharge

2-3.2.1 Intermittent Sand Filter.



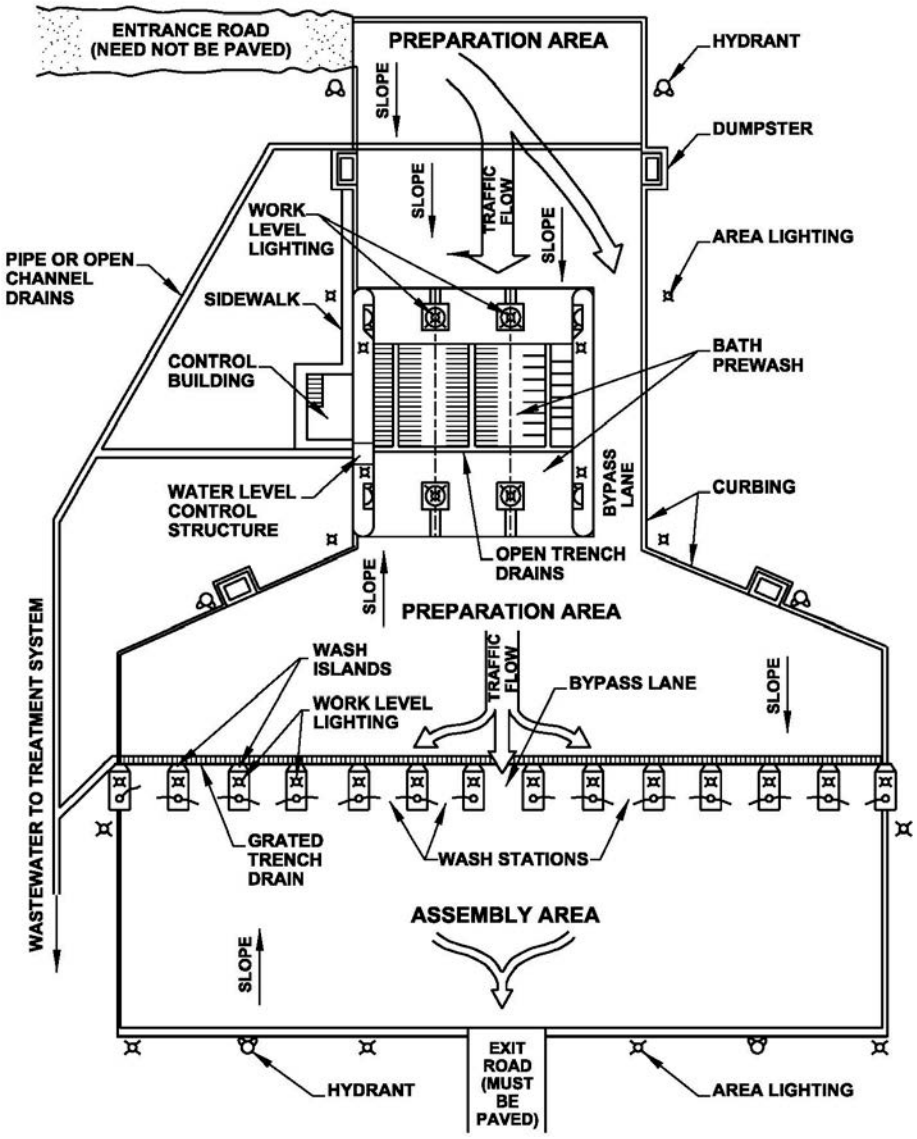
This secondary treatment system is comprised of an equalization basin and an intermittent sand filter. The equalization basin holds the wastewater after primary treatment and before it is applied to the filters to equalize flow rates by dampening the high and low- flow variations.

- A dosing tank may be provided after the flow equalization basin to provide a water volume of one charge or dose to a portion of the sand filter. The dosing tank is a designer's option which allows for flexibility in sizing the pumping facilities. The sand filter shall not be dosed more than 2 hours in any 8 hour period.
- Water quality testing and metering capabilities are recommended to be provided at a point following the intermittent sand filters to measure the quality and amount of the treated wastewater to be recycled. At this point, facilities should be provided which allow recirculating all or a portion of the filtered water back though filters via the equalization basin. The remaining filtered water flows into the water supply basin and is stored for reuse.
- Water overflow facilities to provide hydraulic protection for the secondary treatment process should be located at the water supply basin for emergency storm release. This overflow system should also be able to make controlled partial wastewater releases to further assist in maintaining the quality and quantity of the recycled water. Hydraulic protection should also be provided at the equalization basin as a backup. Chapter 6 presents details of the sand filter treatment system.

2-3.2.2 Lagoon System.

This secondary treatment system consists of a basin or a series of basins where the wastewater is held for an extended period of time to achieve the desired water quality. The treated water is allowed to flow to the water supply basin for reuse. Water quality testing and metering capabilities are recommended to be provided, as well as overflow protection. Chapter 6 explains the lagoon treatment system in greater detail.

Figure 2-1 Standard Central Vehicle Wash Facility Plan



2-3.2.3 Discharge System.

If a recycle treatment system is not economically or technically feasible and/or operationally practical, and if was water supply is available, wastewater from the CVWF may be discharged to a sanitary sewer system or some other conveyance for further treatment elsewhere. Primary treatment is the minimum level of treatment required to ensure that the wastewater discharged into a system is of a quality acceptable to the receiving authority. Quality, however, may not be the only criterion. The rate of discharge may also be a limiting factor, thus requiring an equalization basin prior to the point of release to the discharge system. The discharge type treatment system is discussed in detail in Chapter 6.

For Air Force projects, before discharging into an existing sanitary or stormwater system approval by the base or regional environmental section must be granted prior to discharge.

Figure 2-2 Central Vehicle Wash Facility Plan with Bath Prewash

2-3.3 Water Supply Basin.

After secondary treatment in a recycle system, the water is discharged to a water supply basin for reuse in the CVWF. In a system without recycling, the water supply basin is optional. If a reliable, consistent source of water is not available, a water supply basin may have to be constructed in a size large enough to hold the wash water volume required. This basin can be filled from the water source at a slower rate during nonpeak hours for the high demand required during the washing operations. The design must protect the water source through the use of air breaks or equipment to prevent backflow and back siphonage. In addition, makeup water that enters the water supply should be metered.

CHAPTER 3 MASTER PLANNING

3-1 SIZING.

3-1.1 User Input.

The wash facility must be designed to meet the user's needs. The design will determine the type, size, and configuration of the wash facility and treatment system based on information supplied by the installation. Proper initial planning will result in the best final design. The planner will have to assemble data from many sources and use judgment in applying this data to the guidelines provided for sizing the facility components. Where data is not available, estimates must be made.

3-1.1.1 Military Missions Data.

The wash facility must support the particular needs of the installation. Troop types, their vehicle types, and their training program, both current and future, must be considered. This includes resident troops as well as transient troops. The combination of numbers of vehicles, types of vehicles, and frequency of washing will determine the type and size wash facility required. A complete list of each military unit which will use the facility is required, along with its vehicular complement and the expected frequency each vehicle would be washed.

3-1.1.2 Wash Frequency Data.

Certain components of the wash facility will be sized based on long term or average numbers of vehicles washed. Other components are sized on short term or peak use numbers. In both cases, the mix of vehicle types is an important consideration.

- The average use of the facility should be provided by the user broken down as weekly or biweekly, monthly, and annually. Seasonal variations must also be a consideration. Where training programs are impacted by seasonal weather or where large numbers of transient units in a particular part of the year impact expected use, the average weekly or monthly numbers would not be a fixed ratio of the average annual numbers. Monthly average should be the average of the six highest use months; weekly should be the average of the ten highest use weeks.
- The peak use of the facility should be provided by the user as the largest number of vehicles to be washed in a continuous short term period. If night washing is to be designed for, the peak use may, for example, be a continuous three day (72 hour) period. The peak use will represent full utilization of the wash facility components for the chosen time period. The planner must consider the length of time it will take for all the vehicles scheduled to wash in this peak exercise to return to the cantonment area after training. The rate of movement of these vehicles will help determine the time period to allow for in the peak use operation. Ideally the CVWF would accommodate all units as they arrived, without excessive backup, and at a continuous full

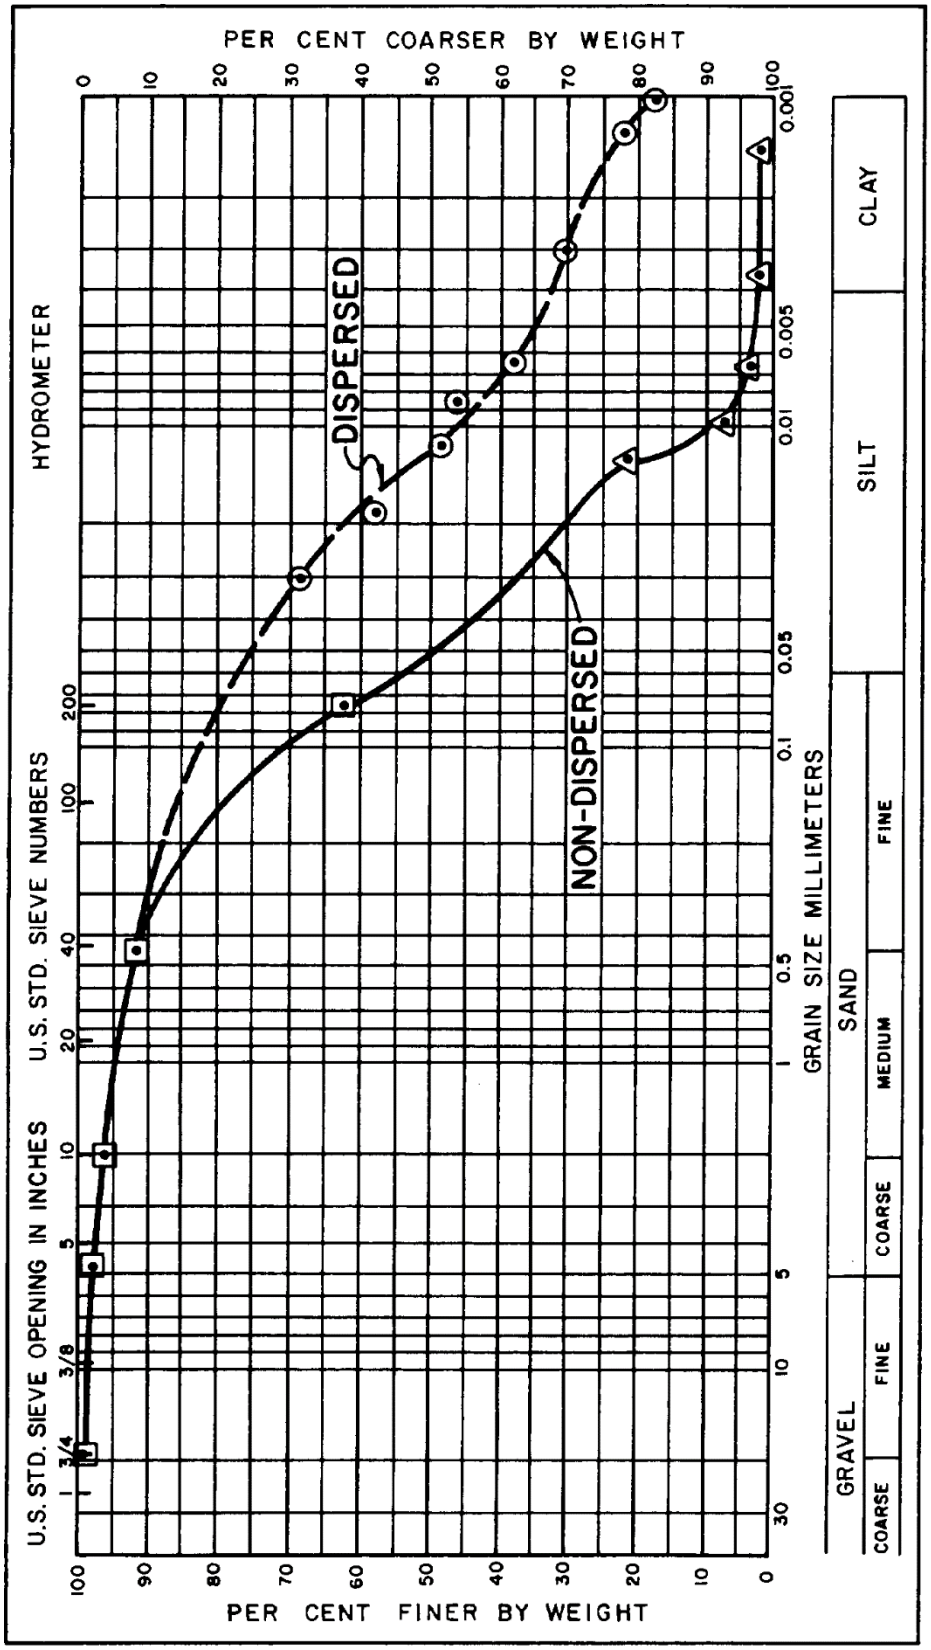
utilization of the washing components. It is important that the planner consider the frequency of the defined peak use; in some cases, a large-scale facility may not be justified based on the low frequency of this peak activity. The peak use should be a condition expected to occur at least three times per year.

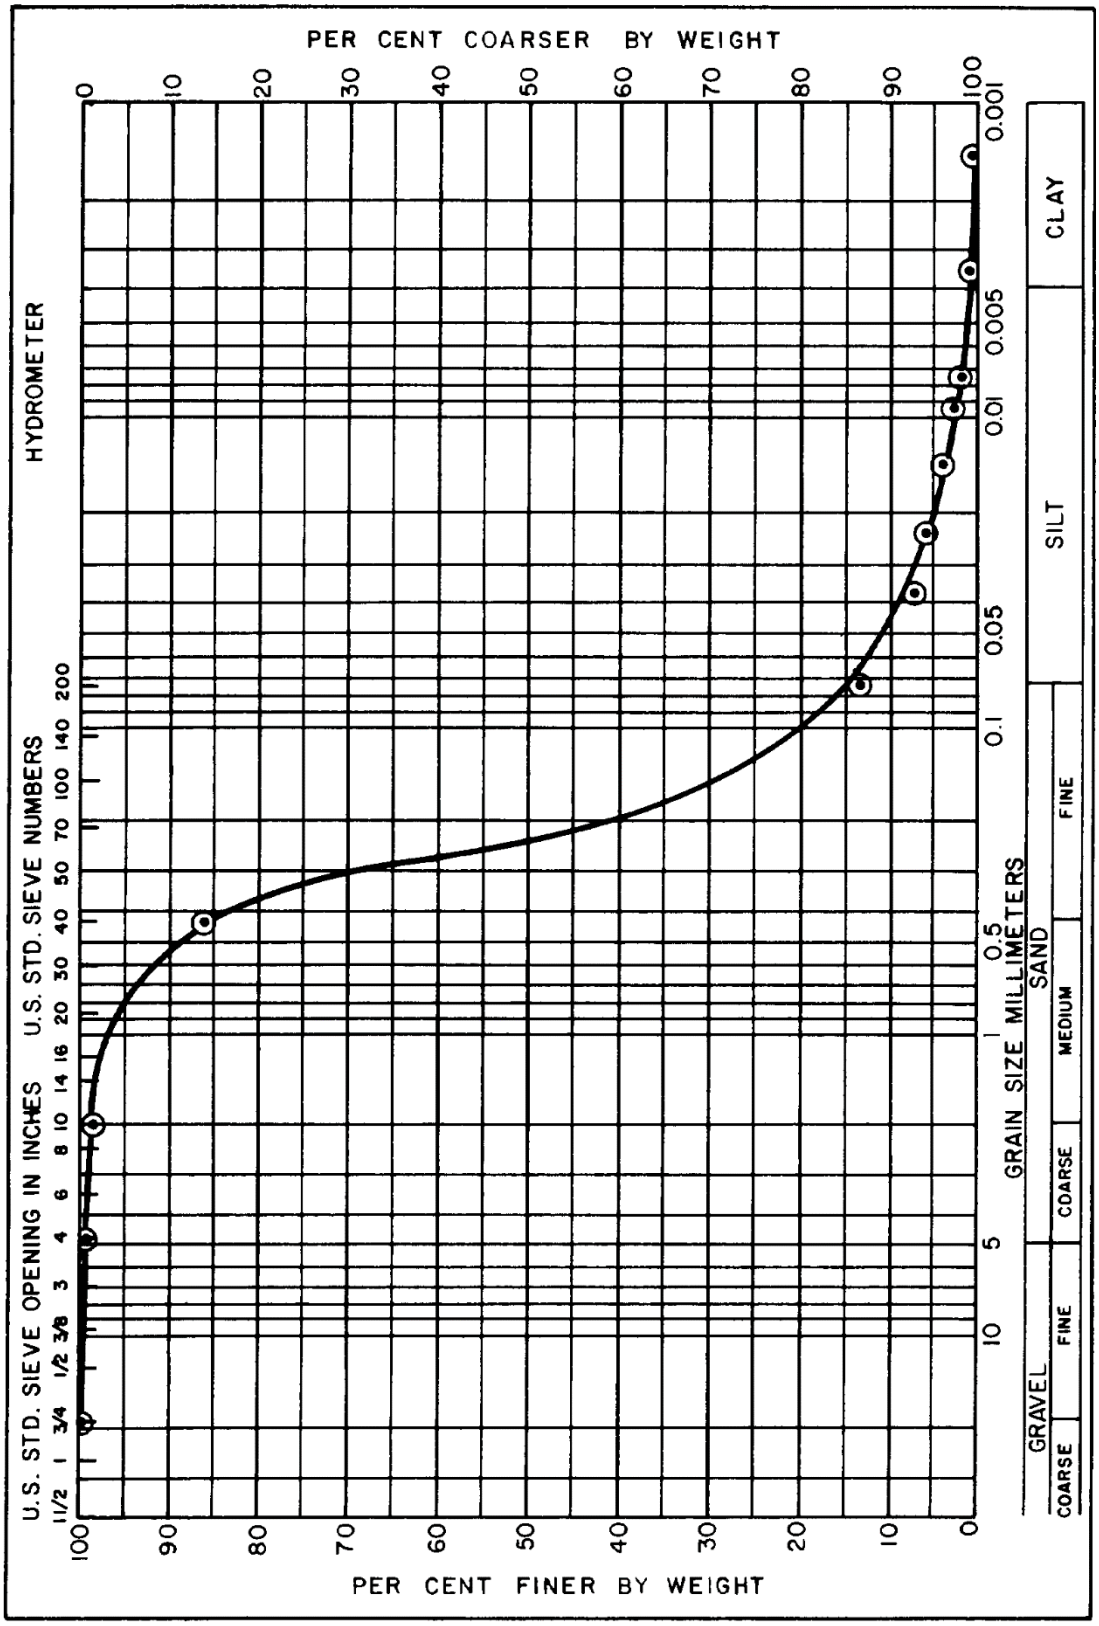
3-1.1.3 Vehicle Soiling Data.

The types of soil found in the training ranges along with weather conditions are predictors for the amount of dirt which will have be able to washed off of the vehicles. This will affect the type of washing components, the time required for washing, the amount of water used and the waste- water treatment components.

- A characterization of the soils is needed. A study of the installation maps showing soil types throughout the total training areas should be made to determine if sands, clays, or combinations of soils occur. Samples of Soils should be taken from the range areas, as well as samples taken directly from dirty vehicles returning to the cantonment area after a heavy rain. Separate samples should be collected for each identifiable soil type (3 to 5 gallons each) and analyzed in a soils laboratory. The laboratory should prepare a standard gradation curve of grain size distribution showing gravel, sand, silt, and clay utilizing both a mechanical analysis and a hydrometer analysis down to 0.001 mm diameter. Both a dispersed and a non- dispersed hydrometer analysis need to be performed. The dispersed, which breaks the particles into individual grains, is used for standard classification. This will be used to categorize the soiling expected on the vehicles. The dispersed, which assesses the agglomerated particles, is used in the treatment analysis (chap 6), since the washing operation does not totally disperse the soil. Figure 3-1 shows an example of a cohesive (silty clay) soil gradation curve both dispersed and dispersed. Figure 3-2 shows an example of a noncohesive (sandy) soil.

Figure 3-1 Cohesive Soil Gradation Curve





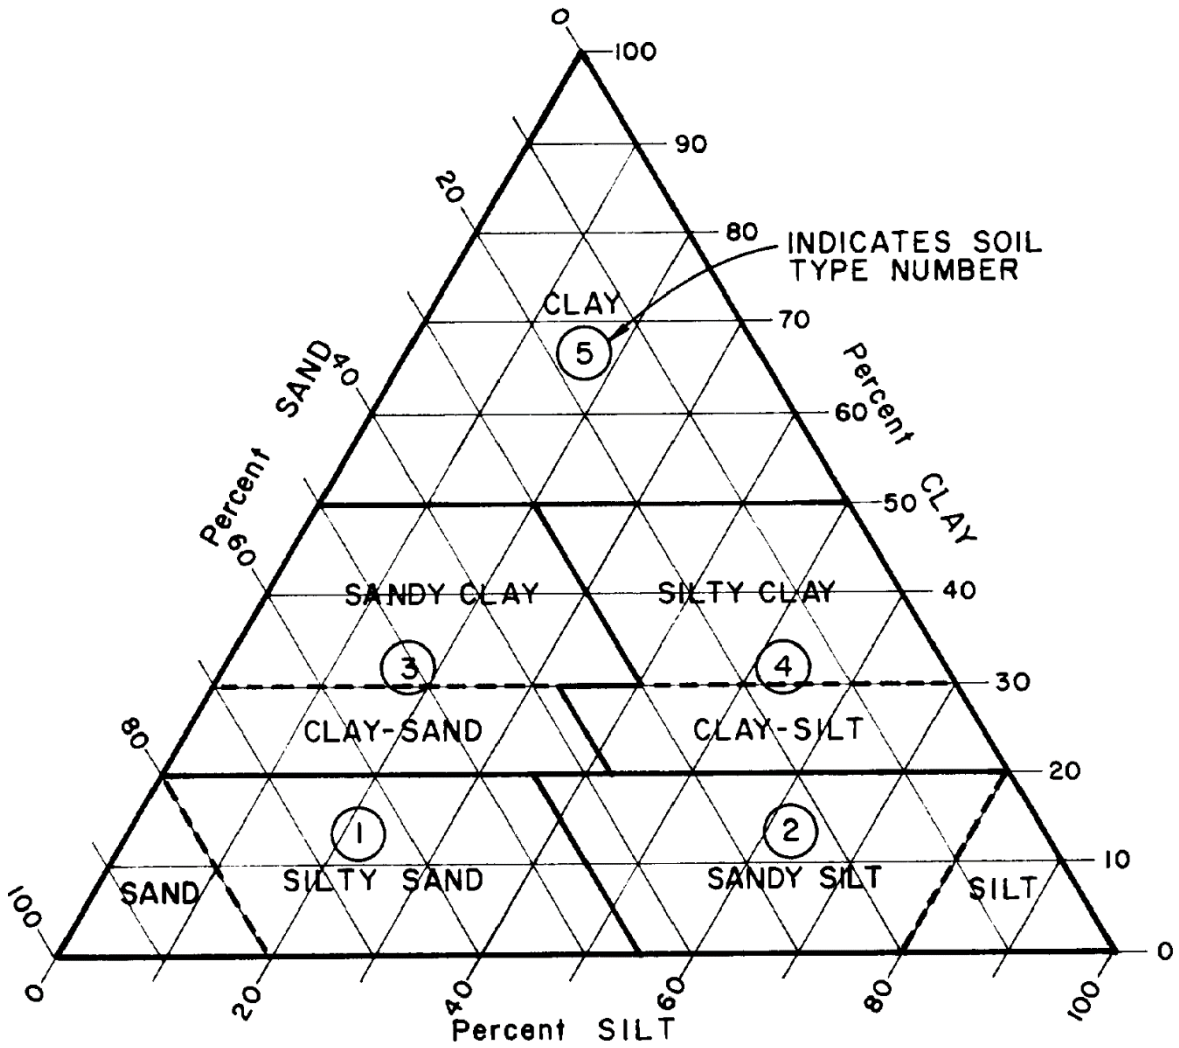


Figure 3-2 Noncohesive Soil Gradation Curve

- A classification of the soils expected to be on the vehicles is needed. By taking the particle size curve previously discussed and plotting the percentage of sand, silt, and clay (dispersed) on a triangular classification chart shown on Figure 3-3, a combined classification can be made. As a indicator of soiling potential expected on the vehicles, the chart is divided into 5 categories or soil type numbers (S_t). The sands and silty sands are given a type number of 1, being the likely to soil a vehicle and being the easiest to clean. The clays are given a type number of 5, being the most likely to soil a vehicle and being the hardest to clean. There a particular analysis may plot on the chart close to the line between two types, interpolation should be applied (i.e. a soil could be given a type number of 2.5). Where different soils occur in the training ranges, an average of those found may be used. The designer should use judgment when making this determination and give due consideration to the extreme adverse effects caused by high clay content soils.

Figure 3-3 Soil Classification and Soil Type Number Diagram

- Actual soiling of vehicles is a function of both soil type and the amount of rain or wet conditions expecting in the training areas. Therefore, climatic data must be provided in order to fully assess the potential for vehicle soiling. Arid regions would have minimum soiling potential where rainy regions would have maximum soiling potential. By assigning a climatic factor (Fc) to the area, ranging from 1 being arid to 2 being very rainy or wet, and multiplying this by the soil type number, a soiling index can be obtained for the installation. This is given by Equation 3.1.

$$\mathrm{Si} = \mathrm{St} * \mathrm{Fc} \qquad \text{(eq. 3-1)}$$

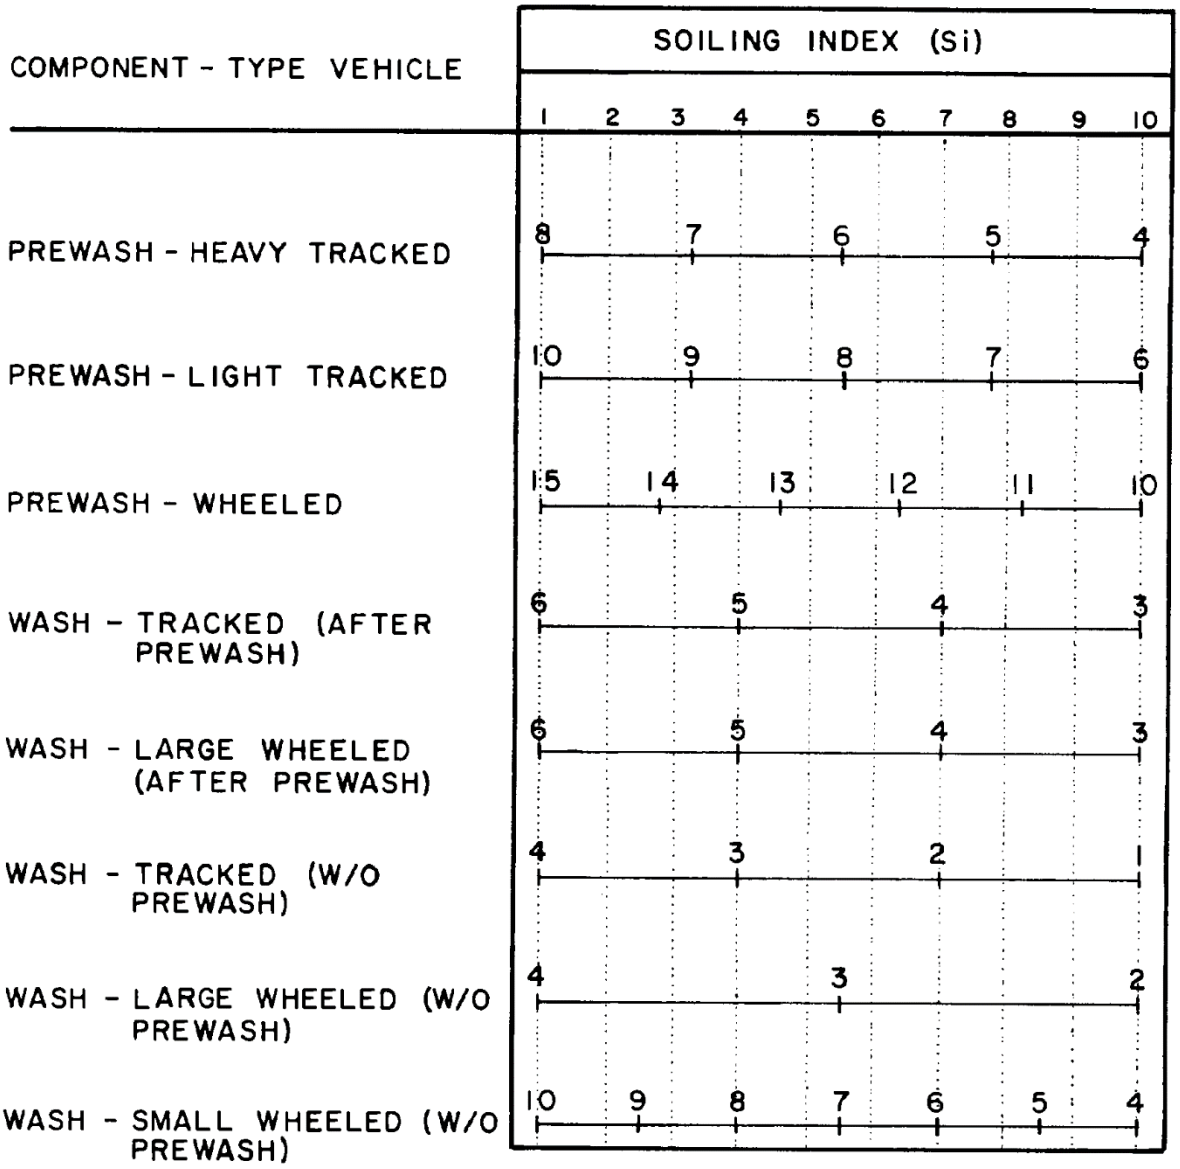
  The soiling index will be used to predict times and determine the need for prewash.

3-1.1.4 Climatic Data.

As previously stated, climatic data at the installation is necessary. In addition to amount of rain, seasonal variations in moisture and temperature are needed. Areas with long periods of freezing weather will require special design considerations to protect wash components, pumps, and piping. Most of the wash components, particularly the prewash, may not be feasible to operate near freezing conditions because of the safety hazard caused by overspray freezing on the pavement. Enclosed facilities may be warranted, however, they are very expensive from both a capital and operations standpoint. Another climatic consideration in the design is the evaporation rate in the region. In an area with high evaporative losses and low rainfall, certain features of the CVWF may not be practical. For example, a spray stand creates large water losses due to overspray. Use of any prewash system increases the volume required in the treatment system, with the higher water volume, the surface area of the basins must be increased (particularly a lagoon treatment), which promotes evaporative losses even more. The designer must evaluate the potential evaporative loss as it affects the need for make-up water and weigh this against the benefits of either a recycle system or a discharge system.

3-1.2 Prewash.

A prewash is used to reduce the time needed to wash vehicles, since it removes the bulk of the dirt in a timely, efficient way. Its function is to reduce the amount of time each vehicle must spend at the wash stations.



3-1.2.1 Bath Prewash.

A bath prewash is currently the most efficient and effective method to remove dirt from the exteriors of tactical vehicles. A large volume of water is required to fill the bath, but because of the reduced wash time required, the overall water volume required for cleaning a large number of vehicles may be reduced. Lanes specifically designed for washing tracked vehicles can be provided; lanes which can accommodate both tracked and wheeled vehicles (referred to as dual purpose lanes) can also be provided. These are described further in Chapter 5. Wheeled vehicles under 2.5 tons would not normally use the prewash bath.

3-1.2.1.1 Process Rate.

In a tracked bath lane, six to ten tracked vehicles per hour can be washed. In a dual-purpose lane, ten to fifteen wheeled vehicles per hour can be washed. The amount of soiling will determine the actual number of vehicles that can be processed through the facility; the heavier the soiling, the slower the vehicles can be processed. By using the Soiling Index (Si) in conjunction with the processing rate chart shown on Figure 3-4, the throughput rate can be determined for a particular design.

Figure 3-4 Vehicle Processing Rates (Vehicles per Hour)

- The number of lanes for the prewash will depend on two factors: The maximum number of vehicles that must be washed at the facility in a time specified by the installation (peak wash period) and the expected process rate through the facility. Equations 3-2 and 3-3 will help the designer determine the number of each type of lane needed for the prewash

system. The installation's requirements will dictate how the result should be treated. If the maximum washing time is critical, the number should be rounded up, otherwise, the number of lanes should be rounded to the nearest whole number.

$$\text{No. of tracked Lanes} = \frac{\text{Max.No.Tracked Vehicles to be Washed}}{\text{Process Rate} * \text{Peak Washing Period}} \quad \text{(eq. 3-2)}$$

- In equation 3-3, only the tracked and wheeled vehicles expected to use the dual-purpose lane should be considered in the equation. The number of tracked vehicles using the lane should not be included, since they will not be washed twice in the prewash.

$$\text{No. Dual Purpose Lanes} = \frac{1}{\text{Peak Wash Period}} * \frac{\text{No.Tracked}}{\text{Process Rate}} * \frac{\text{No.Wheeled}}{\text{Process Rate}} \quad \text{(eq. 3-3)}$$

3-1.2.1.2 Equation Example.

An example will better explain how to use the equations. Consider an installation that needs to wash 42 heavy tracked vehicles, 88 light tracked vehicles, and 125 wheeled vehicles in the prewash during peak use. The installation requires that all of the vehicles be washed in 9 hours. Soils at the installation are extremely cohesive clays, so the process rates through the prewash are expected to be slow. The designer had determined that the soiling index (Si) is 8 and from the chart (Figure 3-4 estimates that five heavy tracked vehicles per hour can be washed in each lane; seven light tracked vehicles per hour per lane can be washed; and eleven wheeled vehicles per hour per lane can be washed in a dual-purpose lane. For initial calculations the following will be used.

$$\frac{42 \text{ heavy tracked}}{5\frac{\text{veh}}{\text{hour}}{\text{lane}} * 9 \text{ hr}} + \frac{88 \text{ light tracked}}{7\frac{\text{veh}}{\text{hr}}{\text{lane}} * 9 \text{ hr}} = 0.93 + 1.40 = 2.33 \text{ tracked lanes}$$

$$\frac{125 \text{ wheeled vehicles}}{11\frac{\text{veh}}{\text{hr}}{\text{lane}} * 9 \text{ hr}} = 1.26 \text{ dual pupose lanes}$$

- The designer realizes that, with three tracked vehicle lanes one dual-purpose lane, the tracked vehicles will be washed in less than 9 hours, but the wheeled vehicles will require more than 9 hours. To achieve a more even distribution of vehicle washing, the designer recalculates the number of lanes needed by assuming that some of the light tracked vehicles will use the dual-purpose lanes. The designer adjusts the process rate for the light tracked vehicles in a dual-purpose lane. It will take longer to process a tracked vehicle in dual-purpose lane than in a tracked lane, since the flexors in a dual-purpose lane are not as effective as those in a tracked lane at removing the embedded soil from the tracks.

$$\frac{42 \text{ heavy tracked}}{5\frac{\text{veh}}{\frac{\text{hour}}{\text{lane}}} * 9 \text{ hr}} + \frac{65 \text{ light tracked}}{7\frac{\text{veh}}{\frac{\text{hr}}{\text{lane}}} * 9 \text{ hr}} = 0.93 + 1.03 = 1.96 \text{ tracked lanes}$$

$$\frac{125 \text{ heavy tracked}}{11\frac{\text{veh}}{\frac{\text{hour}}{\text{lane}}} * 9 \text{ hr}} + \frac{23 \text{ light tracked}}{5\frac{\text{veh}}{\frac{\text{hr}}{\text{lane}}} * 9 \text{ hr}} = 1.26 + 0.5 = 1.76 \text{ dual purpose lanes}$$

- Two tracked vehicle lanes and two dual-purpose lanes would offer a more efficient use of the bath than would the results given by the first calculations.

3-1.2.2 Automatic Washers.

The types and number of vehicles in the motor pool must be considered in sizing the automatic wash area. Administrative-type vehicles in a TMP usually return one at a time and are washed as they return. Thus, large numbers of units will not be waiting to be washed in a limited amount of time as is the case with tactical vehicles at CVWFs. Civilians usually are employed to do the washing at TMP wash facilities; therefore, all of the daily washing normally will occur during an 8-hour period during daylight. A one-or-two position automatic prewash unit may be all that is required. Again, the number of vehicles per cycle and average time of washing are used to determine the size of the prewash unit.

3-1.3 Wash Stations.

Before sizing the facility, with or without a prewash, the designer must have a clear understanding of the installation's washing requirements. The number of stations needed at the wash facility will depend on whether a prewash system is provided. A prewash will lessen the time that these vehicles must spend at the wash stations, thus reducing the number of stations needed

3-1.3.1 Sizing with a Prewash.

Sizing with a prewash. When a bath prewash is provided, the number of wash stations should be between two and five per tracked vehicle bath lane. A process rate of 3 to 6 vehicles per hour at each wash station can be expected after the vehicles have been washed in the bath. Since all vehicles will not go through the prewash bath, calculations of lanes must account for longer wash times for these vehicles. A process rate of 2 to 4 vehicles per hour for large, odd shaped, or tandem units can be expected. A process rate of 4 to 10 vehicles per hour for small wheeled vehicles such as jeeps or ½ tons can be expected. Installations with a limited washing time or a large percentage of wheeled vehicles to wash will require more wash stations. In any case, the number of stations can be calculated using the processing rates for each type of vehicle and its type of wash, as shown on Figure 3-4, and following the same logical steps used to size the prewash.

3-1.3.2 Sizing without a Prewash.

If no prewash is provided, the planner predicts the number of wash stations needed based on soiling conditions and process rates.

- The process rate for vehicles at the wash stations will depend on several factors, but usually will be between 1 and 10 vehicles per hour. This range is given to allow an adjustment for the vehicle types and soiling index at the site. Installations that have vehicles soiled with large amounts of cohesive soils (clays) will have slower processing rates than those with only noncohesive soils (sand) or dust on the vehicles. By using the Soiling Index (Si) in conjunction with the processing rate chart shown on Figure 3-4, the throughput can be determined for each vehicle type. The mission of the installation also will affect the rate. At some installations, vehicles may return to the motor pool immediately for inspection. In this case, the processing rate will be slower than if the vehicle were not being inspected, since the troops will most likely perform a detailed washing. Less time will be taken to clean the vehicles if they will be returned directly to the field for further training.
- The number of tracked and wheeled vehicles to be washed is used in equation 3-4 to estimate the number of wash stations needed at the facility:

$$\text{No. Stations} = \frac{1}{\text{Max. Wash Period}} * \frac{\text{No. tracked}}{\text{Tracked Process Rate}}$$

$$+ \frac{\text{No. Wheeled (Lg.)}}{\text{Lg. Wheeled Process Rate}} + \frac{\text{No. Wheeled (Sm.)}}{\text{Sm. Wheeled Process Rate}}$$

(eq. 3-4)

The user's requirements will determine how this number should be rounded. If the maximum washing time is critical, the number should be rounded up; otherwise, it should be rounded to the nearest whole number.

3-2 SITING.

3-2.1 Geography.

All future development and land uses at the installation must be considered when siting a CVWF. These future plans must not adversely affect the vehicle and equipment movement inside and outside the facility. At the same time, the facility must not interfere with activities in the cantonment and training areas and vice-versa; the land uses should be compatible. Vehicle noise and movement must not interfere with family housing, hospitals, and other installation activities. If night washing is planned, it must not disrupt local activities; for example, the lighting at the facility must not disturb the surrounding area.

3-2.1.1 Space Requirements.

Planners and designers must consider overall space requirements for the facility. Large, open areas will be needed if a total recycle treatment system is to be installed. Lagoon treatment systems require even larger areas than intermittent sand filter systems. Smaller areas will suffice for partial or total discharge systems. A CVWF with eight wash stations, no prewash, and no recycle system can require 2 to 4 acres; one with 20 wash stations, 4 lane prewash, and a complete recycle treatment system can require as much as 50 acres.

3-2.1.2 Cantonment Boundary.

The wash facility should be located near the permanent cantonment boundary and between the training areas and maintenance shops/motor pools. The vehicles must be cleaned before they enter the cantonment area; otherwise, the dirt will fall onto the roads and trails within this area. Future changes in the cantonment boundary must also be considered when siting the CVWF.

3-2.1.3 Training Area.

The facility should be located as close as possible to the main tank trails, access roads from the training areas, or similar sites. The vehicles are washed as they return from the training field areas prior to entry onto cantonment roads. Future locations for training areas also must be considered with respect to the CVWF site.

3-2.1.4 Transportation Arteries.

Several routes usually enter the cantonment area from many different training areas. A CVWF usually cannot be constructed at each entry point, so new roads or tank trails may have to be built to link the primary routes from the training areas with the wash facility. To prevent the vehicles from becoming soiled immediately after washing, they must return from the wash facility to the maintenance shops/motor pools on paved roads or tank trails. If the exit from the facility is placed close to existing roads or tank trails that are paved, new construction will be kept to a minimum. The facility must also be located to minimize the distance that dirty vehicles must travel on major transportation arteries. Otherwise, the dirty vehicles will drop soil on roads over which other vehicles travel. The number of tank-trail crossings over major roads, both to and from the wash facility, must also be minimized. The entrance and exit of the wash facility should be sited to avoid adverse effects on traffic both there and in the cantonment area. The facility should not be located in congested areas such as near the main gates, major intersections, hospitals, administration offices, and other high traffic areas.

3-2.1.5 Maintenance Shops/Motor Pools.

Present and future locations for tactical maintenance shops and motor pools must be considered in siting the CVWF. The facility should be located between the training areas and the maintenance shops/motor pools. The vehicles should return from the training areas and, after washing, return to the maintenance shops/ motor pools with minimal travel on cantonment roads.

3-2.2 Weather.

The wash facility must be designed with due consideration to all local and regional weather conditions.

3-2.2.1 Temperature.

If the installation is in a region with long periods of freezing temperatures, some standard CVWF components, such as the prewash bath may not be useable since the CVWF is not intended to be operated continuously at temperatures below 40 F. In areas with seasonal or occasional freezing temperatures, special piping and plumbing fixtures must be installed at the outdoor facilities to drain the exposed pipes and keep them from freezing. South-facing slopes should be considered for construction sites to take the greatest advantage of the sun for heating during the winter months. The washing structures and treatment system still must be protected from freezing temperatures to prevent pipes and other vulnerable components from freezing and rupturing.

3-2.2.2 Winds.

The designer should consider locating the wash facility and treatment system to minimize adverse effects from wind. Wind blowing over basins increases the rate of evaporation. In addition, winds that blow over the long axis of an elongated basin can create waves that will erode the banks. Wind can be used to move surface oil toward the oil skimmer in sediment basins provided the oil skimmer is located properly. Strategically placed vegetation, structures, and fences can reduce the adverse effects of wind. However, vegetation must not interfere with pipes, trenches, pavement, liners, or other functional parts of the facility.

3-2.2.3 Precipitation.

Gently sloping ground which is elevated slightly with respect to the surrounding grounds should be chosen to ensure that stormwater can be controlled. Stormwater collected on the pavement during washing operations should be directed toward the treatment system since this water may require treatment; in addition, it can be used as makeup water for a recycle system. Curbing should be installed where the soil and pavement interface, and where it is needed to control the drainage flow and to prevent erosion. Rainwater falling on the surrounding area should be directed away from the facility unless it is to be used as a source of makeup water.

3-2.2.4 Vegetation.

The site layout should make effective use of existing vegetation to protect the buildings, personnel, and basins against wind and sunlight. Trees, shrubs, and grass should not be removed except as necessary for construction or operation. The roots hold soil in place, thus preventing sheet wash and soil deposition onto the paved surfaces and into the stormwater collection system. Moisture in the treatment basins will promote growth of vegetation such as trees and shrubs on the surfaces and along the edges of the basins. Trees and shrubs that grow very close to the filters and the basins must be

cleared because their root systems may penetrate the liners and cause leaks. Slopes for berms should be designed to allow convenient maintenance.

3-2.2.5 Fauna.

The abundance of water will promote insect and animal life in the area around the basins. Fences may have to be constructed around the basins, especially in arid regions, to prevent wildlife from entering the area to drink or bathe since their activities could damage the slopes and liners. The water also may attract burrowing animals that can damage liners and berms; their presence may, in time, increase maintenance needs.

3-2.2.6 Evaporation Rates.

The region's evaporation rate must be considered when siting and designing the facility.

3-2.2.6.1 Arid Regions.

Wash facilities in arid regions must have the wash structures and treatment system designed to minimize the effects of evaporation. Water from the pavement should be directed toward the treatment system; in this way, stormwater can be collected and used as an additional source of makeup water. In hot, arid regions, the pavement should be light-colored to reflect heat; the evaporation rate will be less when the wash water hits a cooler, lighter surface than when it hits a hotter, darker one. Another major point of evaporation is from the basins in the treatment system. A high rate of evaporation from the basins can increase the concentration of dissolved solids in the water. This higher dissolved solids content can result in spotting on vehicles after washing and increased corrosion. The exposed surface area of the basins should be minimized. The basins' depth can be increased to the upper limits to allow them to hold the required volume while reducing the exposed surface area. Wind blowing over the basins also can raise the evaporation rate. Fences and shrubs can be placed around the basins to help block winds. Vented covers also can be placed over the basins to reduce evaporation. Basin liners and the materials used for filters should be light-colored.

3-2.2.6.2 Water-Rich Regions.

In water-rich areas, provisions must be made to handle a heavy water volume. Onsite control to prevent stormwater damage to the treatment system becomes critical when heavy rainfalls are expected.

3-2.3 Geology.

3-2.3.1 Topography.

The site should have some fall if the designer is to consider using a gravity-controlled recycle wastewater treatment system. A 2 to 3 percent slope across the site is desirable, with the high side being adjacent to access roads or tank trails. If the terrain is too flat, the treatment system would require extra pumping in order to recycle the water. This requirement would increase costs for initial construction and for operation.

It is essential that the wastewater flow by gravity from the wash structures to the sediment basins. Should the wastewater be pumped before primary treatment, any oils in the water would become emulsified and thus more difficult to remove. Low-lift pumps can be used elsewhere in the facility if necessary. The entire site should be elevated with respect to the surrounding area. Slopes in the immediate area should fall away from the site to help move stormwater and cold air away from the site. It is desirable that the local topography not funnel water or strong winds toward the site.

3-2.3.2 Soils.

Soil borings must be taken at the proposed site to determine the soil types, the depth of the bedrock, and the depth of the water table. The soil should be able to support concrete, bentonite, and similar sealers that will be applied to the bottoms of basins, sand filters, and facilities such as pump houses and control buildings. Large soil particles tend to slide and shift more than small ones; therefore, in sandy areas, the walls of excavated basins will have to be built with a low-sloped angle to prevent this problem. Excavation of a basin at a site with cohesive soils may be more expensive than a site with non-cohesive soils. However, it may be more expensive to stabilize the slopes at the site with non-cohesive soils. It may also be more cost- effective to use native, cohesive soils for basin construction than other types of liners or imported soil. Bentonite liners may be difficult to seal on non-cohesive soils; later, settling and shifting of the soils may create leaks in the liner. Bentonite liners can also be damaged by hydraulic pressure from groundwater, especially when non-cohesive soils are present.

3-2.3.3 Bedrock.

The site should have deep bedrock since shallow bedrock hinders excavation. An excavation into bedrock may penetrate into fissures that are part of a subsurface water recharge network for a public water supply; this supply could become contaminated by wastewater from the facility. Excavation into bedrock also increases construction costs. If no other site is available, fill material may be used to increase the soil depth at the site. Another alternative would be to excavate material that is easy to remove down to the bedrock, then use the excavated material to build a berm around the basins. The gradient of the berm slopes must be low enough to avoid interfering with operations and maintenance (O&M) and to prevent sheet erosion of the slope.

3-2.3.4 Water Table.

The planner must know the depth of the water table at the proposed construction site. Sites near marshes, swamps, or low areas should be studied to determine if the water table will have an adverse effect on construction or O&M of the facility. The facility must be placed above the maximum height of the seasonal and permanent water tables. Areas with high water tables may require complex drainage systems, usually with high construction costs. Should the basins and filters be constructed when the water level is low and then water rises and surrounds the structures, the hydraulic pressure can damage the liners and cause leaks. Clay lenses or other impervious sub-surface features can create a high, perched water table. Excavation to repair the subsurface structures would be hindered by the high water table; it would also be expensive

because the groundwater would have to be removed from the site to allow personnel to work.

3-2.3.5 Drainage.

It is important that wastewater generated by the facility not contaminate drinking water supplies. Therefore, wastewater from the washing structures must not drain into a surface or subsurface water recharge area for a public drinking supply. Surface and shallow subsurface water should be directed away from the site unless it will be used as a source of makeup water. The area will be wet due to washing, storage, and treatment; in certain climates, ponding and uncontrolled collection of stormwater can cause discomfort to the workers (i.e., from being cold and wet) and speed the rate at which equipment wears. Sites with permeable soils allow surface waters to percolate, which prevents ponding and sheet erosion.

3-2.3.6 History.

It is important to have historical knowledge of the site. Past uses of the site may make it unsuitable; this could be from an archaeological standpoint such as old burial grounds, or from a hazardous standpoint such as old landfills or old firing ranges and impact areas.

3-2.4 Utilities.

The planner must consider all utilities required at the facility with respect to those available at the site. If some of the utilities are not available; the best alternative must be found.

3-2.4.1 Water.

The wash facility should be sited near existing water or supply lines if possible. Water meters should be installed so that the potable and recycled water can be metered.

3-2.4.1.1 Potable Water.

A potable supply must be provided as drinking water for personnel. If it is not feasible to tie the facility into the potable water system, portable equipment can be used to supply drinking water. Signs must be posted informing personnel not to drink the wash water and telling them where drinking water is available.

3-2.4.1.2 Makeup Water.

Potable water is not required for washing the vehicles; however, the water must be free of particulate matter that would interfere with pump operation and cause premature wear of the wash equipment. The water source must charge and maintain a working water level in the treatment system. A dedicated well may be used if that proves more economical than tying into the existing water lines. If the planner considers using an untreated well, the groundwater must be of an acceptable quality and must provide a consistent supply. If the area is water-rich, rain can be used as a source of makeup water. Ponds, lakes, and streams are other potential raw water supply sources for the

facility. The amount of water needed at the facility will depend on several factors: frequency washing, number of vehicles, types of vehicles, and type and size of treatment system provided. The planner must also consider the best source and method of charging a recycle treatment system initially. Once a recycle treatment facility is charged, the only demand for water will be to makeup that lost to vehicle carry-off, evaporation, and leakage.

3-2.4.2 Sanitary.

The facility should be located near the sanitary sewer lines if possible. This arrangement allows the designer to tie latrines at the wash facility into the sanitary lines. Other options such as pit latrines, composting chemical toilets, or septic tanks with field lines are possible; selection will depend on local practices and preference. A location near sewer lines also allows the designer to divert all or part of the wastewater to the installation's sewer plant. If this type of discharge system is used, the planner must determine if the sewage treatment facility can handle the discharged wastewater, including the hydraulic and solids loadings created. The cost of connecting with and maintaining the sewer lines must also be considered when deciding whether to tie the facility into the sewage treatment system.

3-2.4.3 Electrical.

The electrical provisions shall comply with UFC 1-200-02 and UFC 3-501-01. The wash facility should be located near an electrical distribution source. If electrical power is not available at the site, new service must be provided. Electrical distribution will be required to serve the area lighting canopy lighting, power, security, and other appurtenances associated with these facilities.

3-2.4.3.1 Planning.

As a minimum planning should fund the electrical service to the facility as 208/120 volt, 200 amp, 3-phase, 4 wire. The designed electrical service distribution will need to be based on expected loads and available distribution. A few key items that may affect the service. What services are available nearby? What is the expected load? Will there be supporting facilities such as a canopy, observation building, and equipment building? What is the volume of water treated, recycled, and discharged; the type of washing operations; the frequency and; and the number of washing operations performed each year?

Where local utility power sources are unavailable, onsite generation may be provided to the facility in accordance with UFC 3-540-01. If known at planning the funding documents should reflect these costs. Security services and extent of these provisions needs to be determined during planning. Whether these provisions can be provided under the Construction Contract also needs to be determined at planning to insure the proper funding streams are available.

3-2.4.3.2 Electrical Power Distribution.

Exposed electrical power lines shall not span areas of vehicle movement. Proximity of personnel, continuous presence of water, and uncertain vehicle dimensions (e.g.

antennas, etc.) create an operationally hazardous environment for overhead electrical distribution. UFC 3-550-01 provides further guidance for exterior electrical power distribution requirements.

3-2.4.4 Lighting.

The lighting provisions shall comply with UFC 1-200-02 and UFC 3-530-01. The wash facility should be located near existing lighting sources if possible.

Adequate lighting should be provided if nighttime washing operations are required by the installation. For worker safety, overhead lighting is required in the areas of vehicle movement.

- Work-level lighting must be provided at the bath prewash so that users can see the vehicle areas to be cleaned. Provide lighting level of 3 foot-candles minimum, measured at pavement/grade level.
- In the wash area provide a lighting level of 5 foot-candles minimum, measured vertically, on the vehicle from end to end.
- The two types of lighting should not be additive in computing lighting intensity levels since one is a vertical projection and the other is a horizontal projection.

3-2.4.4.1 Minimum Lighting Levels.

All areas of adjacent hardstand such as assembly/staging and travel lanes should have a minimum lighting level of one foot-candle.

3-2.4.4.2 Security and National Fire Protection Association (NFPA) 101 Lighting.

Security and NFPA 101 lighting is required at entrance/exit doors of each building and other locations. A selected portion of the tower fixtures may be used as security lighting.

3-2.4.5 Telecommunications.

Telecommunication provisions shall comply with UFC 3-580-01. Telecommunication services shall be provided at the facilities. Outside Plant Provisions shall be coordinated with the local Network Enterprise Center or Communications Squadron. The extent of work shall depend on the facilities involved. As little as a telephone at a canopy to an Equipment room with Copper and/or Fiber optic cables in a control building. A few factors should be addressed in planning. The first is there an equipment building? This building will need direct digital controls and may need to report to the installation system. Is there a contact protocol requiring remote reporting by telephone or data system? Is there a security system involved and does it require reporting to another system?

It is important that aerial telecommunications services not span areas of vehicle movement. Vehicle antennae, especially on wet vehicles, and must not come into contact with this distribution as this occurrence would pose a safety hazard to the area.

Planning should account for all working clearances being addressed and the design stage has these requirements identified.

CHAPTER 4 DESIGN

4-1 VEHICLE PREPARATION AREA.

4-1.1 General.

CVWFs have two types of paved staging areas, each with different functions. These are designated as the preparation and vehicle assembly areas. Staging involves alignment of vehicles for orderly movement through the CVWF; in addition, vehicles are sorted according to type and washing requirements. Vehicles waiting and being prepared for washing are aligned for direct entry into the designated wash stations. The preparation area provides troops with a location to remove trash from vehicle interiors, plug drain holes, open bilge pump discharge lines, remove camouflage, check tiedowns, and use restroom facilities (when provided) prior to washing the vehicles.

4-1.2 Sizing.

The area and configuration requirements of the staging areas at CVWFs depend on the queuing arrangement, amount of assembly needed, and the number and types of vehicles washed.

4-1.2.1 Preparation Area.

The preparation area should allow at least one vehicle to be staged behind each wash station. Additional vehicles using the CVWF during a major washing effort are queued in a linear fashion along the CVWF entrance road and/or trails leading to the facility. The paved preparation area should be sized to accommodate a minimum of 1000 square feet (92.9 square meters) of paved area per lane. This figure includes the vehicle area and a minimum of 10 feet (3.0 meters) of pedestrian clearance in all directions between vehicles. Since vehicles are aligned in rows according to wash station lanes, the layout of the preparation area can be established based on the gross width of the facility, including vehicle wash lanes, sidewalks, and bypass lanes. The staging area configuration will vary, depending on whether the wash station is linear, skewed, or parallel.

4-1.2.2 Vehicle Assembly Area.

This area can be sized to accommodate a company of vehicles which is assembled as a group prior to exiting the CVWF for the cantonment area. If vehicles are allowed to proceed to the cantonment area individually, the vehicle assembly area requirements can be reduced or eliminated. The layout of this area is based on the gross width dimension of the wash station divided into the required area; however, the area should be designed such that no vehicles in the wash stations are slowed because of a backup of units in the assembly area.

4-1.3 Staging Area Cleanup.

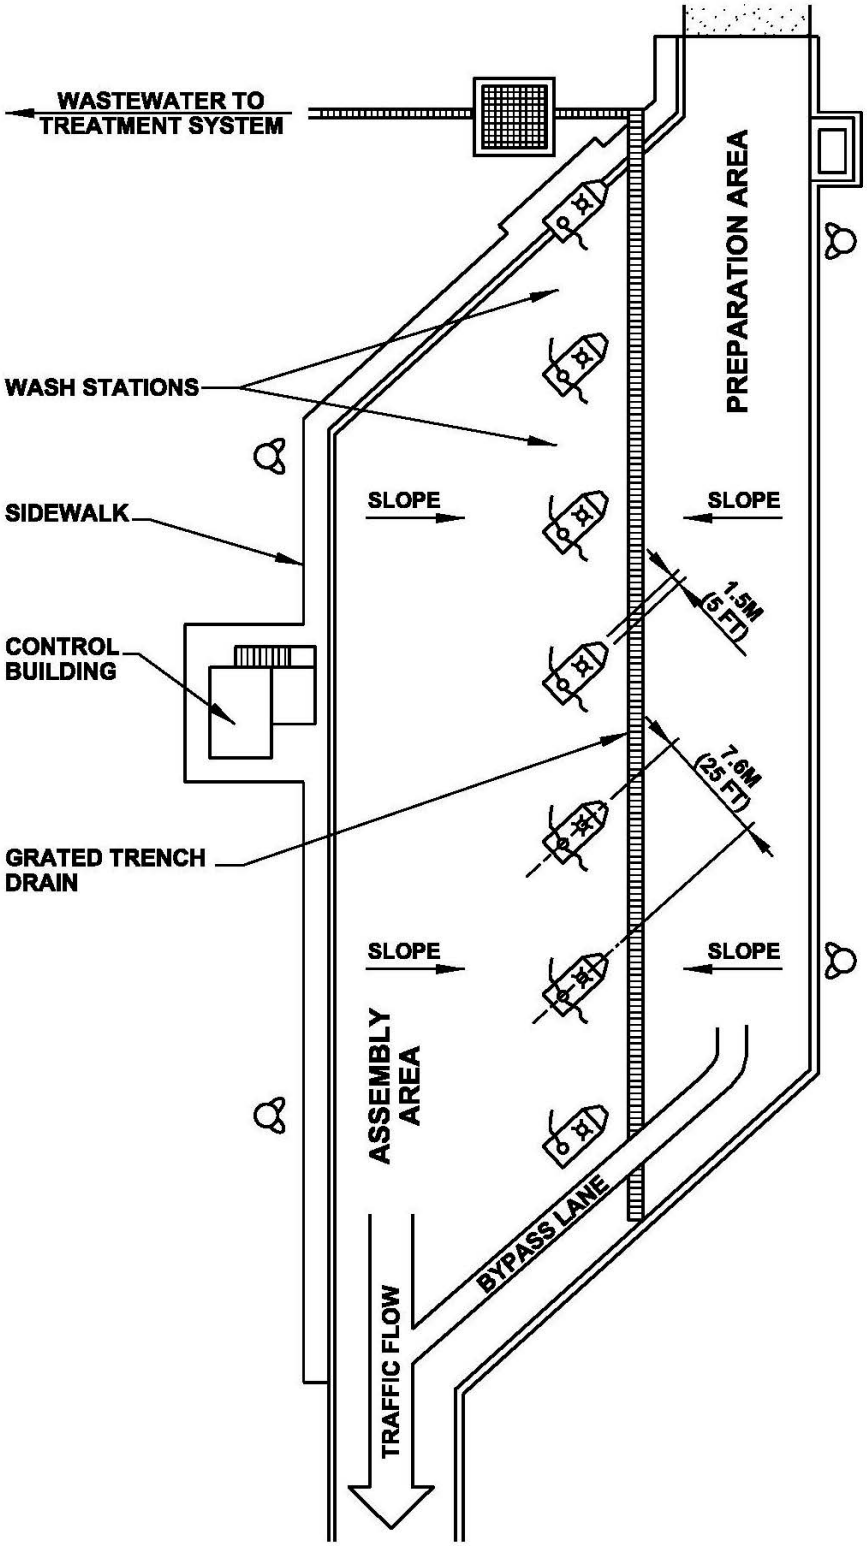
Hydrants should be provided adjacent to the vehicle preparation areas to aid in cleanup of the pavement after a washing effort. Design flow rate for these hydrants should be

25 gallons per minute (gpm) (95 liters per minute). The location of hydrants must be such as to allow hose streams to move soil from all portions of the paved area toward trench drains.

4-1.4 Drainage.

The vehicle preparation areas are sloped to drain from the edge of the pavement toward the trench drains. Trench drains may be required in the assembly areas to facilitate drainage and cleanup. Flushers are included in the trench drains to move the dirt and debris to the collection system. Vehicle preparation areas are generally not curbed; however, curbs may be used at the entrance for traffic control, at locations where vehicles might back off the pavement, or where water would otherwise run off the pavement edge and cause undermining of slab. Curbs used at tracked facilities should be designed to resist damage from tracked vehicles.

4-2 WASH STATION.



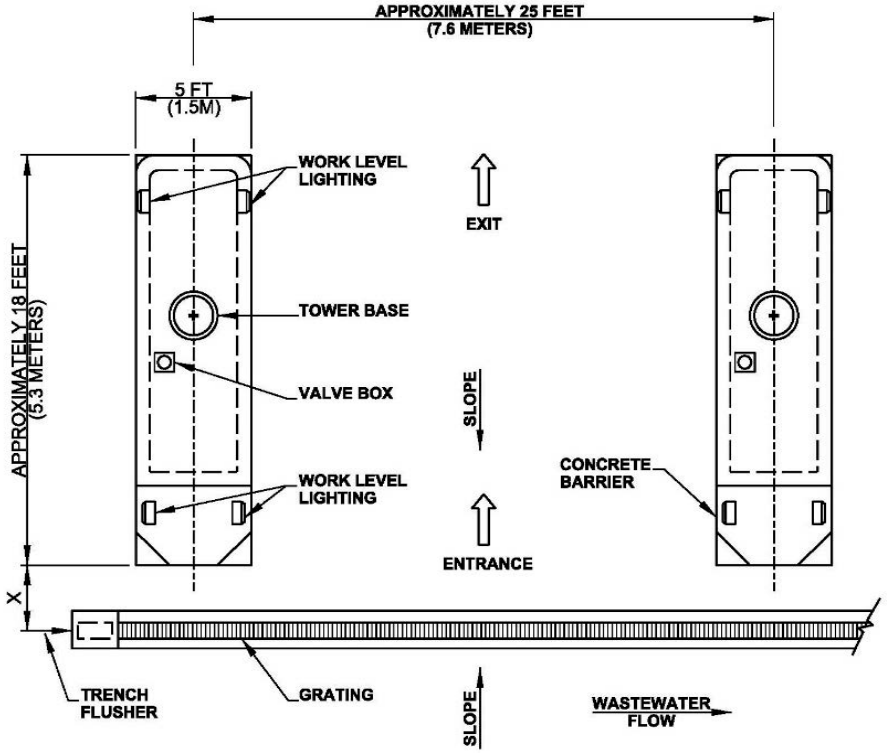
4-2.1 Function.

The wash station is the central feature of the CVWF which permits manual washing of both tracked and wheeled vehicles. The stations consist of concrete islands with towers placed on either side of the lanes. The vehicles enter the lane and stop for washing. Water hoses are hung from towers so that they do not clutter the area of vehicle movement. The stations should be designed such that two persons can use the hoses from two adjacent towers to wash a single vehicle. This design saves time by allowing both sides of a vehicle or piece of equipment to be washed at once. No solvents or detergents are used to wash vehicle at a time to pass vehicles at the facility.

4-2.2 Configuration.

The islands should be spaced in a single, straight line (as in Figure 2-1) or skewed (Figure 4-1) so that traffic lanes are parallel. This design will ensure smooth traffic flow with a minimum of turning, because vehicles move in only one direction. Vehicles waiting to be washed can queue behind those being washed. Since the vehicles always move forward, there is no hazard due to reverse travel. The islands should have a center-to-center spacing of approximately 25 feet (7.6 meters) (Figure 4-2) to allow the widest vehicle to pass easily between the islands. However, the lane width should allow only one vehicle at a time to pass through the station. If the installation will wash very long vehicles, semitrailers, or units in tow which could not be cleaned easily at a standard island, double-tower stations may be desirable. At a double-tower station, a tower is placed each end of the island. A longer island may have to be constructed to accommodate the arms of the two towers. The hose located on each arm is intended to service one-quarter of the oversized vehicle, unlike the hoses on a single-tower island at which are designed to service one-half of the vehicle. Figure 4-3 shows the layout of a double-tower station.

Figure 4-1 Skewed Wash Station Arrangement



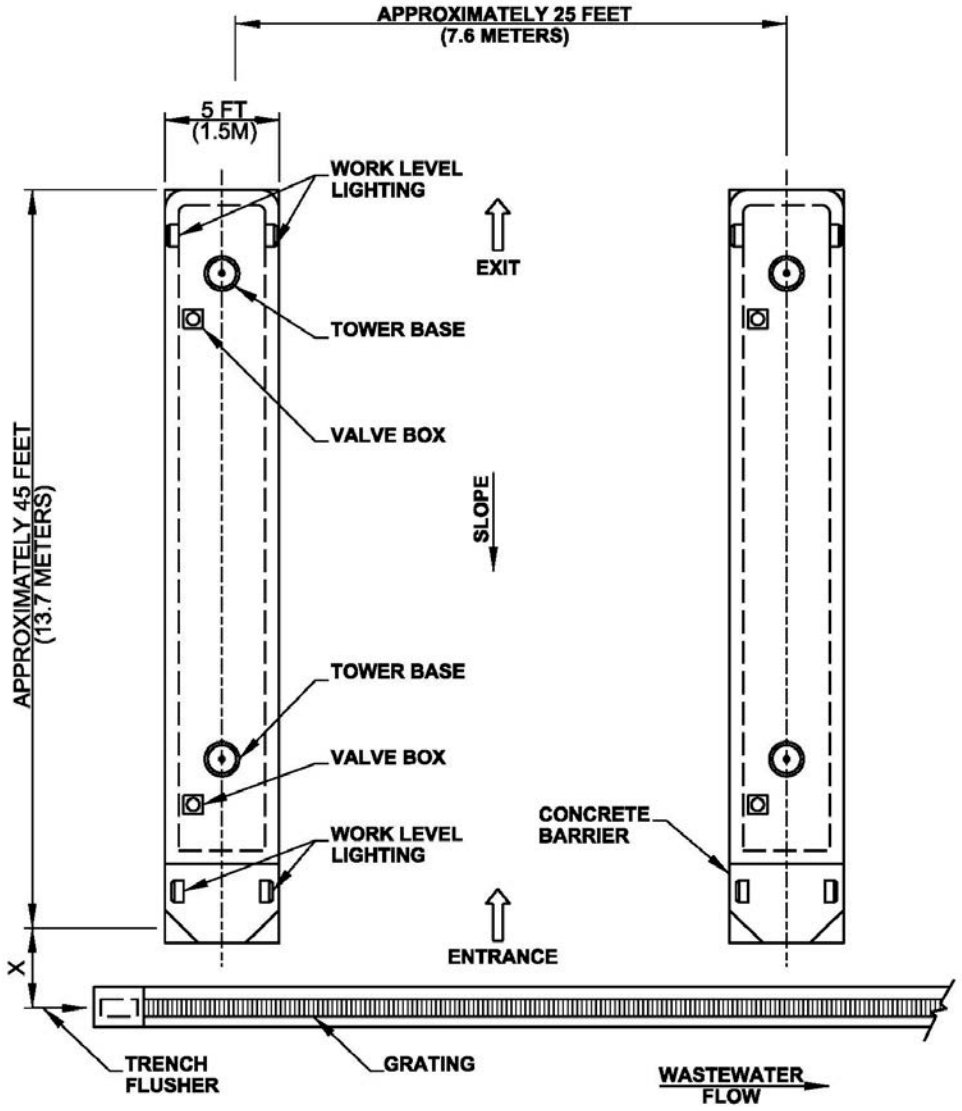
4-2.3 Island Design.

Each island should be approximately 5 feet wide (1.5 meters). Figure 4-4 shows the island in cross section. The top of the island should have a crest to prevent water from pending on the island. The surface of the island should have a broom finish to help provide traction to troops when the area becomes wet. At all wash facilities, concrete barriers should be placed on the entrance ends of each island as shown on (Figure 4-5). These barriers will protect the tower and the person working at that station against damage or injury by the vehicles.

4-2.4 Tower Design.

The tower should be constructed of standard pipe, tapered- metal signal pole or structural equivalent. The tower should support the flexible wash hose and any related lighting. Towers installed on interior wash lanes can support two wash hoses fastened horizontally above the island with swivel-type joints. The exact height of pole and length of the hoses will be site-specific, depending on the orientation of the island and the size of the vehicles to be serviced. Towers installed on outer wash islands only need one hose, since only one vehicle will be served by the island. Figure 4-6 shows the tower in cross section.

Figure 4-2 Wash Island Plan Showing Spacing



4-2.4.1 Height.

At least 15 feet (4.6 meters) clearance is needed between the pavement and the hose pivot point. If a vehicle taller than this height will be washed at the facility, a higher clearance can be used at one or more wash stations, as required.

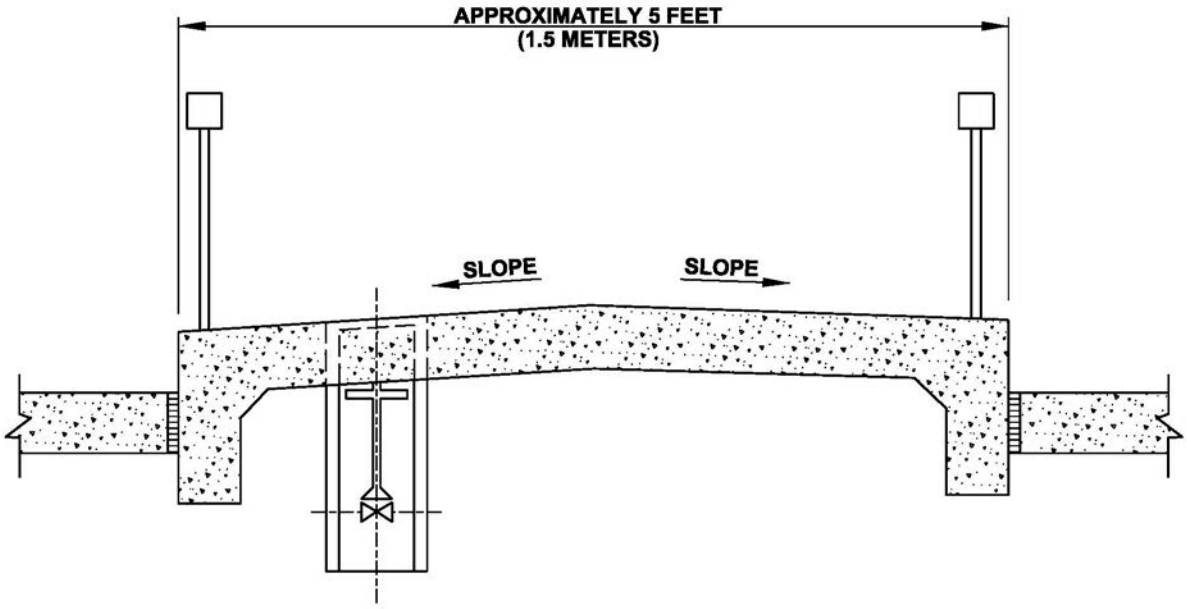
4-2.4.2 Hose Pivots.

The hose pivots support the hose and should be properly sized steel beams which support the hose and allow horizontal rotation of the hose. Cushioned stops should be installed on the towers to limit the movement of the pivot to 180 degrees in the horizontal plane. A tie rod or other form of brace should be used to stabilize the pivot in the vertical direction. A system should be included to secure the hose after use. This system shall allow for draining of all water out of the hose and keep it from being run over by the vehicles.

Figure 4-3 Double-Tower Island

4-2.4.3 Water Pressure and Flow Rates.

The recommended design pressure is 75 pounds per square inch (psi) (5.2 atm.). The water pressure is measured at the nozzle. The recommended design flow rate is 25 gallons per minute (95 liters per minute). Pressures and flow rates are given here to facilitate pump selection. Control should be provided to limit maximum pressures at the nozzle to 90 psi. Valving must be installed to allow each island to be isolated from the water supply. Manually operated valves are required to allow troops to control flow from each hose on the island.



4-2.4.4 Hoses.

The hoses to be specified at the vehicle wash stations are made of reinforced rubber. The reinforcement should be an all-textile braid made of resilient synthetic yams; this material is covered with thick rubber. The hoses must be flexible for ease of handling and rated for a minimum working pressure of 300 psi (20.4 atmospheres). Hoses must be durable, suitable for use in water, and resistant to abrasion, oil, and sunlight. Orifice diameter of the nozzle should be 5/16 inch in order to provide chosen flow at 75 psi (5.2 atmospheres) pressure at the nozzle inlet. Each hose must be long enough at each location to reach the side, front, and back sections of the vehicles being washed.

4-2.4.5 Nozzles.

The nozzles must be durable to withstand frequent punishment and heavy use. The inner diameter of the hose connection at the tower will be determined by the required pressure and flow rate. The hoses should be designed with rubber nozzles built in by the manufacturer.

Figure 4-4 Cross Section of an Island

4-2.5 Protection Against Freezing.

In regions where freezing conditions may occur, the water supply piping, valves and fittings at the wash stations must be self-draining and designed for protection from damage due to freezing.

4-2.6 Water Supply Piping.

Valves which will be frequently operated on the supply piping to the wash stations must be accessible through valve pits, valve boxes, or manholes. Isolation valves within the system can be directly buried.

4-2.7 Paved Area Drainage.

4-2.7.1 Surface Drainage.

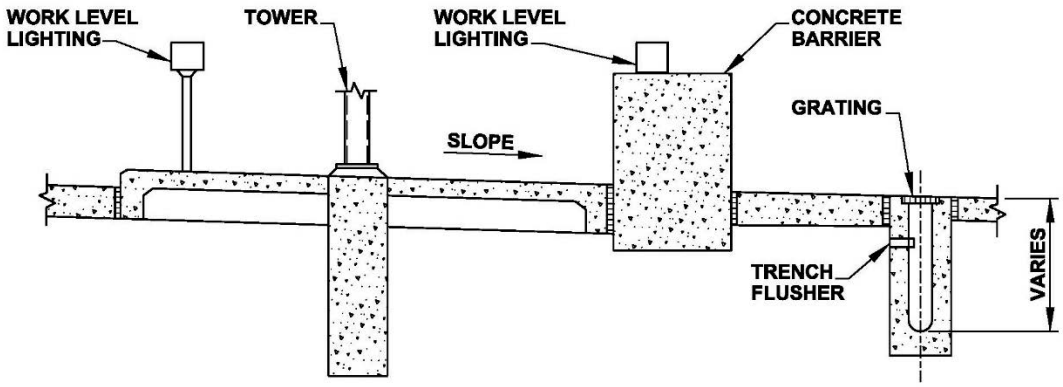
All water used for washing vehicles and cleaning the CVWF as well as all precipitation falling on or flowing through the paved area shall be collected through a drainage system that flows to the primary treatment basin. This volume may be captured as makeup water if necessary. The assembly area located after the wash area and the preparation area shall be paved and sloped toward a grated trench drain. Concrete curbing should be installed at all pavement/soil interfaces when the designer deems necessary to contain and direct the runoff to the treatment system. In areas where water is not expected to occur and vehicular control is not required, such as the preparation area, the designer may choose to limit or not use curbing. Other surface water shall be drained away from the facility unless it is to be captured for use as makeup water.

4-2.7.2 Trench Drains.

Open-grated trench drains are provided to move soil-laden wastewater from the paved staging and wash station areas to the wastewater collection system. Figure 4-7 shows a typical trench drain in cross section. The trench should have a circular (U-shaped) bottom with a smooth surface for good open channel hydraulics and abrasion resistance. Grating should be cast iron and able to support the vehicle loads to be imposed. Grate openings should be at least 1 inch wide to allow gravel to pass through. Grating sections should be of a weight and attachment design that allow easy removal for maintenance of flow in the trench drain system.

4-2.7.2.1 Trench Drain Layout.

Trench drains are usually oriented transverse or diagonally across the direction of vehicular traffic. A trench drain system is required the length of each row of wash stations at the entrance end (see Figure 2-1 Standard Central Vehicle Wash Facility Plan, Figure 4-1, Figure 4-2 and Figure 4-3). The location of additional trench drains in the staging areas will depend on the following:



- The amount and distance that soil-laden material must be moved during wash area cleanup operations.

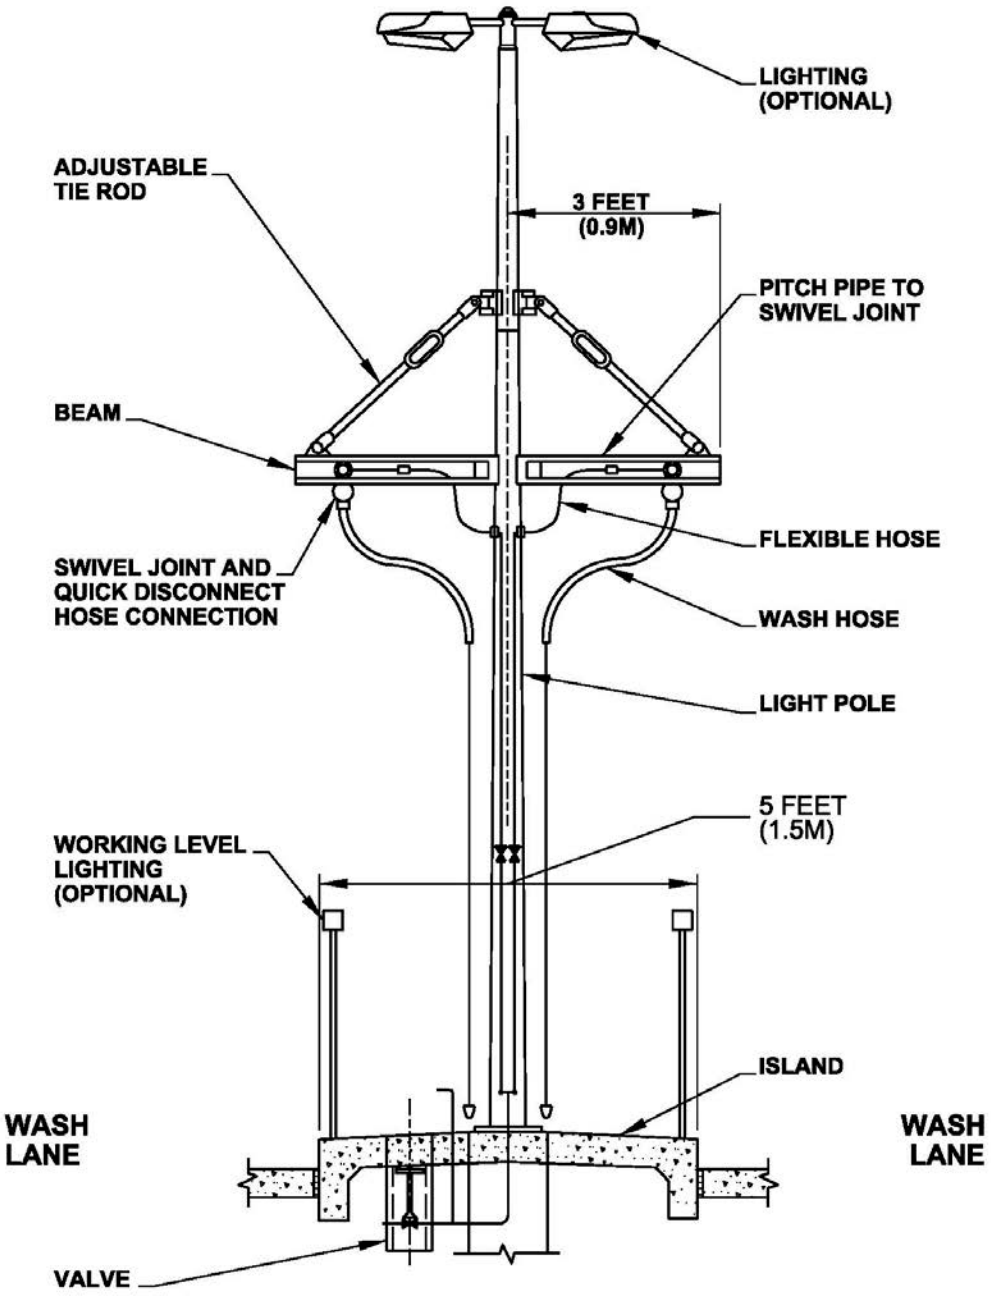
- The location of staging area hose hydrants and their effective area of coverage.

4-2.7.2.2 Trench Drain Flushing System.

The trench flushing system consists of a supply line with motor-operated valve and nozzle injection points along the trench drain. An adequate slope must be maintained in the trench which will move the dirt and debris to the collection system. Flow velocities of at least 5 fps (1.5 meters per second) are required. Trench slopes shall be at least 2 percent. Bottom grades at bends, junctions, slope changes, and section changes in the trench drains should be designed for energy losses. The flushing nozzles are located in the trench just above the normal flow surface and point downward and downstream. Flushing is accomplished intermittently during vehicle washing periods and during cleanup operations at the wash station trenches, and only during cleanup in other staging area trenches. Flush system control by the facility operator is critical and is independent of other pumping supply systems. Flushers are operated only when necessary in order to conserve water and electrical consumption. A well designed flushing system utilizes water drawn from the equalization basin as discussed in Chapter 6.

Figure 4-5 Longitudinal Section of an Island

4-2.7.3 Wastewater Collection System.



4-2.7.3.1 General.

Wastewater and storm water collected on the paved areas and moved to the trench drains are tied to an open trench or underground piping network, or combination thereof, and conveyed by gravity to the sediment basin for primary treatment. If site conditions and grades permit, the collection system for storm water to the sediment basin should be an open channel for easy cleaning of the open trench. Lines and channels should be as straight as possible. Minimizing the number of changes in direction will avoid mud and debris accumulation. Manholes should be provided for pipe systems at pipe intersections, changes in direction, and changes in slope, and at no greater than 400-foot (121.9-meter) intervals on straight runs. Gravity collection systems without flushers that empty into the sediment basin are designed to maintain a minimum velocity of 5 fps (1.5 meters per second). A minimum of 2 percent slope shall be required on all gravity wastewater lines.

4-2.7.3.2 Material.

Open channels are cast concrete rectangular, trapezoidal, or semicircular cross sections. Semicircular channels limit areas where dirt and debris can accumulate. Gravity pipe systems usually are reinforced concrete, steel, or ductile iron pressure piping. Plastic pipe may be used, as local practices and experience permit, except under pavements.

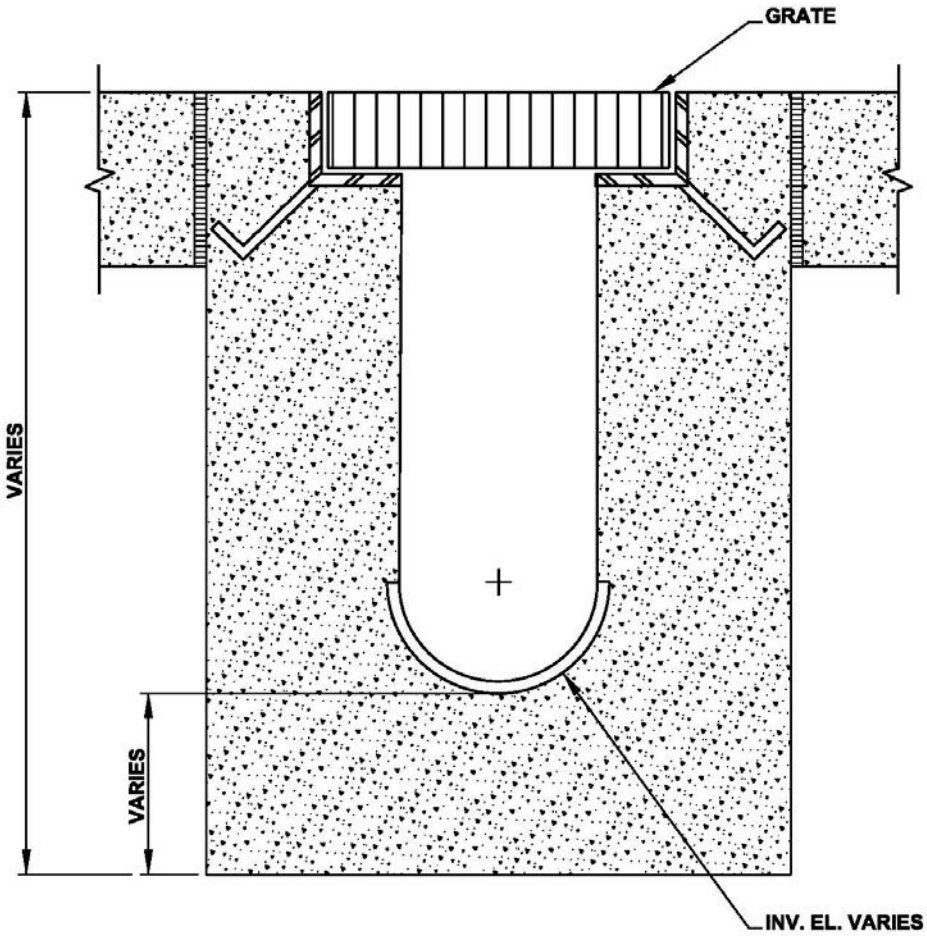


Figure 4-6 Tower Detail in Cross Section

4-2.8 Pavement.

All ground surfaces within the CVWF that will support vehicle movement must be covered with a hard surface and curbing for water and vehicle control. Pavement is required to keep the clean vehicles from driving and parking on surfaces where they become soiled. It also ensures that vehicles do not track dirt from unpaved areas into places reserved for clean vehicles. Concrete is recommended in areas of tracked vehicle movement, including pavements over which both tracked and wheeled vehicles will maneuver. Asphalt paving will suffice in most areas where only wheeled vehicles will operate or in areas of straight tracked vehicle movement. The paving and base should be designed to meet the needs of the vehicles that will use the facility. Concrete should be used around critical drainage structures, such as at wash stations. Roads and trails leading to motor pool areas from the wash facility shall be paved to prevent clean vehicles from be-coming soiled again. Roller-compacted concrete should be considered for all paving areas except at critical drainage structures, where form-worked concrete should be used. When water recycling is to be used, light pavement color should be utilized to decrease the evaporation volume.

Figure 4-7 Cross Section of a Trench Drain

4-2.9 Interior Wash Equipment (Optional).

Low-flow, interior wash equipment should be provided at islands, at user request, for washing truck beds, cab floors, jeep interiors, and other such areas. This equipment is used for washing personnel compartments only and is not intended for cleaning engines. Engine cleaning is prohibited at these locations. The outlet should provide a water pressure of 40 psi (2.8 atmospheres) and a flow rate of 5 (19 liters per minute). A 3/4 inch heavy duty utility hose is attached to the outlet. A sign shall be posted warning personnel not to wash engine compartments.

4-2.10 Lighting.

Adequate overhead and working-level lighting must be provided at CVWFs where users will be washing vehicles at night. On overhead tower structures provide lighting for the staging areas. Towers may be high-mast or low-mast, but must be located so as to provide total wash area coverage without interfering with traffic. Wash station towers may have lighting fixtures for this area as shown on Figure 4-6. A selected portion of the tower fixtures may be used as security lighting. For additional requirements see section 3-2.4.4 lighting.

4-2.11 Physical Security.

Physical security consists of locks on building doors. The CVWF usually is not fenced unless the user requests it for safety and protection against vandalism. Fencing of the basin areas is recommended.

4-2.12 Signage.

Signs must be posted warning personnel not to drink the wash water and directing them where potable water is available. Traffic flow signs as well as pavement markings should be provided to ensure safe, effective use of the facility.

4-2.13 Solid Waste Collection.

Commercial dumpsters should be located strategic points along the edge of the preparation area for disposal of solid waste. Dedicated concrete pads adjacent to the pavement are preferred to avoid damage to dumpsters and moving vehicles. Extra dumpsters may be required at the wash stations.

4-2.14 Operation and Controls.

Equipment operating, maintenance, and repair manuals should be specified to be provided by the contractor at completion of the construction contract.

4-2.14.1 Operator.

The requirement for an operator will depend on the size and complexity of the CVWF. The operator is responsible for shutting off the equipment in times of emergency and at the end of the washing operation. This person controls the pumps and valves, oversees cleanup, reports any maintenance problems, and assures safe operations. At facilities

which have recycled water systems, the operator will also be responsible for monitoring the treatment process.

4-2.14.2 Control Building.

A building shall be provided to house controls for the wash facility in one central location. A master control panel shall be installed to permit the operator to shut off all washing operations at one point. This design allows the operator to shut down the facility quickly and efficiently if required. The building shall provide protection for the operator during inclement weather. Insulation, heating, ventilation, and air-conditioning may have to be provided for the control building at some installations. Latrines and potable water for the troops can also be included in the control building. A telephone should be installed in this building to allow the operator to report O&M problems and emergencies. UFC 3-101-01 Architecture and UFC 3-110-03 Roofing should be consulted for more specific information on building and roof design. Figure 4-8 shows a recommended layout, for the control building.

4-2.14.2.1 Location and Design.

The control building must be located such that the operator can easily see washing operations at all wash stations. The entire treatment system also should be visible from the control building. Latrines for troops and operators and a lockable storage space can be included in the building as required. An efficient design places the control panel in a second-story room above the latrine and/or storage rooms (Figure 4-9). This allows the operator to have a good view of all washing and treatment operations. The operator should be able to operate the control panel and still have a clear view of the operations. Depending on the orientation of the facility and the control building, tinted glass or sunscreens may have to be installed to reduce glare which may inhibit the operator’s view of the wash facility or control panel. Area and control-room lighting must not interfere with the operator’s visibility during nighttime operations. Provide projection calculations during design to insure compliance.

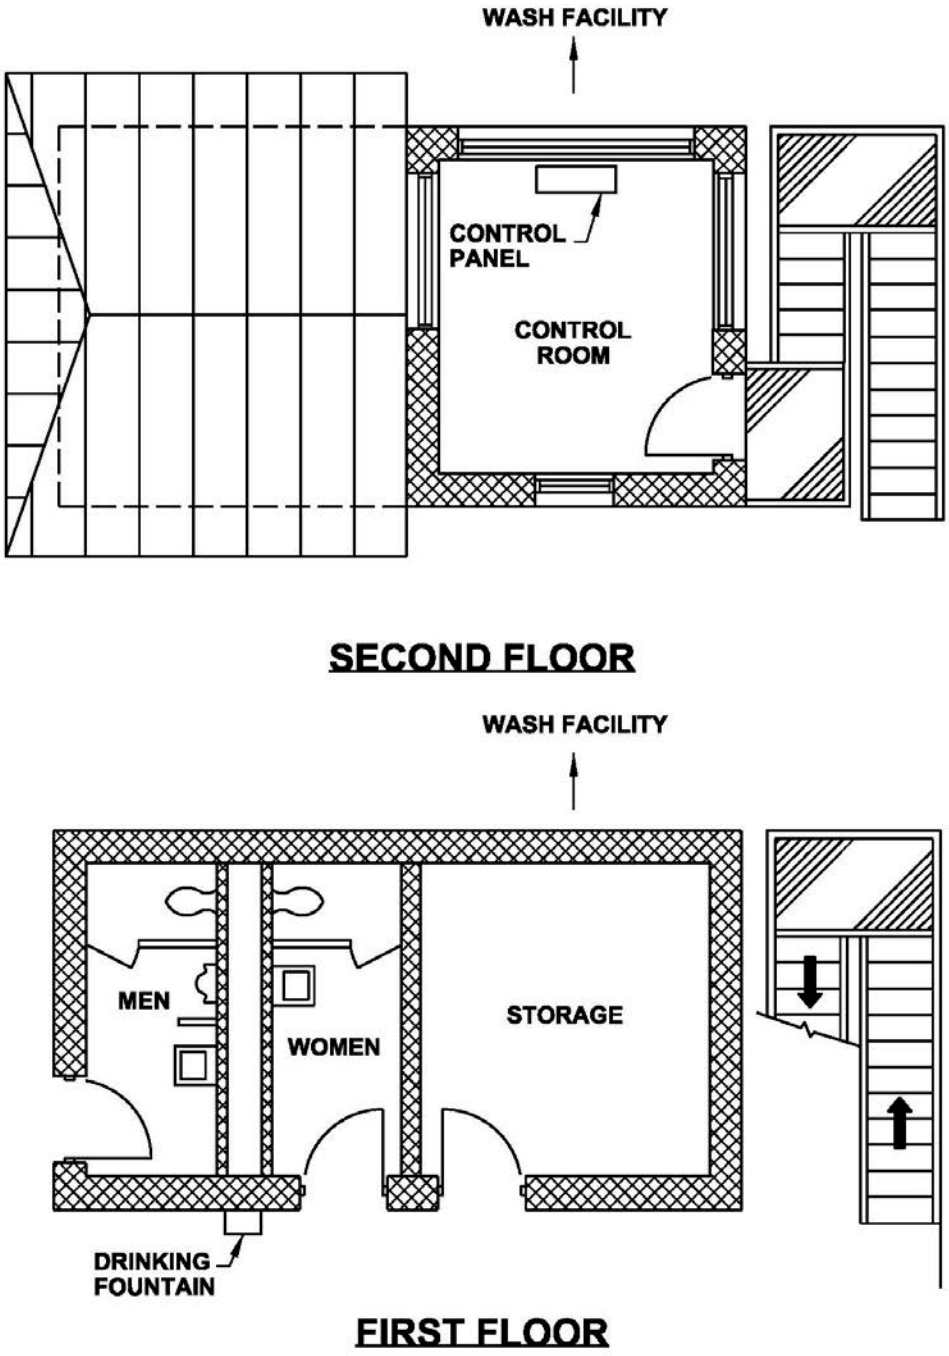
4-2.14.2.2 Size.

The control building must be sized to house wash facility controls, building electrical and mechanical equipment, storage, and latrines for the wash facility in one location.

4-2.14.2.3 Protection.

If the control building is to be located adjacent to vehicle movement, protective barriers must be installed at its comers. Other protective barriers such as guard rails may also be required.

Figure 4-8 Example Floor Plan for the Control Building



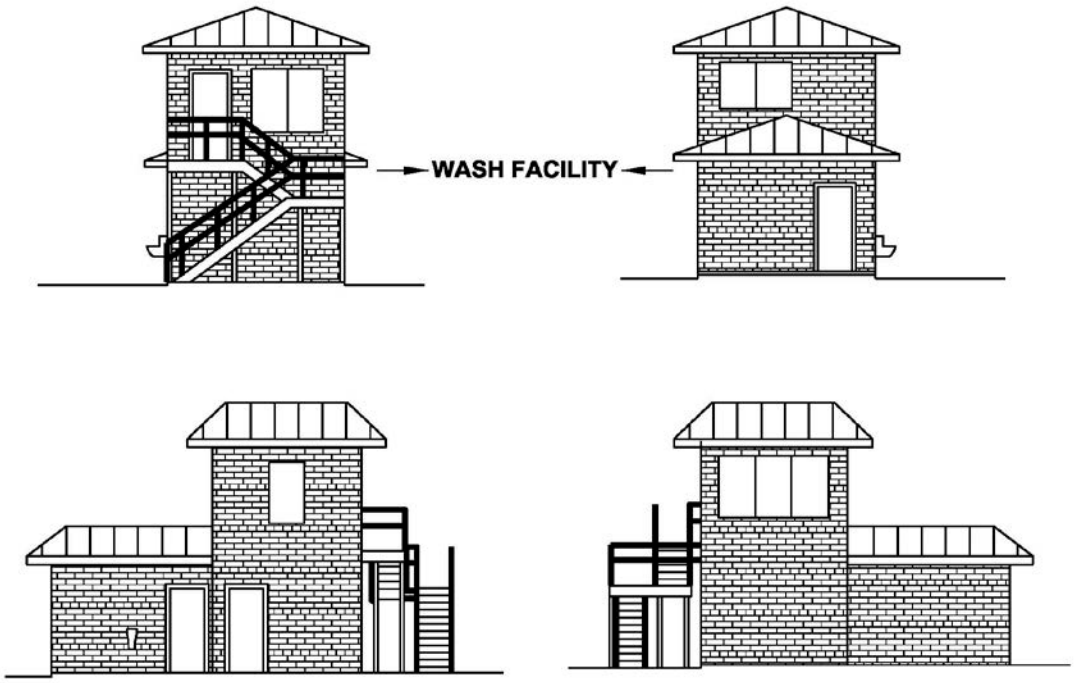


Figure 4-9 Control Building Exterior

CHAPTER 5 OPTIONAL PREWASH

5-1 TYPES OF PREWASHES.

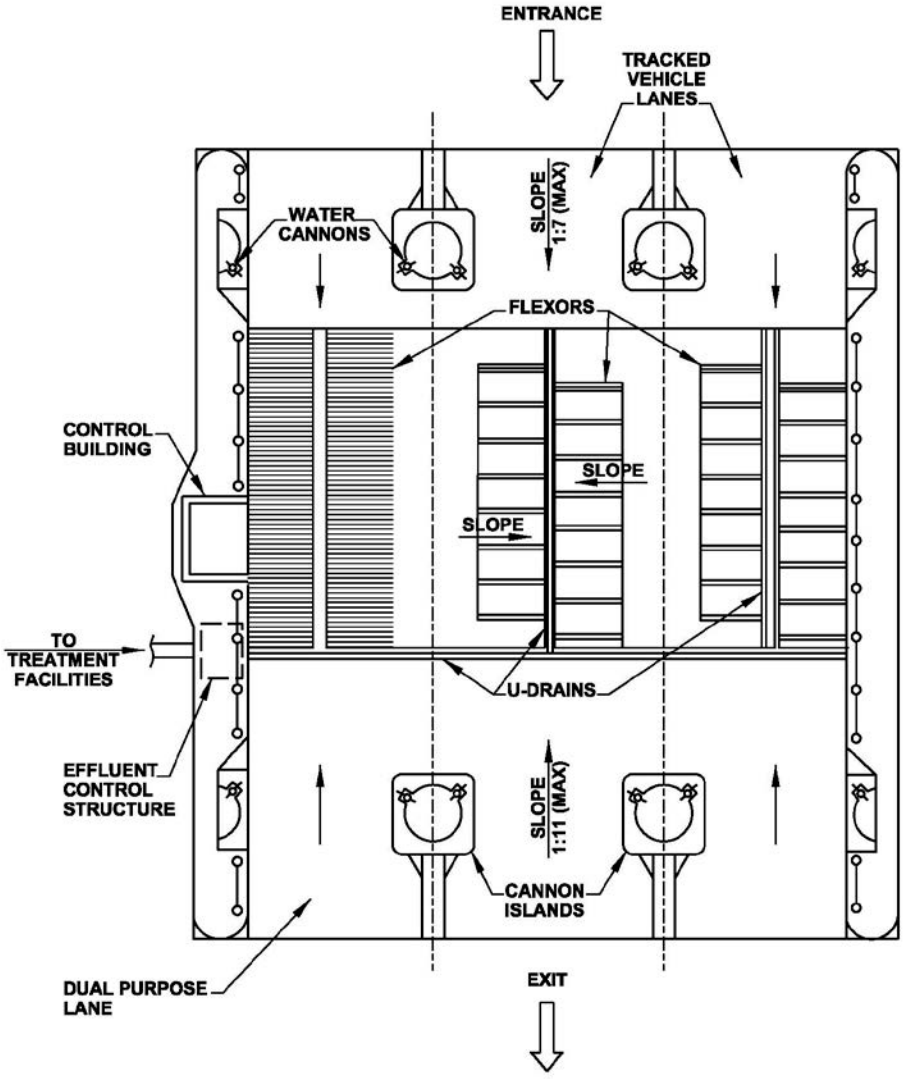
The prewash is designed to remove a large amount of dirt from vehicle exteriors in the most efficient way. The prewash should be flexible enough to handle the number and types of vehicles expected to use the facility. After the prewash, most vehicles will require additional washing at the wash stations so that troops can do a more detailed cleaning, reaching into crevices where a prewash might not clean. Not all vehicles will require cleaning at a prewash. Lightly soiled and smaller vehicles, such as jeeps, may proceed directly to the final wash stations.

Two types of prewash facilities have been constructed for washing tactical vehicles: baths and spray stands. The bath is a water-filled basin with water cannons mounted at each of the four corners of each lane. As vehicles are driven through the bath, persons stationed at the water cannons spray them with high -pressure water to remove the dirt. Spray stands emit high- pressure streams of water from many small nozzles directed toward vehicles driving through the facility. The bath is the recommended prewash, since it removes the bulk of the dirt, including that under the vehicle, and is the most efficient water conservative method. The spray stand is neither as efficient nor as effective as the bath for gross removal of soil from tactical vehicles.

5-1.1 Bath Prewash.

The bath is a water-filled basin through which vehicles drive. Three actions in the bath operate at the same time to remove dirt from tracks, from wheel wells, and tank side skirts. First, the water in the bath provides a soaking action that allows the dirt to be more easily removed. Second, troop operated water cannons placed at each corner of the bath lane spray high- pressure streams of water at the vehicles. Third, raised pipe flexors built into the bottom of the bath flex the tracks and wheels of the vehicles to aide in loosening embedded dirt. This, flexing motion is accomplished by driving the vehicle back and forth through the bath. The combination of wave action and turbulence helps remove dirt from under skirts and wheel wells. Under light to average soiling conditions, one pass through the bath may be sufficient to remove the dirt. However, for heavier soiling, vehicles may require two or more forward and reverse passes over the flexors. An additional advantage of a bath prewash over the spray stand system is that various types and shapes of tactical vehicles can be cleaned without modifying the equipment. Also, the bath is more efficient at water usage than is the spray stand, so treatment systems can be smaller. Finally, the bath can more efficiently clean “skirted” vehicle types such as the M-1 battle tank.

5-1.1.1 Types of Bath Lanes.



Two types of lanes have been designed and developed to accommodate all type tactical vehicles. Tracked vehicle lanes are designed for use by tracked vehicles only. Large, offset flexors on the bottom of the tracked vehicle lane allow maximum flexing of tracks but make it difficult for wheeled vehicles to traverse and maneuver. Dual- purpose lanes can be used by both tracked and wheeled vehicles. In the dual-purpose lanes, the smaller pipe flexors, which are not offset, are easily traversed by wheeled vehicles.

However, the smaller flexors are not as effective as the track lane flexors for cleaning tracked vehicles.

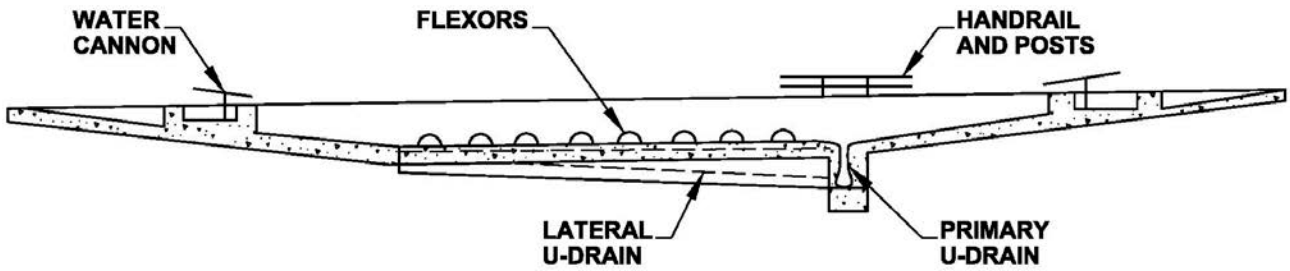
5-1.1.2 Configuration.

Dual-purpose lanes can be used in conjunction with tracked lanes at the same facility. Figure 5-1 shows a prewash design that uses both types of lanes. It is recommended that no more than three lanes be combined to form one bath. Multiple baths can be linked with walls between them. This configuration will provide maximum flexibility for the installation, since not all bath facilities will need to be filled to wash vehicles if a small group arrives. If tracked and dual- purpose lanes are combined to form one facility, the tracked lanes should be located as close as possible to the sediment basin. Most of the sediment leaving the bath will be removed from the vehicles in the tracked lanes. This layout will reduce the distance that wastewater with high suspended solids content must travel prior to primary treatment. Figure 5-2 presents a tracked lane in cross section. Signs may be required to direct users to the proper type of bath lane.

Figure 5-1 Example of Combined Bath Lane Facility, Plan view

5-1.1.3 Lane Width.

The recommended effective width of a lane is 22 feet (6.7 meters).



5-1.1.4 Bath Bottom Length.

The length of the bath bottom is based on the track perimeter of the largest tracked vehicle expected to use the bath. A typical lane is 50 feet (15.2 meters) long from the bottom of the entrance ramp to the bottom of the exit ramp, including the width of the trench drain opening.

5-1.1.5 Water Level.

The water level in the bath should be adjustable. A range of 0 to 3.5 feet (0 to 1.10 meters) is recommended for maximum flexibility. Depth of water is measured at the deepest point in the bath (Figure 5-2), excluding the depth of the trench drain. Not all vehicles can operate in a 3.5-foot (1.10-meter) water level; in these cases, it must be possible to lower the water level. Depending on the types of vehicles using the bath and the different units' requirements, an operator can regulate the level within the recommended range. An extra 1.0 foot (30.5 centimeters) of freeboard should be added to the walls of the bath. A staff gauge or other water level indicator should be placed in the bath or painted on the side wall to guide the operator when adjusting the bath depth.

Figure 5-2 Tracked Bath Lane, Cross Section

5-1.1.6 Water Cannons.

The bath prewash is equipped with two stages of stand-mounted fire-fighting-type hardware with nozzles, each of which can deliver the required design wash water pressure and flow to the exterior tracks or wheels of the vehicle being washed. Each bath lane is provided with a total of two primary (entrance) cannons and two secondary (exit) cannons, one at each corner of the lane. Each lever-directed cannon system consists of water supply riser, manually operated flow control valve, play pipe, and nozzle. During the first stage, a vehicle enters the bath slowly from the entrance staging area and troops aim the primary cannon water stream at it for gross removal of solids from wheels, tracks, idlers, and behind skirts and fenders. During the second stage, parts of the vehicle with soil not dislodged at the primary cannons or by submergence and flexing in the bath are exposed to the high-pressure, high-volume water stream from the secondary cannons prior to exiting the bath. To allow flexibility of lane usage, each water cannon system is designed to deliver and operate in the

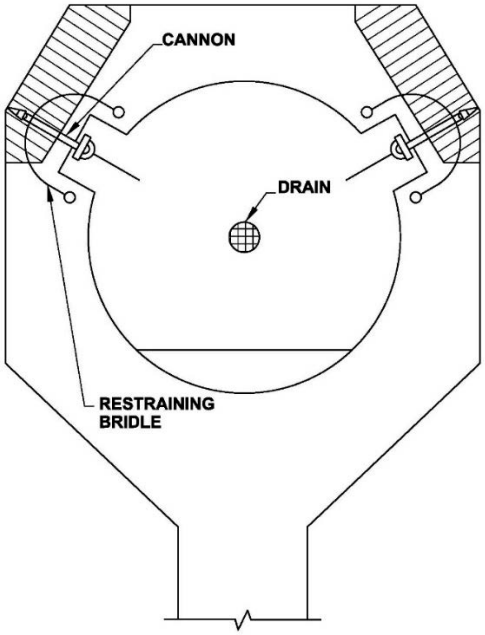
required flow and pressure ranges, regardless of whether a lane is dual-purpose or tracked.

5-1.1.6.1 Water Pressure and Flow Rates.

The recommended the water pressure is 100 psi (6.8 atmospheres) at the nozzles. The recommended nozzle flow rate is 80 gpm (300 liters per minute). A flow control valve shall be installed on each cannon to allow troops to stop and start the water flow. As discussed in Chapter 4, pressure and flow rates are provided to facilitate pump selection and control, and to handle different soiling conditions.

5-1.1.6.2 Height.

The center line of the nozzle on the cannon should be 50 inches (127 centimeters) above the pavement adjacent to the island as shown Figure 5-5.



5-1.1.6.3 Nozzles.

The nozzle tip shall provide a stream of water with a zero-degree spray-angle nozzle. The inner diameter of the nozzle orifice should be ½ inch (12.7 millimeters). The nozzle must be able to deliver pressures and flow rates within the recommended ranges with minimum losses.

5-1.1.6.4 Motion Restriction.

Adjustable restraining bridles (Figure 5-3) should be placed at each water cannon position to limit both horizontal and vertical movement. Without the restraints, personnel could accidentally spray each other during cleaning operations which could result in injury.

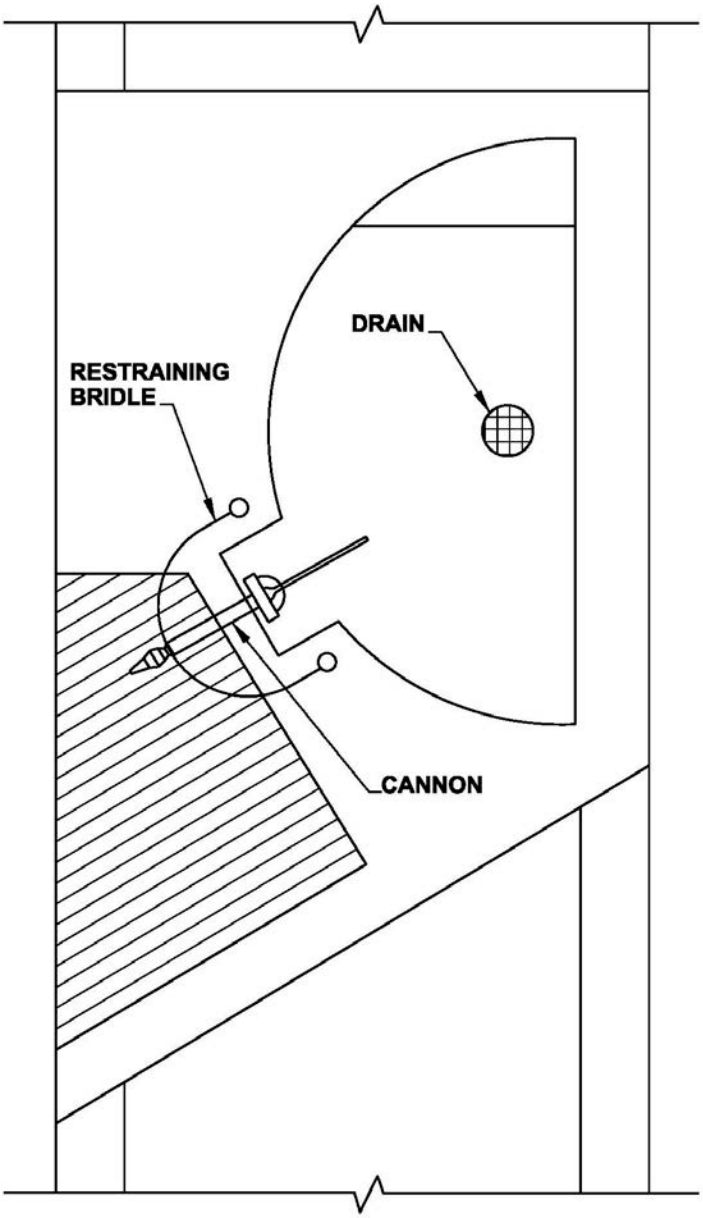


Figure 5-3 Example Inner Wash Island

5-1.1.7 Cannon Island.

Water cannons are mounted in concrete islands constructed at each corner of the bath lane. Figure 5-3 shows two example configurations. The concrete islands should be located on the entrance and exit ramps of the bath. Two cannons should be placed in each inner cannon island (Figure 5-3). The outer islands should have one cannon per island (Figure 5-4). The islands must have drainage so that troops will not be standing in water. All corner sections within the bath should be filleted to avoid the buildup of debris. Cannon island shall be designed such that they do not impede the movement of the cannons or the wash water flow stream. If the user requires, hose connections may be included in the island design for clean-up purposes. Figure 5-5 shows a cross section of the wash island.

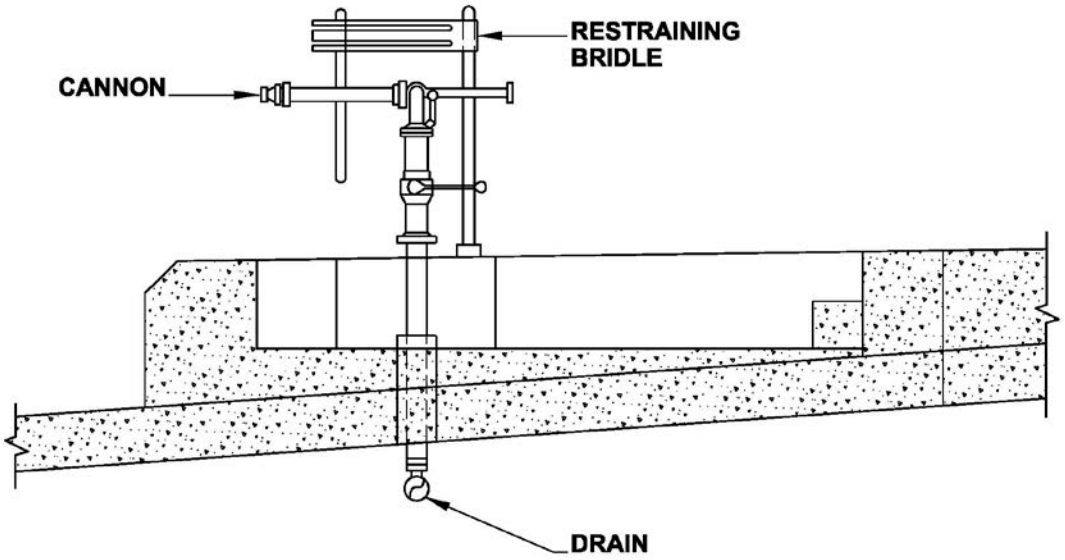

Figure 5-4 Example of Outer Wash Island

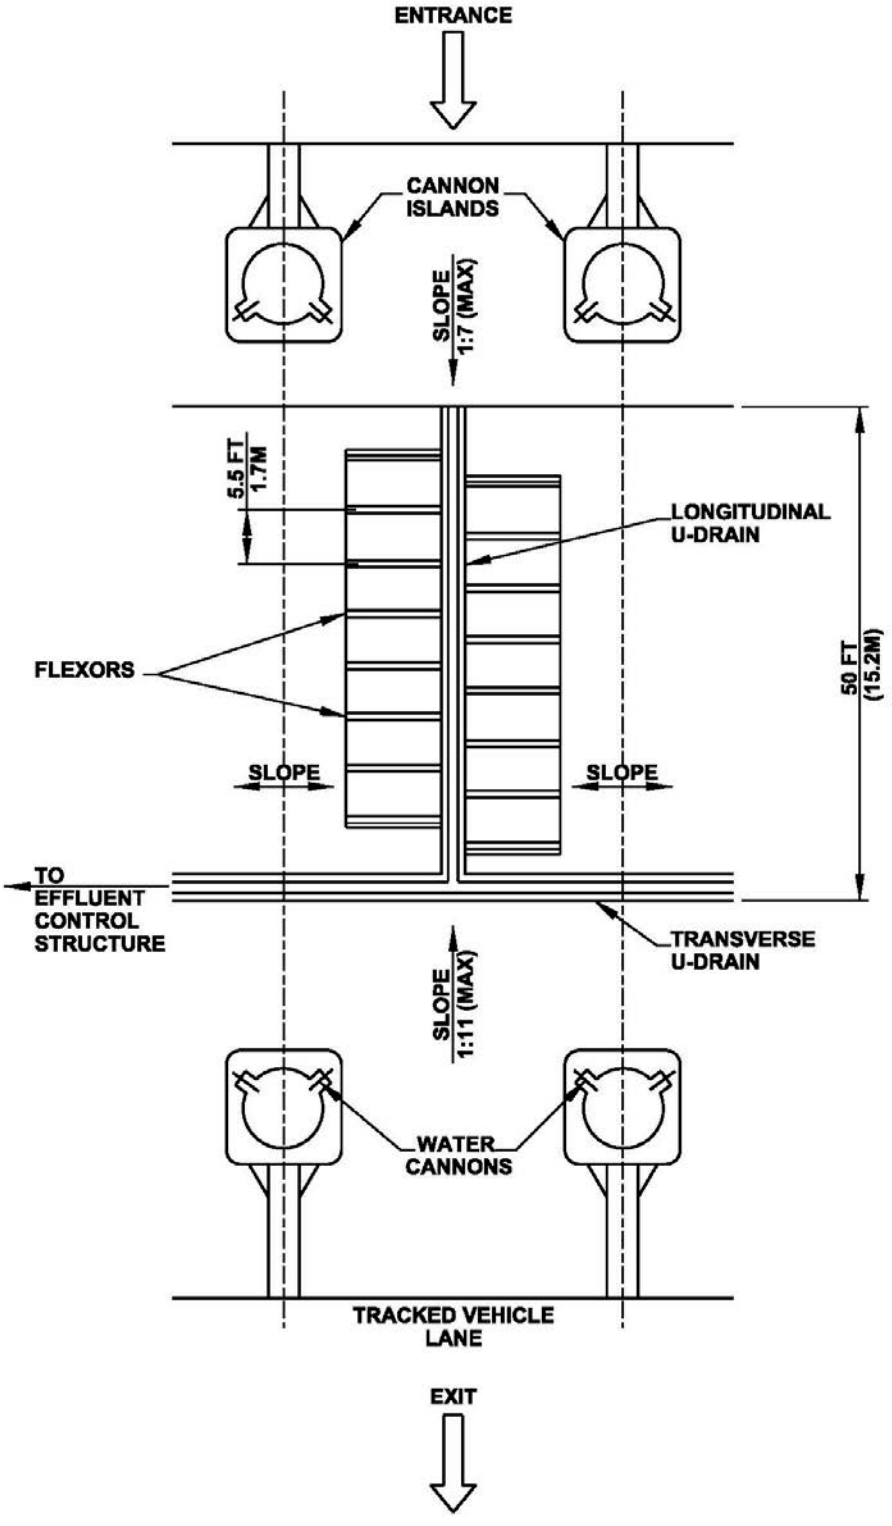
5-1.1.8 Flexors.

Flexors are grout or concrete filled, steel piping installed on the bottom of the bath lane to improve removal of encrusted dirt from under the skirts, around drive wheels, and other areas of the vehicles that cannot be cleaned by the water cannon flowstream. By driving the vehicles back and forth over the flexors, much of the dirt can be loosened and removed. The turbulence created from this action also removes dirt from hard-to-reach areas in the undercarriage, and behind side skirts. The spacing and height of the flexors cause the tracks and wheels to move in an up-and-down motion. This movement loosens dirt from the tracks and from under wheel wells and skirts. The space between the flexors also serves as a collection channel sloped toward bath lateral trench drain.

Figure 5-5 Example Cross Section of a Cannon Island

5-1.1.8.1 Tracked Vehicle Lanes.



The recommended center-to-center flexor spacing is 5.5 feet (1.7 meters). The flexors are offset (Figure 5-6) to allow the vehicle's running gear to achieve the maximum flexing motion possible. Outer lanes of the bath should have the flexors extended to the side walls to prevent dirt from building up between the ends of the flexors and the walls. Each flexor in a tracked vehicle lane should be 9 inches (22.8 centimeters) high. The method of connecting or imbedding the flexors to the bottom of the bath must be able to withstand the impact of all types of vehicles using the bath.

5-1.1.8.2 Dual Purpose Lanes.

The design of flexors in dual-purpose lanes will be similar to those in the tracked lanes. The flexors should be spaced 18 inches (45.7 centimeters) apart. The flexors shall be installed at right angles to the lane and extend from the edge of lateral trench drain in the lane to the side walls of the bath. This design prevents dirt from collecting between

the wall and the flexor. The flexors are not offset (Figure 5-7) in order to allow better vehicle control. Each flexor shall be 3 inches (7.6 centimeters) above the floor level and constructed in such a way to withstand the impact of both tracked and wheeled vehicles.

Figure 5-6 Tracked Bath Lane

5-1.1.9 Entrance Ramp.

The slope of the entrance ramp is measured from the top of the first flexor in the bath lane. The maximum allowable slope into the bath is 1:11 (9 percent).

5-1.1.10 Exit Ramp.

The maximum allowable slope for the bath exit ramp is 1:11(9 percent).

5-1.1.11 Ramp Slope.

Slopes selected will affect the volume of water required to fill the bath and the resulting amount of wastewater to be treated. Therefore, the maximum slopes allowable should be selected except where local conditions require flatter slopes.

5-1.1.12 U-Drains.

Open u-drains shall be used to move soil-laden wastewater from the bath area to the collection system (Figure 5-8). The bottom of the bath should slope toward these drains at a minimum of 2 percent to help move mud and debris into the collection system (Figure 5-9).

5-1.1.12.1 Configuration.

A lateral u-drain is installed along the centerline of each bath lane. Each lateral drain is connected to the transverse u-drain that runs perpendicular to the lanes. This transverse drain discharges directly into the bath outlet control structure. Figure 5-10 shows how these drains are arranged.

5-1.1.12.2 Fill/Flush System.

A fill/flush system with motorized valves is provided in the bath to allow for timed filling of the bath and movement of dirt and debris to the outlet structure when the bath is drained, flushed and cleaned. A flusher supply discharge should be placed into the uppermost end of each u-drain. The flushers will provide increased flow in the u-drains to prevent sediment deposition. The recommended flushing rate is 600 gpm (2280 liters per second) for the lateral u-drains and 900 gpm (3420 liters per second) for the primary u-drains and should be set to provide 5 fps (2.4 meters per second) velocity in the u-drain. Flushing time is arbitrarily set at 15 to 25 minutes, depending on soiling conditions. The flow rate for filling may be increased in order to fill the bath in a reasonable amount of time; a fill time of 30 minutes or less is recommended. The fill/flush procedures are controlled by the wash facility operator (see chap 4.) The system of pumps and supply piping is designed to be independent of other systems. The source of fill/flush water is the equalization basin.

5-1.1.12.3 Design.

U-drains are to be designed to handle the peak solids and hydraulic loadings that occur in moving wastewater to the effluent structure. A minimum grade of 2 percent is required in the drains along with 5 fps velocity to prevent settling.

5-1.1.12.4 Materials.

U-drains should be lined with concrete or other impervious material such as plastic, metal, or vitrified clay. The liner should have a smooth, circular finish to reduce roughness in the trench.

5-1.1.13 Outlet Control Structure.

A moveable weir on the outlet structure is used to regulate the depth of water in the bath (Figure 5-11). This weir is located at the interface of the structure and the bottom of the bath and is designed to be raised or lowered to vary the water depth. A valve or gate is located in the structure at the intersection with the transverse u-drain to allow wastewater to discharge into the structure. Weirs, valves and gates may be motorized or manually operated. The structure should be designed to minimize solids deposition.

5-1.2 Vehicle Spray Stands.

A spray stand operates much as a commercial car wash in that the vehicle is driven into the facility and sprayed by high-pressure water from many small nozzles. This method is not suited, nor recommended, for the irregular-shaped tactical vehicles, because M-1 tanks and other vehicles with heavy side skirts cannot be cleaned effectively. The spray does not effectively remove dirt from the treads, under the skirts, and other places that are difficult to reach. Spray stands also require larger amounts of water than comparably sized bath prewash facilities. Therefore they are not recommended for use at CONUS installations.

Figure 5-7 Dual Purpose Lane

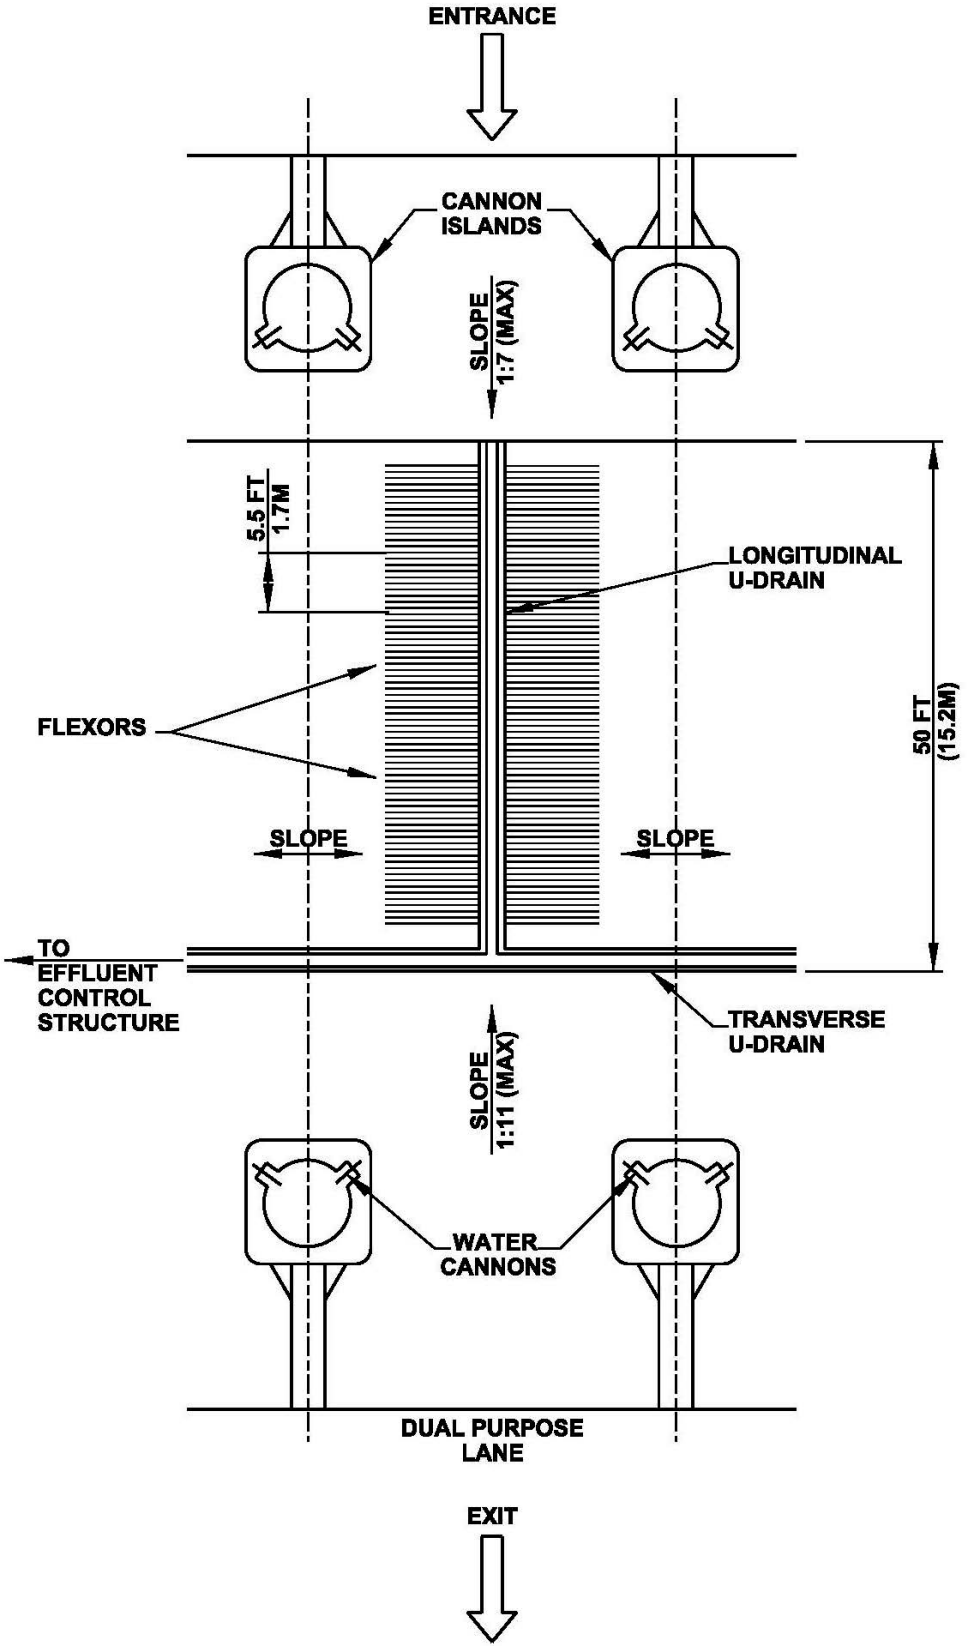


Figure 5-8 U-Drain

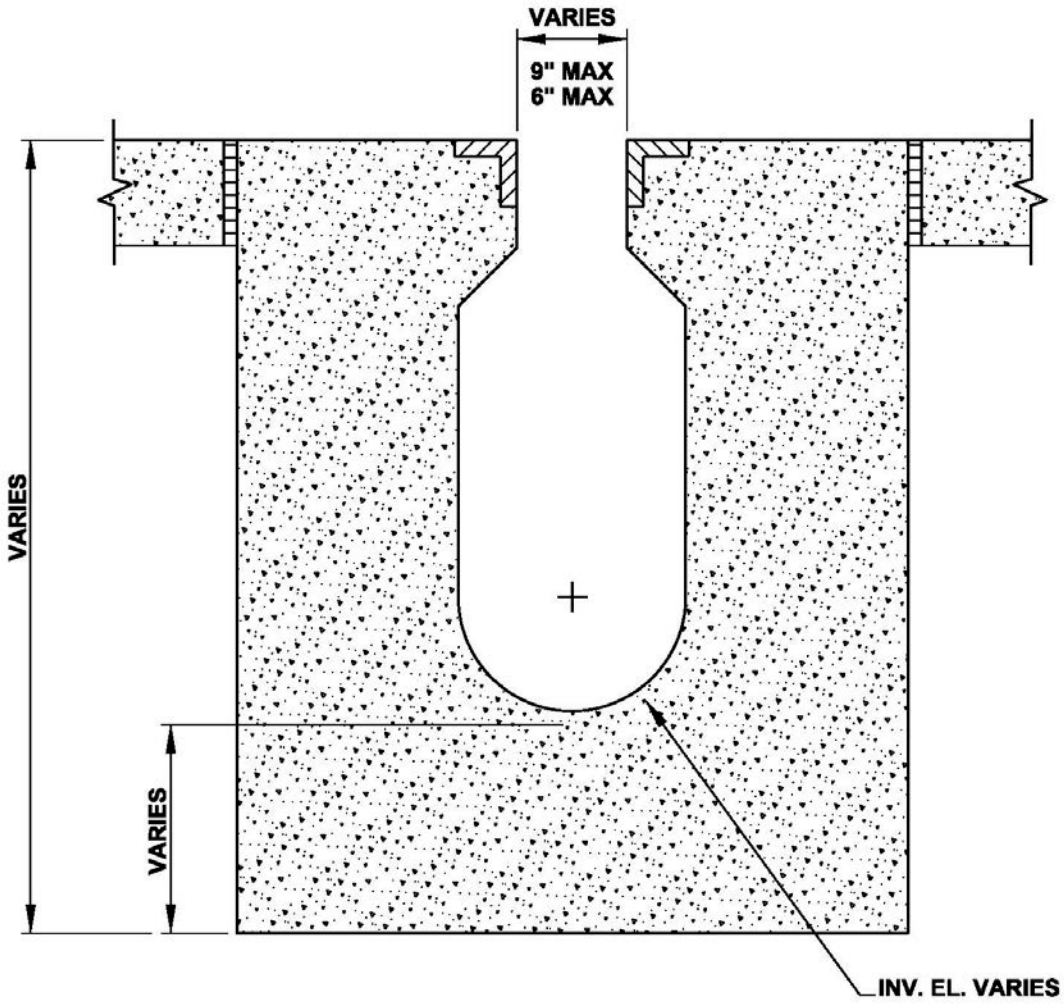

Figure 5-9 Bath Cross Section

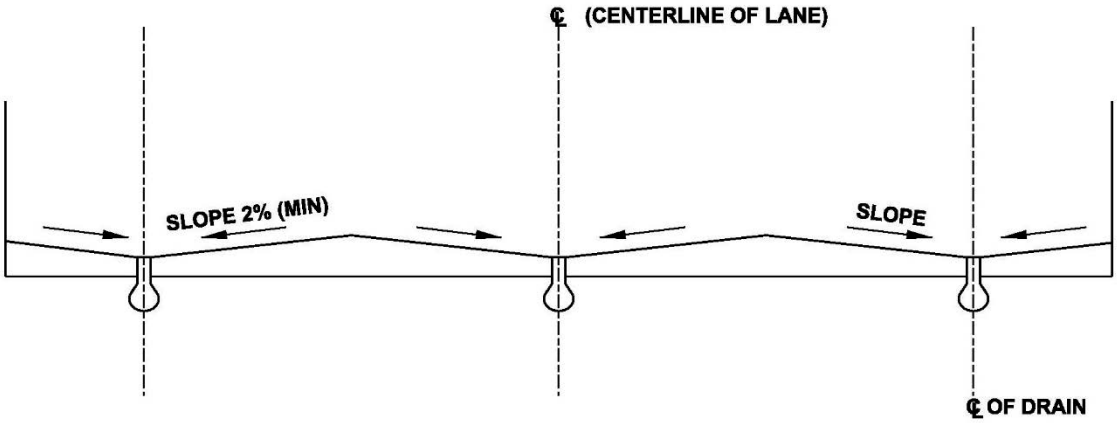

Figure 5- 10 Configuration of U-Drains in the Bath

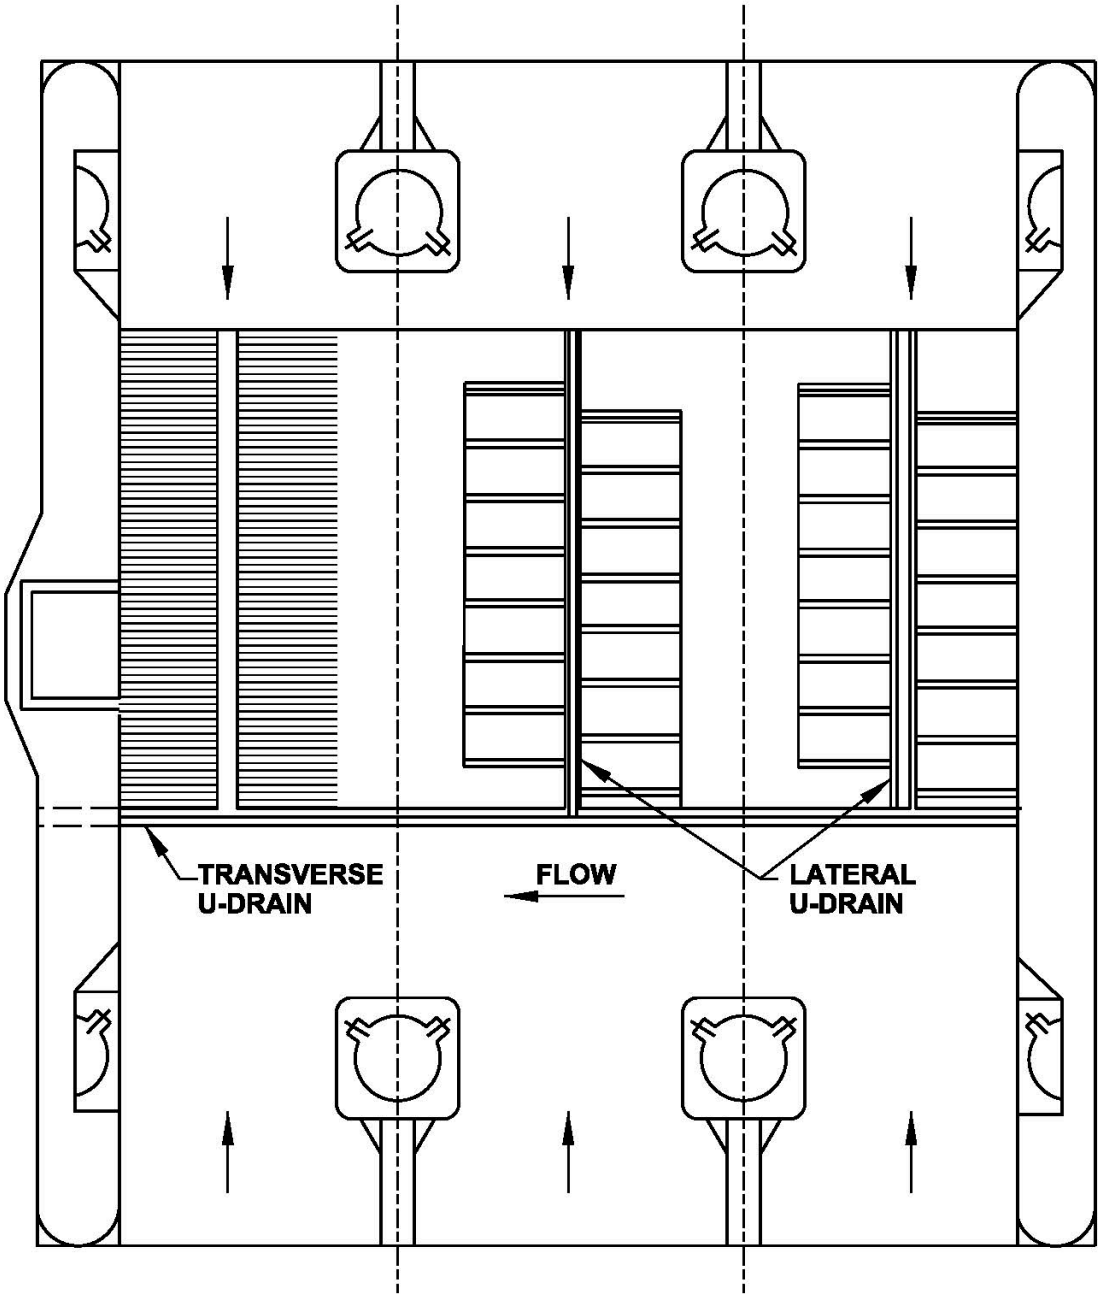

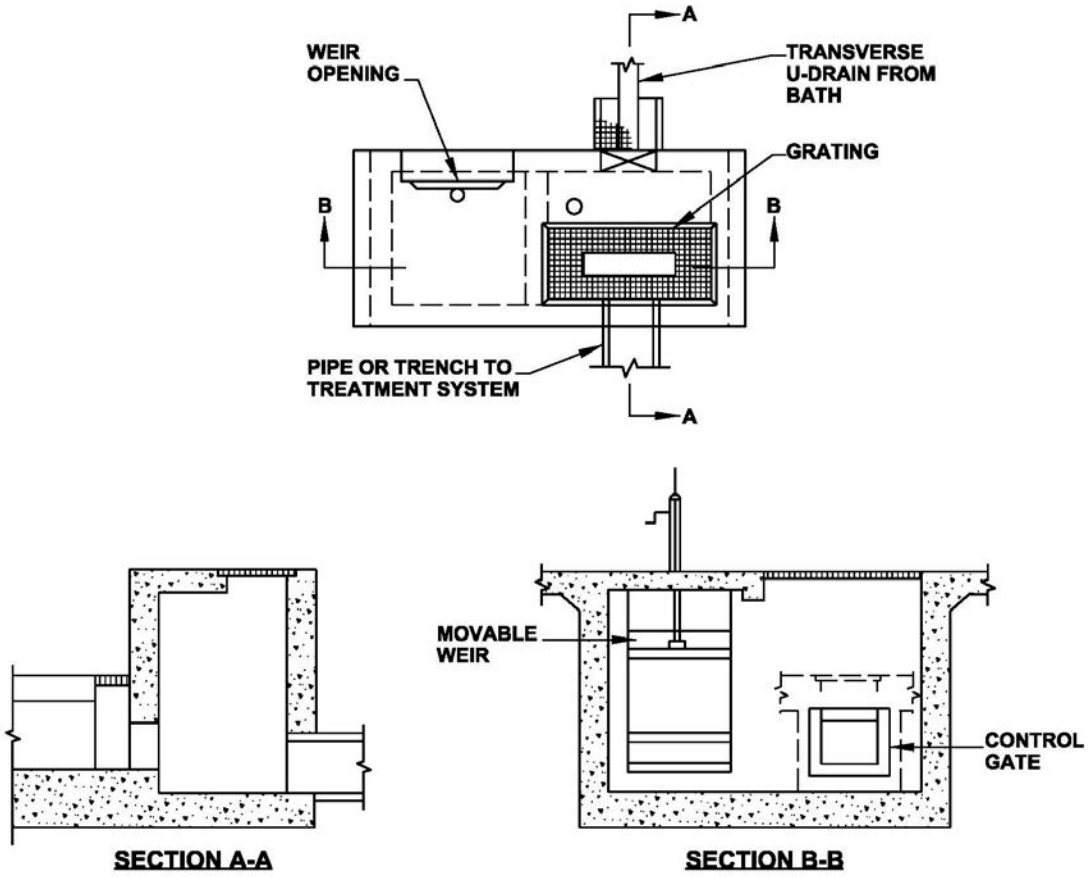

Figure 5-11 Water Level Control Structure

5-1.3 Bath Prewash Support Facilities.

5-1.3.1 Wash Water Supply Lines.

Wash water supply lines transport water under pressure, from source to the washing structures. Supply piping shall be ductile iron, steel or other material resistant to damage from water hammer. Plastic pipe is not acceptable for use in the supply piping. Frequently operated underground valves shall be accessible via manholes or valve boxes. In regions that have freezing temperatures, the system must be self-draining to prevent freezing. Adequate valving should be incorporated to allow for isolation of individual wash stations or wash positions.

5-1.3.2 Wastewater Conveyances.

The wastewater conveyances from the washing structure to the treatment system should be open trenches with a slope sufficient to produce 5 fps (1.8 meters per second) velocity. The conveyances to the treatment system shall be as straight as possible; limiting the number of turns will minimize solids deposition which can build up and block the pipes and trench drains. If closed conduit is used due to site constraints, such as the need to pass under a road, manholes must be provided at each change in pipe direction and slope and at each pipe intersection (see chap 6).

5-1.3.3 Bypass Lane.

A bypass lane is provided to allow lightly soiled vehicles to bypass the prewash and advance to the wash stations. Experience has shown that wheeled vehicles bypass the prewash most often. The recommended lane width is 22 feet (6.7 meters). The bypass lane must have positive drainage to prevent the buildup of water and sediment. When a prewash is provided, a bypass lane around the wash stations must also be provided. This enables the vehicles leaving the prewash which do not require additional washing to bypass the wash stations and advance to the final assembly area.

5-1.3.4 Lighting.

Adequate lighting should be provided if nighttime washing operations are required by the installation. For additional requirements see Section 3-2.4.4 lighting.

CHAPTER 6 WASTEWATER TREATMENT

6-1 GENERAL CONCEPTS.

6-1.1 Overview.

The wastewater generated at a CVWF is widely variable in quantity and quality. The frequency and duration on the system will be site-specific. In addition, CVWF wastewater properties differ greatly from those of a typical sewage waste-water. The suspended solids concentration in a sewage wastewater is 200 to 400 milligrams per liter. In contrast, suspended solids in CVWF wastewater will range from 100 to more than 20,000 system must first undergo primary treatment in a sediment basin milligrams per liter.

Typical sewage treatment collection systems and plants are not equipped to handle the high suspended solids loading generated at a CVWF. A typical sewage treatment wastewater will flow through the collection system without depositing in the sewers because of the low solids content. However, the solids in a CVWF wastewater will deposit readily in the collection system if proper precautions are not taken. This buildup occurs primarily because of the large amount of solids and the fact that they are generally heavy compared with those in a sewage wastewater. These precautions include steeper slopes, higher velocities and a flusher system in the collection system. The wash facility will discharge a large volume of silt, clay, sand, and gravel, and an array of solid debris, such as ordnance, rags, rocks, and ration cans. This type of material does not normally occur in such large volumes in a sewage treatment wastewater. The wastewater from a CVWF also will contain higher levels of grease and oils than a typical sewage treatment wastewater. Therefore, oil removal equipment must be installed at a CVWF waste treatment facility. The biological oxygen demand (BOD) and chemical oxygen demand (COD) are usually in the 200 to 400-milligram per liter range in a sewage treatment waste stream compared with 20 to 100 milligrams per liter in CVWF wastewater.

6-1.2 Treatment System.

The water used to wash vehicles at CVWFs must be reasonably clean but is not required to be drinking water quality. All wastewater to be recycled or discharged to an offsite treatment system must first undergo primary treatment in a sediment basin to remove gross sediment, free oils and grease.

- A recycle system is a closed-loop system in which wastewater is treated, circulated, and reused. Secondary treatment of this wastewater is considered essential to minimize pump O&M, meet all regulations, and protect the environment and health of the users. The waste water overflows from the sediment basin to a secondary treatment system consisting of either an equalization basin, followed by intermittent sand filters or a lagoon system, and wash water supply basin. A recirculation loop may be needed to meet state quality standards.

- In a non-recycle (or discharge) system, the sediment basin is followed only by an equalization basin, if required, to bring the discharge to a quality and quantity that complies with requirements of the offsite treatment plant.
- A water supply basin may also be required in a discharge system if the water source cannot meet the immediate demands of the wash facility. If water is not recycled, a good quality, reliable water-source must be used. If a discharge system is being considered, the designer should consider the flow and quality requirements of the installation's sewage treatment plant authority and design the onsite treatment system and conveyance accordingly.

6-2 DESIGN PARAMETERS.

6-2.1 Criteria.

In designing the wastewater treatment system for the CVWF, the hydraulic floor will dictate the size of the collection and treatment system needed. Local water supply and weather conditions also affect the choice of treatment systems. In regions with a limited water supply, strict water conservation and reuse techniques need to be reviewed before deciding to recycle the water. Factors to consider in designing the treatment system are the wash period, cleanup time, water usage factor, wash, stormwater, water flow demand, and wastewater volume.

6-2.2 Wash Period (T_w).

The wash period is the continuous time, in hours, that the CVWF is expected to operate each time the facility is used. This time is not the minimum or maximum time that individual vehicles spend at the facility; it is the time during which the facility is expected to be operated (see Chapter 3). The wash period does not include the time required to fill and drain the prewash bath (when included) or to clean the facility. The installation must establish an operating schedule of the CVWF based on projected facility demand.

6-2.3 Cleanup Time (K).

The recommended design time to drain the prewash bath and clean up the facility is one (1) hour.

6-2.4 Water Usage Factor (U_f).

The usage factor is the estimated percentage of time that water will be flowing at maximum capacity for any component at the facility. This factor is used in determining the overflow rate into the sediment basin. The range is between 20 and 90 percent. Usage factors vary between component parts of a CVWF; a prewash bath will normally require the use of a different usage factor than a wash station.

6-2.5 Storm Water.

Rain that falls onto the pavement should be directed toward the treatment system since this stormwater may contain residual contaminants from the handstands. Stormwater runoff from adjacent unpaved areas should be directed away from the wash facility. The treatment system should be large enough to treat stormwater collected on the paved areas of the wash facility or captured on the basins; but not necessarily concurrently with water generated during a peak use period. Excess water generated from a storm event can be treated during low use periods. Stormwater flow is estimated by the Rational Method as discussed in TM 5-820-1. The area of each surface type must be estimated first. After the treatment system is sized, the computations used for each surface type should be compared with those used for the estimate and appropriate adjustments made to sizing the basin.

6-2.6 Stormwater Bypass.

A stormwater bypass should be provided at the head end of the treatment system just before the sediment basin. Stormwater diversion prior to treatment should be considered standard practice only if the CVWF is in a shutdown mode and the wash facility has been cleaned up. This diversion should be operated after each day's shutdown and when it is expected that the facility will not be in use for long periods of time, such as over a winter season.

6-2.7 Washwater Demand.

The following section defines the washwater demand parameters and computations for use in sizing the various conveyances, wash facilities and treatment facilities in a CVWF.

6-2.7.1 Parameters.

V_B = Volume of tracked baths plus volume of dual-purpose baths filled to maximum operating depth, in gallons

N_{wc} = Total number of water cannon nozzles at the bath

$F_{(i)}$ = Design flow rate per demand location, in gpm (1pm)

i = Demand Location

$N_{(st)}$ = Total number of wash hoses at the wash stations

N_{tl} = Total number of flusher points in additional trench drains at preparation areas.

N_{ud} = Total number of flusher points in u-drains at the baths

C = Coefficient of runoff

I = Rainfall intensity for region

A = Area of rainfall for surface type

N_{t2} = Total number of flusher points in trench drains at the wash station area

N_{int} = Number of vehile interior wash points at the wash stations

N_y = Number of yard hydrants in wash area

6-2.7.2 Water Demand Calculations.

Water demands in gpm (1 pm) are calculated using the following formulations.

Demand	Formulation
1. Bath flush, each occurrence	$Q_1=V_B/D$
2. Bath water cannons, vehicle washing	$Q_2=N_{wc}\,F_{wc}$
3. Wash Stations, vehicle washing	$Q_3=N_{st}\,F_{st}$
4. Flushing, additional trench drains	$Q_4=N_{tl}\,F_{tl}$
5. Flushing, bath u-drains	$Q_5=N_{ud}\,F_{ud}$
6. Flushing, wash station trench drains	$Q_6=N_{t2}\,F_{t2}$
7. Wash Station, interior washing	$Q_7=N_{int}\,F_{int}$
8. Yard hydrants, clean-up	$Q_8=N_yF_y$
9. Stormwater runoff, paved areas	$Q_9=C_p\,I\,A_p$
10. Stormwater, on basins	$Q_{10}=C_b\,I\,A_b$

6-2.7.3 Maximum Flow.

The pipes, trench drains, and weirs at the facility must be designed to handle the maximum (Q_{max}) flow rate expected at any given instant. The designer must consider all of the water and solids from each source expected at any instant. The maximum flow is usually expected to occur during cleaning operations when the bath is flushed, the trench flushers are on, and the wash station hoses and water cannons are in full use. The usage factor adjustment is not applied, since this is the peak situation and all systems are operating. The maximum flow rate is the greater of either the sum of Q_1 thru Q_8, contributions or the sum of Q_9 and Q_{10}

$$Q_{max}=Q_1+Q_2+Q_3+Q_4+Q_5+Q_6+Q_7+Q_8 \qquad \text{(eq 6-1)}$$

or

$$Q_{max}=Q_9+Q_{10}$$

Note: The designer must determine which combination of flows are applicable to any particular conveyance feature; not all flows will be present in all conveyances, trench drains, or overflows.

6-2.8 Water Volume.

6-2.8.1 Parameters.

Water volume computations are based on the following parameters:

K = Cleanup time (generally 1 hour)

T_w = Wash period

T_t = Wash period including cleanup

T_s = Storm Duration (10 year, 24 hour)

B = Number of times the bath is filled from the water supply basin per wash

period. (Bath volumes taken from the equalization basin are not counted since these volumes do not receive complete treatment through the secondary treatment system. The number of times that the bath is drained and filled will depend on the length of the was period and the visual quality of the bath water)

U_i = Usage factor (from 20% to 90%) source

6-2.8.2 Volume Calculation.

Volume	Formulation
1. Volume from bath flush	$V_1=V_BB$
2. Volume from bath water cannons	$V_2=Q_2T_t$
3. Volume treated at wash station hoses	$V_3=Q_3T_t$
4. Volume from additional preparation area flushers	$V_4=Q_4K$
5. Volume from bath U-Drain flushers	$V_5=Q_5K$
6. Volume from wash station trench flushers	$V_6=Q_6T_t$
7. Volume from interior wash points	$V_7=Q_7T_w$
8. Volume from yard hydrant	$V_8=Q_8K$
9. Volume of stormwater runoff-pavements	$V_9=Q_9T_s$
10. Volume of stormwater falling on basin surface	$V_{10}=Q_{10}T_s$

6-2.8.3 Average Volume (V_{ave}).

V_{ave} is an estimate of the total volume of water used during an average wash period. The average wash period is the period of time during which the vehicles are being washed in typical washing operation. Usage factors are applied to each source of water, since not all water cannons, hoses, and trench flushers will be operating at all times. V_{ave} (eq 6-2) is used to estimate the size of the water supply basin and the equalization basin or polishing lagoon:

$$V_{ave}=U_1V_1+U_2V_2+U_3V_3+U_4V_4+U_5V_5+U_6V_6+U_7V_7+U_8V_8+U_9V_9+U_{10}V_{10} \quad \text{(eq. 6-2)}$$

Note 1: V_1, V_5, and V_6 are included in the equation only if these volumes are withdrawn from the water supply basin. Volumes withdrawn from the equalization basin are not included in the formulation.

Note 2: V_9 and V_{10} are not part of V_{ave} in a standard design. Including V_9 and V_{10} as part of V_{ave} is the designer's option.

6-2.8.4 Maximum Volume (V_{max}).

V_{max} is an estimate of the total volume of water used during the peak use period of the facility. The same equation (6-2) used to calculate V_{ave} is also used to calculate V_{max}; the difference is that the wash period used to calculate the individual volumes, V_2 through V_8, is the length of the peak washing operations, not the length of the average

washing conditions. Usage factors are still applied in the equation to compensate for the time during which the nozzles are not operating. The V_{max} value is the primary volume used in sizing the water supply basin and the equalization basin or settling lagoon. V_{max} is also used in the sizing of the intermittent sand filters.

6-2.8.5 Water Balance.

The designer must perform a water balance during the preliminary design phase. The purpose of the water balance is to ensure that basins such as the equalization basin do not overflow and that the water supply is not totally drained. Thus, the designer must make provisions to handle the peak use water volume in each basin during the washing operations. Based on the results of the water balance, the designer may be required to increase, or may be able to decrease the size of the basins.

6-3 PRIMARY TREATMENT.

6-3.1 Function.

All wastewater from the CVWF must undergo primary treatment. A concrete sediment basin with an oil skimmer device is provided to separate and remove contaminants such as grease, oil, and sediment by gravity. Free oil shall be removed in this basin prior to pumping which could cause oils to emulsify. Wheeled vehicle access shall be provided to this basin for removing the large volumes of sediment that accumulate in this basin. The bottom of the basin should be sloped approximately one percent away from the entrance ramp to assist in dewatering when the basin is emptied. Sediment basins are designed with oil recovery, inlet and outlet control structures, and drains.

6-3.2 Number of Basins.

In a wash facility, with or without bath, a sediment basin with only one cell may be provided, however, it must be designed to treat the entire volume of water and sediment expected. Maintenance procedures must insure minimizing down time when the single basin is cleaned. A sediment basin with two cells should be provided if the wash facility cannot be shut down for scheduled cleaning and repairs. Providing a two-celled sediment basin allows one cell to be isolated for cleaning and repairs while the other one remains in service for primary treatment. The detention time of the waste water may be reduced in the basin if only one cell is operable due to closure of the other, but the wash facility may still be utilized. During normal operations of a facility with a bath, one cell is used to treat the volume of waste wash generated from vehicle washing water from the wash, while the adjacent cell is used to treat the volume of water from the bath flush and clean-up activities. The functions of the two cells should be alternated frequently, to distribute the sediment loads evenly between basins.

6-3.2.1 Single-cell Configuration without Bath.

At small facilities without bath, a single-basin system as depicted in Figures 6-1 and 6-2 should be provided. A single sediment basin system should function hydraulically, such that the inflow volume is equivalent to the overflow volume. If a large surge of water is

expected, then sufficient storage volume must be allowed in the basin to ensure that a minimum detention time of 2 hours is maintained. The basin volume must account for the accumulated sediment storage volume between cleanouts. The outlet structure is a weir constructed across the width of the access ramp. The location of overflow weir ensures a constant water level in the basin.

6-3.2.2 Dual-Cell Configuration without Bath.

At larger facilities, without bath, where washing down time during basin cleaning may not be desired or practical, dual cells similar to Figure 6-1 and Figure 6-2 should be provided. Cells would have a common wall and be provided with common inflow and outflow control structures.

6-3.2.3 Dual-Cell Configuration with Bath.

A dual-cell system for use with baths in large facilities is shown in Figure 6-3 and Figure 6-4. Before bath(s) are to be emptied into the sediment basin, the operator should assure that the water level in one of the basin cells in the sediment basin is at low level. The volume of bath water will be stored in this cell. The adjacent cell continues to provide primary treatment for wastewater from the washing facilities. This configuration allows the entire surge volume of wastewater from the bath to be held for the proper detention time and not become short circuited in the sediment basin. The volume of each cell is designed to hold the storage of sediment between scheduled cleanouts plus the entire volume of a bath release and clean-up water.

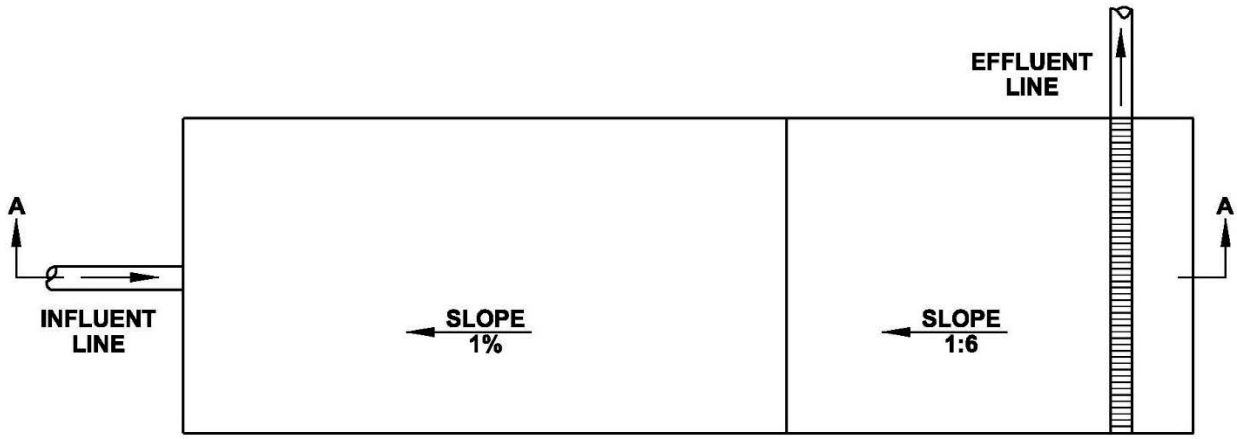
6-3.2.4 Single-Cell Configuration with Bath.

For small facilities with bath, a single-cell configured similar to that depicted in Figure 6-3 may be provided if the wash facility can be taken out of service during the cumulative period of time to drain the bath(s) and draw down the sediment basin.

6-3.3 Siting.

Sediment basins are sited to receive gravity flow of wastewater from the wash facility. The basin should be close to the washing operations to avoid long conveyance distances and severe depths of conveyances being placed at the required grades. Basins should be oriented along the axis of prevailing winds with the outlet end and oil skimmers located downwind so that surface currents will carry free oils toward the removal equipment. The basins must not be readily accessible to troops but should be visible from the control building and easily accessed by the CVWF operators.

Figure 6-1 Single Cell Sediment Basin, Plan View



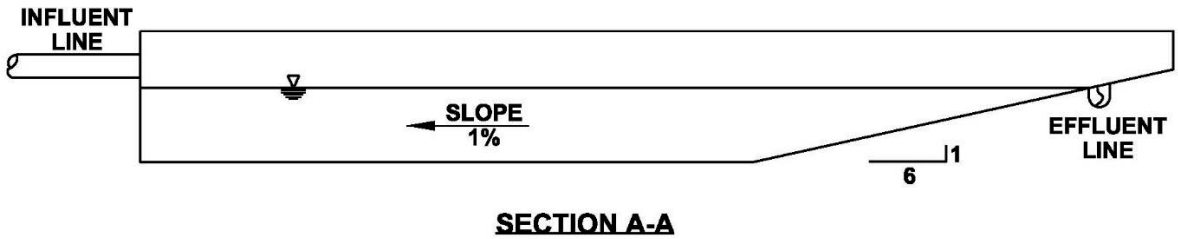


Figure 6-2 Single Cell Sediment Basin, Cross Section

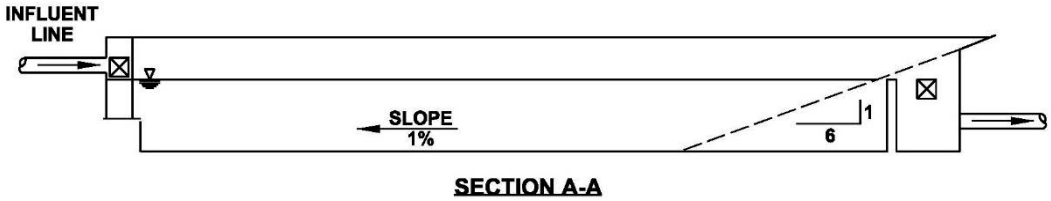

6-3.4 Sizing.

The size of each cell in the sediment basin will be based on the volume of water to be treated and the volume of sediment to be stored in the basin between cleanings. The user must determine how often the sediment will be removed from the basin. It is recommended that each cell of the basin be cleaned at least once per year; however, the exact number of basin cleanings will depend on variations of soiling, user requirements, and other considerations unique to the installation. In addition to the water and sediment depths, from 1 to 2 feet (0.3 to 0.6 meter) of freeboard must be provided. Figure 6-4 shows typical water and sediment depths. Each cell should have a minimum length-to- width ratio of 3 to 1 to allow for the proper settling time. The turning radius of cleaning equipment, such as a front-end loader, should be considered in determining the width of the cells.

Figure 6-3 Dual Cell Sediment Basin, Plan View

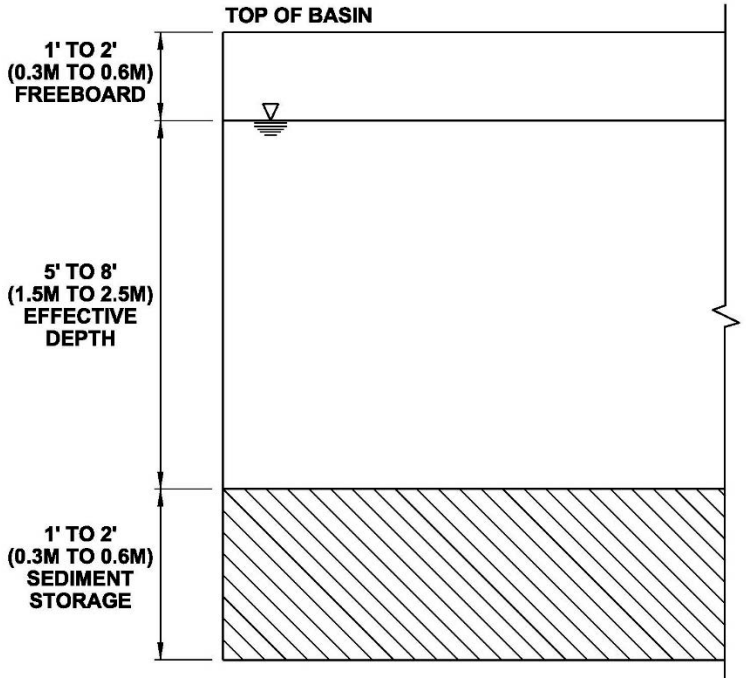

Figure 6-4 Dual Cell Sediment Basin, Cross Section

6-3.4.1 Velocity.

A uniform horizontal flow-through velocity of from 0.5 to 2 feet per minute during washing operations is desirable. The lower range is preferred for predominantly silt and for clay-type soils; the higher rated applies predominantly to sandy soils.

Figure 6-5 Typical Design Water and Sediment Depths

6-3.4.2 Sediment Volume (V_{sed}).

Each basin must store the volume of sediment expected to accumulate between basin cleanouts. The value used to predict sediment volume (V_{sed}) must be based on the expected vehicle soiling and number of basin cleanings per year. Heavy soiling can be expected on vehicles returning from training exercises in off-road areas that have wet field conditions and cohesive soils. The sediment volume will vary between installations and even within the installation due to different soil types in the training areas, training schedules, climate and weather conditions. Table 6-1 lists estimates of the amount of dirt removed from different tactical vehicles each time it is washed. Experience may indicate that a value outside of this recommended range be used to estimate the sediment volume.

Table 6-1 Estimated Volume of Material per Vehicle

Vehicle Type	Average Heavy Soiling cu ft/vehicle (m^3/vehicle)	Average Light Soiling cu ft/vehicle (m^3/vehicle)
Tracked	2.0 (0.06)	1.5 (0.04)
Wheeled	0.6 (0.02)	0.5 (0.01)

Equation 6-3 can be used to determine to predict the total annual sediment volume. If dual-cells are provided, each basin will store half of the total sediment volume expected over the time period between cleanouts, assuming cells have been evenly alternated. Equation 6-4 is used to calculate the required basin volume.

6-3.4.3 Water Volume.

For a single-cell sediment basin, the cell should be sized for a detention time of from 2 to 4 hours with cells operating in parallel; or from 1 to 2 hours with one cell in operation. Wastewater having a high cohesive soil content will require settling times at the upper limit of the range; settling times for noncohesive soils should be at the lower end of the range. One method of determining optimal detention time (T_D) and settling velocity is to perform bench-scale settling tests for the soil conditions at each training site. Another method is to use Stoke's Law in computing trap efficiency. The basin should have a total effective water depth of 5 to 8 feet (1.5 to 2.5 meters).

6-3.4.3.1 Sediment Basin Overflow Rate.

The basin overflow rate is an estimate of the flow rate of wash water used during a wash period (T_w (Equation 6-5). It is determined by reducing the maxi- mum flow rate by usage factors. This flow rate is used when determining the detention time and sizing the cells for the sediment basin. The designer must use discretion as to whether the trench flushers in the wash area will be operable while the vehicles are being washed. The trench flushers in a bath will not operate during washing. The designer also must

use engineering judgment as to what percentage of time the trench flushers (if any) in the vehicle preparation area will be operable while the vehicles are being washed.

$$Q_{over}=U_2Q_2+U_3Q_3+U_4Q_4+U_5Q_5+U_6Q_6+U_7Q_7 \quad \text{(eq 6-5)}$$

6-3.4.3.2 Single Cell System.

In a single-cell system, the cell should be designed to store the water for the designed detention time and should also hold the sediment volume collected between cleanouts. Equation 6-6 gives the water and sediment volumes needed for sizing a single cell at a facility without a bath. If a bath is provided, the bath volume, V_1, must be added to the equation. This equation calculates only water and sediment volumes; it does not include the freeboard which must also be added. Also Q_9, stormwater flow, would not be normally considered an additive flow. The basin should be sized to handle the greater of two volumes, maximum wash water volume or stormwater volume.

$$\text{Volume} = (Q_{over}+U_8Q_8)*T_D+V_{sed} \quad \text{(eq 6-6)}$$

6-3.4.3.3 Dual-Cell System.

In a dual-cell system, each cell must be sized to store the maximum volume expected at any given time. The volume of each cell will depend on the larger of:

$$\text{Case 1: Volume} = 0.5\ V_{sed}+Q_{over}T_D+V_1$$

$$\text{Case 2: Volume} = 0.5\ V_{sed}+0.5\ Q_9T_s$$

6-3.5 Sediment Basin Influent Structure.

The influent line should empty into the deep end of each cell of the basin, opposite a ramped entrance that provides access for the cleaning equipment. A structural baffle or energy dissipater may need to be installed at the influent end to disperse the wastewater and solids across the width and to help prevent water and solids from short-circuiting to the effluent structure. The inlet invert must be placed higher than the maximum water level in the basin to prevent deposition of solids in the influent line or inlet structure. Motorized gates may be used in a two cell basin to make it convenient for the operator to switch the influent flow from one cell to the other or to use both.

6-3.6 Sediment Basin Effluent Structure.

The effluent structure must be located opposite the influent end in order to maximize the detention time in the basin. Protective baffles, fixed or removable, may be installed in front of the effluent opening to prevent discharge of floating debris and oil. A section through the overflow trench for a basin without bath is shown in Figure 6-6. The effluent structure for a basin with bath consists of adjustable, motorized gates used to regulate the height of the water in the basin (Figure 6-7). This arrangement allows the operator to alternate treatment from one cell to the other or use both cells in parallel.

6-3.7 Sediment Basin Construction.

Sediment basins are constructed of concrete in order that a front-end loader can enter the basin at the ramp and remove the sediment without damaging the liner. In addition, a concrete basin prevents oil and other wastes from seeping out of the basin into the surrounding soils.

6-3.8 Sediment Basin Drainage.

The sediment basin must be provided with a drainage system which allows the captured sediment to dewater for easier removal from the basin, controls the discharge of large volumes after draining the prewash bath facilities, permits other routine maintenance to the structure and/or equipment, and permits preparation for winter shutdown.

6-3.8.1 Draining System.

Drain down of the basins for cleaning is accomplished through a drain line with a manually operated valve as depicted in Figure 6-8. Drain down of water trapped in the sediment is aided by gravel packed drains placed along the center wall or in the bottom of each cell. The pumping system shown in the figure is an alternate since, at this point in the treatment system, the main stream flow is by gravity and drainage may occur below the hydraulic grade line. The immediate return of the water drained from the sediment basin to the treatment process is desirable in order to facilitate the removal of any disturbed sediment and oil.

6-3.8.2 Valving.

The valving depicted in Figure 6-8 allows lowering the water level in the sediment basin to the expected maximum sediment level and dewater the captured sediment. Gravel packed drains or trenches are located around the inside perimeter of the basin or in the floor and consist of a perforated pipe encased in filter fabric and gravel. Valving and pumping facilities may be placed at either end of the sediment basin. Drains shall be located below the bottom of the basin or otherwise protected so that, during removal of sediment, they will not be disturbed or damaged. The trench method can be used at either the influent or effluent end of the sediment basin.

Figure 6-6 Typical Effluent Structure with an Overflow Trench, Sedimentation Basins without Bath

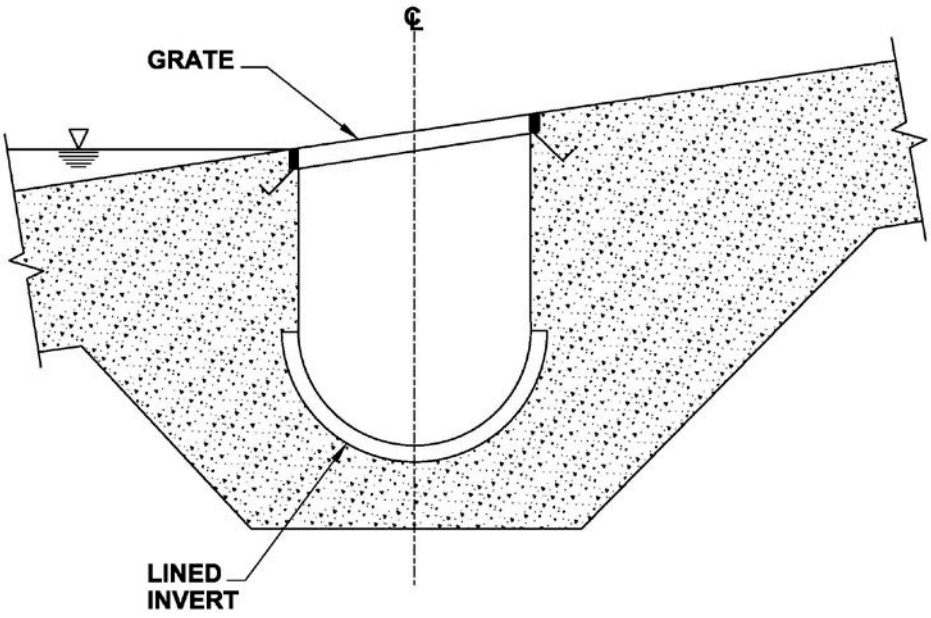

Figure 6-7 Typical Effluent Structure with Motorized Gates, Sediment Basins with Bath

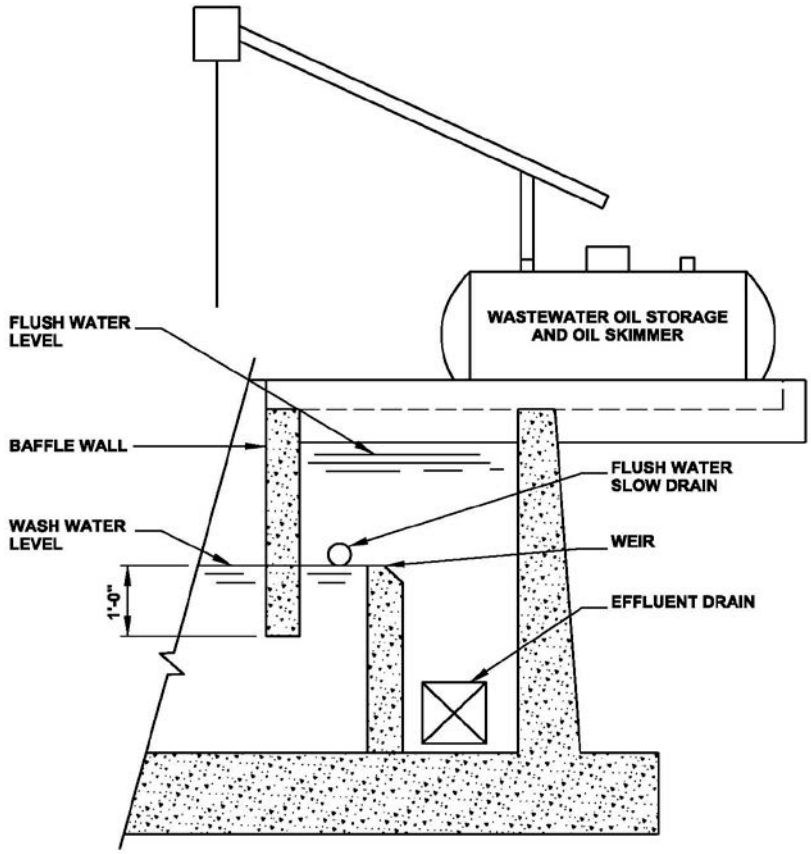

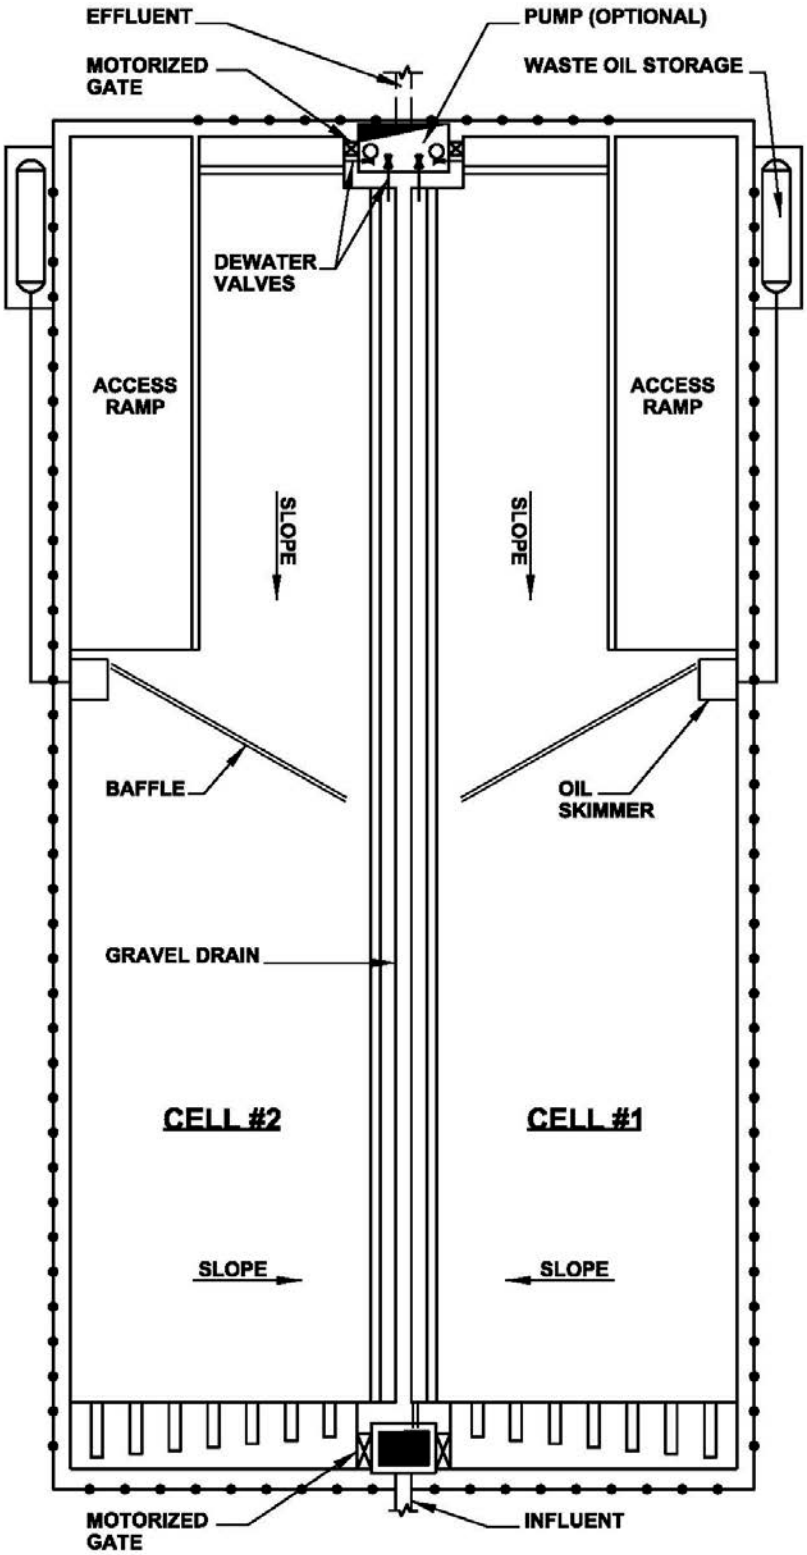

Figure 6-8 Sedimentation Basin Drain System

6-3.9 Sediment Removal.

Sediment basins are not equipped for continuous removal of solids and therefore, the basin should be sized to allow solids accumulation over at least one year based on the estimated solids removed from the vehicles. To remove the accumulated solids, the basins are first drained of water to the maximum extent possible with slow drains, sediment dewatering drains, and/or pumps as described in the previous section. The solids are then removed using front-end loaders and dump trucks that access the solids zone via the concrete ramp. The material is hauled away for proper disposal in accordance with local, State, and Federal regulations.

6-3.10 Oil Removal.

Free floating oils and greases carried into the sediment basin as a product of vehicle washing are lighter than water and therefore rise to the surface. The oils and greases are removed using motorized surface tube-type oil skimmers in each basin. The skimmings are stored in an above-ground or underground waste oil storage tank located near the sediment basins. Skimmers are usually located at the downwind end of the basins. Floating or fixed baffles which extend below the effluent weir elevation may be provided to direct oils toward the skimmer and to prevent the carryover of oils past the effluent weir.

6-3.11 Waste Oil Storage.

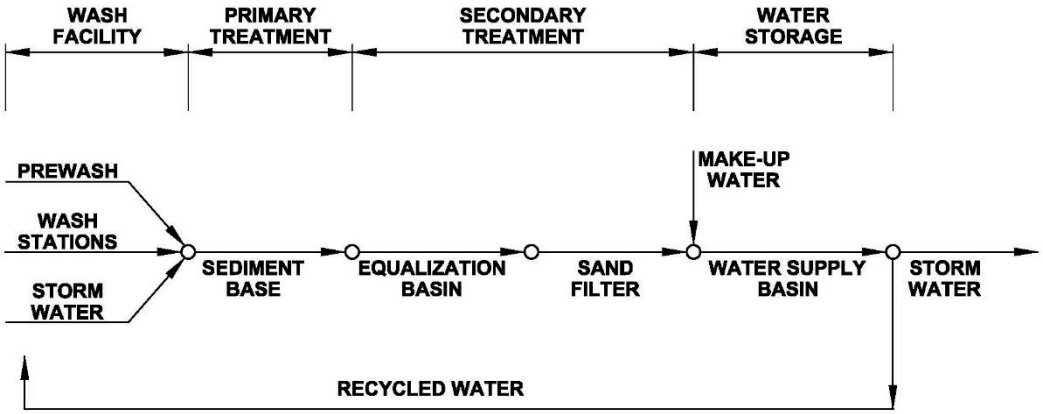
Waste oil storage tanks are designed, constructed and installed in accordance with current U.S. Environmental Protection Agency, State, or Local regulations for above ground or underground storage tanks. Storage tanks should be 500 to 2000-gallon (1893- to 7570-liter) capacity, depending on the estimated amount of oil recovery and frequency of cleanout. Positive spill containment should be provided at the cleanout port and directed back to the sediment basin.

6-3.12 Maintenance.

Routine maintenance of the sediment basin and appurtenances will be minimal. Sediment should be removed from each cell at least once per year. The waste oil storage tank should be emptied before its capacity has been reached. Provide appropriate site gauges and/or high level alarms. Oil skimmer devices must be strategically located, easily accessible for servicing and durable. Daily inspection of the oil skimmer unit is required to insure continuous, trouble-free operation.

6-3.13 Other Considerations.

Sediment basins should have pipe rail or fencing mounted on the wall in accordance with OSHA requirements for safety considerations; or the grade surrounding basins located lower than top of wall to provide a safety barrier. Hydrostatic pressure relief should be provided where generally high water tables exist and basins should be designed to prevent flotation when empty. Access ramps should be serrated for vehicle traction. Inlet and outlet ends should be readily accessible to operators, through an



access road around the basins. Lighting should be provided at the inlet structure and at the outlet structure.

6-4 SECONDARY TREATEMENT.

6-4.1 Onsite Secondary Treatment.

At installations where an adequate, dependable, low-cost wash water source cannot be found, and favorable site and weather conditions exist, a recycle water system should be used. The water source must adequately supply clean water on demand during the peak wash periods. The quality of effluent from a sediment basin usually is not adequate for discharge to a sewage treatment plant, even if treating non-cohesive soils and therefore, cannot be used as recycled water. For recycling, secondary treatment is required. If an adequate water source is available and recycling would not be economical, the wastewater may be discharged to an existing sewage treatment plant for further treatment. In this case, onsite sediment basins followed by an equalization basin would still need to be provided. Two alterative onsite secondary treatment systems are available for treating waste washwater to a quality suitable for reuse in vehicle washing, namely, intermittent sand filtration.

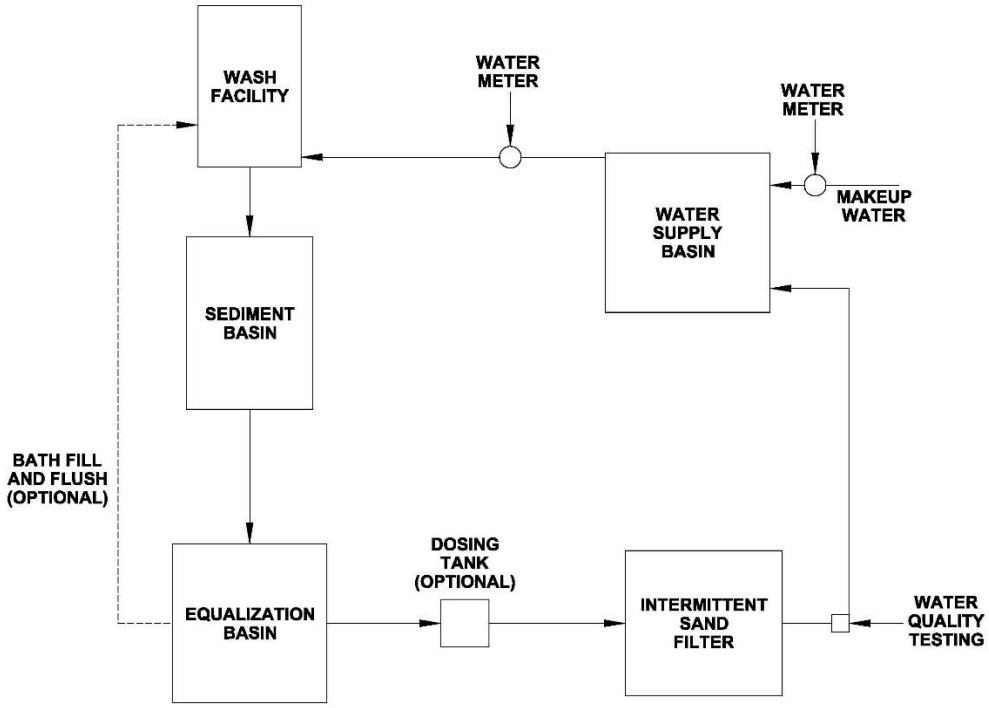


Figure 6-9 Components of an Intermittent Sand Filter System

6-4.2 Objective.

Secondary treatment removes suspended matter, microorganisms, impurities, and minor residual oils from the product water. These materials are carryovers from the primary treatment process and consist mostly of colloidal materials such as clays and fines that have not been removed during sedimentation. The removal of these suspended solids is essential to produce a relatively clean, clear, acceptable product for recycling as wash water.

Figure 6-10 General Schematic of an Intermittent Sand Filter Recycle System

6-4.3 Intermittent Sand Filter System.

This system, depicted in Figure 6-9 and Figure 6-10, consists of three components: equalization basin, optional dosing tank, and intermittent sand filter. All three units are located downstream of the sediment basin in the order listed.

6-4.3.1 Equalization Basin.

The equalization basin (Figure 6-11 and Figure 6-12) serves two main functions. First, it is considered a part of secondary treatment because it provides storage and flow dampening of the sediment basin effluent so that this water can be delivered at a controlled rate to the intermittent sand filters for final treatment. The basin buffers the fluctuations in wastewater flow and quality caused by variable use of the wash facilities. It also compensates for the difference between basin in- flow and intermittent sand filter application rates. By regulating the dose of water to the intermittent sand filter at designated intervals and rates, the filter size can be minimized. Second, the equalization basin provides a quiescent zone for settling of fine, suspended solids that have been carried over from the sediment basin. This function improves the overall suspended solids removal efficiency of the treatment process. Unfiltered water from the equalization basin should be used as a source of water for filling the bath prewash and for trench drain flushing, thereby conserving the water supply. When equalization basin water is used in this way, separate delivery pumps and piping are required, but the size of intermittent sand filters and water supply basins are usually reduced.

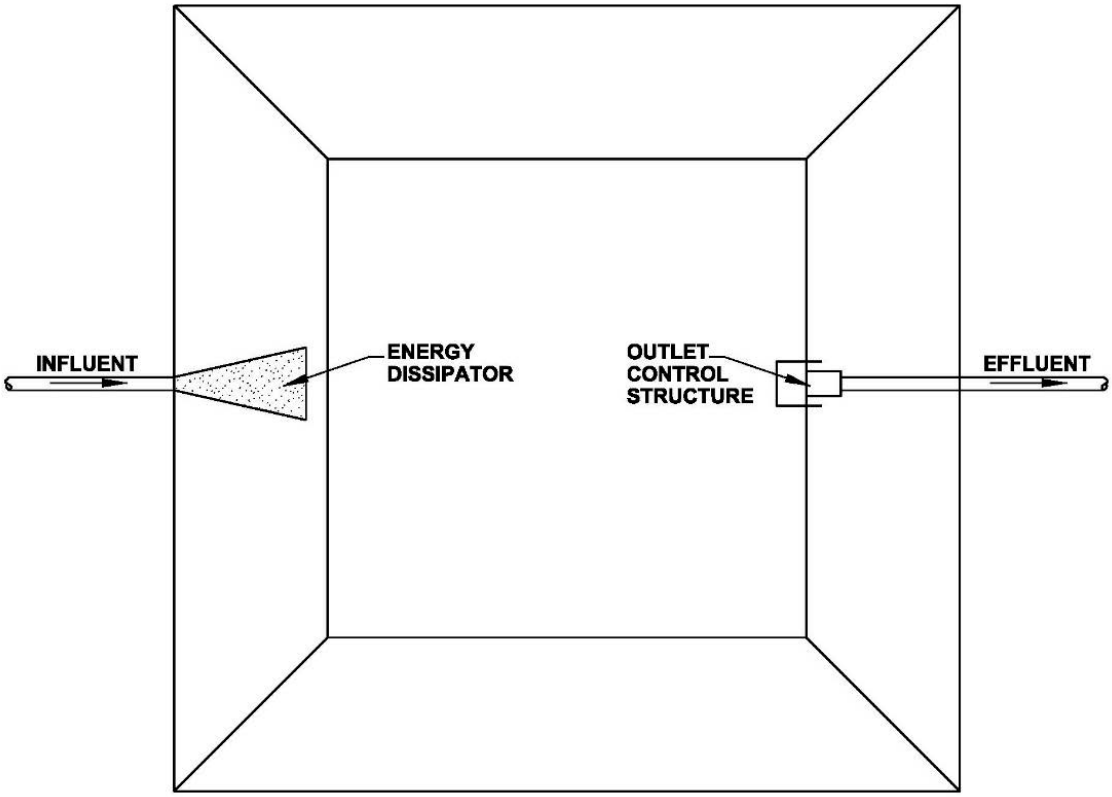
6-4.3.1.1 Siting.

The equalization basin is located at a lower elevation than the sediment basin and the wastewater should flow by gravity from the sediment basin to the equalization basin.

6-4.3.1.2 Sizing.

The size of the equalization basin will be based on several factors, including the volume of water from the sediment basin, the number and capacity of intermittent sand filters, the frequency of dosing the filters, and the volume of sediment expected to collect between cleanouts. The designer must ensure that the size of the equalization basin is compatible with the influent volume from the sediment basin and the effluent to the dosing tank or intermittent sand filters. If it is too large, it will not be cost effective. If the basin is too small, it will overflow. An extra 2 to 3 feet (0.6 to 0.9 meter) of freeboard should be included above the maximum loading volume.

Figure 6-11 Example Equalization Basin, Plan View



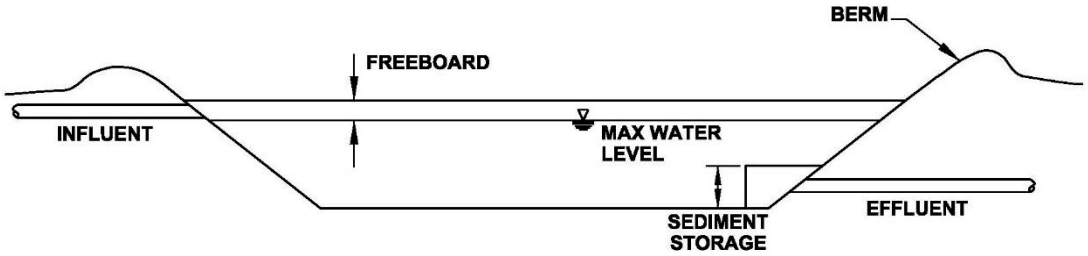


Figure 6-12 Equalization Basin, Cross Section

- Water Volume. The basin's size should be based on V_{ave}, for a one week wash period or V_{max} for a peak use period, whichever is greater. A safety factor ranging from l.25 to 2.0 times V_{ave} or V_{max} should be incorporated to help insure adequate water volume at all times. The effective depth of the basin should be 5 to 8 feet (1.5 to 2.4 meters). Deeper basins should be considered in arid regions to reduce water surface areas, thereby minimizing evaporation.
- Sediment Volume. A depth of from 1 to 2 feet (0.3 to 0.6 meter) should be allowed for sediment storage at the bottom of the basin and this volume added to the water storage requirements.
- Dead Storage Volume. A depth of 2 to 4 feet (0.6 to 1.2 meter) should be allowed directly above the sediment volume for dead storage. This additional volume allows for submergence of the basin effluent control structure and provides a minimum water volume to optimize settling.

6-4.3.1.3 Influent Structure.

A concrete trough should be installed at the inlet to prevent liner erosion. The inlet pipe should he higher than the maximum water elevation in the basin to allow free discharge of wastewater. If the wastewater Influent line were submerged, sediment could collect and eventually clog the line.

6-4.3.1.4 Effluent Control Structure.

The effluent structure should be located opposite the Influent structure thereby maximizing the water detention time in the basin. If cohesive soils are present, float supported baffles may be required to increase the detention time and minimize short circuiting of wastewater in the basin. Stormwater diversion prior to treatment should be considered as standard procedure only if the CVWF is in a shutdown mode. This diversion should be in operation after each day's shutdown and when it is expected that the facility will not be in use for long periods of time, such as during winter.

6-4.3.1.5 Construction.

In-ground equalization basins are designed and constructed with water-tight walls and bottom. Several liner materials, or combinations, can be considered for water- tight construction. However, local experience with earthen basins may suggest that no lining is needed. In-ground basins should be de- signed and constructed in accordance with

and with approval by the state regulatory authority in which the facility is located. The most cost effective, environmentally acceptable basin construction should be provided.

- Concrete. A concrete liner is permanent and can resist freeze/thaw cycles. If a concrete lined basin is used, the foundation must support the weight of the structure, concrete, sediment, and water at maximum depth. Concrete can crack and deteriorate and can be relatively expensive to install and repair compared with other types of liners. The slope of the walls will depend on the method of construction. Expansion/contraction joints are required and may be difficult to seal tightly.
- Bentonite and Natural Clay. A bentonite or natural clay liner can be installed only over certain soils. Non-cohesive soils that contain large amounts of fines without coarse lenses (sands and gravels) are susceptible to movement which can cause leakage in bentonite and clay liners. A site without shallow bedrock and without a perched water table is desirable for installing these types of liners. When these materials are used, the slope of the walls will vary, depending on local conditions such as the soil's angle of repose. Sediment removal equipment could damage a bentonite liner, since movement of the bentonite can cause leakage. Therefore, a concrete ramp and floor must be installed to provide access for removing the sediment. Leaks may occur at each point where the bentonite and concrete interface. The inlet must have an energy dissipater such as a concrete trough with rocks to prevent erosion of the bentonite walls. Bentonite-treated basins must be protected from stormwater erosion to maintain their integrity.
- Synthetic Materials. Various types of synthetic rolled material can be used to line the equalization basin. A synthetic liner is installed in the same way that a landfill is lined. A proper base is pre- pared and the liner is positioned, then covered with soil. Equipment can move over the bottom of the basin if the soil covering the liner is thick enough to protect it, a proper base is under the liner, and the walls are not sloped too steeply. A concrete ramp and floor can be installed in the basin before the rolled material is placed. A concrete trough must be used to channel the Influent over rocks and other obstacles to dissipate the energy of the falling water. If a synthetic liner material is selected, it should be resistant to petroleum products and sunlight such as high density polyethylene (HDPE).

6-4.3.1.6 Sediment Removal.

The equalization basin design should include means for dewatering and gaining access to the basin. Basins should be designed for infrequent sediment removal in the range of from 10 to 20 years based on solids carryover from the sediment basin. Sediment storage should be from 1 to 2 feet (0.3 to 0.6 meters). In selecting the liner, designers should consider the method and equipment the facility will use to remove sediment. The liner used should sustain the least damage to its bottom and side walls during cleanout. A ramp with a slope of 1 to 6 (17 percent) may have to be constructed to allow cleaning equipment access to the basin.

6-4.3.2 Dosing Tank.

A dosing tank or device is a storage structure or component located after the equalization basin and before the filters. The purpose of the dosing tank is to discharge settled water to the intermittent sand filters at the desired dosing rate and frequency. The first choice for delivering influent to the filter surface is by gravity flow; however, if this design is not possible, automatic operation is an important alternative. Automated delivery is done using flow-activated valves, dosing siphons, timer-controlled valves, or pumps. It is suggested that a dosing siphon or electronically triggered valve be provided in the dosing basin in conjunction with the distribution piping. The most economical dosing siphon in sewage systems is the type with proper bypass pipes and valves; however, electronic float-actuated valves with manual over-ride mechanisms are also effective. Both approaches require a minimum elevation differential between equalization basin water level and filter surface. Water flows by gravity from the equalization basin to the filter pump wet well and then is pumped to the filters via a filter valve control box or valve house.

6-4.3.3 Intermittent Sand Filters.

Intermittent sand filters provide an economical, effective method of treating water prior to reuse at the wash facility. Filters provide a final polishing step by further reducing residual BOD5 and suspended solids that maybe in the water. This step renders the water suitable to be pumped and reused for washing. The mechanisms involved in removing suspended solids by filtration are complex. Some straining occurs at the filter surface; however, most solids removal in granular filters of the type used at CVWFs occurs within the pore space of the filter media particles and by absorption of impurities onto the filter media surfaces. Additional straining between media particles in the filter also contributes to overall solids removal. Although the primary purpose of the filters is to remove suspended solids and provide a polishing step prior to recycling, they also are effective in reducing BOD5, nitrogen compounds, and algal populations through a combination of physical and biological processes without the addition of chemicals. The effluent quality filtration is such that any discharge or reuse is environmentally safe and will cause no increased pump wear. Adequate product water is achieved with minimal O&M costs and personnel. This type of sand filter does not require backwashing.

6-4.3.3.1 Configuration.

The surface of an intermittent sand filter may be divided into two, three, or four cells. The cells may share a common underdrain collection system, but will have separate distribution systems. Each cell should be physically separated by surface partitions to prevent wastewater from spilling over from one cell to another. At the designer’s option, the partitions may also completely separate the 36-inch (0.9 meter) sand layer between cells; a minimum of 12-inch (0.3 meter) penetration is recommended.

6-4.3.3.2 Siting.

Intermittent sand filters can require large areas. Therefore, the most desirable topographic and location criteria would include a level site that is free of trees,

woody vegetation, and rock; a deep groundwater table; good natural drainage away from the filters; and proximity to the main pump station and water supply basin. Open filters should be located away from or protected against windblown dust from unpaved tank trails. Site conditions may require windbreaks such as fences, trees, or shrubs to prevent wind erosion of the filter media and/or prevent dust from settling on the filter surface. It is desirable that the site be high enough above the maximum water elevation in the water supply basin to allow for gravity flow into the water supply basin.

6-4.3.3.3 Sizing.

The size of these filters and their pumping system is determined by three factors: daily dosing rate, dosing frequency, and dosing rate.

- Daily Dosing Rate. This rate is the maximum wastewater volume per day per unit area (in acres) which is applied to the surface of the filter and depends on the loading rate. Typically the application rate is between 490,000 and 980,000 gallons per acre per day (524 and 1048 liters per square meter per day), which is the equivalent to flooding the filter to a depth from 6 to 12 inches (15.2 to 30.4 centimeters) every 8 hours. The daily dosing rate of the filter currently is chosen according to soil conditions. Soil type (S_t) for the installation (chap 3) should he used in evaluating the design loading rate. CVWFs serving installations with mainly sandy soil (S_t=1) and little or no suspended clay in the training areas may be designed at higher loading rates. However, since some clay-type soils (S_t=5) occur at most installations, design should he adjusted toward the lower end of the recommended loading rate.
- Dosing Frequency. The daily dosing volume is applied to the filters in three intervals to maintain wetness of the filter and also allow the filter to "breathe" between doses, thus maintaining the aerobic biological treatment which results from intermittent dosing. Normally, a filter will have more than one cell and each cell must be dosed every 8 hours, but the actual dosing interval may be alternated from cell to cell. A dosing sequence using equal dosing per day per filter to he delivered by an automatic dosing device or pumps is recommended. Using the available filters on an alternating basis, with rest periods between doses, effectively reduces the hydraulic dosing rate. This procedure is achieved by using electronic timers to control the application of wastewater to the filters.
- Dosing Rate. This value is the flow rate to the filter during each of the three dosing intervals. Dosing flow to the filter should be 95 to 190 gpm per 1000 square feet of filter surface area (6 to 8 inches [15.2 to 20.3 centimeters]) applied for 20 to 40 minutes to give the desired daily loading rate.
- Filter Surface Area. The total filter surface area is calculated by dividing the average weekly flow by the daily loading rate x 7 as the

filter can be designed to operate 7 days per week unattended. The total filter surface area is then divided into two or more filter cells. This design minimizes the size of the wastewater distribution network on the filter surface and lowers the effect of taking one filter cell off-line for servicing. Because the distribution lines must be easily removable for servicing the filter surface, it is useful to limit their length and size. Small filters also minimize pump capacity and velocity of flow through the distribution systems. Cell sizes of approximately 1/4 acre (1012 m^2) are desirable; however, they may be larger.

- Example Sizing. Assume that a CVWF requires an average weekly wash water flow of 1.6 million gallons per day for 5 days/week; soiling conditions indicates a loading rate of 650,000 gallons/acre/ day.

  Further assume that two filters will be used, each divided into four cells:

  Cell Size = 1.76 acres/ filters*4 cells/filter

  = 0.22 acres/cell

  Dosing frequency: one of the eight cells is dosed every hour.

  Volume per filter dose = 8,000,000gal / 21 doses= 380,950 gal per dose.

  Volume of dose per filter cell = 380,950 gal / 8cells = 47,620 gal.

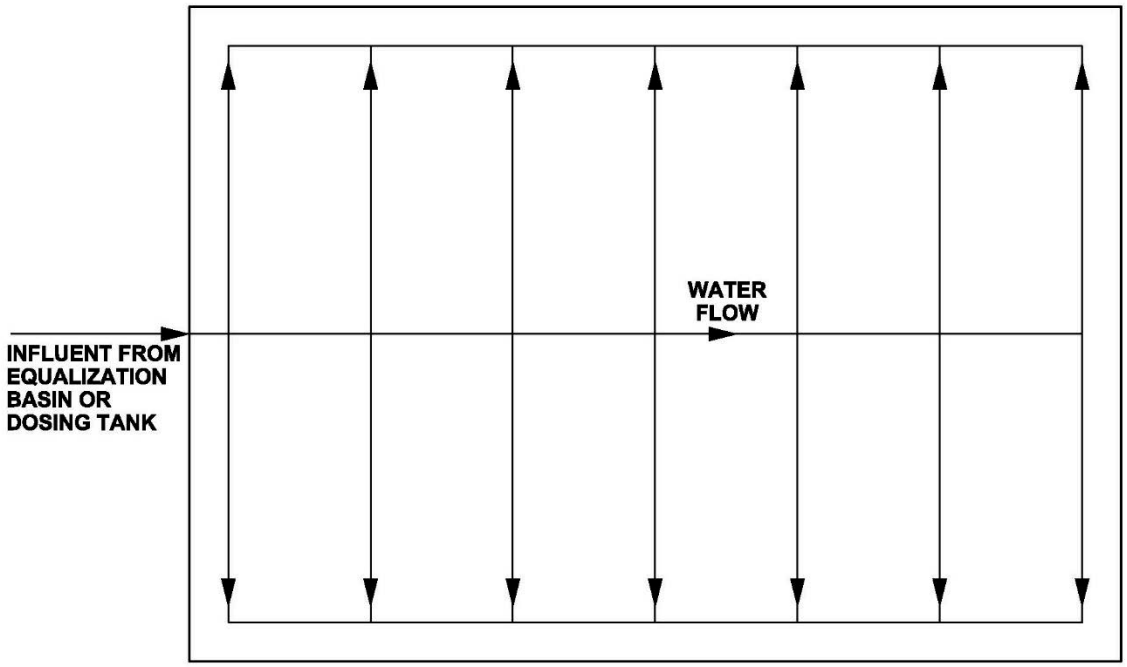
  Dosing rate = 150 gpm / 1000 square feet x 0.22 acre (9,583 square feet) = 1438 gpm.

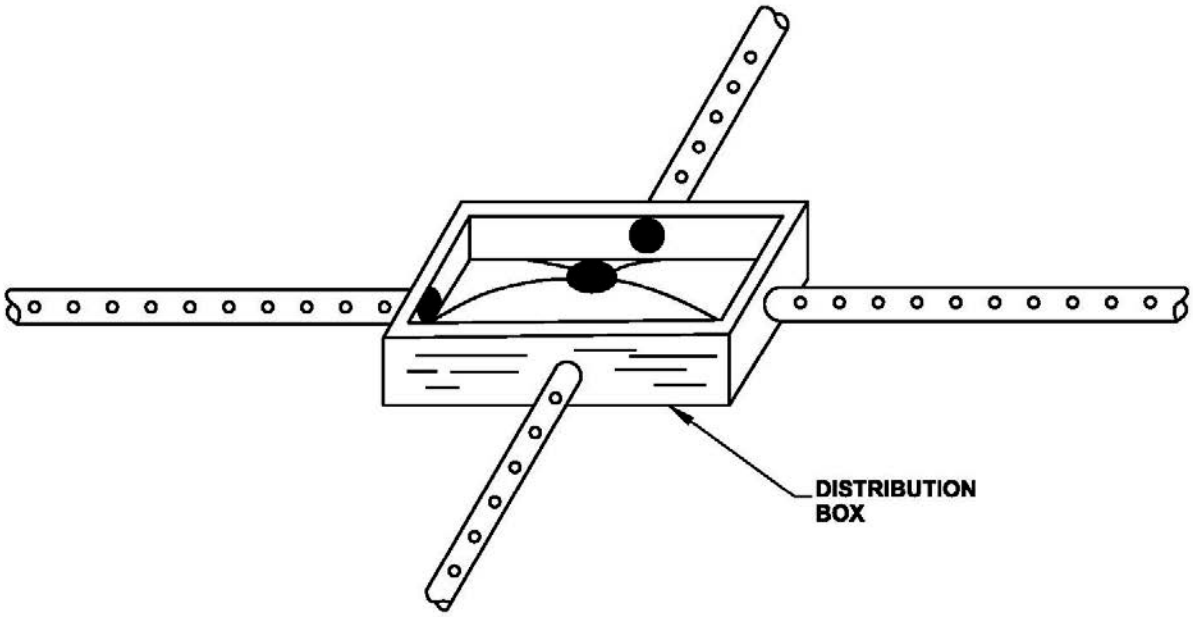
  Pumping time to dose each cell = 47,620 gal/I 438 gpm = 33 min.

6-4.3.3.4 Distribution System.

The designer may choose one of several distribution systems to apply waste water evenly over the surface of the sand. Whichever system is chosen, the de- signer must ensure that it will be easy to remove and replace for cleaning. One design uses perforated plastic pipes placed on the surface of the sand in a grid pattern (Figure 6-13). The drilled orifices in the pipes should be at least 0.16 inch (4 millimeters) in diameter or larger to prevent the openings from clogging. The pipes must be sized to distribute the water as evenly as possible. Another distribution system uses wooden troughs placed on the surface of the filter (Figure 6-14) and positioned so as to apply water to the surface of the filters as evenly as possible (Figure 6-15). The number of distribution troughs needed will depend on the area of the filters and the volume of water to be filtered. Plastic pipes with drainage holes may have to be installed in the troughs to extend the distribution system and apply the water uniformly over the surface. The holes in the pipes should be the same size as those in the grid system. The filter distribution system used should he capable of being disassembled when maintenance of the filters is required and the supply pipe to the distributors should he buried.

Figure 6-13 Distribution System Using Grid Arrangement





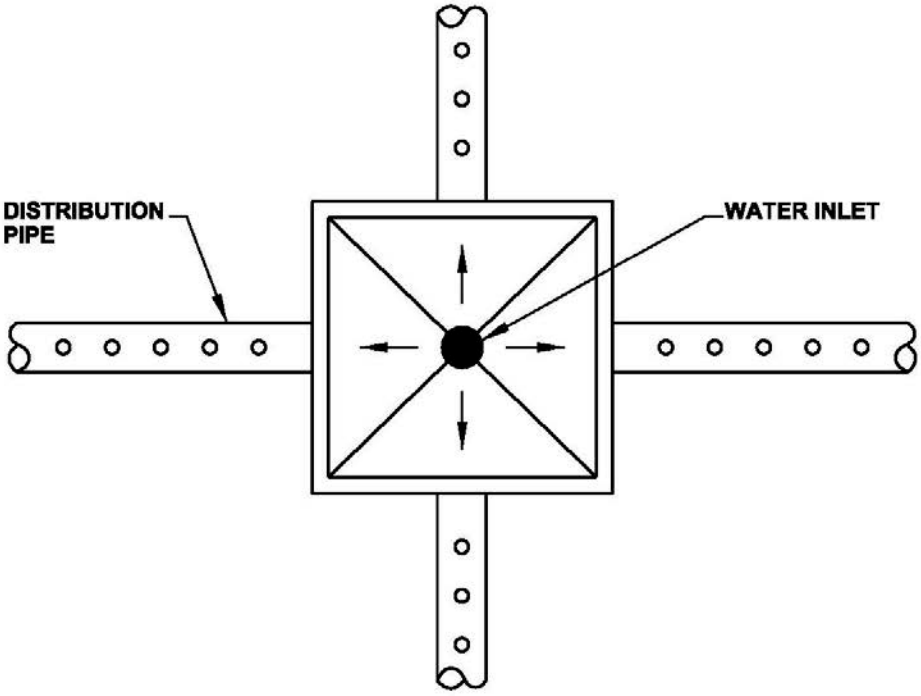


Figure 6-14 Distribution Box

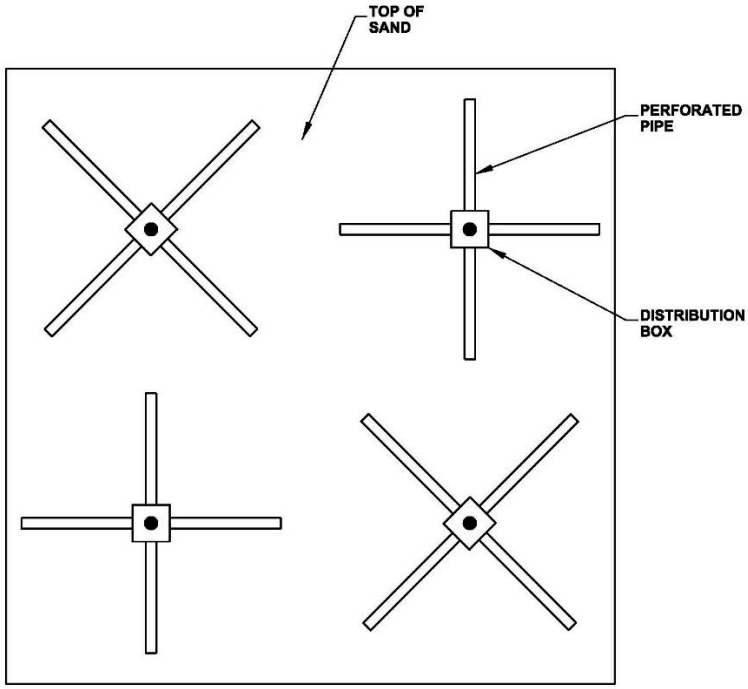


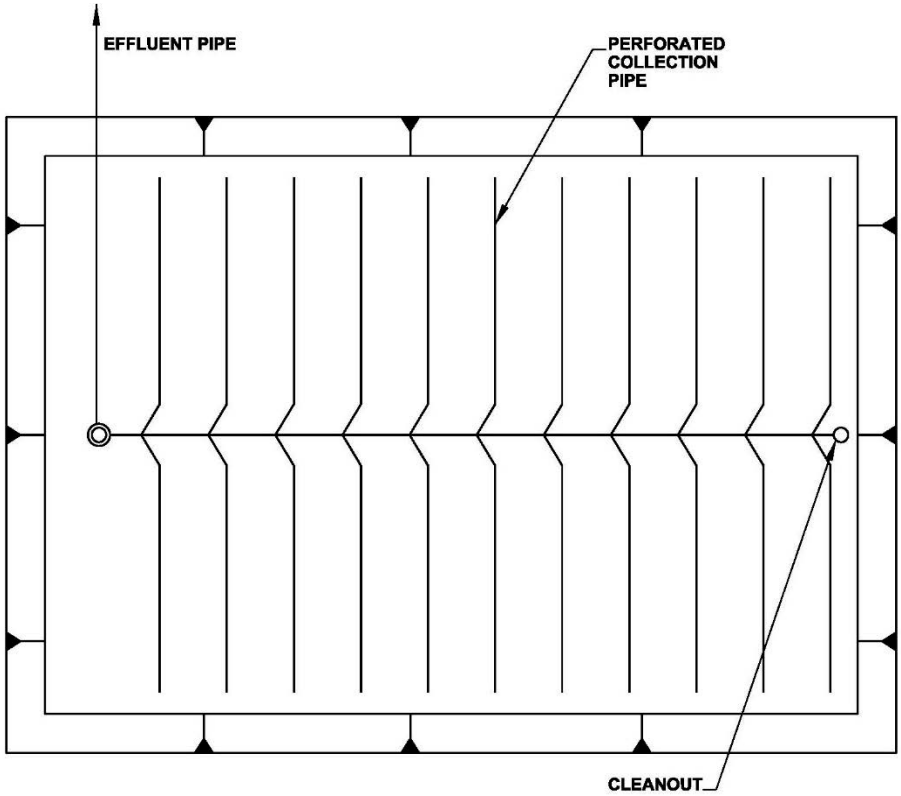
6-4.3.3.5 Underdrain System.

Perforated collection pipes for the filters are installed near the bottom of the filter embedded in gravel just above an impervious layer. Water will percolate downward through the sand and collect in the pipes (Figure 6-16). These underdrains should be placed on a minimal grade (less than 0.25 percent) to provide gravity flow. The designer must consider the surface area of the filters and design the collection system to also handle stormwater falling on the filter.

6-4.3.3.6 Materials.

Local sands and gravels should he used whenever possible. The material may have to be washed and screened to obtain clean and properly sized aggregate. The top 36 inches (0.9 meter) of the filter should contain sand with less than 1 percent of the fines passing the number 200 sieve. The D_{10} should be between 0.2 and 0.4 millimeters with a uniformity coefficient (D_{60}/D_{10})1 of less than 3.5. The next layer contains 4 inches (10.2 centimeters) of 0.5-inch (1.3- centimeter) aggregate. The next layer is 3- inches (7.6- centimeter) of 1-inch (2.5- centimeter) aggregate. The bottom layer consists of 11 inches (27.9 centimeters) of aggregate ranging in size from 1.5- to 2.0- inch (3.8-to 5.1-centimeter). The depth of the bottom layer should be measured from the bottom of the lowest collection pipe. The bottom and walls of the filter must be relatively impervious. Liners of clay soil or geotextile membranes should be provided similar to those described for the earthen basins (para 6-26). Figure 6-17 shows an intermittent sand filter in cross section.

Figure 6-15 Distribution System Using Distribution Boxes

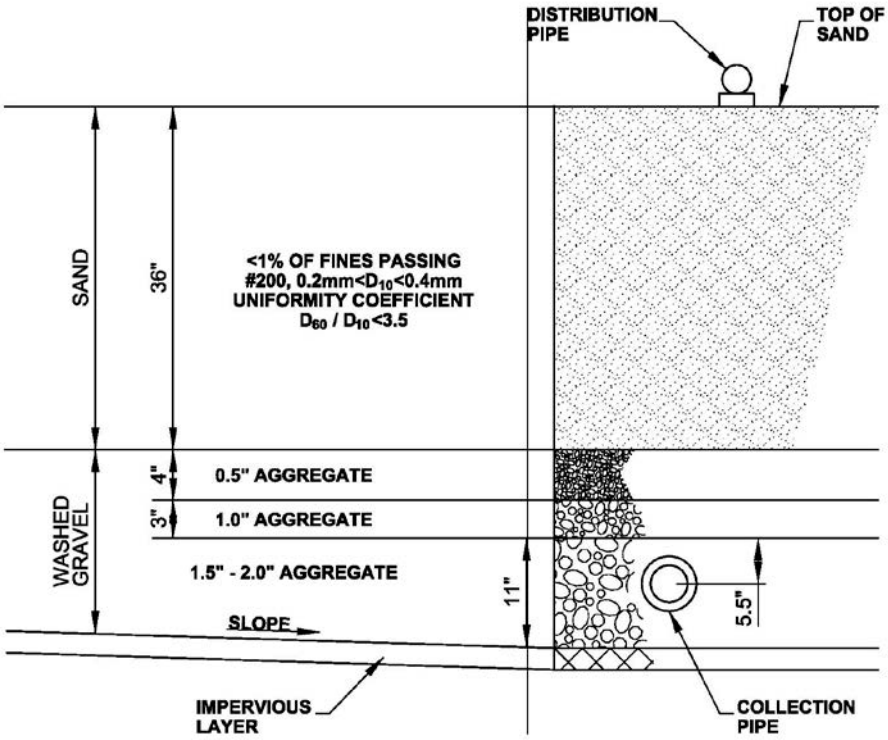


6-4.3.3.7 Filter Maintenance Considerations.

The filter sand and the filtered matter support the growth of weeds and grass. Weed control is not required since low grasses and weeds can protect the surface sand from direct sun rays. This shades the sand and reduces evaporation. However, trees and other plants with root systems that could clog or otherwise interfere with the filtering process should be removed.

- Winter operations are mostly similar to those during warm weather except that cleaning the filters during cold weather is more difficult. Cold season filtering should be started with a clean, raked filter surface. If the CVWF (and therefore the filters) will not be used during freezing months, the distribution piping including header, distribution main, and laterals must be designed to be fully drained to prevent damage due to freezing. The underdrain network must also be designed to be fully drained or to prevent water from collecting in the filter and underdrain to a depth at which freezing damage can occur.
- Where wind-blown dust and dirt could be transported to the filters from unpaved tank trails or erosion-prone areas, natural or artificial screens may be considered.
- When a filter is observed to be plugged or approaching a plugged condition, it will be necessary to rejuvenate the filter surface. Two approaches are recommended. The first consists of raking the media surface to remove debris and breaking the surface incrustation that results from the drying of fines and debris. The filter is raked manually with a garden rake or a small tractor rake or disk attachment. When raking no longer appears to rejuvenate the filter surface due to the buildup of filtered matter in the top layer of the sand media, then it is necessary to remove and replace the solids-laden layer. The sand is removed manually or with mechanical devices. A four-wheel-drive garden tractor equipped with a hydraulically operated scraper, bucket loading device, and either flotation-type or dual rear tires works well. The decision to discard or reuse the spent filter sand will largely depend on local availability of this material. When sand costs are high, the removed sand should be stockpiled, washed, and recycled. This approach is especially attractive in wet climates. It is also possible that filter effluent could be used to clean the sand.
- The designer must consider the above maintenance aspects of intermittent sand filters and include in the design measures for access, cleaning equipment, intermittent sand filter layers, distribution piping design and ease of removal, and freeze protection.

Figure 6-16 Collection System



6-4.3.3.8 Monitoring.

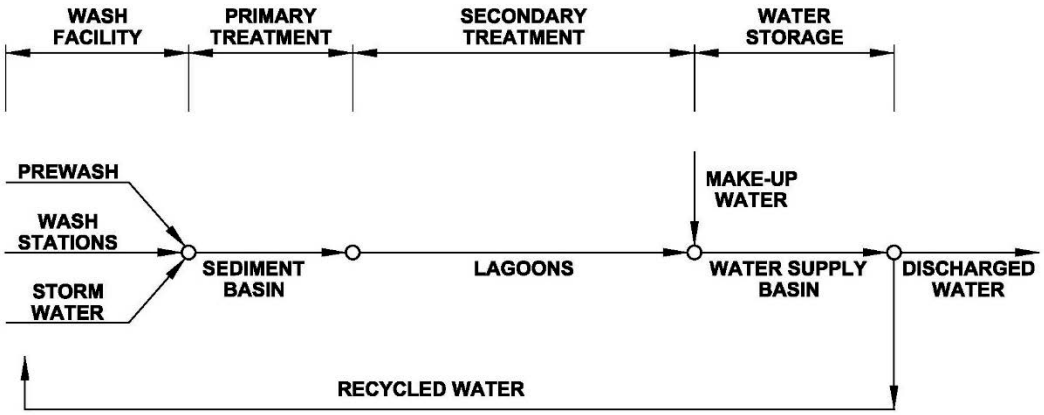
The effluent stream should be monitored for quantity and quality at a point between the intermittent sand filters and the water supply basin. If the water quality meets the standards of the regulatory agency, it is allowed to flow into the wash water supply basin. Otherwise, it is rerouted to the equalization basin for further treatment. The effluent also should be tested periodically for grease, oil, BOD_5, COD, hydrogen-ion concentration (pH), total dissolved solids (TDS), and suspended solids (SS) levels.

- A recycle system should be monitored at least weekly for the first year of operation. This time span will give the installation a good profile of the treatment system's operation. After the first year, the system may need to be monitored once per month or every other month. These data should be compared with the initial profile data to confirm that the system is working properly.
- If primary treated and equalized water is discharged to a sewage treatment plant, the system should be monitored weekly for the first 3 to 4 months to assure the plant operator that the biological, solids, oils, or hydraulic load being discharged from the wash facility are in compliance.
- A system that discharges to the environment will require permitting in accordance with the state regulatory agency. The agency must be

consulted to determine the monitoring frequency required. Measurements and laboratory tests should he performed in accordance with the instructions in Standard Methods for the Examination of Water and Wastewater.

Figure 6-17 Intermittent Sand Filter Cross Section

6-4.4 Lagoon System.



Using lagoons as a secondary treatment system for wastewaters from a CVWF is not the recommended standard. The use of lagoons instead of intermittent sand filters requires Office of the Chief of Engineers (OCE) approval prior to programming and design. Lagoons can be used for secondary treatment only if ponds exist in the vicinity of the CVWF and they are environmentally, hydraulically and structurally acceptable; and if they are more cost effective than sand filters; and long term settling test confirm the ability of lagoons to produce acceptable water quality. However, past designs have used the lagoon treatment system for secondary treatment at CVWFs as described below.

6-4.4.1 Description.

A lagoon system, like an intermittent sand filter system, includes a sediment basin for sediment and free oil removal (Figure 6-18). If the wastewater is to be recycled, an equalization basin and wash water supply basin are also required. The polishing lagoon is sized to give a minimum of 14 days detention time for the wastewaters after pre-treatment. This minimum detention time is calculated at peak hydraulic flow conditions into the lagoon. Sediment storage within the lagoon must be provided for the design life

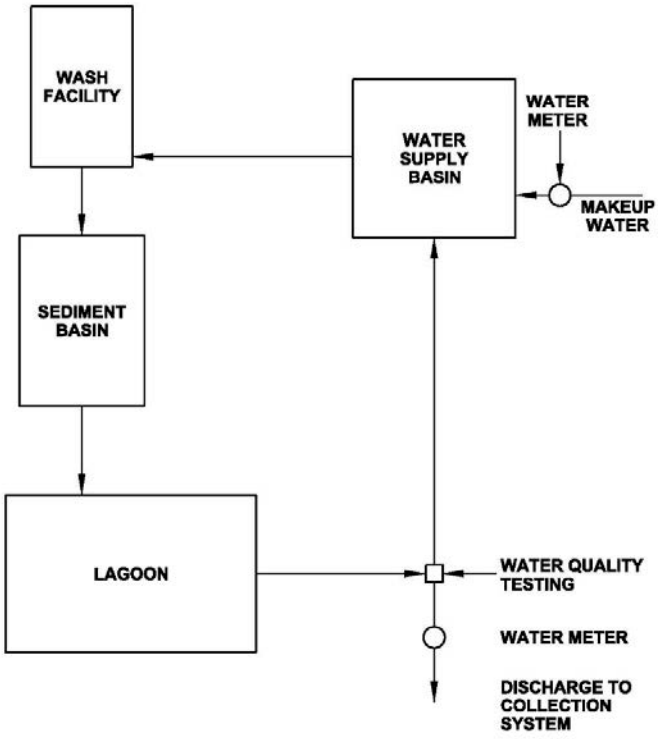
of the lagoon. This storage volume is calculated by multiplying the anticipated flow by the sediment load in the flow by the design life. Figure 6-19 shows the basic lagoon arrangement.

Figure 6-18 Components of a Lagoon System

6-4.4.2 Components.

- Influent Structure. The influent structure is located and designed so that it is not sub- merged.
- Effluent Structure. The effluent structure is designed to prevent the overflow residual floating oils and solids.
- Liner. Liner performance should be resistant to the action of petroleum products.
- Oil Removal. Continuous oil removal in the lagoon is not required.
- Stormwater. Stormwater capacity is designed into the lagoon based on rainfall for the site. It should be assumed that washing operations at the CVWF can occur during a design storm event.
- Waste Discharge (recycle only). The lagoon should have the capability of discharging 50 percent of its capacity to control dissolved solids that will have accumulated in the wash water. This amount can be reduced to 30 percent in areas where the rainfall meets or exceeds the evaporation rate. The lagoon should be monitored for dissolved solids each month of operation.
- Maintenance. The lagoon should be monitored for deterioration of water quality and for leakage.

6-4.5 Discharge System.



A total discharge treatment system removes dirt and debris from the wastewater before discharging the entire volume to a secondary treatment system, usually a sewage treatment plant Figure 6-20 shows the unit process in a discharge system, and Figure 6-21 is a schematic depicting the treatment sequence. Primary

treatment is required to remove free oils and prevent sediment deposition in the conveyances and causing a blockage. This treatment also prevents large volumes of sediment and oil slugs from entering a sewage treatment plant which is usually not designed to handle this type of waste. If it is not feasible or practical to discharge the wastewater to a sanitary sewer system, the water may have to be discharged to stormwater surface drainage channels or storm sewers. If one of these methods is used, the water must be treated to produce an effluent quality complying with the installation's National Pollutant Discharge Elimination System (NPDES) permit since this type of discharge is classed as a point source. The discharges must be regularly monitored and reported.

6-4.5.1 Equalization Basin.

An equalization basin may be required if the sewer lines or plant cannot accept the total instantaneous volume of pretreated wastewater. If the water volume is to be introduced slowly to the discharge location, an equalization basin should be constructed to hold wastewater until it is discharged. The basin should be designed as previously described.

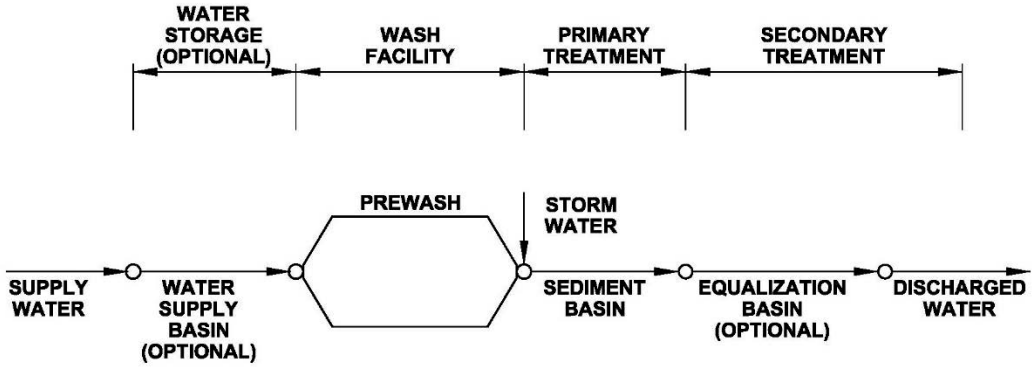


Figure 6-19 General Flow Schematic of a Lagoon System

6-4.5.2 Water Supply Basin.

A water supply basin may be required in a non-recycle system if the wash demand exceeds the available source of supply. This should be planned, designed and constructed as previously described.

Figure 6-20 Components of a Total Discharge System

6-5 WATER SUPPLY BASIN.

6-5.1 Introduction.

Filtered water from the secondary treatment facility (sand filter or lagoon) flows by gravity into the wash water supply basin. This is a lined basin which stores the filtered wash water supply for the vehicle wash area. Maximum and minimum operating levels are monitored by level sensors in the wash water pumping station. The basin is sized to store, at a minimum, the quantity of water required to wash the maximum number of vehicles for which the facility is designed during the design wash period. Makeup water for the CVWF is added into the water supply basin. If necessary, excess water can be discharged from this basin; however, the basin should be sized to hold the water demand volume plus storm water from a one hour duration 10-year storm event.

6-5.2 Capacity.

The effective water volume of the basin should be based on V_{ave} for a one week wash period or V_{max} for a peak use period, whichever is greater. A safety factor ranging from 1.25 to 2.0 times V_{ave} or V_{max}, should be incorporated to help insure adequate water volume at all times. The basin should include 3 feet (1.0 meter) of freeboard above the highest water level, including an allowance for stormwater. There is no need to provide for sediment storage in this basin since the water in the basin should not contain sediment. A depth of 2 to 4 feet should be allowed for dead storage at the bottom of the basin. This additional volume allows for submergence of the effluent control structure. Figure 6-22 and Figure 6-23 show different views of a water supply basin. The designer must ensure that the size of the water supply basin is compatible with the influent volume from the secondary treatment or water source and with the effluent volume to the wash facility. If the basin is too small, there will not be enough wash water, but if it is too large, it will not be cost-effective. The effective depth of the water supply basin should be 5 to 8 feet (1.5 to 2.5 meters). Deeper basins should be considered in arid regions to reduce water surface areas, thereby minimizing evaporation.

6-5.3 Liner.

The water supply basin may be lined with concrete, clay, or a synthetic material, if required, such as those described for the equalization basin (para 6-26 above). In areas with high evaporation rates, light-colored basin liners might be considered to lower solar heat gain and decrease the evaporation rate.

6-5.4 Influent Structure.

An energy dissipation device or treatment should be installed at the inlet to dissipate the energy of the influent water and prevent liner erosion. The inlet should be close to the maximum water elevation in the basin to prevent water from backing up into the pipe and surcharging the sand filter drain system.

6-5.5 Service.

There should be little, if any, solids deposition in this basin, so there is no need for a ramped service entrance into it. There should also be no oil in this basin, so no oil removal equipment is needed.

6-5.6 Security.

Fences may have to installed around the basin to prevent animals from entering the area to drink or bathe.

CHAPTER 7 OTHER DESIGN CONSIDERATIONS

7-1 WATER SOURCE.

All treatment systems will require a reliable source for charging the CVWF initially and for make-up, regardless of the form of secondary treatment. The volume of water required will depend on the type of wash facility constructed, type and configuration of the treatment system, frequency of use, losses, and the local climate. If a recycle system is provided, the designer must determine the most feasible and economical method of filling the system initially, and then maintaining the water level in the system by adding makeup water from the water source. Makeup water will be required to restore the system to a working level as water is carried off by the vehicles or lost to evaporation and overspray. All original source and makeup water should be added at the water supply basin, if provided. This water should be uncontaminated, reasonably clean, and should not require treatment before being introduced into the system. All sources of water available at the installation should be considered for use, singly or in combination, as sources of water at a CVWF including dedicated wells, surface water, tapping into the existing potable water supply or captured rainwater.

7-1.1 Type of Facility.

A wash facility that has a prewash will require more makeup water than a facility with only wash stations because of increased water lost by vehicle carry-off, overspray and evaporation. Water losses from carry-off can be as high as 160 gallons per vehicle. Losses due to overspray and evaporation can be as high as 10 percent from water cannons and 5 percent from hoses at wash stations.

7-1.2 Type and Configuration of Treatment System.

The type and configuration of the treatment system is another factor to consider when estimating the volume of makeup water required. A discharge system will require that the total water demand including makeup be taken from the developed water source. In a recycle system, only the water lost to overspray, evaporation and vehicle carry-off will need to be replaced from the water source. Treatment systems with basins that have large surface areas may have greater water losses due to evaporation than basins with smaller surface areas. This loss will increase the volume of makeup water required, as discussed below.

7-1.3 Climate.

The evaporation rate at the installation must be considered when calculating the volume of make-up water needed to maintain the total demand. The volume of rainfall at the installation as well as the amount lost to evaporation should be calculated to determine the volume of water needed from the water source. Water balance computations should be performed by the designer to assure adequate supplies of water throughout the entire washing season.

7-2 PIPING.

Wastewater should be conveyed by gravity whenever possible for economy. Pumping should be avoided because residual oils may become emulsified and difficult to remove, solids cause wear on pumps and pumps add significant capital and operating costs to the facility. Conveyances, whether gravity sewers or open channels, must be constructed to grades which will provide adequate scouring velocity to prevent solids deposition. All pipes must be designed for peak hydraulic and solids loadings, including that contribution from stormwater runoff from hardstands. Because of the external and internal abuse and because of inaccessibility, piping systems must be durable. Leakage or infiltration allowances normally associated with gravity piping should not be used; gravity lines should be watertight. Other factors such as soil corrosion and freeze protection need to be addressed also. Open-channel flow should be used whenever possible for ease of maintenance. If siting problems or severe slopes make open-channel flow impractical, the designer should use large-diameter pipes. Locate manholes at each change in slope or direction and at each pipe intersection. Design long, straight sections of pipe to minimize the number of manholes required. All frequently operated, buried valves should be accessible through pits or manholes.

7-3 HOSES, WATER CANNONS, AND NOZZLES.

Hoses must be of a size and weight which a person can handle, but yet be durable enough to withstand the abuse of repetitive use, vehicular traffic, and internal abrasion from fines in the water. Nozzles and water cannons undergo similar treatment. The industry is lacking for equipment that can stand up under the continuous use given at a CVWF; therefore the designer must be very selective when selecting hoses, water cannons and nozzles.

7-4 CONTROL SYSTEMS.

The process controls for a CVWF can be very complex to a Contractor who has never seen a wash facility. Material specifications for controls are standard. The logic of the control system is special to the design. It is very important that the designer clearly describe within the plans and specifications how the components are to function.

7-5 SYSTEMS OPERATING MANUAL.

Complete manuals should be prepared by the designer de- scribing the various components of the CWF and how they were designed to be used. The manual should establish standard operating procedures including staffing, scheduling, safety, records keeping, and other operational responsibilities. All the control systems should be illustrated and step-by-step instructions provided for not only standard procedures, but also special procedures. The manual should also establish maintenance responsibilities for all the elements in the CVWF. Preventive maintenance will be performed by the operators. Tools for their use must be made available along with spare parts for critical items. Training of operators is very important. Providing them with the written documents previously described is a start, but the best training can be done through hands-on operation under the instruction of the designer. The amount of training time will depend on the size and complexity of the CVWF, whether it has a

prewash and whether it has a recycle water system. For the simplest CVWF, training could be accomplished in a day; for the most complex, the training period could be up to a week.

This Page Intentionally Left Blank

CHAPTER 8 DECENTRALIZED WASH FACILITES

8-1 OVERVIEW.

Installations and Commands are encouraged to review total operations of the units in their command and how they relate to vehicle wash requirements. Commands may have less aggressive vehicle wash requirements or have limited land resources for a large water resource and treatment system. Self-contained units are now available which can be adapted to a local area for the treatment requirements of the command. New self-contained systems can be adapted to the requirements of the local unit such as a National Guard or a Reserve component. Or the Installation may have multiple Commands which can be decentralized to allow for single unit washing capability during hours which would not be fit into the Installations hours of operation. Although a large Centralized Washing Operation is more pertinent to heavy mechanized training operations, the addition of a Net Zero Design to the egress side of the “bird bath” would enhance thru-put and drastically reduce water consumption. A decentralized washing system would be the ideal design for all other military units, weekend Reserve operations or National Guard operations on an as needed basis.

Alternative systems that are now readily available are:

- Self-Contained, Closed Loop Systems (No Discharge to Sanitary System).
- Energy efficient; Meet low consumption energy use.
- Water efficient; Meet low consumption water use.
- Satisfying Net Zero goals.
- Minimizing waste stream wash debris.
