maintenance required for adequate and safe performance of the structure. Monitoring or after care of the structure may be necessary for 2 to 10 years after the structure is completed to ensure the vegetation becomes established and the structure is meeting performance requirements. The impact of changes to site conditions should be evaluated during planning for safety and maintenance requirements. The effect of loss, damage, and change of vegetation species on structure performance should be discussed. The effect of disease, fire, harvesting, or removal related to plants in the structure and impact on performance must be elevated. Requirements for vegetation replenishment, pruning, selective cutting, and replacement should be included in maintenance planning. Repair to the soil, backfill, or hard materials in the structure must be addresses. The accretion of sediment on stream banks due to the trapping of sediment by vegetation should be evaluated for loss of stream conveyance and decreased slope stability due to the increased weight of accreted sediment. Damage due to wave action from storms, navigation, or boats should be determined.

Clear acceptance criteria should be defined for the project as well as warranty requirements. Acceptance and warranty requirements may be more stringent and require longer periods of time than traditional bank stabilization projects due to the need for vegetation to become established.

The following stream flow velocities are recommended for maximum limits on the selected methods of stream bank or channel stabilization.

- Vegetative protection 2.5 m/s 8 feet per second (fps) Structural and bioengineering
  - Woody material, 2.5 m/s 8 fps
  - Woody material and herbaceous species, 1.5 m/s 5 fps
  - Herbaceous alone, 1 m/s 3 fps
  (USDA TN Plant Materials No 23, Technical Notes, September 1993)
  - Flow velocities greater than 2.5 m/s 8 fps may require reinforced matting or hard structures.

Bioengineering methods require construction techniques and materials, which are described by other existing specifications. The following specifications should be included with this specification in the bid package depending on site conditions and design objectives.

Minor clearing and grubbing of vegetation is provided in this specification with an emphasis on salvaging cleared or grubbed material for the construction of the bioengineered structure. For
extensive clearing and grubbing of vegetation for site construction or access, refer to Section 31 11 00 CLEARING AND GRUBBING.

Minor earthworks may be required for the construction of the bioengineered structure. In addition, select fill or backfill materials may be needed. This specification only includes the requirements for the minimal earthworks necessary for key trench installation and surface roughening. For slope reduction, benching, and material specification, refer to Section 31 00 00 EARTHWORK.

The construction of bioengineered structures often results in the exposure of soils that require protection from erosion. This specification mentions the need for erosion control products but does not provide the specifications or installation methods for these products.

Bioengineering methods may incorporate stone or rock. For the requirements for hard armor, refer to Section 35 31 19 STONE, CHANNEL, SHORELINE/COASTAL PROTECTION FOR STRUCTURES.

Seeding is an important component for many bioengineered structures. To specify the requirements for the installation procedures for seeding, refer to Section 32 92 19 SEEDING.

Fencing may be required during and after construction to protect bioengineered structures and associated vegetation from damage due to human and animal activities. For the requirements for fencing, refer to Section 32 31 13 CHAIN LINK FENCES AND GATES or 32 31 26 WIRE FENCES AND GATES.

Bioengineered structures are commonly placed in or adjacent to bodies of water. Best Management Practices for storm water pollution prevention shall be employed in accordance with Section 01 57 19 TEMPORARY ENVIRONMENTAL CONTROLS.

Portions of this specification may not be consistent with sections in the construction contract. The designer will delete unnecessary paragraphs of this specification or provide full requirements to portions in this specification that may conflict with or contradict other sections in the contract. These conflicts, contradictions, or lack of requirements will be resolved between this section and other specifications and the construction contract before the design package is released for review.

For additional information concerning bioengineering practices, methods, structures, construction, and performance, see the following publications:
The publications listed above are a small sample of the numerous publications available with related guidance for bioengineering practices. The designer is encouraged to obtain and review local and State publications that are specific to the region of project work. These publications generally contain useful information on suitable plant species, soil and stream conditions, and regulations. Insert project specific references as needed. Numerous guidance and case history publications on bioengineering by the USACE may be reviewed at http://libweb.wes.army.mil.

Publications may contain drawings of proposed structures that are of value for reference and incorporation in design documents. It is strongly recommended that the designer obtain and review drawings of the various bioengineering methods and structures during the preparation of this specification. These drawings lend considerable clarity to the descriptive text about the structures. These drawings should be included in the specification package as attachments to this specification and should be modified to reflect site-specific conditions and restraints.

1.1 SUMMARY

NOTE: Provide requirements that are specific to the work and that the Contractor will be responsible for completing.

The Contractor should submit sufficient drawings to clearly define site layout, structure, details, site
conditions, extents of features, and the like to allow adequate planning and cost estimating. The designer will delete or add drawings that are necessary to meet project needs.

The work by the Contractor consists of furnishing and installing bioengineered features and structures. Submit design, details, cross sections and profiles of site engineered structures to enhance [stream bank] [and] [shoreline] stability within project limits and in areas outside the project limits where the soil surface is disturbed from work under this contract [and as noted on the drawings]. Include in this work all necessary evaluation, design, materials, labor, supervision, and equipment for installation of a complete system and after construction maintenance. Submit a list of all equipment and tools that will be used for the construction of the bioengineered structure. Include information on products used in equipment such as fuel, hydraulic fluids, and the like. Coordinate this section with the requirements of Section [31 11 00 CLEARING AND GRUBBING] [and] [31 00 00 EARTHWORK] [and] [35 31 19 STONE, CHANNEL, SHORELINE/COASTAL PROTECTION FOR STRUCTURES] [and] [32 31 13 CHAIN LINK FENCES AND GATES] [and] [32 31 26 WIRE FENCES AND GATES] [and] [32 92 19 SEEDING] [and all other specifications or requirements as necessary].

1.2 MEASUREMENT AND PAYMENT

NOTE: Add or delete products and measurement and payment as require for project specific needs.

1.2.1 Binder

Measure the standard binder by the linear meter foot placed.

1.2.2 Live or Dead Cuttings

Measure live or dead cuttings by number and type of individual cuttings. No payment will be made for cuttings not required for use in the structure, defective, or that are trimmed from cuttings. Include all harvesting, soaking, transportation, and preparation in the measurement for payment.

1.2.3 Materials

Measure soil and rock by the [cubic meter yard] [metric 2000 pound ton].

1.3 REFERENCES

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also
use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

ASTM INTERNATIONAL (ASTM)

U.S. ARMY CORPS OF ENGINEERS (USACE)

TR-EL-97-8 (1997) Bioengineering for Streambank Erosion Control; Report 1, Guidelines

1.4 SUBMITTALS

NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy, Air Force, and NASA projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy, Air Force and NASA projects, or choose the second bracketed item for Army projects.
The designer should ensure adequate time is allowed for the review of submittals before the start of work. The designer will clearly note the time for submittals, where required. Insert the number of copies required as needed.

The submittals listed below are for general bioengineering projects. The designer will edit this section to tailor the submittals to the project needs and requirements and include submittals not listed below as necessary.

**************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-01 Preconstruction Submittals

Existing Site Conditions
Site Evaluation Plan
Permits and Regulations
Construction Work Sequence Schedule
Seed Establishment Period
Dewatering; G[, [____]]

SD-02 Shop Drawings

Staging area
Structures; G[, [____]]
Vegetation
Harvest Site Restoration

SD-03 Product Data

Materials
Stakes
Binders
Fertilizer
Sealing of Harvest Cuts
Painting of Stakes and Poles
Lumber
Logs, Trunks, and Brush
Equipment
Harvesting and Soaking Records

SD-04 Samples

Soil
Excavated Sediments
Surface Water
Groundwater

SD-06 Test Reports
1.5 QUALITY ASSURANCE

All Contractor and subcontractor personnel shall be fully qualified to perform the specified work and shall provide the Contracting Officer with such documentation no less than [30] [_____] days before the notice to proceed. Work shall not start until the Contracting Office is satisfied that the Contractor meets or exceeds all required qualifications. All Contractor records, documents, and work may be inspected by the Contracting Officer or designated representative at any time. Replace or repair immediately items not meeting quality requirements at no cost to the Government.

1.5.1 Regulatory Compliance

Perform the specified work in accordance with all applicable Federal, State, and local regulations.

1.5.2 Pre-Installation Conference

Coordinate and conduct meetings with the USACE and all subcontractors prior to the start of any work to ensure all work requirements are fully understood and will be performed. All of these meetings shall take place in the presence of the Contracting Officer.

1.5.3 Substitutions

Substitutions will not be allowed.

1.5.4 Qualifications

1.5.4.1 Installer's Qualification

Submit the installer's company name and address; training and experience and/or certification. The installer shall be certified by the manufacturer for any special training and/or experience required for installation.

1.5.4.2 Personnel Qualifications

Submit a list of personnel working on the project including name, title, and statements of their current positions and previous experiences.
Selected personnel shall have been involved in bioengineering design and construction efforts similar to the proposed site work within the last 2 years.

1.6 DELIVERY, STORAGE, AND HANDLING

**************************************************************************
NOTE: Provide specific information on required delivery procedures, inspection requirements and methods, special storage needs, and specific handling methods.

Edit this section to include materials that are specific to the project work. Add or delete materials or products as required.

Sediment samples should be collected for mechanical and chemical analyses. Rock and stone should be tested for toughness, durability, chemical stability, and freeze and thaw at a minimum. Vegetation to be used in construction should be tested for health and presence of disease. All analyses must be preformed by analytical laboratories that are certified by the USACE. The designer will add or delete sample and testing requirements to this section as needed. Specify the specific tests and methods adjacent to the sample or refer to the accompanying specification in which this information is contained.

**************************************************************************
Submit a list of nonvegetative materials to be used in the construction of bioengineered feature or structure. Include manufacturer's literature regarding physical characteristics, limitations, and application or installation instructions. Store materials in designated areas as recommended by the manufacturer and that are protected from direct exposure to the elements, moisture, and any potential damage. Containers shall not be dropped from trucks. Material shall be free of defects that would void required performance or warranty. Deliver manufactured items in the manufacturer's original sealed containers and stored in a secure area.

Prior to delivery of materials, submit certificates of compliance attesting that materials meet the specified requirements. Certified copies of the material certificates shall include the following for items listed in this section:

a. Certification of recycled content or,
b. Statement of recycled content.
c. Certification of origin including the name, address and telephone number of manufacturer.
d. Certification for binders showing EPA registered uses, toxicity levels, and application hazards.

1.6.1 Erosion Control Blankets

Furnish erosion control blankets in rolls with suitable wrapping to protect against moisture and extended ultraviolet exposure prior to placement. Erosion control blanket rolls shall be labeled to provide identification sufficient for inventory and quality control purposes.
1.6.2 Seed

Inspect seed upon arrival at the job site for conformity to species and quality. Reject seed that is wet, moldy, or bears a test date five months or older. Store seed in a cool dry area protected from moisture.

1.6.3 Lumber

Inspect lumber for straightness and defects. Reject warped, damaged, or used lumber. Lumber shall not be stored directly on the ground and shall be protected from moisture until the time of installation.

1.6.4 Vegetation

Inspect vegetation cuttings, herbaceous plants, and clump plantings for species, size, health, and preparation. Reject diseased, improperly sized, and incorrect species. Specific requirements for storage and handling are provided below.

1.6.5 Earth Materials

Select fill, top soil, stone, rock, aggregate, and sand shall meet design specifications. Store excavated sediments and fill in well drained areas, separated from the ground by a non contaminating isolation barrier. Material not meeting specifications or with contained physical or chemical contaminants shall be rejected.

1.6.6 Logs, Trunks and Brush

Logs, trunks, and brush shall be of the size and quality specified. Place materials in organized manner in stock piles near the work site ensuring they were not damaged during delivery, storage, or installation. Materials shall not rest directly on the ground or be exposed to precipitation if they are to remain at the storage site for longer than 4 week before installation. Coverings or the logs, trunks, or brush shall not promote mold or rotting.

1.7 PROJECT/SITE CONDITIONS

1.7.1 Environmental Requirements

********************************************************************************
NOTE: Include information on the physical and environmental characteristics and limitations at the work site e.g. temperature, illumination, slope, water depth, etc.
********************************************************************************

[____]

1.7.2 Existing Site Conditions

********************************************************************************
NOTE: Include information on site conditions, references to documents and reports about site conditions, and requirements for the Contractor to obtain all literary information available for site planning and design. This paragraph should include
the need for surface mapping, subsurface exploration, hydraulic analyses of streams or lakes, and all other information necessary for successful design and construction that is not provided by the Government. Also note that lack of supply of such information by the Government does not relieve the Contractor of any such necessary research or studies.

Submit a detailed description of the existing site conditions prior to construction work including but not limited to literary references, site visits, public or private reports, studies (engineering, ecological, environmental, etc.) and topographic or other maps. Submit [_____] copies of this survey to the Contracting Officer [_____] days before the start of work.

1.7.3 Site Evaluation Plan

NOTE: Consider the following items during site evaluation and project planning to improve the success of the bioengineered structure. The items below are not all inclusive for every site. Other evaluation factors may be relevant based on site specific conditions.

Do not construct bioengineered structures:

- where soil or water is contaminated with compounds or elements that may damage live vegetation or where disturbance may result in expansion of the area of contamination,
- at locations with unstable slopes that can not be mitigated as part of construction,
- where robust stabilization structures are required for protection of navigation structures, levees, or embankments,
- where damage of the structure could pose a risk to loss of life or property,
- where long-term maintenance and after care of the structure and vegetation is not desired,
- where climate or hydraulic conditions may threaten establishment of vegetation,
- where the streambed is degrading and where such degradation can not be stopped by altering hydraulic conditions of the stream or by the use of hard armor,
- along stream banks or shorelines subjected to high wave action from storms or watercraft,
- in areas subject to shade from other plant species that may hinder growth of the selected plant species for the structure,
- in areas where the structure may not be secured from undesired animal or human traffic and subsequent damage.

Check with local, State, and Federal agencies to ensure all regulations are understood and followed. Do not alter wetland areas.
Know the mean, mean low, mean high, minimum, and maximum water elevations of the stream, river, or lake. The definitions of water levels may be defined in terms of hydrologic analyses or by observation of stream geomorphic features.

- The maximum water elevation should be the highest water possible at the site due to storm surges, waves, floods, or water storage. The elevation of debris associated with flood events or storm waves on the high bank may be used for recent high water elevations.
- The mean high water elevation is the average high water level over 19 years. This elevation is typically located where trees and brush are established on the high bank of the channel.
- The mean water elevation is the average height of water over 19 years. This elevation typically corresponds to the area where reeds and small shrubs are present on the low bank adjacent to the stream channel or shore.
- The mean low water elevation is the average height of the low water over 19 years. This water level is characterized by the upper extent of aquatic plants on the bank or swash zone at the toe of the bank or shore.
- The minimum water elevation may correspond to the minimal flow in the stream channel or lowest elevation of a lake due to drought or human activities such as irrigation or water storage. The minimal water elevation may be the bottom of the stream channel or lake if these water bodies may be completely drained.

The designer is advised to modify these definitions and water level elevations based on the growing and dormant seasons for species of vegetation used in construction to ensure establishment, performance, and survivability. Determine the amount and rate of change of water elevations due to natural or human activities.

Determine the possible height of waves, direction, and frequency due to storms or navigation operations.

Determine the changes in current velocities and flow direction due to different stages, seasons, or storm events.

Known the sediment load, composition, size, and rates of deposition or erosion at the site.

Know the climate of the work area. Severe flooding, drought, or cold during construction or in the future may damage the structure.

Determine the requirements for regular monitoring and maintenance of the structure to ensure plant survival and structure performance.
Specify the need for and the role and responsibilities of a multidisciplinary team for design and planning, construction, and after care.

The site evaluation plan may require literary searches; subsurface and surface exploration, sampling, and testing; surface topographic, geological, biological mapping; hydraulic engineering studies; assessment of the site in relation to residences, commercial property, and biological communities; and impact of navigation or water storage projects on the site. The report should contain sufficient information to determine if the site is viable for the proposed structure and sufficient information for structure design and planning.

Furnish a site evaluation plan stating clear and concise project objectives and assessment criteria of the viability of the proposed structure based on the physical, chemical, biological, political, and social site conditions and aspects. Submit the contents of the plan developed by the Contracting Officer and the Contractor in [_____] copies of this plan to the Contracting Officer [_____] days before the start of work. The plan should contain supporting documentation and studies, which include but are not limited to climate, geological, geotechnical, hydraulic, botanical, geomorphic, project cost estimates, and regulatory and permitting requirements. The site evaluation shall include a review of case histories of bank stabilization methods at other similar sites, reconnaissance report on site conditions and suitability for bioengineering structures or methods, design alternatives, potential problems, and recommendations for the types and methods of bioengineered structures if applicable to site conditions and uses. The plan shall include lists of all applicable permits and regulations and methods of compliance related to construction. Submit list and copies of all required and approved permits for site work and of all regulations that pertain to site work to the Contracting Officer [_____] days before the start of work. The plan shall include a report identifying the species of vegetation and plants that will be used for construction. Refer to TR-EL-97-8 for site evaluation and planning guidance. The report shall include but not be limited to:

Supply of vegetation,
Harvest area and procedures,
Retention of existing vegetation,
Short and long-term interaction of selected species with existing vegetation,
Interaction of species with existing structures,
Retention or elimination of nonnative or invasive species,
Performance of selected vegetation in the proposed structure,
Maintenance and replacement.

1.8 SEQUENCING AND SCHEDULING

NOTE: Most bioengineered structures must be completed during the period of dormancy of plant growth unless otherwise noted. Structures completed outside of this dormant season will not be accepted.
by the Government unless provided with specific information on the need for such schedule and survivability of plant species used for construction. Local requirements may limit construction periods and must be fully complied with and adhered to unless granted waiver rights by the appropriate regulatory authorities. See paragraph TIME OF PLANTING in PART 3 for additional information.

Conduct all work [during the period of plant dormancy] [as stated below] and in accordance with all Federal, State, and local requirements for in-stream or near stream construction. The construction sequence shall result in successful completion of the structure. Submit a construction work sequence schedule, detailing the work tasks and order of completion, to the Contracting Officer for approval a minimum of [90] [_____] days prior to the start of construction. Work shall not commence without the approval of the schedule and construction sequence by the Contracting Officer. Construction shall not occur if climatic conditions threaten the survivability of plants or worker safety. Construction sequence schedule.

1.9 WARRANTY

NOTE: The designer should consult with the manufacturer to ensure proper application and installation techniques for the site specific project conditions. Warranties vary with different materials and may be void if proper technical advice is not obtained. Seed germination is not covered under the warranty.

The structure and all manufactured materials shall be under Contractor warranty for a period of [2] years including vegetation and earthworks. Stone and rock shall be under warranty from decomposition for [5] years.

1.10 MAINTENANCE

NOTE: Bioengineered structures require observation and maintenance for up to 5 years after installation to ensure the vegetation becomes established. Observation should be done on a weekly basis for the first year and bimonthly thereafter for the second year at a minimum. A minimal level of acceptable survival of plants should be established. The Contractor should be required to replace plants that die above the allotted percentage and area of concentration that may adversely effect structure performance.

1.10.1 General

Include in maintenance eradicating weeds; protecting embankments and ditches from surface erosion; maintaining the performance of the erosion control materials and mulch; replacement of dead or non-viable plants;
repair of soil, stone, rock, or hard structures, and protecting installed structures from human and animal activities.

1.10.2 Maintenance Instructions

Furnish written instructions containing drawings and other necessary information to the Contracting Officer, describing the care of the installed material; and including when and where maintenance should occur and the procedures for material replacement. Submit instruction for year-round care of installed products including schedule, materials, and tasks. Instructions shall describe the methods for specific maintenance activities and equipment and tools required for such efforts. Requirements on safety and regulations and permits shall be included.

PART 2 PRODUCTS

**************************************************************************
NOTE: Consult local codes and regulations for additional information that may effect the project before design work begins. The choice of methods and materials will be project specific and will be at the discretion of the designer. Edit the specification choices of products to best suit the needs of the project.
**************************************************************************

2.1 BINDERS

Submit certification for binders showing EPA registered uses, toxicity levels, and application hazards. Prior to delivery of materials, submit certificates of compliance attesting that materials meet the specified requirements and certified copies of the material certificates. All binders shall be biodegradable and untreated hemp or coir rope or fasteners, which shall be able to withstand 2 years minimum exposure to the environment of placement without significant degradation in strength or quality. Steel or plastic binders or fasteners shall not be used.

2.2 EROSION CONTROL ITEMS

**************************************************************************
NOTE: Several structures require the application or integration of erosion control products. These products include but are not limited to mulch, straw, hay, shredded bark, coir, mulch control netting, and erosion control mats. Products selected for use should be biodegradable and non-damaging to the environment in which they are placed. Sediment retention products may also be required as part of construction efforts. Mention the specific needs and types of products below.
**************************************************************************

Provide [erosion control products] [and] [sediment control structures or products]. Install materials and structures according to manufacturer's recommendations based on [actual site conditions] [and] [as shown in the drawings].
2.3 SEED

**************************************************************************
NOTE: State-certified seed is more stringently monitored than State-approved seed, and therefore, more expensive.
**************************************************************************

Provide seed in accordance with Section 32 92 19 SEEDING. [State-certified] [State-approved] seed of the latest season's crop shall be provided in original sealed packages bearing the producer's guaranteed analysis for percentages of mixture, purity, germination, hard seed, weed seed content, and inert material. Labels shall be in conformance with AMS Seed Act and applicable State seed laws. Provide classification, botanical name, common name, percent pure live seed, minimum percent germination and hard seed, maximum percent weed seed content, and date tested. Submit the Seed Establishment Period calendar time for seed establishment. When there is more than one seed establishment period, describe the boundaries of the seeded area specific for each period. Permanent seed species and mixtures shall be proportioned by weight as follows:

<table>
<thead>
<tr>
<th>Mixture Percent by Weight</th>
<th>Percent Pure Live Seed</th>
<th>Botanical Name</th>
<th>Common Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>[_____]</td>
<td>[_____]</td>
<td>[_____]</td>
<td>[_____]</td>
</tr>
</tbody>
</table>

2.4 PERMANENT VEGETATION SPECIES AND MIXTURES

**************************************************************************
NOTE: Live or dead cuttings from locally harvested stock should be specified in this section. Nursery stock may also be used for design purposes or in areas with limited supplies of cuttings at or near the work site. Nursery stock has a higher chance of survival due to developed root systems but may add cost to the project.
**************************************************************************

The selection of the appropriate vegetation species for the site should be made by consultation with a qualified geotechnical engineer, hydraulic engineer, biologist, and botanist based on site conditions, stability requirements, desired habitat creation, and blending ability with surrounding vegetation. The soil types, hydraulic conditions and requirements, and ability of the selected species to survive in the work area must be determined and considered in species selection. Selected species should improve or enhance slope stability and should be flexible and of low height at maturity to allow maximum conveyance of water in the channel.

At some sites, nonnative species may be more appropriate due to changed site conditions or alterations by natural or human activities. Native species may not be able to survive in such alternated settings. For restoration projects, non-native or intrusive species may need to be removed before planting native species to reduce
competition for resources and to improve the survivability of the native plants. Plant species should be collected from the same watershed and near the work site to prevent the import of differing genetic stains into the project area.

Woody vegetation that matures to have trunk diameters greater than four inches should not be used. Such species when mature pose a threat of scour to the bank down stream of the trunk during high flow events. In addition, these species may develop extensive root system that may damage the structure when the tree dies and rotates into the stream or lake. In this case, the root wad typically removes a large amount of soil as it is pulled from the bank. The resulting hole may be subject to scour and result in structure damage or failure during moderate or high flow events.

Sedimentation types and depositional rates should be determined. Some streams may transport sediment that may abrade or break vegetation. Alternatively, large amounts of sediment may be deposited at the site and cover vegetation. The combined effect of the trapping of large amounts of sediment by the selected vegetation species may result in the accretion of sediment onto the bank. While this accretion of material provides additional bank protection in the short term, the long term effects may be large bank failures due to the added weight of the sediment on the bank. The structure may be damaged or destroyed if the failure plane cuts the structure. Therefore the vegetation species in such areas should allow adequate water flow through the vegetation to reduce the amount of sediment that accumulates at the site.

On banks down stream of water storage project, selected vegetation should be able to survive or recover rapidly in the event water levels must remain at elevated levels for an extended period of time due to flood or navigation releases.

Provide specifics on quality requirements.

Submit classification, botanical name, common name, harvest location, plant heath, and date tested, (live or dead cuttings, nursery stock, plants). Permanent vegetation type and planting plan, species and mixtures for [live and dead cuttings] [and] [nursery stock] [and] [herbaceous plants] shall be as follows:

<table>
<thead>
<tr>
<th>Mixture Percent by Volume</th>
<th>Percent Live and Dead</th>
<th>Botanical Name</th>
<th>Common Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>[_____]</td>
<td>[_____]</td>
<td>[_____]</td>
<td>[_____]</td>
</tr>
</tbody>
</table>

Weed seed or noxious plants shall be a maximum of 1 percent by weight of
the total seed mixture. [Undesired], [non native] [and] [or] invasive vegetation species shall not be allowed. All live cuttings and containerized plantings shall be capable of growth and rooting and free of disease or defects at the time of installation.

2.5 **STAKES**

Stakes shall be 100 percent biodegradable materials and shall be designed to safely and effectively secure erosion control blankets, coir logs, fascines, and other bioengineered structures for temporary or permanent applications. The biodegradable stakes shall be fully degradable by biological activity [within 2 years]. The stakes must exhibit ample rigidity to enable being driven into hard ground, with sufficient flexibility to resist shattering.

2.6 **STAPLES**

Do not use metal or plastic staples.

2.7 **SYNTHETIC GRID AND SHEET SYSTEMS**

Do not use synthetic grid and sheet systems.

2.8 **CRUSHED ROCK, GRAVEL, SAND, STONE, RIPRAP, and BACKFILL**

The quality of rock, gravel, sand, stone, riprap, and backfill shall be in accordance with requirements in Section 31 00 00 EARTHWORK and Section 35 31 19 STONE, CHANNEL, SHORELINE/COASTAL PROTECTION FOR STRUCTURES. Materials not meeting specified requirements shall be rejected and immediately replaced by suitable material at no cost to the Government.

2.9 **WATER**

Water for irrigation, soaking of plants and cuttings, and dust control shall be the responsibility of the Contractor. Water shall be clean, free of contaminants, and have a turbidity of less than 20 NTU. Water shall be from [a public source of know quality] [local surface water source] [groundwater well] near the work site. [Test water obtained from non public sources for quality in accordance with paragraph MATERIAL TESTING REQUIREMENTS.]

2.10 **FENCING**

******************************************************************************

**NOTE:** Permanent or temporary fencing may be required around work sites to prevent vandalism and damage to newly planted vegetation by livestock, animal, or human activities. Fencing may be temporary or permanent. Specify temporary fencing such as plastic construction fence, snow fence, or rental fence below. Use Section 32 31 26 WIRE FENCES AND GATES or 32 31 13 CHAIN LINK FENCES AND GATES to specify permanent wire and chain link fabric fences and gates if required.

******************************************************************************

[All fencing shall be in accordance with Section [32 31 26 WIRE FENCES AND GATES][32 31 13 CHAIN LINK FENCES AND GATES].] Fencing shall be temporary and consist of [_____] fence. Fencing shall be secured to [wood] [metal...
T-poles that are driven 600 mm 2 feet into the ground and extend 1.2 m 4 feet above the finish grade. Install fencing [at the start of work] [after construction]. Fencing shall remain in place [until vegetation is established] [for 3 years].

2.11 IRRIGATION

**************************************************************************

NOTE: Sites may require extended periods of irrigation to ensure vegetation establishment. Irrigation systems may be on the surface or underground. Water retention in the structure in arid regions may be aided by the use of super absorbent polymers. Edit this specification for products that may be used with open trench irrigation.

Some sites may be remote and may not have electrical or water supplies available. In this case, the designer should include products for solar power, water tanks, or methods such as daily watering by water truck.

**************************************************************************

[All underground irrigation shall conform to Section 32 84 24 IRRIGATION SPRINKLER SYSTEMS or as approved by the Government.] Provide the following products and materials for irrigation.

2.12 FERTILIZER, PESTICIDE, HERBICIDE

**************************************************************************

NOTE: Edit this paragraph as required. Fertilizer, pesticide, and herbicide may be required for the construction, establishment, and maintenance of bioengineered structures. The designer will consult with a qualified botanist, biologist, landscape engineer, and regulatory agencies before selecting the use of or type of fertilizer, pesticide, or herbicide for application at the site. Products, if selected for use, should not pose a threat to water quality or the environment. Pesticides and herbicides will only be used when absolutely necessary. Use of biological methods for pest or plant control is encouraged. Provide specific product names, manufacturer, method and concentration of application, and other required product information below.

**************************************************************************

Provide the following products and materials.
NOTE: Edit this section as required. Provide specific methods, procedures, sample numbers, test, and the like.

The Contractor should collect samples of select fill and site soils for physical and chemical analyses to ensure these materials are appropriate for growth of the selected plant species. Refer to specific soil requirements needed for healthy plant growth to complete this section. Imported soil or select fill must be tested to ensure the material is free of seeds or root stocks of non-native or invasive species or detrimental biological organisms.

Soil samples from the surface and subsurface of the site should be collected for geotechnical and chemical analyses. Geotechnical test parameters should be at a minimum grain size with hydrometer, moisture content, density, and Atterberg limits as required. Testing of site soils and select fill for permeability, consolidation, and soil strength may also be required depending on site conditions and selected structure. Soil samples should be collected to confirm that soils at the site are not contaminated with hazardous, toxic, or radioactive compounds that would require special handling.

Samples of surface and groundwater should be collected to verify that seepage into the stream or water body at the work site is not contaminated with compounds that will endanger plant survival or pose a hazard to human health and the environment. Water that is not obtained from a public source should be tested for biological and chemical contaminants.

Specify analytical laboratories for analyses, turn around time for samples, and holding times for chemical samples.

The soil and water samples must be collected and analyzed a minimum of 120 days before the start of construction. The analytical results must be reviewed by the Contracting Officer before work continues at the site. If hazardous compounds or chemicals are discovered, then the work will be terminated. All testing must be performed by USACE validated laboratories.

Several different types of samples and tests may be required depending on structure design,
construction, and location. Soil samples should be collected for geotechnical analyses for grain size, moisture content, density, Atterberg limits, compaction, shear strength, and pH. Soil at the site and fill that may be imported should also be tested for these parameters. The chemistry of the soil should be tested to ensure the soil will support vegetation growth and is free of contaminates. Soil should be tested for deleterious microorganisms that could increase plant mortality. Surface and groundwater should be sampled for chemistry and quality.

Submit certified reports of inspections and laboratory tests, prepared by an independent testing agency, including analysis and interpretation of test results. Each report shall be properly identified. Test methods used and compliance with recognized test standards shall be described. Collect samples of soil and water at and for use at the site, collected at the locations as shown in the drawings and at source locations for the materials or water. Collect these samples and test as specified below.

PART 3 EXECUTION

3.1 SITE VERIFICATION OF CONDITIONS

Coordinate, through the work schedule, the timing of land disturbing activities with the provision of erosion control measures. An erosion control plan will be required in accordance with applicable Federal, State, or local requirements. Perform erosion control operations under favorable weather conditions. When excessive moisture, frozen ground, or other unsatisfactory conditions prevail, stop the work as directed. When special conditions warrant a variance to earthwork operations, a revised construction schedule shall be submitted for approval. Bioengineering materials shall not be applied in adverse weather conditions, which could affect their performance. Complete all tasks necessary for the required submittals.

3.2 SITE PREPARATION

3.2.1 Temporary Construction Facilities

NOTE: Access roads or paths may need to be permanent to allow ease in future monitoring and maintenance. If such access is required, provide requirements or references to appropriate specifications below.

Establish access routes to the construction site prior to the start of work and show them on the drawings. All temporary construction facilities shall be in accordance with Section 01 50 00 TEMPORARY CONSTRUCTION FACILITIES.
AND CONTROLS. Provide access to the work site and harvest area by [temporary] [permanent] [roads] [and] [paths] designed for [motorized vehicles] [and] [pedestrian access] if acceptable and in accordance with regulations and property owner restrictions and permission. Select access methods that have the least impact on existing site conditions and that may be easily removed and restored upon the completion of work. Provide strict access control to the work and harvesting sites to prevent access by non-authorized personnel. Install [access gates] [barricades] at the entrances of temporary [roads] [paths] to the sites. [These gates shall be secured with a keyed lock and shall remain closed at all times when personnel are not present at the gates for access. Provide duplicate keys for the lock to the Contracting Office, landowner, authorized regulatory personnel, and fire and law enforcement as required.] [Place appropriate signage on the gates that clearly specify site access is restricted.]

3.2.2 Clearing and Grubbing

The access route and construction site shall be cleared of vegetation necessary for the construction of the bioengineered structure or staging area in accordance with Section 31 11 00 CLEARING AND GRUBBING. Efforts will be made to salvage vegetation suitable for use in the bioengineered structure.

3.2.3 Erosion and Sediment Control

Install erosion and sediment control measures prior to active construction efforts to prevent erosion of soil and offsite releases of sediment.

3.2.4 Earthwork

**************************************************************************
NOTE: Minor or extensive earthwork may be required as part of the construction of the bioengineered structure. This specification only includes the requirements for minor earthworks for trench excavations and soil roughening. Dimensions for minor earthworks are provided in the specific bioengineering method sections below. Site grading, shaping, or trenching for drains and utilities, and material types and gradations should be included in Section 31 00 00 EARTHWORK.
**************************************************************************

The [stream bank] [shoreline] shall be sloped and graded [in accordance to Section 31 00 00 EARTHWORK] [and] [as shown on the drawings].

3.2.4.1 Trenches

Unless otherwise stated, trenches shall be to the depth, width, and line as shown on the drawings. Side slopes, unless otherwise indicated, shall be at the angle of repose. Material removed from the trench shall be [used as backfill] [removed from the site]. [Trenches shall be backfilled with select fill]. [The floor of the trench shall be compacted to 90 percent maximum dry density and smooth.] Place backfill in 150 mm 6 inch lifts compacted [to 80 to 90 percent maximum dry density] [sufficiently to improve soil density but not impede vegetation root growth]. [Trenches shall be keyed into the stream bank for a distance of 3 feet]. [Shoring shall be installed [if the trench exceeds 1 m 3 feet in depth] [as required by regulations]]. [The Contractor is responsible for dewatering of
trenches for construction purposes.]

3.2.4.2 Finished Grade

Finish grade shall be smooth and as shown on the drawings and in accordance with Section 31 00 00 EARTHWORK.

3.2.4.3 Surface Roughening

**************************************************************************

**NOTE:** Surface roughening should be performed on all slopes with exposed earth that are greater than 3H:1V. Surface roughening reduces surface runoff velocities and provides depressions that collect sediment, seed, and water, thereby improving vegetation establishment on the slope. Roughening may be accomplished by traversing the surface with track-mounted equipment, manual efforts such as hand raking, or terracing of the slope during excavation or the placement of fill. The method of roughening may vary depending if the slope is a new cut or fill surface or an existing or graded slope. Surface roughening should not create ridges or depression that hinder the mowing of slopes that are 3H:1V or less.

**************************************************************************

The surfaces of all barren slopes related to work efforts shall be roughened by [equipment] [and] [manual efforts] to reduce erosion and promote trapping of seed, water, and sediment. All lifts shall be compacted as specified in Section 31 00 00 EARTHWORK. [The surfaces of the lifts shall be covered with loosely compacted soil to a depth of 100 mm 4 inches.] [Track-mounted equipment shall traverse the slope from the toe to the crest to place track imprints parallel to the contours of the slope.]

a. [Slopes on new cut faces greater than 3H:1V shall be roughened by stair-step cuts installed during construction. The faces of the steps shall not exceed 600 mm 2 feet in height in soft material or 900 mm 3 feet in height in hard material. The horizontal spacing between the vertical faces shall not be less than the vertical height of the step.]

b. [Slopes on new fill greater than 3H:1V shall be roughened by the installation of lifts of compacted soil that shall not exceed 200 mm 8 inches in thickness.]

c. [The existing slope of graded areas shall be roughened by tilling, diskng, harrowing and seeding, or other suitable method or equipment to produce ridges and depressions in the surface of the slope, which are parallel to the contours of the slope. These ridges and depressions shall not exceed 25 mm 1 inch in depth or height above the grade surface and shall be spaced no more than 250 mm 10 inches apart.]

d. The final roughened surface shall not be smoothed by blading or scraping. All large soil clumps shall be broken into small clumps not more than 50 mm 2 inches in diameter and dispersed on the immediate surface. Mounds or depressions of soil that are greater in height or depth than those produced by the method of roughening shall be cut or filled with suitable material to grade and shall be roughened to match the adjacent surface. Depressions of depth greater than 150 mm 6 inches
shall be backfilled with compacted suitable material until reaching the design grade of the slope and roughened. Sand or silty sand shall not be compacted to a density that may prevent vegetation planting and growth. Roughened areas shall be seeded, planted, or covered with erosion control products [immediately after roughening] [within [_____] days after completion of roughening].

3.3 FIRE PREVENTION

All efforts possible shall be taken to prevent fire at the work site and harvest area as a direct result of work efforts. Fire prevention or suppression equipment shall be provided to personnel at the work and harvest sites. All equipment shall be in compliance with applicable regulations and shall be kept in working condition at all times and within no more than 5 m 15 feet distant from the active work areas.

3.4 SANITATION

Provide adequate portable sanitation facilities for persons at the construction and harvest sites that are in compliance with all Federal, State, and local requirements.

3.5 HARVESTING OF VEGETATION

**************************************************************************

NOTE: Most plants for bioengineering structures constructed near water are wetland plants except for species used for the vegetation of high bank areas. Woody plants or herbaceous plants may be used and should be somewhat flood tolerant. Harvesting may include the collection of woody plants, herbaceous plants, or single or clump plantings. Vegetation should be harvested from local sources and native plant species near the construction site. The need to obtain vegetation from distant sources should be evaluated in terms of cost and the risk of introducing foreign genetic material into the watershed in which work occurs. Vegetation should be obtained when at all possible from the same watershed in which the work will occur. Other stabilization methods may be more appropriate for the site due to high transportation and handling costs.

Site harvesting shall require the cutting of existing vegetation for live and dead stakes, poles, or cuttings, collection of roots or tubers, or excavation of plants with root mats intact. The harvest site must not be over harvested and must be restored as much as reasonably possible after harvest work is completed. The number and location of the vegetation that may be harvested shall be determined before construction by a qualified botanist or forest engineer.

**************************************************************************

3.5.1 Harvesting of Woody Plants

**************************************************************************
NOTE: Woody plants consist of stem cuttings that quickly sprout roots and stems from the parent stem. These plants are typically willow and perhaps some species of dogwood and alder. Nursery stock with established roots may also be used.

The length of the harvested vegetation will vary with site conditions and structure design. In general, stakes and poles should extend at least 300 mm 1-foot above the top of structure. Cuttings should extend at least 300 mm 1-foot beyond the edge of a structure or 600 mm 2 feet above the ground surface. The actual lengths of the stakes or poles shall be based on the depth of soil from the surface to the mid summer capillary zone or water table. For guidance, the minimum length is three feet. The diameters for the base of cuttings and stakes may range from 19 to 38 mm 0.75 to 1.5 inches and should be of sufficient diameter to resist buckling when driven into the streambed or bank. Live poles may range from 50 to 100 mm 2 to 4 inches. Live or dead logs used for crib walls should be at least 100 mm 4 inches in diameter for gullies and 200 mm 8 inches in diameter for use in streams or rivers. To improve survivability, live stakes and poles must be of sufficient length to penetrate the soil 600 mm 2 feet below the bioengineered structure or to within the capillary zone of moisture in the soil.

[Stakes] [poles] [and] [cuttings] shall be harvested from local sources of selected species. Species of plants foreign to the ecosystem environment at the work site shall only be imported if they pose minimal threat to interfering with the native vegetation, are accepted by regulatory and environmental management, and are able to survive at the specific site. Unless otherwise stated below, [cuttings] [and] [stakes] shall be 19 to 38 mm 0.75 to 1.5 inches in diameter and at least 1 m 3 feet in length. [Stakes] [poles] with a diameter of 50 to 75 mm 2 to 3 inches and minimum length of 1.5 m 5 feet shall be used for insertion into armored stream bank structures. [Stakes] [and] [cuttings] [and] [poles] shall be cut from healthy plants and shall be as straight as possible. Plants for harvest shall be a minimum of one-year-old, preferable 2 to 5 years in age. Suckers or current year growth shall not be used. All cuts shall be clean and free of splits or excessive peeling of bark. At least two bud scars shall be visible on the [cutting] [stake] [pole] above the surface of the ground or structure when installed. [Stakes] [poles] with deviations or curvatures greater than 13 mm 0.5 inch from vertical per 200 mm 1-foot of length will not be accepted. [All branches emanating from the [stake] [pole] shall be trimmed as close as possible to the surface of the stake without damage to the bark.] [The bottom end of the [stake] [pole] shall be cut at an angle of 60 degrees to the horizontal. The top of the [stake] [pole] shall be cut normal to its length.] [Live cuttings shall be harvested from branches and shall include the growth tips of the branch. The butt of the cutting shall be cut at an angle to the vertical to aid in placing into soil.] If trunks of vegetation remain after cutting, these trunks shall have a sufficient number of healthy branches remaining to allow survival.
3.5.2 Harvesting of Herbaceous Plants

NOTE: Edit this section as required. Consult a qualified botanist for harvesting, handling, growing, and transplanting requirements if herbaceous plants are to be used. Herbaceous plants may be emergent aquatic plants such as reeds, rushes, and sedges or may be non aquatic plants such as grasses or other forbs that require moisture during some portion of the year. Harvesting of these plants requires the collection of seeds, roots, or tubers. The roots or tubers may be transplanted directly to the site. Plants from the roots may be grown in a nursery and subsequently transplanted to the site. Plants or roots collected in the field must be placed in containers filled with water and kept cool until being transplanted to growing media at a nursery. Exposure of the harvested plants to wind or dry and hot conditions should be avoided. Consult a wetlands expert for methods for collecting and growing of wetland plants.

3.5.3 Harvesting of Reeds or Clump Plantings

NOTE: Edit this section as required. Consult a qualified botanist for harvesting and transplanting requirements of reed or clump plantings. Single plants or groups of plants may be harvested, which include the root mass in soil plugs. Large clump plantings require the removal of vegetation with the root mass and surrounding soil intact. These larger plantings may be extracted by hand and shovel methods or the use of light or heavy equipment.

3.5.4 Sealing of Harvest Cuts

All harvest cuts on trunks or branches of the host vegetation shall be trimmed of loose wood or bark and sealed with an approved sealant to prevent desiccation and disease or infestation at the end of the workday without exception.

3.5.5 Harvest Site Restoration

The harvest site shall be restored to preexisting conditions as best as possible after harvesting is completed. Restoration shall include but shall not be limited to removal of aggregate or wood chip roads or access paths, access gates, and ruts or depression, or other items or features related to work activities.
3.5.6 Disposal of Excess Vegetation

Excess cut vegetation from harvesting shall be [thinly distributed on site] [collected and removed from the site] [staked on-site and burned] [left in place] [collected and transported to the work site for incorporation in the designed structure].

3.6 TIME OF PLANTING

**************************************************************************
NOTE: Edit this section as needed for site specific conditions. Provide specific dates for the planting window below.

Woody plants and nursery stock should be planted in the dormant season. These plants are dormant when buds are set in the fall after the first hard freeze until the time when the buds begin to swell in the early spring. If planting can not be done during the dormant season, then the cuttings may be stored in a cold environment at -2 degrees C 28 degrees F until planting is possible.

Herbaceous plants may be planted during the dormant or non dormant seasons. If planted in the non dormant season, these plants should be placed as early as possible in the spring to allow the greatest amount of time for root development and growth. Herbaceous plants should not be planted during hot or dry weather if at all avoidable.

The time of planting is also dependent on site climatic and hydrologic conditions. The best time to plant is when the stream or lake is at mean water level. Planting should occur in the fall at sites where the water levels are expected to be low from the fall to the spring and if the plants may experience some growth and establishment before spring floods. Planting at sites where water levels fluctuate during the winter due to flooding or where frost heaving of soil occurs should be delayed until late spring. Late fall plantings may be preferable at locations subject to winter flooding and summer droughts. Fall planting is not recommended for areas where late season droughts or frost heaving occurs below the root level. The designer should consult a hydraulic engineer to determine water levels and flow velocities at the site during the planting and initial growth periods. Clump planting of shrubs or reeds should occur in the spring or early summer.

**************************************************************************
Planting shall occur in the [spring] [fall] [summer] starting no earlier than [_____] and shall be completed by no later than [_____].

3.7 TRANSPORTATION OF HARVESTED VEGETATION

a. All freshly harvested and prepared live woody vegetation shall be
immediately submerged in clean uncontaminated water and shall not be allowed to dry out. Cut vegetation shall be transported to the work staging area submerged in water. If site conditions prohibit direct access to storage bins filled with water, then the freshly cut live vegetation shall be wrapped in cloth, which is thoroughly saturated with water, and shall be transported to a storage bin filled with water within no more than one hour from the time of cutting.

b. Live vegetation shall be transported from the staging area to the work site in containers fully covered with clean water. Vegetation shall be removed from the containers and immediately placed in the ground. In the event that access to the installation site is limited, vegetation shall be removed from the soaking tanks and wrapped in bundles that are completely covered with at least three layers of saturated highly absorbent cloth or saturated biodegradable paper product with high saturated strength. The cloth and bundles shall be placed in plastic liners for greater ease in transportation to the work site.

c. Cut vegetation shall not be left uninstalled at the work site and exposed to air or heat or excessive cold for any reason. Dead [cuttings] [stakes] [poles] shall not be soaked unless the design requires this vegetation to be flexible. Cut live vegetation that is exposed to air for longer than 15 minutes during harvesting, transportation, installation, or which were not collected or transported as specified above shall not be accepted. Damaged live vegetation shall not be accepted and shall be replaced at no expense to the Government.

d. [[Herbaceous plants] [Nursery stock] shall be transported to the work site in covered vehicles. Plants shall not be subjected to cold or excessive heat or drying during transport. The plants shall be carefully unloaded at the staging area and placed in a shaded area. Plants shall be watered and maintained in healthy condition until the time of installation. The plants shall be transported to the work site [by hand] [push cart] [vehicles] and immediately installed at the site. Damaged, wilted, diseased, or dead [plants] [nursery stock] shall not be accepted and shall be immediately replaced at no expense to the Government.]

3.8 SOAKING AND PAINTING OF LIVE WOODY VEGETATION

**********************************************************
NOTE: Make all possible efforts to prevent the harvested live vegetation from losing moisture from the time of cutting to insertion into the ground. Soaking of the live vegetation greatly improves the ability of the plants to survive transplant into the bioengineered structure.
**********************************************************

a. All harvested live vegetation shall be soaked in clean water for 3 to 5 days before installation into the ground. The live vegetation shall be placed in clean, leak proof, large plastic storage containers or similar, which are at least 300 mm 12 inches longer in length than the cut vegetation. Reused or new metal drums or drums used for the containment of hazardous wastes or chemicals shall not be used. The containers shall be placed in organized lines in a shaded location separated by a sufficient distance to allow access of a vehicle to the containers for the placement and removal of the vegetation. Each
container shall be given a unique identification number or series of numbers and letters that shall be clearly visible at the end of the container that shall be approached for the placement or the removal of vegetation. The identification numbers shall be recorded and referenced in relation to the contained vegetation for quality control and construction purposes.

b. The water levels in the containers shall be checked twice daily and water shall be added as needed to ensure the containers are filled with sufficient water to completely cover the contained vegetation with a minimum of 50 mm 2 inches of water. Rust proof weights or clean cobbles or boulders may be used to weight down the vegetation and retain it under the water surface. These weights shall not crush or damage the vegetation. Water in the containers shall be completely replaced with fresh and clean water every 3 days without exception. Vegetation that remains in water that has not been replaced as required shall be deemed defective and shall not be accepted by the Government. Water replacement schedule may be adjusted to compensate for weekends and holidays with the notification and approval of the Contracting Officer.

3.8.1 Mixing of Live Vegetation

Vegetation of a specific species shall not be commingled with another species during cutting, soaking, or transportation.

3.8.2 Painting of Stakes and Poles

******************************************************************************
NOTE: The painting of the tops of the live stakes and poles will reduce desiccation of the cuttings, potential for disease mortality, and allow ease in locating once installed. All painting shall occur after soaking. Stakes or poles made of lumber may be painted at the option of the designer to improve visibility.
******************************************************************************

The top ends of the [stakes] [and] [poles] shall be painted with a latex paint diluted with water at a ratio of one part paint to one part water. The tops of the [stakes] [and] [poles] shall be [dipped in the dilute paint mixture to a depth of 75 mm 3 inches after soaking] [painted immediately after planting by [brush] [spray applicator]]. The color of the paint shall be [caution yellow] [safety orange]. The top ends of dead [stakes] [and] [poles] shall [not] be painted.

3.8.3 Harvesting and soaking records

Daily logs shall be prepared documenting the activities of plant harvesting, transportation, and soaking. These records shall contain at a minimum: name, date, weather conditions, company, location of harvest area, location of soaking area, site rehabilitation, species harvested, number of cuttings harvested, number of cuttings placed in soaking tanks, damage to cuttings, problems, and solutions to problems encountered. Records shall clearly indicate the health of the primary vegetation from which the cuttings are obtained, diameter of cuttings and primary vegetation, length of cuttings, trimming procedures, time of cutting, time of placement in transportation bins, handling procedures, sealing of harvest cuts, time the live vegetation is delivered and transferred to soaking tanks, and
identification label of the tank in which the cuttings are placed. The records shall contain the duration of soaking of the vegetation, water quality and time and amounts of water added to the tank during soaking, time of removal of the cuttings from the tanks, time of planting of the cuttings, and procedures used for removal, transportation, and planting of the vegetation at the construction site. The records shall be signed by the lead harvest person or person in charge of soaking and planting and shall be provided to the on-site manager at the end of each day. Records shall be provided to the Contracting Officer within [24] [_____] hours of completion.

3.9 STAGING AREA

**************************************************************************

NOTE: A staging area for operations may be required. This staging area should be level and of sufficient size for the positioning of numerous bins for the soaking of live vegetation before installation. The staging area should also be of sufficient size to allow parking, storage of equipment, construction of bioengineering components, work trailer, sanitation, and water tanks if necessary.

**************************************************************************

A staging area shall be constructed at the work site for the storage of equipment, work trailer, portable sanitation, water tanks, parking, and all other materials and equipment required to complete the work. The site should have a level portion for the placement of soaking tubs for the live vegetation. [The staging area shall be secured by an eight feet high chain link security fence to prevent vandalism or unauthorized access to the staging area.] Adequate surface preparation shall be performed to prevent excessive settlement, ponding of water, or rutting. The location and design of the staging area shall be shown in the drawings.

3.10 SITE DRAINAGE

**************************************************************************

NOTE: The designer should specify the site specific requirements for temporary and permanent drainage in this section. Work and harvest sites should be well drained at all times to prevent the ponding of water. Runoff water may need to be stored in retention or settling ponds before release to surface water bodies or channels. All temporary drainage features and structures shall be removed and restored to preexisting or design conditions at the end of work. Drainage may be a requirement for structure stability and for final grade of the work site. Some structure may require internal drainage of groundwater to improve stability. The requirements for internal drainage design should be stated in the requirement paragraph of the selected structure. Best Management Practices shall be employed in accordance with Section 01 57 19 TEMPORARY ENVIRONMENTAL CONTROLS.

**************************************************************************
3.11 DEWATERING

**************************************************************************

NOTE: Excavations may need to be dewatered to allow construction. Failure to due necessary site investigation or characterization may result in construction delays, unsafe working conditions, and cost claims.

It is important to understand the subsurface groundwater conditions, surface drainage, and precipitation in the area of the work during the selection and design of a structure. Water in excavations may delay work efforts, interfere with proper soil placement and compaction, and damage vegetation. Structures that incorporate large amounts of woody vegetation may be damaged due to buoyant forces if these excavations fill with water before sufficient material or binders have been placed to hold the vegetation in place. Water removed from excavations may require treatment before release.

Excavations adjacent to tidally influenced water bodies offer challenges in water control and drainage of excavation in terms of construction timing. Time of construction and dewatering may need to be adjusted to match tidal events and require work during time periods other than normal working hours. Similarly, work schedule and dewatering of excavations may need special attention adjacent to rivers or streams that fluctuate seasonally or daily due to water releases from water storage or hydropower projects. In areas where water levels fluctuate, precautions should be taken to ensure the structure will not be damaged by buoyant forces or by currents.

Dewatering of excavations can be expensive due to planning, equipment, labor, and disposal efforts. Alternative designs, locations, or foundations should be considered to reduce project costs if required. Groundwater should be tested for chemical contamination before the start of work. The cost of dewatering and treatment of such water may be high.

**************************************************************************

Submit overall plan for dewatering and any required diversion of water. Completely address in the plan installation and removal of the required systems and features. Dewater for construction, obtain and review all necessary information to ensure dewatering efforts are in compliance with regulations, and ensure the designed dewatering efforts are adequate based on site conditions and climate and other variables that may affect dewatering efforts. [Submit a technical memorandum detailing all dewatering requirements, locations, methods, and disposal procedures to the Contacting Officer at least [60] days before the start of work.] Information provided by the Government regarding dewatering requirements and site conditions shall in no way relieve the Contractor of full
responsibility for all dewater planning, efforts, and costs. Ensure the structure will not be damaged by buoyant forces or by currents should water enter the excavation or during the removal of this water. Ensure dewatering efforts do not impact adjacent structures or property, result in instability of the excavation floor or slopes, produce unsafe working conditions, or damage to animals or the environment.

3.12 BIOENGINEERED STRUCTURES

**************************************************************************

NOTE: The most common types of bioengineered structures are described below. These structures may be categorized as common, transverse, deflector, or longitudinal. Common structures are generic bioengineered structures applicable to gullies, stream banks, and lake shores. Transverse structures are constructed across stream channels that are less than 4.5 m 15 feet wide and 3 m 10 feet deep. Deflector structures are constructed from the bank into a stream or river to deflect flow away from the bank. Longitudinal structures are constructed parallel to stream banks or lake shores. Bioengineered structures may be used separately or in combination for bank protection and stabilization depending on the geotechnical and hydraulic site conditions, physical setting, desired habitat, and supply of construction materials. Structures not pertinent to the proposed design should be deleted from this specification. Structures described below are:

Common Structures
Permanent seeding
Live Staking
Joint planting
Pole planting
Live fascine
Siltation structures
Brush mat
Clump planting

Transverse Structures (streams less than 4.5 m 15 feet wide, gullies, small tributaries)
Palisade
Brush and stone sill
Wattle fence sill
Vegetated crib wall or wood sill
Vegetated dry stone barrier
Brush works or brush packing
Live fascine sill

Deflectors (Streams wider than 9 m 30 feet, stream bank protection)
Vegetated deflector (groins, dikes, spurs)
Live brush sill
Brush transverse
Brush grid

Longitudinal Structures
Single or clump reed planting
Live stone revetment
Brush layered revetment
Longitudinal live fascine
Longitudinal brush packing
Live crib wall

The specific names for bioengineered structures have not been standardized. The names of the structures listed above are not inclusive of all structures mentioned in literary sources and only represent a general compilation of the most commonly referenced names assigned to the structures. Therefore, individuals may have a different understanding of the function and design of a structure when provided with only a name. A diagram of the proposed structure is recommended for inclusion in this specification to provide clarity in the description and intent of the requirements. The designer may obtain these drawings from numerous literary sources, private vendors, or State resource agencies. It is recommended that the designer review these drawings during the selection of the structures for use and that the designer should provide these drawings to other personnel involved in the design and planning of the project to reduce confusion in design objectives and requirements. These drawings may be edited for site specific conditions as needed and should be included in or attached to this specification.

The following paragraphs provide the general types of information that are required for the description of requirements for the structures. The designer must edit the selected requirements to meet project objectives and performance criteria based on actual site conditions.

3.12.1 Common Structures

3.12.1.1 Permanent Seeding

NOTE: Permanent seeding is a simple method of stream bank stabilization that may be used along low velocity streams or channels with peak flows less than 0.08 cubic meter per second 3 cubic feet per second. Seeding must be combined with erosion control stabilization methods to prevent or reduce soil erosion during germination and the first several years of vegetation growth. Selected species of grasses and/or plants should be native to the area, resilient, provide a dense root mat, and be able to withstand being submerged in water for extended periods. The placement of rock or woody debris may be required at the toe of the bank to reduce undercutting.

Selected seed shall conform to all required regulations and requirements and all seeding shall be performed in accordance with Section 32.92.19
SEEDING. Seed shall be placed before installation of erosion control mats or the application of other erosion control materials or products.

3.12.1.2 Live Staking

**************************************************************************

NOTE: Live staking is the insertion of living stakes of vegetation into the ground. Live staking may be used to cover large areas of stream banks and to infill areas between other bioengineered structures. Live poles may also be used in lieu of stakes if deeper ground penetration is required. In this event, the method should be referred to as live pole staking. Combining live stakes with dead stakes may be feasible where the trapping of debris on the bank is desired or where there is a limited supply of local live vegetation.

**************************************************************************

Live stakes shall be driven into the ground in a row parallel to the stream bank with the stakes spaced 1 meter 3 feet apart. Rows of stakes shall be installed starting from the toe of the bank and progressing landward and shall be spaced 1 meter 3 feet apart. Successive rows of stakes shall be offset from the preceding row by one half the spacing distance between the stakes. Construction shall be performed in accordance with ASTM D6765 Standard Practice for Live Staking.

3.12.1.3 Joint Planting

**************************************************************************

NOTE: Joint planting is a variation of live staking in which live stakes or poles are driven between the joints of large natural stone, rip rap, or other forms of bank armor. This method may be used to add vegetation to stretches of stream bank, which are protected by barren armor to improve habitat and add areas of shade. Vegetation will improve bank stability due to the development of root mats. The vegetation will also decrease the velocity of water adjacent to the bank during high flow events. Caution is advised to check the stability and condition of the armor before using these methods on existing protected banks. The amount of sediment that may accumulate on the back as a result of the vegetation should be considered in long term design performance since the deposition of large amounts of sediment may overload the bank and result in failure.

**************************************************************************

Live [stakes] [poles] shall be installed in rows parallel to the stream bank with the [stakes] [poles] driven into joints between the [stones] [rocks] of the bank armor. [Stakes] [Poles] shall be driven a minimum of 600 mm 2 feet into the soil behind the armor and shall be spaced 1 meter 3 feet apart. The [stakes] [poles] shall be inclined at 15 to 45 degrees from horizontal. Rows shall be installed starting at the toe of the bank and progressing landward and shall be spaced 1 meter 3 feet apart. [Stakes] [Poles] in successive rows shall be offset from the [stakes] [poles] in the preceding row by half the spacing distance. The tops of the [stakes] [poles] shall extend at least 0.5 m 1.5 feet but not more than 1
3.12.1.4 Pole Planting

NOTE: Pole planting is the placement of vertical live or dead poles in multiple rows along the toe of a stream bank. The poles may trap debris between the poles and between the poles and the bank. The accumulation of debris should reduce the flow velocity adjacent to the bank and encourage the deposition of sediment and thus promote the aggradation of the bank over time. The structures will not provide immediate erosion protection, habitat, or bank stability. Erosion protection and habitat should develop as debris is trapped and the vegetation begins to grow. The stability of the bank should improve over time as new bank is formed and vegetation and root mats become established in the new bank material. Pole planting may be used in areas with steep or vertical banks or in areas with a limited supply of the vegetation that is necessary for the construction of other types of bioengineered structures. Pole plantings may be combined with brush mats or brush grids. Pilot holes may need to be drilled to allow the installation of the poles in coarse alluvial streambeds. Pole planting is not recommended for use in stream channels that contain large boulders or where bedrock may be within a few feet of the channel bottom. The depth to scour must be known to ensure the poles will not be lost due to degradation of the stream bottom during a flood event.

Live poles shall be driven vertically into the stream bed to a minimum depth of 1 m 3 feet. [No more than one-half the length of the pole below grade shall extend above the ground.] [The poles shall be driven to refusal.] [Pilot holes shall be drilled at the locations where the poles shall be installed using a steel rod or mechanized drilling machine. The poles shall be placed into the holes and loose sediment around the poles shall be compacted in place. Additional sediment shall be added as need to fill any space between the pole and the inner wall of the pilot hole until the hole is filled to the existing surface.]

a. Poles shall be straight and at least 100 mm 4 inches in diameter. The driving tip shall be shaped to a point to aid in installation. Branches shall [not] be stripped from the pole [where exposed above grade after installation]. The top of each pole shall be cut normal to its length.

b. Install poles in rows parallel to the stream bank at a nominal spacing of 1 m 3 feet. Install rows starting at the toe of the bank and progressing towards the stream channel to the mean low water level. Offset poles in successive rows from the poles in preceding rows by one half the spacing distance. The tops of the poles shall be at a uniform elevation [of 1 m 3 feet] above the mean low water level along the bank.
3.12.1.5 Live Fascine

**************************************************************************
NOTE: Live fascines are long bundles of live or dead branch cuttings tied together in tubular sections from 1 to 10 m 4 to 30 feet in length and up to 300 mm 1-foot in diameter. Smaller diameters and lengths of fascines are advantageous in areas where access by vehicles is not possible and materials must be provided to the site by manual labor. Fascines are recommended for sites close to large supplies of vegetation. Fascines are advantageous in stabilizing slopes of long length and for protecting the toes of banks. The structures are effective in reducing erosion on sloped banks that are subjected to bank scour or high surface runoff. The horizontal arrangement of fascines will reduce erosion and trap sediment and seed on the slope. The structures will deflect and insulate the bank from the stream current.

The stability of the bank will improve as the live vegetation develops root systems. Steep or undercut banks must be reduced in slope to provide a stable slope for construction and installation of the fascines. Banks that have experienced sloughing or rotational failures must be repaired by the removal of the failed material and the reconstruction of a stable surface before the installation of the fascine structures.

Fascines require large amounts of live vegetation for construction. Therefore, these structures are best suited for temperate regions where there is a significant supply of available and suitable vegetation near the work site. Staggered fascine structures are recommended in areas with limited supplies of vegetation or as a means to reduce project costs. Fascines are suitable to protect the toes of banks when used in combination with other bioengineering methods on the slopes. Fascines may be used at transition areas between different types of erosion or stabilization structures such as between erosion control mats and live siltation structures at the toe of a stream bank, or with brush mats or layered structures.

Fascines may be referred to as horizontal or vertical structures. Horizontal fascines are placed parallel to the stream channel. These fascines will reduce bank erosion by scour and surface runoff. The recommended spacing between horizontal fascines based on bank slope are:
<table>
<thead>
<tr>
<th>Slope</th>
<th>Slope Distance Between Trenches (mft)</th>
<th>Maximum Slope Length (mft)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1H:1V to 1.5H:1V</td>
<td>0.9-1.23-4</td>
<td>4.515</td>
</tr>
<tr>
<td>1.5H:1V to 2H:1V</td>
<td>1.2-1.54-5</td>
<td>620</td>
</tr>
<tr>
<td>2H:1V to 2.5H:1V</td>
<td>1.5-1.85-6</td>
<td>930</td>
</tr>
<tr>
<td>2.5H:1V to 3H:1V</td>
<td>1.8-2.46-8</td>
<td>1240</td>
</tr>
<tr>
<td>3H:1V to 4H:1V</td>
<td>2.4-2.78-9</td>
<td>15.250</td>
</tr>
<tr>
<td>4H:1V to 5H:1V</td>
<td>2.7-39-10</td>
<td>18.360</td>
</tr>
</tbody>
</table>

Vertical fascines are placed normal to the stream channel. These fascines may be used to serve as drainage conduits between the key trenches of horizontal fascines and are recommended in temperate regions and banks composed of poorly drained soils. Vertical fascines may be used to protect the bank from scour. The spacing of the vertical fascines shall be determined by site conditions, but should be close enough to prevent scour of the bank between the vertical bundles.

The trenches for the horizontal fascines may extend the full width of the work area or may be of shorter length and staggered to reduce the amount of material and labor required for the project. Key trenches must be installed at the toes of banks for horizontal fascine structures. The key trenches may be filled with natural stone and live and/or dead fascines up to three bundles in height. The ends of all trenches should be keyed into the bank or protected with large natural stone to prevent scour.

The trenches for vertical fascines should extend from the crest to the toe of the bank if these fascines are used without other structures on the slope. The trenches for the vertical fascines may extend between the trenches of horizontal fascines if used in combination. In this case, the vertical fascine trenches should connect the lowest portions of the horizontal fascine trenches to allow drainage. Trenches for both horizontal and vertical fascines may be installed landward of the crest of the bank if additional protection is desired and sufficient room for these trenches is available.

Fascines composed of live cuttings may be placed on bank slopes to the mean high water level of the stream. Live cuttings capable of growth under saturated conditions may be placed in the stream and in key trenches to elevations below the mean water level. Dead cuttings may be used for fascines placed in saturated conditions or may be interwoven with live cuttings to provide added resiliency to
live fascines. Fascines composed of dead cuttings may also be used separately at the toe or on the bank slopes where erosion and scour protection are desired and other bioengineered or hard structures are used for bank stability. Fascines should be wrapped with erosion control matting when installed in fine-grained cohesionless soil to reduce erosion of backfill.

Fascines should not be constructed on the ground. Elevated tables or braces should be used for assembly. All fascines bundles should be constructed by laying live cuttings parallel to one another with all growth tips oriented in the same direction. The cuttings should have a minimum of 300 mm 1-foot of overlap on successive layers. The live vegetation cuttings should be secured into a bundle using biodegradable binders spaced every 450 to 600 mm 1.5 to 2 feet along the length of the bundle. The fascines should be carried to the installation site in a manner that prevents excessive bending or breakage. Fascines with broken or loose cuttings due to excessive bending or the failure of binders must be repaired or replaced at no expense to the Government.

3.12.1.5.1 Horizontal Fascines

Install all trenches parallel to the direction of the bank contours. All trenches shall be 450 mm 18 inches wide and not more than 50 mm 2 inches deeper than the diameter of the fascine bundles.

a. A key trench shall be excavated [at the toe of the bank] [at the mean [high] water level] [at the location shown on the drawings] [to a depth of 1 m 3 feet below the mean high water level] and shall extend the full length of the working area. Trenches up slope of the key trench shall be [the same length as the key trench] [3 m 10 feet in length and separated by a spacing of 3 m 10 feet longitudinally. The midpoints of the trenches placed up slope shall coincide with the midpoints of the spaces between the down slope trenches]. Trenches shall be spaced 1.2 m 4 feet apart. A trench shall be installed at the toe and at two feet below the crest of the bank regardless of spacing interval. These trenches shall extend the full length of the work site. [At least [2] [_____] trenches shall be placed landward of the crest of the slope at a spacing of 1.2 m 4 feet.] All trenches shall be [keyed into the bank slope] [and] [filled for a distance of 1 m 3 feet with large natural stone at the up stream and down stream ends of the trenches].

b. The fascine bundle shall be placed in the center of the trench with at least 50 mm 2 inches of the bundle exposed above the top of the existing grade of the stream bank. The junction between the ends of adjacent fascine bundles in the same trench shall be [offset side-by-side] [interwoven with each other] for a distance of 300 mm 1-foot. The fascine bundle shall be anchored in the trench with [live] [and] [dead] [stakes] [and] [poles] that are at least 50 mm 2 inches [square] [in diameter] at the top, 700 mm 2.5 feet in length, and tapered from the top to the base. The [stakes] [poles] shall be driven vertically through the fascine until flush with the top of the bundle.
starting 1-foot from the end of each fascine and spaced every 1 m 3 feet thereafter. A terminal [stake] [pole] shall be driven 300 mm one-foot from the end of the fascine regardless of spacing interval. [Stakes] [Poles] shall not be driven through or within 150 mm 6 inches of the binders. Live [stakes] [poles] shall be driven into the slope on the downhill side of the fascine bundle at an angle not to exceed 45 degree from vertical. The [stakes] [poles] shall be placed at the midpoint between the anchor [stakes] [poles] and shall contact the underside of the fascine, but shall not penetrate the fascine. At least 75 mm 3 inches of these downhill live [stakes] [poles] shall extend above the ground surface. Soil shall be placed and lightly tamped into place around the fascine and brushed into the voids in the fascine until only the top of the bundle is partially exposed. The top of the backfill shall slope towards the back of the fascine trench to prevent overtopping by runoff and to retain water and sediment.

c. [A single fascine shall be placed in the key trench.] [Up to [3] [_____] fascines shall be stacked on top of one another in the key trench.] Live poles shall be driven vertically into the ground to a minimum depth of 600 mm 2 feet to secure the [stacked] fascine bundle(s) in the key trench. These poles shall extend at least 600 mm 2 feet above the top of the upper most bundle. Key trenches shall be backfilled with compacted [removed sediment] [select fill] to match the [existing] [final grade of the] surface.

3.12.1.5.2 Vertical Fascines

Trenches shall be installed normal to the bank contours and shall be spaced 3 m 10 feet apart starting from the up stream end of the work site. A trench shall be placed at the down stream end of the work site regardless of spacing interval. The trenches shall extend [from the [toe of the bank] [key trench]] to [[the crest of the bank] [3 m 10 feet landward of the crest of the bank]] [between the horizontal fascine trenches. Vertical trenches shall be offset by 1.5 m 5 feet between horizontal trenches to prevent through flow of drainage]. All trenches shall be 450 mm 18 inches wide and not more than 50 mm 2 inches deeper than the diameter of the fascine bundles. [A key trench shall be excavated parallel to the bank contours at the [toe of the bank] [mean high water level] and shall extend the full length of the working area. The key trench shall be filled with horizontal fascine bundles as specified above in paragraph HORIZONTAL FASCINES].

a. The fascine bundle shall be placed in the center of the trench with at least 50 mm 2 inches of the bundle exposed above the top of the existing grade of the stream bank. The junction between the ends of adjacent fascine bundles in the same trench shall be [offset side-by-side] [interwoven with each other] for a distance of 300 mm 1-foot. The fascine bundle shall be anchored in the trench with [live] [and] [dead] [stakes] [and] [poles] that are least 50 mm 2 inches [square] [in diameter] at the top, 700 mm 2.5 feet in length, and tapered from the top to the base.

b. The [stakes] [poles] shall be driven vertically through the fascine until flush with the top of the bundle starting 300 mm 1-foot from the end of each fascine and spaced every 1 m 3 feet thereafter. A terminal [stake] [pole] shall be driven 300 mm one-foot from the end of the fascine regardless of spacing interval. [Stakes] [Poles] shall not be driven through or within 150 mm 6 inches of the binders. Live [stakes] [poles] shall be driven into the slope on the up stream and down stream
sides of the fascine bundle at an angle not to exceed 45 degree from vertical. The stakes shall be placed at the midpoint between the anchor stakes and shall contact the underside of the fascine, but shall not penetrate the fascine. At least 75 mm 3 inches of the up stream and down stream live stakes shall extend above the ground surface.

c. Soil shall be placed and compacted into place around the fascine and brushed into the voids in the fascine until only the top of the bundle is partially exposed. The top of the backfill shall be roughened, seeded, and covered with erosion control matting to prevent the loss of soil.

3.12.1.6 Siltation structures

**************************************************************************

NOTE: Siltation structures are composed of live or dead cuttings that are placed parallel to the toe of a stream bank at or below the mean high water elevation of the stream. These structures provide immediate erosion protection, fish habitat during high flow events, and trap sediment that results in bank aggradation. The structures deflect the current in the stream away from the toe of the bank to prevent scour and undercutting. The stability of the bank is improved as root systems develop.

Siltation structures are recommended for sites with low flow velocities such as the insides of meander bends, side channels, and in areas of bank scour behind obstructions. The structures are well suited for locations where the development of new bank is desired. Siltation structures should be combined with large natural stone, coir logs, root wads, or other hard structures if used in areas subject to high flow velocities and scour.

The structures may be constructed of live or dead cuttings. Live cuttings should be 1 to 2 m 3 to 6 feet in length, flexible, and from species of plants with do not mature to heights greater than 3 m 10 feet. Side branches may remain on the cuttings. Live cutting structures should be placed at the mean high water elevation of the stream to allow growth of vegetation unless the selected species is capable of root generation under saturated conditions.

Dead cuttings may be incorporated into a live structure to improve its resiliency and resistance to abrasion by sediment and debris. The dead cuttings may be from any locally available species of vegetation. Structures composed completely of dead cuttings are suitable for areas were temporary bank aggradation and erosion protection are desired. Dead cutting structures may be placed above or below the mean high water level of the stream. If the dead structure is placed below the mean high water level, it is recommended that large natural stone be placed on the cuttings to reduce...
floating of the cuttings. More than one row of live or dead siltation structures may be placed along a stream bank to increase the width of coverage.

Siltation structures may be placed on the stream bank normal to the toe of the bank and oriented up to 15 degrees downstream from the perpendicular to the toe. These structures are recommended for low slope banks to reduce erosion of low banks, improve bank stability due to root development, and for areas where sedimentation is desired. The spacing between these structures should be determined based on actual field conditions and flow velocities to prevent scour between the structures. Live stakes or poles may be placed between the siltation structures.

**************************************************************************

a. The siltation structure shall [be [parallel] [normal]] [consist of segments parallel and normal] to the contours of the bank. The structure shall be composed of [live] [dead] [live and dead cuttings, comprising [80 percent] [and] [20 percent] of the structure, respectively]. Cuttings shall be 1 to 2 m 3 to 6 feet in length [and flexible] with side branches attached.

b. The cuttings shall be placed in a trench that is excavated [at the toe of the bank] [1 m 3 feet from the toe of the bank towards the stream channel] [as shown on the drawings]. The trench shall [be parallel to the bank contours and at the mean high water elevation.] [extend the entire length of the work site.] [normal] [inclined at 15 degrees downstream to the bank contours.] [The trench shall extend from the toe of the bank to the mean water elevation of the stream.] All trenches shall be 600 mm 2 feet deep with a 'V' shaped cross section. [Trenches shall be spaced 1 m 3 feet apart.] [All trenches shall be keyed 1 m 3 feet into the stream bank.]

c. The ends of the cuttings shall be pushed vertically into the bottom of the trench along the centerline and shall have the growth tips extending 450 mm 1.5 feet above the top of the trench. The cuttings shall be placed to form a layer that is 150 mm 6 inches thick with at least [15] [_____] cuttings per 300 mm linear foot of trench. Large natural stone shall be placed on either side of the bases of the cuttings and backfill shall be placed to infill between the stones to the top of the existing [design] grade. [The stream side portion of the structure and the toe of the bank shall be protected with [coir logs] [exposed dead fascines] [large natural stone with joint plantings of [live] [and] [dead] [poles] [stakes] [root wads]]. The ends of the structure shall be protected with large natural stone placed on the upstream side of structure where it ties into the stream bank.

3.12.1.7 Brush Mat

**************************************************************************

NOTE: A brush mat is composed of live or dead cuttings that are placed on the stream bank to form a densely packed layer of cuttings. These structures provide immediate erosion protection, habitat for fish during high flow events, and the rapid establishment of extensive root systems in the
bank. Brush mats are well suited for erosion protection of banks damaged by flooding. The growth of the vegetation composing the mat structure may be improved by placing an initial lift of brush and covering it with soil and then placing a second lift of brush to the design surface. The mat is held in place by anchor stakes or poles and further secured to the slope by rope or binding products that are laced between the anchor poles. Erosion control matting may be installed beneath the brush mat to reduce erosion of slope soil, especially if this soil is poorly compacted or easily eroded.

Brush mats require large quantities of vegetation and labor for construction. If an insufficient supply of live cuttings is available, then dead cuttings may be intermixed with the live cuttings in approximately equal portions. Dead cuttings should be flexible to allow construction and interweaving with the live cuttings. The base of the mat at the toe of the bank should be secured with rock or longitudinal bioengineered structures to prevent erosion or damage of the mat. The cuttings for the mat may be placed in small trenches cut into the face of the bank or pushed directly into the slope without the excavation of trenches.

**************************************************************************

a. [Live] [and] [dead] cuttings shall be generally straight, supple, 1.5 m 5 feet long, and shall have lateral branches still attached. The cut ends of the cuttings shall be shaped to sharp tips for penetration into the stream bank. The cuttings shall be placed in rows parallel to the contours of the bank starting 1 m 3 feet below the bank crest. The rows shall be spaced every 600 mm 2 feet thereafter down slope to the toe of the bank. All rows shall extend the full length of the work site.

b. The cut ends of the cuttings shall be pushed into the bank at the same contour elevation for each row with the growth tips toward the top of the bank. The cuttings shall be oriented [normal] [at an angle of 15 degrees down stream from normal] to the bank toe. At least 15 cuttings shall be placed per 300 mm liner foot in each row. A light roller and foot pressure shall be used to push the cuttings of subsequent rows against the bank over the cuttings of preceding rows to achieve a mat thickness of 100 mm 4 inches. [Up to 15 percent of the cuttings shall be placed parallel to the slope of the bank and interwoven with the cuttings that are placed with the growth tips toward the top of the bank. These parallel cuttings shall reinforce the brush mat. The growth tips of the parallel cuttings shall be oriented down stream.] The process of placing and compressing cuttings shall continue down slope until the toe of the bank is reached. A row of cuttings shall be place along the toe of the bank regardless of spacing interval.

c. The toe of the bank shall be protected by [large natural stones] [[live] [dead] fascines] [coir logs] that overlie the base of the cuttings of the row at the toe of the bank. [An erosion control mat shall be installed on the prepared grade of the bank slope before the placement of the cuttings.] [The ends of the mat shall extend 1.2 m 4 feet over unprepared bank.]
d. [Live] [Dead] anchor stakes that are 50 mm 2 inches in diameter shall be driven through the mat and 600 mm 2 feet into the stream bank. The tops of these stakes shall not extend more than 300 mm 1-foot above the top of the mat. The stakes shall be placed in rows parallel to the bank contours starting at the crest of the bank with the stakes spaced 1 m 3 feet apart. Subsequent down slope rows shall be spaced every 1 m 3 feet to the toe of the bank. A row of stakes shall be installed along the toe of the bank regardless of spacing interval to anchor the base of the mat. The top of each anchor stake shall be notched with a 13 mm 1/2-inch deep triangular cut that is normal to the length of the stake and 25 mm 1 inch below the top of the mat when compressed by foot pressure adjacent to the stake.

e. The up stream and down stream ends of the mat shall be secured with anchor stakes that shall be placed with a spacing interval equal to one half the above specified spacing distance of stakes in the rows. The one half distance spacing of stakes shall extend for 1 m 3 feet towards the center of the structure from the up stream and down stream ends of the mat and shall extend from the base to the top of the mat at these locations.

f. The mat shall be secured to the slope using binding ropes. The ropes shall be laced across the mat in a diagonal. A single length of rope shall be secured to a stake in the row of stakes at the toe of the bank. The rope shall be secured to each stake that is oriented diagonally to this stake in a single direction from the toe of the bank to the crest of the bank. Ropes that cross between stakes shall be tied together. Ropes shall be secured parallel and normal to the slope along the rows of stakes and to the stakes that lie in a line from the crest to the toe of the bank. These ropes shall be tied together where they meet between stakes. All ropes shall be secured to the stakes with non raveling knots. No more than 150 mm 6 inches of rope shall remain at the ends of the rope lengths after they are installed.

g. [Removed soil] [Select fill] shall be brushed into the mat to within 50 mm 2 inches of the top of the structure.

3.12.1.8 Clump Planting

**************************************************************************
NOTE: Clump planting requires the excavation, transport, and placement of live vegetation with root wads and attached soil. This planting method is recommended for establishing vegetation on steep banks of limited height and on the upper banks or floodplains of a stream where the plants will not be subjected to long periods of inundation by water and where adequate moisture is available. Plantings should not be subjected to erosion, flooding, animal traffic or grazing, dry conditions, or high winds during the first several years after installation. Minor earthwork is recommended to reduce vertical faces or remove undercut slopes from the bank to limit the loss of plant clumps due to scour or flooding. Selected woody vegetation should not grow to large mature trees, which could induce scour and loss of the bank due to obstruction of the stream flow or the rotation of the tree into the stream.
channel and creation of a large hole as the root wad is pulled from the bank. Heavy equipment may be required if plant clumps or root wads are too large to be easily moved by manual efforts. The toe of the stream bank should be protected from erosion by the placement of large natural stone, erosion control matting, or construction of longitudinal bioengineered structures. Irrigation and fencing may be required to ensure the survivability of the plants.

**************************************************************************

a. The stream bank shall be prepared for clump planting by excavating 600 mm 2 feet deep holes with floors that slope into the bank and that are at least 150 mm 6 inches longer and wider than the same dimensions of the removed clumps. The floors of these holes shall not be within 150 mm 6 inches of the groundwater table. The excavations shall be [spaced at 2 m 6 feet and separated by 1 m 3 feet of existing bank] [1 m 3 feet in width, continuous, and separated by 1 m 3 feet of existing bank] along the extent of the work site. Removed soil shall be used as backfill. Excess soil from the excavations shall be [removed from the site] [thin spread on the upper bank landward of the clump plantings]. The exposed surface of the backfill shall be roughened and seeded [and covered with erosion control products].

b. Suitable species for transplant shall be located in the vicinity of the work site. Plant species shall not mature to heights greater than 4.5 m 15 feet or trunk diameters exceeding 100 mm 4 inches. Clumps of plants shall not exceed the width of the removal equipment. If clumps are removed by hand, these clumps shall not exceed 1 m 3 feet in any dimension. The clumps shall be removed with existing soil and as many shallow roots as possible to aid in growth and survival, and shall be transported immediately to the work site and placed.

c. Prior to placement, the excavation shall be flooded with water to moisten the soil and aid in plant survival. The plant clumps shall be placed with vegetation [standing vertically] [slightly inclined towards the stream] and firmly pushed into the soil at the base of the excavation to prevent rafting. At least [3] [_____] [dead stakes] [or] [live poles] shall be driven through each clump to secure it to the bank. Biodegradable coir net with a minimal life of 2 years shall be placed on top of the soil of the clump and shall extend 1 m 3 feet onto the bank beyond the limits of the excavation.

3.12.2 Transverse Structures

**************************************************************************

NOTE: Transverse structures consist of live vegetation or a combination of live vegetation and hard material (dead vegetation, logs, rock, and natural stone) that are constructed normal to and across small stream or river channels or narrow gullies. These structures are recommended for streams with low flow, intermittent streams, or dry gullies subject to flow after precipitation events. The harder structures may be used in narrow channels that experience infrequent or seasonally torrential flows.
The transverse structures function as weirs and drop structures, which reduce the velocity of stream flow, bed degradation, and may result in the transformation of the channel profile to a stepped profile due to the retention of sediment and debris. The reduction in flow velocity aids in reducing bank erosion. In addition, these structures may be placed at the toe and parallel to the stream bank, thus directly improving bank stability and reducing undercutting and erosion especially in areas with banks composed of low cohesive materials. Structures should be placed with key trenches into the banks to improve stability and to prevent the bypass of the structure due to lateral erosion of the bank.

Advantages of transverse structures are ease of construction at remote sites using locally available materials and the establishment of habitat with time. A primary disadvantage of these structures is that they may obstruct fish passage and may reduce the conveyance of the channel resulting in local flooding. Therefore, the structures should be designed to allow fish passage and constructed of supple vegetation that matures to minimal height. Some transverse structures require significant amounts of manual labor and may not be economical in areas of limited vegetation supply. Periodic maintenance may be required to remove excessive amounts of trapped debris to prevent possible flooding, fire dangers, build up of decomposing plant material, or health hazards caused by habitation of the debris by insects or vermin or trapping of dead fish or animals. These structures may be combined with other forms of live and dead bioengineered structures and hard structures such as gabions, or riprap.

Stagnant water may become present behind transverse structures depending on site conditions. These areas of stagnate water may become breeding grounds for mosquitoes or other insects and undesirable aquatic plants and animals. The designer shall include adequate drainage features in the design to remove water from behind the structure, such as open channels, drainage pipes, or passive subsurface drains.

3.12.2.1 Palisade

NOTE: A live palisade is a weir composed of live poles, which develops into a transverse zone of vegetation that crosses the stream channel. These structures may be installed rapidly, are easy to construct, and provide shade to the stream channel as the vegetation matures. Palisades are best suited for small gullies or streams in low-lying
areas that are less than 10 m 30 feet wide and 4 m 12 feet deep. The streambed should consist of loose sand, silt, or soft clay to allow easy installation of the poles used in the construction of the palisade. A steel rod may be required to install pilot holes for the driving of the poles in medium to hard clay, dense sand, sand with fine gravel, and medium dense silt. Palisades may be installed in coarse alluvial streams if placed in a trench excavated in the streambed. These structures in coarse alluvial systems should be viewed as temporary and expendable since they may be damaged by bed load and large debris transported during periods of high flow.

A palisade may be constructed entirely of dead poles if the project objective is the temporary stabilization of the stream channel. These structures will not become reinforced with time by root structures and will deteriorate. However, depending on the site conditions, these structures may be adequate for the retention of sediment on which native grasses and vegetation may take root, thus resulting in the evolution of the dead structure to a live transverse brush sill. Dead palisades may be used in coarse alluvial streams since the establishment of a vegetated structure is not expected and may not be desired.

The live or dead poles should be driven a minimum of 600 mm 2 feet into the streambed for poles under 1.5 m 5 feet in length. Poles over 1.5 m 5 feet in length should be driven a minimum of 1 m 3 feet into the streambed. The poles should be harvested from local vegetation and should be a minimum of 38 mm 1.5 inches in diameter. The bottoms of the poles should be formed to sharp points to aid in the driving of the poles into the streambed.

The strength of the palisade may be increase by attaching a cross beam to the structure. A cross beam is recommended for palisades with widely spaced or thin poles and that have a height greater than one-foot above the streambed. The cross beams should be at the same height and inclination on both sides of the palisade. The beams are attached to the palisade with binders composed of untreated coir or hemp rope that is capable of withstanding several years of exposure. The binder must be looped and tied around the cross beams and the adjacent poles in a manner that tightly secures the members together. The binders should not unravel if a portion of the binder or structure is lost or damaged. Cross beams may be composed of untreated dimensional lumber or straight poles of similar diameter as the palisade poles.

**************************************************************************

a. Live poles shall be 1 m 3 feet long, 38 to 100 mm 1.5 to 4 inches in
diameter, and the bottom ends of the poles shall be cut to form sharp drive points. The poles shall be driven vertically into the streambed to a minimum depth of 600 mm 2 feet and shall be placed across the channel in a [straight row] [row that is deflected down stream by 15 degrees] ['V'-shaped row pointing down stream with the apex at the center of the channel]. Poles shall have a spacing of no less than 50 mm 2 inches but not greater than 150 mm 6 inches. [The center poles of the structure shall extend a maximum of [300] [600] mm [1] [2]-foot above the existing grade of the streambed.] [The center poles shall be dead poles placed for a distance of 1 m 3 feet about the centerline of the structure.] [The central span of the structure shall be composed of large natural stone keyed 600 mm 2 feet into the streambed with a top elevation 300 mm 1 foot above the existing streambed. The stone shall extend 600 mm 2 feet on each side of the centerline of the structure and shall be tightly butted with [live] [dead] poles of the palisade structure.] [The tops of the poles shall increase in height outward from the center of the structure by no more than 15 mm 0.05-foot for each adjacent pole to form a notch at the center of the structure.] [The tops of the poles shall be at the same elevation.]

The ends of the structure shall be placed in key trenches that extend 1 m 3 feet into the stream bank.

b. Cross beam members of untreated [straight 25 by 100 mm 1 by 4 inch dimensional lumber] [long straight poles at least 50 mm 2 inches in diameter] shall be attached to the palisade with binding products, which shall be wrapped at least two times around the cross beam and adjacent pole. Binding products shall be installed to prevent raveling of the binder in the event of the loss of a portion of the binder or structure. The cross beam members shall be [horizontal] [inclined] and at the same elevation on each side of the palisade and shall extend the entire width of the structure. The beams shall be 600 mm 2 feet greater in length than the structure and the ends of the beams shall be placed in key trenches in the bank. Key trenches shall be excavated to the depth and width necessary for the placement of the ends of the cross beams and shall be backfilled with soil removed by excavation.

c. The sediment in the streambed shall be compacted around each pole using a tamping bar. [The sediment removed from the streambed for the installation of the poles shall be placed as compacted backfill around the poles.] Dead cuttings and excess live cuttings shall be placed in a criss-cross pattern on the up stream and down stream sides of the structure for a distance of 600 mm 2 feet and shall be tightly packed against the stream bank at the ends of the structure to a thickness of 150 mm 0.5-foot for 600 mm 2 feet beyond the limits of backfill exposed at the key trenches.

3.12.2.2 Brush [and Stone] Sill

**************************************************************************
NOTE: Brush sills are transverse structures similar to palisades, but composed of live or dead cuttings. These structures reduce stream channel degradation, are easy to construct, and may be combined with natural stone to improve performance. Selected vegetation should mature to low height, remain supple with time, and be capable of good root mat development. Live or dead cuttings may be used for the structure and the cuttings may retain small branches and do not need to be straight. Sills may
also be placed along the toes of stream banks separately or adjacent to the transverse brush sills. Sills do not trap large amounts of sediment or debris since the vegetation used in construction is pushed against the stream channel during high flow events and does not form an obstruction to flow. Therefore, these structures are suitable for channels where minimal changes to the stream profile are desired. Sills may be constructed in most types of alluvial material and will function in coarse alluvial streams. Backfill and the buried portions of cuttings should be wrapped in several layers of coir mat if the sill is constructed in a stream channel subject to infrequent torrential flows. The width of the construction trench may be increased up stream of the vegetation and filled with large natural stone to reduce damage to the structure by bed load in high flow channels. Live stakes may be planted between the joints of the stone.

A 600 mm 2 feet deep trench shall be excavated normal to and across the entire width of the stream channel. Live cuttings shall be placed in a criss cross manner with 20 cuttings per 1 meter 3 linear feet of trench on the down stream face of the trench. [Cuttings shall be placed in the same pattern and concentration as in the trench for the sill on the stream side faces of trenches excavated at the toes of the banks for a distance of 4.5 meters 15 feet up stream and down stream of the ends of the sill structure]. The cut ends of the cuttings shall be pushed into the bottom of the trench to [refusal] [150 mm 6 inches] and the growth tips shall extend 600 mm 2 feet above the top of the existing streambed. Large natural stone shall be placed on top of the cut ends of the cuttings [to the top of the existing streambed to fill the entire trench] and shall be tamped into the streambed to secure the stones in place. Removed sediment shall be placed in the voids between the natural stone [and shall be placed over the lower stone work to fill the entire trench]. Excess sediment shall be thin spread up stream of the structure. Large natural stone shall be placed at the ends of the structure against the bank [and at the upstream and down stream ends of the trenches excavated parallel to the banks]. [Live stakes] [and] [dead cuttings] up to 600 mm 2 feet in length shall be driven into the [sediment backfill on 150 mm 6 inch centers] [between the joints in the natural stone] across the entire width of the trench and 1 m 3 feet up each bank from the toe of the bank. Sills shall be spaced [15 m 50 feet apart] [as shown on the drawings].

3.12.2.3 Wattle fence sill

NOTE: Wattle fence sills are recommended for narrow and slow flowing streams, small gullies, agricultural drainage ditches, or open channel drains. These sills are best suited for streams or drainage systems with coarse-grained bed load, which will be trapped by the weaves of the fence. The sills may not trap fine-grained sediment or reduce erosion in fine-grained alluvial streams since the fine sediment may pass through the structure. These fence structures may be constructed of live or dead vegetation. The use of live poles and cuttings
should result in the establishment of a row of vegetation across the stream channel with time. Cross beams are recommended for structures over two feet in height. These sills may be combined with brush sills and brush layer structures.

a. A trench 600 mm 2 feet deep and 300 mm 1 foot wide shall be excavated normal to and extend across the entire width of the stream channel. [Live] [Dead] poles shall be 1 m 3 feet long with a minimum and maximum nominal diameters of 38 and 100 mm 1.5 and 4 inches, respectively. The bottom ends of the poles shall be cut to form sharp drive points. The poles shall be driven vertically into the streambed to a minimum depth of 600 mm 2 feet and shall be placed across the channel in a [straight row] ['V'-shaped row pointing down stream with the apex at the center of the channel with the poles] at a spacing of 600 mm 2 feet. The poles shall extend a maximum of [300] [600] mm [1] [2]-foot above the existing grade of the streambed. [The center poles shall be dead poles placed for a distance of 1 m 3 feet about the centerline of the structure.]

b. The wattle fence shall extend from the bottom of the trench to the tops of the poles. The top of the fence shall be [at the same elevation] [sloped to the center of the channel]. The fence shall be constructed of flexible [live] [and] [dead] cuttings that are 2 meters 6 feet in length and from 19 to 38 mm 3/4 to 1.5 inches in diameter. The cuttings shall be [laced horizontally between the poles in an alternating woven pattern with the cuttings being placed on the up stream and down stream sides of adjacent poles across the structure starting from the steam bank] [placed on the up stream side of the poles and shall be tightly packed and interwoven to form a braided vertical structure]. The ends of the cuttings shall overlap 300 mm 1-foot with adjacent cuttings. The cuttings of the fence shall be secured to the poles with binding products. The binders shall be installed to prevent raveling of the binders in the event of the loss of a portion of the binders or structure.

c. [Sediment removed from the trench shall be placed in the excavation as compacted backfill around the poles and lower fence.] [Live stakes shall be placed at 300 mm 1-foot spacings in the backfill.] [Large natural stone shall be placed at the bottom of the trench along the up stream and down stream toes of the fence [and shall extend to the top of the existing streambed]. [The stones shall be tamped into place and sediment shall be used to fill voids between the stones.] [Live stakes shall be placed in the joints between the stones.]] Excess sediment shall be thin spread up stream of the structure.

d. [Cross beam members of untreated [straight 25 by 100 mm 1 by 4 inch dimensional lumber] [long straight poles at least 50 mm 2 inches in diameter] shall be placed on the down stream side of the poles and overlie the fence on the up stream side of the structure. The beams shall be attached to the structure with binding products wrapped at least two times around the cross beam and adjacent pole and laced through the wattle fence cuttings.] [The cross beams shall be horizontal and at the same elevation on each side of the structure and shall extend the entire width of the structure.] Both ends of the structure [shall extend into a key trench that is excavated 600 mm 2 feet in the banks] [extend to the existing stream banks and be covered on both sides with large natural stone placed from the channel bottom]
to the top of the structure. The stone shall rest on the stream bank, be at least 600 mm 2 feet thick, and extend 1.5 m 5 feet away from the structure in the up stream and down stream directions.

3.12.2.4 Vegetated Crib Wall or Wood sill

**************************************************************************

NOTE: A vegetated crib wall consists of a hollow box-like structure of timber or logs filled with earth and live cuttings. A wood sill is a vertical open wall composed of timber or logs that forms the front header, which is not tied to a similar structure, or rear header, up stream by stretchers as is the case with the crib wall. The crib wall is more stable than the wood sill. These structures may last 20 to 30 years depending on the type of timber used, are quick to construct, and may use locally available materials. The live cuttings take over the function of the crib wall as the cuttings grow and mature and the timber decays. These structures should not exceed 1.5 m 5 feet in height and are well suited for gullies with fine-grained sediment bed load and narrow streams less than 4.5 m 15 feet wide with steep gradients.

Crib walls or wood sills may be combined with brush sills, brush mats, or large natural stone on the up stream or down stream sides of the structure to reduce erosion. Stability of the structure may be improved using a double crib design composed of front and back rails. Backfill should be free draining material with less than 10 percent fines. However, if such backfill material is not readily available, removed sediment may be placed as compacted backfill. Timber used for the crib wall may be untreated manufactured 100 mm 4-inch square posts, locally harvested vegetation with trunk diameters greater than 100 mm 4-inch, or a combination of these materials. Treated lumber will not be used.

**************************************************************************

a. A trench shall be excavated that is 1.5 m 5 feet wide and 600 mm 2 feet deep and extends normal to and across the entire width of the stream channel. The floor of the trench shall be sloped at 15 degrees up stream and shall be [manually compacted using a tamping bar weighing at least 18 kg 40 pounds] [compacted using a small motorized tamping machine] until the bottom of the trench is dense and provides a solid base for the crib wall [wood sill]. The floor of the trench shall be [as shown in the drawings] [of uniform grade across the trench width]. Depressions in the trench floor shall be filled with compacted material to raise these areas to grade and positive areas above the floor design elevation shall be reduced to grade. The trench shall be keyed into the stream banks for a distance of 1 m 3 feet. Material removed from the key trenches shall be used as compacted backfill in the key trenches. Sediment removed from the trench in the stream channel shall be [removed from site and replaced with select fill] [used as compacted backfill].
b. The [crib wall] [wood sill] shall be framed with [untreated, straight 100 mm 4-inch square by 2.5 m 8 feet long posts] [100 to 150 mm 4 to 6 inch diameter by 2.5 m 8 feet long straight logs harvested from local sources. The logs shall be cut normal to the trunks with all branches stripped from the trunks]. The down stream header shall be placed [parallel to the bottom of the trench and extend the full width of the trench] [along the alignment shown in the drawings]. [The up stream header shall be placed parallel and 1.5 m 5 feet up stream of the down stream header.] Splices between members shall be placed end-to-end and in line. Wood posts that are at least 100 mm 4 inches in diameter shall be driven vertically 150 mm 6 inches from the splices on the up stream and down stream sides of the headers. Wood post shall be driven on both sides of the headers at the midpoints between the splices. The members at the ends of the structure shall be firmly placed against the faces of the key trenches. Wood posts shall be driven on both sides of the headers at the toes of the banks and the toes of the key trenches.

c. Stretchers [for wood sills shall be 1.2 m 4 feet] [for live crib walls shall be 2 m 6 feet] in length. Stretcher shall be placed between the vertical splice poles and normal to the down stream header. The stretchers shall be spaced every 1.2 m 4 feet between the poles and have a minimum of 100 mm 4 inches extending down stream of the header face. The rear butt of the stretcher shall be placed [firmly against the upstream face of the trench] [on top of the up stream header]. The stretcher shall be attached to the header(s) with binding products wrapped three times around the stretcher and header in a criss cross pattern and secured with a non-raveling knot. A 13 mm 1/2-inch diameter hole shall be drilled vertically through the stretcher and header. A 16 mm diameter by 300 mm 5/8 inch diameter by 12 inch long [non-galvanized steel spike] [steel rebar] [hard wood dowel] shall be driven into the hole and set flush to the top of the stretcher.

d. The open area between the down stream header and the upstream [trench face] [header and the portion of the trench upstream of the upstream header] shall be backfilled with compacted [sediment removed from the trench excavation] [select fill] to an elevation that is at the middle of the stretchers. Live cuttings that are 19 to 38 mm 3/4 to 1.5 inch in diameter and 2.4 m 8 feet long shall be placed in a criss cross manner on top of the compacted backfill with the cut ends pushed into the up stream face of the trench. At least 600 mm 2 feet of growth tips of the cuttings shall extend beyond the face of the down stream header. Backfill shall be placed and lightly compacted on top of the cuttings to the top of the stretchers. Additional lifts of headers, stretchers, backfill, and cuttings shall be placed until only the final lift remains. The centerlines of the down stream headers shall be offset 50 mm 2 inches upstream of the lower headers to provide an incline to the down stream face of the structure.

e. The top down stream header shall be 100 mm 4 inches larger in diameter than the headers used for wall construction to reduce sediment loss due to scour. The vertical poles on both sides of the headers shall be cut flush with the top of the final down stream header [and the top rear header]. A header shall be placed at the midpoint between the top down stream and up stream headers and secured with binders and [spikes] [rebar] [dowels] to the underlying stretchers. The lift of backfill immediately below the completion headers shall be filled with a tightly packed brush mat composed of live [and dead] cuttings that are placed in an alternating pattern perpendicular and parallel to the wall. Each layer of cuttings shall be 100 mm 4 inches thick and shall be covered
with a thin layer of lightly compacted backfill. [Rounded clean natural stone from 200 to 300 mm 8 to 12 inches in diameter] [Excavated sediment] shall be placed from the top of the packed brush to the top of the down stream header and shall be graded up stream to match the existing slope of the stream channel up gradient of the work site. [Live stakes shall be driven vertically on 600 mm 2 feet centers into the backfill at the top of the structure.] [Large natural stone armor 600 mm 2 feet thick shall be placed at the ends of the structure and on the slopes of the banks for a distance of 2 m 6 feet upstream and down stream from the structure. Live stakes shall be planted in the joints between the stones.] The trench down stream of the structure shall be filled with [large natural stone] [a brush [and stone] sill] [a brush mat].

3.12.2.5 Vegetated Dry Stone Barriers

**************************************************************************

NOTE: Vegetated dry stone barriers are constructed of large natural stone with interlayered live cuttings. These structures may be built to heights of 4.5 m 15 feet and serve as weirs or drop structures in high gradient streams with torrential flows and heavy coarse bed load. Stone barriers may also be constructed to slightly above the existing elevation of the stream channel to prevent bed degradation. The largest stones that may be moved by manual efforts should be used. Construction of barriers adjacent to existing large boulders may reduce the amount of work required.

**************************************************************************

A trench that is 1.2 m 4 feet wide and 1 m 3 feet deep shall be excavated normal to and across the entire width of the stream channel and shall be keyed 1 m 3 feet into the stream banks. The bottom of the trench shall be sloped at 15 percent in the up stream direction and shall be compacted using a manual tamping bar weighing at least 18 kg 40 pounds. Large stone of similar size shall be placed on the entire floor of the trench with a minimum of voids between the stones. The stones shall be covered by [fine sediment] [select fill] that shall be worked into the voids between the stones until only the tops of the stones are visible. Live cuttings that are 2 m 6 feet long and up to 38 mm 1.5 inches in diameter shall be placed on top of the stones in a criss cross pattern with the butts of the cuttings in contact with the up stream face of the trench. The growth tips of the cuttings shall be oriented down stream and shall extend 0.5 m 1.5 feet beyond the farthest down stream placed stones. Addition lifts of stone, fill, and cuttings shall be placed on the lower lifts until the design height of the structure is reached. The stones of each successive lift shall be placed to interlock with the tops of the stones of the lower lift. Live cuttings at the top of the structure shall be placed in between the stones and inclined slightly down stream. [Live stakes that are 600 mm 2 feet long shall be driven between the joints of the stones at the top of the structure on 600 mm 2 feet centers and for a distance of 1 m 3 feet up the stream banks.] The top stones shall be covered with a 100 mm 4 inch thick layer of [fine sediment] [select fill].

3.12.2.6 Brush Work or Brush Packing

**************************************************************************

NOTE: Brush work or brush packing uses live and
dead cuttings to fill a section of a gully or stream channel to reduce erosion of stream banks. These structures provide erosion protection to the channel by covering the channel with a mat of brush and are recommended for intermittent streams with fine-grained sediment. Brush works refers to brush mats placed across the stream channel with growth tips pointing up stream and which extend up the stream banks. Construction of brush work starts at the upstream limit of the work site and progresses down stream with each new layer of cuttings overlying the immediately up stream layer of cuttings. Brush packing refers to thickly packed layers of brush placed with the growth tips inclined slightly down stream that fill a gully or small stream channel. Brush packing starts at the down stream limit of the work site and progresses upstream with each new layer of cuttings overlying the immediately down stream layer of cuttings. Bank stability is improved as the vegetation grows and develops root systems in the lower bank. The cuttings may be anchored in the channel by cross logs secured to vertical poles driven into the streambed.

**************************************************************************

a. [Brush work construction shall start at the upstream end of the work site and progress down stream with each down stream layer of cuttings overlying the layer of cuttings immediately upstream.] [Brush packing construction shall start at the down stream end of the work site and progress upstream with each upstream layer of cuttings overlying the layer of cuttings immediately down stream.]

b. Trenches that are 300 mm 1-foot deep shall be excavated normal to and across the entire stream channel [and shall extend 1.5 m 5 feet up the stream banks]. Trenches shall be spaced 1.5 m 5 feet apart. Live cuttings that are 2 m 6 feet in length shall be placed in the trench in a herringbone pattern at an angle of 30 degrees from the centerline of the channel with the growth tips pointing [upstream] [inclined down stream at an angle of 45 degrees from vertical]. The cuttings shall [not] extend up the stream banks. The cut ends of the cuttings shall be pushed firmly into the streambed. [Removed sediment] [Select fill] shall be placed and compacted over the cut ends of the cuttings to the elevation of the existing channel. This procedure shall be repeated for the specified length of channel at the work site.

c. Cross logs shall be placed normal to the channel and on top of the cuttings every 1 meter 3 feet. The logs shall be 100 mm 4 inches in diameter and shall extend the full width of the channel. [Cross logs shall be placed parallel to the slope of the bank on top of the brush [work] [pack] layers that extend up the stream banks. The ends of the cross logs at the toes of the banks shall be shaped to sharp tips and the logs shall be driven 500 mm 1.5 feet into the streambed at the angle of the slope of the stream bank.] [Live] [Dead] poles shall be driven vertically into the streambed on the down stream sides of the cross logs. The poles shall be spaced at 600 mm 2 feet intervals and the tops of the poles shall not be greater than 150 mm 6 inches above the tops the cross logs. Poles shall be driven at the toes of the stream banks regardless of spacing interval. The poles and cross logs

SECTION 31 32 39 Page 58
shall be tied together using binders that shall be wrapped around the logs and poles in a manner that shall prevent raveling.

3.12.2.7 Live Fascine Sill

**************************************************************************
NOTE: Live fascine sills are more resilient and less prone to damage by scour than brush sills. However, heavy coarse bed load and large woody debris transported during high flow events may damage the fascines. Fascine sills may be used to form low drop structures to prevent streambed degradation in narrow streams with low flow velocities and minimal coarse bed load. Sills may be combined with other bioengineering methods for channel stabilization of high gradient or torrential flow streams. Fascines have the advantage of being flexible and therefore may be placed to conform to the existing profiles of the stream channel and may be easily extended up the banks of the channel. The diameter and strength of the fascine may be increased by adding dead branches and gravel or cobbles to the fascine. Fascines should be placed in trenches that are normal to the stream channel and that are at least 50 to 75 percent the diameter of the fascine in depth. Live fascines may be placed on top of one another to form step sills. Step sills are constructed by placing a down stream fascine in a trench and positioning a fascine directly up stream of the down stream fascine. The up stream fascine should rest on the upper one quarter of the exposed down stream fascine.

**************************************************************************
Each Fascine shall be 300 mm 12 inches in diameter and 3 m 10 feet in length and shall be constructed of live cuttings that are from 19 to 38 mm 3/4 to 1.5 inches in diameter. Up to 35 percent dead branches [and 15 percent rounded gravel or cobbles] shall be interwoven with the live cuttings. A 200 mm 8-inch deep by 0.5 m 1.5 feet wide trench shall be excavated normal to and across the entire width of the stream channel [and at least 1.5 m 5 feet up the faces of the stream banks]. The fascine shall be placed in the trench. The junction between fascine bundles in the same trench shall be [offset side-by-side] [interwoven] for a distance of 300 mm 1-foot. The fascine shall be anchored in the trench with 700 mm 2.5 feet long [live] [dead] stakes that are at least 50 mm 2 inches [in diameter] [square] at the top and tapered from the top to the base. The stakes shall be driven vertically through the fascine until flush with the top of the bundle starting 300 mm 1-foot from the end of the fascine and spaced every 1 meter 3 feet thereafter. A terminal stake shall be driven 300 mm one-foot from the end of the fascine regardless of spacing interval. [Live] [Dead] stakes shall be driven at a 45-degree angle on the down stream side of the fascine but shall not penetrate the bundle. The fascine shall be secured to the stakes with binders that shall be wrapped around the fascine and secured to the stakes. The binders shall be tied to prevent ravel in the event of damage. Removed sediment shall be used as backfill and placed and compacted on the up stream and down stream sides of the fascine and shall be brushed into the fascine structure until only the top of the fascine is visible. Fascine sills shall be [spaced 8 m 25 feet apart starting from the down stream end of the work site] [placed at the locations shown on the
3.12.2.8 Vegetated Deflector

NOTE: Vegetated deflectors are traditional hard structures composed of rock (groins, dikes, spurs) or timber (log or pile revetments) that incorporate live vegetation and which provide excellent long-term bank protection with the added benefits of shade and habitat enhancement. These structures protect the banks of large streams and rivers, which are subjected to high velocity flows, by deflecting the energy of the current away from the banks. The incorporated vegetation improves the strength of the structure and the quality of habitat over time. A key component for the establishment of vegetation on these structures is the retention of fine-grained material and the exposure of the hardened structure above the mean water level of the stream or river. Only vegetation that matures to trees or brush of less than 2 m 6 feet in height and which remains flexible should be used. Species that may mature to tall trees with extensive root systems may not be used, since these trees may damage the hard structures.

For existing structures, fine-grained material may be placed in open voids and live posts driven into these voids in the structure. For new construction, the interior of the structure may be composed of fine-grained material capable of supporting root growth. This core should be covered with rock of suitable size to resist transport by the stream or river. The cover armor must be anchored along the perimeter of the structure in a key trench below the scour depth of the high flow events. Additional stability of the armor may be gained by inserting dead stakes between stones in areas below the mean water level. Live poles may be driven into the joints of the armor above the mean water level.

Retention of fine-grained material in the core of the structure may be improved by placing this material in untreated sand bags composed of natural fibers. The lifetime of the sand bags should be sufficient to prevent the loss of fines until the roots of the live poles lock this material in place. The surface of the sand bag core may be covered with a coir erosion mat prior to the placement of armor. To reduce the number of sand bags, the core may be constructed of compacted material overlain by a three-bag thick layer of sand bags, which is in turn overlain by the stone armor. A layer of well-graded fine gravel and coarse sand may be placed beneath the stone armor to form a filter layer and thus further reduce the loss of fines from the core. Other deflector alternatives include the use of logs or wood structures as cores.
surrounded by fine-grained material with exterior stone armor. These structures may be used to assist in trapping sediment behind rock groins or dikes to in fill large scour areas in a stream or river banks.

a. Excavate a trench [4.5 m 15 feet wide, 1 m 3 feet in depth below the lowest elevation of expected scour, that extends from the toe of the high bank to 3 m 10 feet into the stream below the mean low water elevation. The trench shall be [keyed 1.5 m 5 feet into the bank.] [as shown on the drawings]. [Live cuttings shall be placed against the face of the trench from the mean water level to the high bank. These cuttings shall extend at least 450 mm 1.5 feet above grade and the cut ends of the cuttings shall be firmly pushed into the bottom of the trench and covered with a thin layer of [sediment] [select fill]]. [Natural stone] [Quarry rock] at least 1 m 3 feet in the minimal dimension shall be placed against the outer perimeter face of the trench and maintain as much contact with adjacent stones as possible. [The [stone] [rock] shall be placed to a height of 600 mm 2 feet above the high mean water level of the stream]. The outer face of the [stone] [rock] shall slope at [2H:1V] while the face towards the center of the trench shall be at the angle of repose. [Sediment removed from the trench] [Select fill] shall be brushed into the voids between the [stones] [rocks] until the soil is even with the tops of the [stones] [rocks]. Live cuttings shall be placed on top of the outer [stones] [rocks] with the cut ends of the cuttings firmly pushed into the bottom of the inside trench. The ends of the cuttings shall be covered with a thin layer of sediment that shall be overlain by [backfill] [sandbags]. [Live poles shall be driven between the [stones] [rocks] to a depth of at least 1.2 m 4 feet.] The core of the structure lying inside the larger outer [stones] [rocks] shall be filled with [removed sediment] [select fill] [in untreated biodegradable sand bags that are placed tightly end to end and in vertical overlapping pattern] [compacted cohesive sediment removed from the trench separated from the outer [stones] [rocks] by a 600 mm 2 feet thick layer of select fill contained in untreated biodegradable sand bags].

b. Successive lifts of armor [stone] [rock] shall be placed on top of the completed lifts to the design slopes and grades of the structure. Live cuttings shall be placed on the top of each lift. The core of the structure shall be raised concurrently with the lifts of armor material. The final lift shall consist of interlocked [stone] [rock] that extends across the entire top of the structure. [Removed sediment][Select fill] shall be brushed into the voids between the [stones] [rocks]. Live stakes shall be planted in the joints between the [stones] [rocks] with a spacing of 1 m 3 feet. The top of the rock structure shall be 300 mm 1 foot above the top of the original elevation of the high bank.

3.12.2.9 Live Brush Sill

NOTE: Live brush sills are structures composed of live vegetation that extend perpendicular from the toe of the bank into the stream channel. These structures may extend landward to the high bank. The sills trap sediment and debris, reduce scour, and are useful in establishing vegetation on point bars of barren flat expanses of low bank. These
structures are inexpensive, easy to construct, and may reduce the amount of rock or stone armor required for bank protection. The development of root systems and the growth of vegetation improve bank stability and develop riparian habitat. Dead cuttings may be used in these structures to improve their resistance to erosion and damage due to currents or debris. Sills composed entirely of dead cutting may be placed below the mean high water elevation separately or between harden transverse structures. These dead brush sills trap debris, sediment, and result in bank aggradation. Live sills, or other live bioengineered structures, may be placed on the new bank created by the dead sills at a future date to promote improved stability and habitat development.

******************************************************************************

A 600 mm 2 feet deep trench with a 'V' shaped cross section shall be excavated normal to the toe of the stream bank from [the mean high water level] for a distance of [3 m 10 feet into the stream channel [from the mean high water level]] [and] [6 m 20 feet landward of the toe of the bank.] [to the edge of existing vegetation] [as shown on the drawings]. Live cuttings shall be placed in the trench with the cut ends pushed firmly into the bottom of the trench with the growth tips extending at least 600 mm 2 feet above the top of the existing grade. At least 20 cuttings shall be placed per 300 mm linear foot of trench and all cuttings shall rest against the down stream side of the trench. Large stone up to 150 mm 6 inches in diameter shall be placed on the bottom of the trench against the cut ends of the cuttings and shall be covered with loosely compacted [sediment] [soil] [select fill] to the existing surface. [Excess material removed from the trench that is to remain on site shall be mounded around the base of the sill at the surface.] Sills shall be spaced 1.5 m 5 feet apart.

3.12.2.10  Brush Transverse

******************************************************************************

NOTE: Brush transverses are stone structures augmented with live or dead brush cuttings that are easy to construct and inexpensive. These structures are useful in deflecting high velocity flows away from stream banks to prevent scour and erosion and may be used to aid in the repair of scoured or failing areas of stream banks. The live vegetation will develop root systems that shall strengthen the structure and provide shade and habit. The stone structure deflects and dissipates the stream velocity away for the bank thereby creating areas of still water down stream of the structures in which sediment may be deposited. The brush cuttings assist in sediment trapping during periods of high flow. This vegetation matures with time and will eventually completely cover the scour area. Brush transverses may be combined with brush grids to repair areas of bank scour in high flowing rivers.

Brush transverse structures are not suitable for use in streams with torrential flows and heavy clastic bed load. Installation trench depth and width must
be based on hydraulic analyses of stream velocities and bed load transport. The structure may be normal to the stream bank or inclined at an acute angle to the stream bank in the down stream direction. The use of subrounded large natural stone from the immediate area of work is preferred for construction. If such material is in limited supply, then the available natural stone may be used as cover stone and the core of the structure may be constructed of angular to subangular quarry rock. In areas that lack natural stone, local durable quarry rock may be used for the entire structure.

**************************************************************************

a. A trench 600 mm 2 feet deep by 1.5 m 5 feet wide shall be excavated from [the face of the high bank] [edge of the stream bank] to [3 m 10 feet beyond the low mean water elevation of the stream] [the new bank alignment as shown on the drawings]. [The trench shall be keyed into the stream bank for a distance of 1 m 3 feet.] The base of the trench shall be firmly compacted. Live [and] [dead] cuttings that are at least 1.5 m 5 feet in length and that have side branches attached shall be placed on the down stream side of the trench. The cuttings shall be placed with a concentration of at least 20 cuttings per 300 mm linear foot of trench to form a layer with a thickness of 100 mm 4 inches. The cut ends of the cuttings shall be pushed firmly into the streambed with a minimum of 1 m 3 feet of the growth tips extending above grade and inclined in the down stream direction. The cut ends of the cuttings shall be covered with a 75 mm 3 inch layer of moderately compacted [fine-grained sediment] [select fill] that shall extend from surface grade to the base of the trench at the angle of repose.

b. Durable [large natural stone] [quarry rock] that is 450 mm 1.5 feet in minimal dimension shall be placed along the up stream side of the trench, against the fill covering the cut ends of the cuttings, and completely fill the key trench. [Natural stone] [Quarry rock] ranging from 150 to 450 mm 0.5 to 1.5 feet in minimal diameter shall be placed to cover the floor of the trench and firmly tamped into place to provide the greatest contact with adjacent [stones] [rocks]. [Fine sediment] [Select fill] shall be [brushed] [washed] into the voids between the [stones] [rocks] until only the tops of the [stones] [rocks] remain exposed. Successive layers of [stone] [rock] shall be placed on lower lifts in a pattern that allows the greatest amount of interlocking of [stones] [rocks] and the voids between the [stones] [rocks] shall be filled with [fine sediment] [select fill] to the top of the structure. The end of the structure that projects into the stream shall be constructed of [large stone] [rock] that is 1 m 3 feet in minimal dimension for a distance of 2 m 6 feet. [Excess sediment removed from the trench shall be placed along the up stream and down stream toes of the structure.] The farthest up stream structure in the work area shall be placed at an angle of 30 degrees to the direction of stream flow to deflect the current towards the center of the channel. Subsequent down stream structures shall be constructed at right angles to the stream bank with a spacing of the average length of the structure.

3.12.2.11 Brush Grid

**************************************************************************

NOTE: A brush grid consists of layers of brush laid
out in a rectilinear pattern with each successive lift being placed normal to the lower lift. The structures are well suited for the repair of severely scoured or sloughing areas on banks in streams with high flow velocities and large range or frequent changes in water level. These structures may be used on portions of the streambed from the toe of the high bank to the edge of the mean low water level of the stream. For large scour areas, a brush grid may be constructed at the upstream end of the scour hole between the stream bank and a brush traverse or vegetated groin or dike. The remaining portion of the scour area may be filled with widely spaced brush transverse structures. The areas between the transverses may be filled with brush sills. A brush grid requires significant manual labor and a large supply of brush. The amount of labor and materials may be reduced by combining the grid with brush sills, vegetated dikes, gabions, or by constructing a widely spaced grid work of brush instead of a complete cover of brush.

**************************************************************************

a. [An excavation that is 4.5 m 15 feet wide and 1 m 3 feet deep shall extend from the edge of the high bank 6 m 20 feet into the stream channel. The floor of the excavation shall be sloped towards the bank at 2H:1V and shall be smooth and compacted. The side slopes shall extend beyond the above specified dimensions and shall be at the angle of repose. The trench shall be keyed 1.5 m 5 feet into the stream bank.] [Sediment shall be excavated to form a level floor at the installation area to the grades and dimensions shown on the drawings.] [Live] [Dead] poles composed of [untreated manufactured lumber] [straight sections cut from local trees] shall be driven vertically 1 m 3 feet into the streambed [along the alignment of the proposed bank] [as shown on the drawings] [in a straight row that is 4.5 m 15 feet from the edge of the high bank]. Additional poles shall be placed between the new alignment of poles and the stream bank on 1.5 m 5 feet centers. The poles shall be 100 mm 4 inches in diameter. The length of the poles shall be such to allow 600 mm 2 feet of pole to extend above the mean water level. The bottoms of the poles shall be shaped to sharp tips to facilitate driving them into the streambed. The tops of the poles shall be cut normal to the lengths of the poles. The top elevations of the poles shall be the same for all poles. [Pilot holes, slightly larger in diameter than the poles, shall be drilled into the streambed using a [steel punch rod] [mechanical drill] in coarse alluvial sediment]. The poles shall stand erect without support after installation in the streambed. Loose or nonvertical poles shall be reinstalled. Poles damaged during installation shall be replaced at no expense to the Government.

b. The base layer of the structure shall consist of 150 mm 6 inch diameter by 6 m 20 feet long trunks of trees with their branches still attached. The root wads shall not be attached to the trunk. These trunks shall be tightly packed between the poles with the growth tips extending 600 mm 2 feet into the stream beyond the new bank alignment. The trunks shall be placed horizontally in the excavation with the cut ends placed [in the key trench] [firmly butted against] the stream bank.
c. [Removed sediment] [Select fill] shall be placed over the trunks until only to tops of the trunks are exposed. Live cuttings up to 50 mm 2 inches in diameter shall be placed vertically in rows spaced 1 m 3 feet apart parallel to the base layer of trees with a minimum of 5 cuttings per 300 mm linear foot of row. The cut ends of the cuttings shall be pushed through gaps between the base logs and into the streambed. The top of the growth tips of the cuttings shall be at the same elevation as the top of the vertical poles and inclined at a slight angle down stream. A layer of live cuttings consisting of 1 m 3 feet wide rows that are up to 300 mm 12 inches thick shall be placed horizontal on top of the first lift of trunks and pulled around the upright live cuttings and poles. The growth tips shall extend 600 mm 2 feet beyond the new alignment into the stream. The rows shall be separated from the vertical posts by a distance of 300 mm one-foot. Sediment shall be placed on top of the cuttings to fill all voids until only the top of the rows are exposed. A lift of cuttings shall be placed normal to the first lift of cuttings with the growth tips extending 600 mm 2 feet beyond the down stream edge of the structure. Sediment shall be placed on top of this lift of cuttings the same as the lower lift. Lifts of rows of cuttings shall be placed in this alternating manner until the structure reaches a minimal height of 1 m 3 feet above the mean low water level. Large natural stone shall be placed along the outer perimeter of the structure to protect it from scour. The top of the structure shall be secured with [a layer of natural stone] [sand bags filled with select fill] placed on top of the horizontal cuttings and around the vertical live cuttings and poles.

3.12.3 Longitudinal structures

**************************************************************************
NOTE: Longitudinal structures or plantings are placed parallel to stream banks or lake shores and may be used in conjunction with hard engineered structures to provide habitat, shade, and to obscure the hard structures from view thus allowing a more natural appearance to the protected bank.
**************************************************************************

3.12.3.1 [Single] [Clump] Reed Planting

**************************************************************************
NOTE: Reed planting involves the planting of single reeds or clumps of reeds along a stream bank or lake shore. This method is well suited for low flowing streams, lakes, canals, and stagnate areas of water that are protected from wave action or strong currents. Such sites may include exposed banks at or slightly below the mean low water level, tidal flats, or areas of low relief shoreline that extends some distance into a water body. The reeds dissipate energy of the water acting on the shore area and reduce erosion while root structures improve the strength of the bank. Planting should begin at the wet shoreline and progress landward. This planting method is simple to implement and complete, but must be accomplished during the first months of summer to allow the plants to become established.
The method does not provide immediate erosion protection to the bank nor will the plants tolerate shade. The effect of the plantings may not be realized until two to three years after planting. Reed planting will not reduce failure of unstable banks or shorelines. Clump planting refers to the planting of a large group of reeds contained in a large soil and root mat in a hole excavated at the site.

Reeds shall be planted during the active growing period. The reeds shall be delivered to the site in bundles in saturated cloth. [Single reeds] [Reed clumps] shall be planted on a grid with a spacing of 600 mm 2 feet starting at the shoreline and progressing landward [for a distance of 16 m 50 feet] [to the existing reed line]. The stems of the reeds shall be slightly above grade and vertical. The shoreline edge of the planting area shall be protected by [a line of natural stone] [coir log] [log] [______]. [Reeds placed between stone armor at the water line shall be placed between the stones in narrow trenches backfilled with fine-grained sediment.]

3.12.3.2 Live stone revetment

NOTE: Live stone revetments are traditional stone or rock armor revetments placed on banks for stabilization and erosion protection with the addition of live cuttings placed in the joints between the armor stones. These structures are well suited for sites where extensive areas of bank must be protected along high flowing streams with heavy bed load or lake shore subject to wave action. Saplings may be placed between the rock joints if topsoil is placed to fill the interstitial voids between the armor stones. Construction must occur in the dormant season for live cutting revetments and in the spring or autumn for transplanted saplings. Expect 30 to 50 percent mortality rate with cuttings, particularly in drier climates. Driving cuttings or live poles deeper into the stream bank and irrigation of the site may improve plant survivability.

The designer is encouraged to review existing references on stone revetment function, performance, and construction. Also, the designer should consider the impact the construction of a hard structure may have to the surrounding banks and channel such as the shifting of erosion to adjacent or cross stream locations that are not protected.

a. The bank shall be prepared by reducing the slope to [2H:1V] [as shown in the drawings]. The surface of the bank shall be smoothed and compacted. A key trench shall be excavated at the toe of the stream bank and shall extend [1 m 3 feet below the mean low water level] [600 mm 2 feet below the lowest elevation of estimated scour]. The bank shall be overlain by a 100 mm 4 inch thick layer of 75 mm 3-inch minus compacted fill that contains less than 5 percent fines that shall serve.
as a filter blanket between the outer armor stone and the bank soil.

b. Large stone with a nominal diameter of 1 m 3 feet shall be placed in the key trench. Armor stone shall be placed up bank from the key stones to the bank crest [and extend 1.5 m 5 feet landward of the bank crest]. Each stone shall be placed to interlock with down slope stones to form a rock mass that covers 100 percent of the exposed bank. The stones shall be placed by [hand] [heavy equipment with placing bucket]. Stones shall not be dumped in mass from the top of the bank. The stones shall be pushed into the bank once the stone is placed. [Top soil] [Excavated bank material] shall be placed on top of the stone and shall be brushed over the surface of the stone to fill the voids between the stones. Live [cuttings] [stakes] [poles] shall be driven between the joints of the rock at least 600 mm 2 feet into the bank soil below the base of the armor stone. Up to 10 live poles shall be placed per square yard of area. Cuttings shall be placed on the entire structure from the mean low water level to the landward end of the revetment.

c. The ends of the structure shall be keyed into the stream bank. Key trenches shall be excavated 1.5 m 5 feet into the stream bank at the up stream and down stream ends of the structure. These trenches shall be 1.5 mm 5 feet deep and the faces of these trenches shall be the same slope as the face of the prepared bank. The trenches shall be filled with large [stone] [rock] that is pushed into the bottom and sides of the trench. The voids between the [stones] [rocks] shall be filled with soil removed from the trench. The [stone] [rock] shall extend to the surface and wrap in a continuous mass into the armor [stone] [rock] on the face of the bank.

3.12.3.3 Brush Layered Revetment

**************************************************************************
NOTE: Brush layer revetments are constructed of alternating layers of live brush cuttings and rock. These structures are easier to construct and of lower cost than live revetments and are suitable for protecting long stretches of stream banks or lake shores. The live brush will cover the armor rock with time and obscure it from view. Angular quarry stone or rip rap may be used with this method.
**************************************************************************

a. The bank shall be prepared by reducing the slope to [2H:1V] [as shown in the drawings]. The surface of the bank shall be smoothed and compacted. A key trench shall be excavated at the toe of the stream bank and shall extend [600 mm 2 feet below the mean low water level] [600 mm 2 feet below the lowest elevation of estimated scour]. The bank shall be overlain by a 100 mm 4 inch thick layer of 75 mm 3-inch minus compacted fill that contains less than 5 percent fines that shall serve as a filter blanket between the outer armor stone and the bank soil.

b. Live cuttings shall be placed in the trench against the stream side wall of the trench. The cuttings shall be pushed into the streambed and the cut ends shall be covered with a thin layer of [sediment] [select fill]. Large stone with a nominal diameter of 1 m 3 feet shall be placed in the key trench. The large stone shall rest on the ends of the cuttings and anchor them in place. Armor stone shall be placed up the bank from the key stones to the bank crest [and extend 1.5 m 5 feet landward of the bank crest].
landward of the bank crest]. Each stone shall be placed to interlock with down slope stones to form a rock mass the covers 100 percent of the exposed bank. The stones shall be placed by [hand] [heavy equipment with a placing bucket]. Stones shall not be dumped in mass from the top of the bank. The stones shall be pushed into the bank using suitable heavy equipment once the stone is placed. [Sediment] [Select fill] shall be [brushed] [washed] into the voids between the rocks as the rocks are placed.

c. Stone shall be placed in lifts not to exceed 1 m 3 feet in height. The top of the lift shall be within 150 mm 0.5-foot of the same elevation across the surface of the lift [and parallel to the water surface of the stream]. A layer of loosely compacted topsoil at least 150 mm 6 inches thick shall be placed on the top of the rock lift. Live cuttings shall be placed in a criss cross manner with 20 cuttings per 1 m 3 linear feet on top of the topsoil layer with the cut ends pushed at least 300 mm 1-foot into the bank beneath the filter layer and with growth tips extending 150 mm 1.5 feet beyond the face of the armor rock. The cuttings shall be covered with 100 mm 4 inches of moderately compacted topsoil. The next lift of rock shall be placed on top of the compacted top soil and these rocks shall be pushed into the topsoil until refusal due to contact with the rocks of the underlying lift. The process of alternating layers of rocks, cuttings, and topsoil shall continue to the [design height] [top of bank].

d. The ends of the structure shall be keyed into the stream bank. Key trenches shall be excavated 1.5 m 5 feet into the stream bank at the up stream and down stream ends of the structure. These trenches shall be 1.5 m 5 feet deep and the faces of these trenches shall be the same slope as the face of the prepared bank. The trenches shall be filled with large [stone] [rock] that is pushed into the bottom and sides of the trench. The voids between the [stones] [rocks] shall be filled with soil removed from the trench. The [stone] [rock] shall extend to the surface and wrap in a continuous mass into the armor [stone] [rock] on the face of the bank.

3.12.3.4 Longitudinal Live Fascine

******************************************************************************
NOTE: Longitudinal live fascines consist of live fascines combined with brush layers and possible bank toe armor stone along the length of a stream bank or lake shore. These structures provide immediate protection of the toe of the bank from current or wave erosion. These structures are inexpensive and easy to construct and suitable for low banks. The method may be used as toe protection for stable high banks if the upper portions of the banks are protected by other bioengineered or hard structures.
******************************************************************************

The fascines shall be composed of live cuttings and constructed in accordance with paragraph "Live Fascines" in PART 3. [A trench shall be excavated at the mean low water level of the stream with a floor that slopes at 15 degrees towards the bank.] [A key trench shall be excavated between the fascine trench and the mean low water line. This trench shall be 600 mm 2 feet deep and 1 m 3 feet wide. The face of the key trench shall terminate at the lip of the trench for the fascine. The trench shall
be filled with [quarry rock] [large natural stone] [rock and brush fascines anchored with dead stakes].] A layer of live cuttings shall be placed in the bottom of the fascine trench in a criss cross manner with the cut ends of the cuttings in contact with the face of the trench and the growth tips extending 150 mm 1.5 feet beyond the lip of the trench. A minimum of 20 cuttings shall be placed per linear foot. The cuttings shall be covered with a layer of compacted soil. The fascine shall be placed in the trench and anchored in place by live poles. The poles shall be 1.2 m 4 feet in length and driven 10 mm 2.5 feet into the bottom of the trench through the fascine. The poles shall be spaced every 1 m 3 feet along the length of the fascine. Backfill shall be placed around the fascine to the [grade of the original bank] [design grade].

3.12.3.5 Longitudinal Brush Packing

**************************************************************************
NOTE: Longitudinal brush packing is a method suited for the repair or protection of near vertical or under cut banks subject to erosion. These structures provide immediate protection to the bank from erosion or wave action. The stability of the bank should improve over time as vegetation becomes established dependent on the properties of the soils that compose the bank. The structures are suited for low to fast flowing streams or active lake shores. They are simple and easy to construct but may require large amounts of fill and vegetation. The structure consists of lifts of soil and brush that are wrapped by erosion control products. Geosynthetic or plastic netting shall not be used unless absolutely necessary and in this case only for the lower lifts of the structure.
**************************************************************************

a. The slope of the bank shall be reduced to [2H:1V] [steps that are 300 mm 12 inches high and 600 mm 24 inches deep from the toe to the crest of the bank] [as shown on the drawings]. A key trench shall be excavated at the toe of the design slope. This slope shall be of the same grade as the adjacent undamaged stream bank. The key trench shall be 1.2 m 4 feet wide and 600 mm 2 feet deep and extend the length of the work site. The trench shall be filled with [large natural stone] [quarry rock] that has a nominal diameter of 600 mm 2 feet and that is well graded with 100 percent greater than 100 mm 4 inches. The [stone] [rock] shall be placed to form a triangular topped dike with side slopes of 2H:1V. The [stone] [rock] shall be tamped into place.

b. A 100 mm 4 inch layer of [select fill] [removed sediment] shall be placed on top of the landward face of the rock dike and compacted. The [fill] [sediment] layer shall be covered with erosion control fabric composed of [coir netting] [____]. The fabric shall extend from the face of the bank to at least 1.2 m 4 feet beyond the top of the rock dike. The netting shall be secured to the soil layer with [staples] [stones] [stakes]. The fabric shall be free of wrinkles and extend the full length of the rock dike.

c. Live cuttings [with 25 percent dead branches] shall be placed on top of the fabric layer in a herringbone pattern. The cut ends of the cuttings shall be pushed into the streambed to refusal. The cuttings shall be placed at a density of 20 cuttings per 300 mm linear foot to a
thickness of 100 mm 4 inches. The growth tips of the cuttings shall extend 150 mm 1.5 feet beyond the top of the crest of the rock dike into the stream channel. [Select fill] [Removed sediment] shall be brushed into the voids between the cuttings. A 100 mm 4 inch layer of [select fill] [removed sediment] shall be placed on top of the cuttings and compacted. The fabric that extends over the rock dike [shall be cut and removed] [tightly rolled and anchored at the base of the cuttings on top of the rock dike].

d. The top of the [fill] [sediment] layer placed on top of the first layer of cuttings shall be covered with a layer of erosion control fabric composed of [coir netting] [____]. The fabric shall cover the top of the lower lift. At least 1.5 m 5 feet of fabric shall remain above the contact of the lower lift and the slope of the bank. This portion of fabric shall be temporarily staked to the bank slope. At least 2 m 6 feet of fabric shall extend beyond the top of the design slope. A 300 mm 12 inch layer of [select fill] [removed sediment] shall be placed on top of the fabric and compacted to 90 percent dry density. The ends of the fabric shall be placed on top of the compacted material. The fabric near the face of the bank shall be placed on top of the compacted material and pulled free of wrinkles. The portion of fabric towards the stream channel shall be placed across the face of the compacted material and pulled tight and secured to the top of compacted material with staples. The staples shall be installed flush with the top of the lift.

e. Live cuttings shall be placed on top of the lift of compacted material in the same manner as the cuttings on the first lift. These cuttings shall be covered by a 100 mm 4 inch layer of compacted [select fill] [removed sediment]. The process of wrapping lifts of compacted soil with erosion control fabric and the placement of layers of cuttings shall continue to the [design height of the structure] [top of the bank]. The height of the soil lift nearest to the top of the structure shall be adjusted in thickness to meet the design grade. The top of the structure shall not be covered with cuttings. [Live stakes shall be placed across the top of the structure on 600 mm 2 feet centers for a distance of 2 m 6 feet landward of the top of the bank and for 2 m 6 feet upstream and down stream of the ends of the structure on the original stream bank.]

f. The structure shall be keyed into the bank on the up stream and down stream sides of the structure. The key trenches shall be 1.2 m 4 feet deep. The lifts of the structure shall be wrapped into the trenches and the ends of the lifts shall butt against the face of the key trench.

3.12.3.6 Live Crib Wall

**************************************************************************
NOTE: Live Crib walls are robust structures suited for stabilization and protection of banks or shores subjected to high flow or moderate wave action. These structures provide immediate erosion protection and possible habitat during high flow events dependent upon design. The structure provides a hard frame that dissipates current or wave energy. Bank stability and habitat improve as the vegetation matures and develops extensive root systems and shade along the bank. These structures typically require earthworks and large equipment for
bank preparation and backfilling. Large amounts of vegetation and labor are required. Crib walls may be used to increase the width of a stream by replacing the natural sloped banks with the near vertical walls of the structure. Crib walls may be used to repair severely scoured banks by placing the structure in the stream at the new bank alignment and backfilling the void between the structure and the existing bank.

The structure may be combined with brush sills, brush mats, or large natural stone on the up stream or down stream sides of the structure to reduce erosion. Stability of the structure may be improved using a double crib design composed of front and back headers. Backfill should be free draining material. Timber used for the crib wall may be untreated manufactured 300 mm 12-inch square posts, locally harvested vegetation with truck diameters greater than 300 mm 12 inches, or combination of these materials.

**************************************************************************

a. The stream bank shall be reduced to the required slope and design grade. A trench shall be excavated that is 600 mm 2 feet deep and extends parallel to the toe of the slope. This trench shall extend the full length of the work site and shall extend [for a distance of 4.5 m 15 feet into the stream channel from the toe of the slope] [in the stream channel to the distance and dimensions shown on the drawings]. The floor of the trench shall slope at 15 degrees towards the bank and shall be [manually compacted using a tamping bar weighing at least 18 kg 40 pounds] [compacted using a small motorized tamping machine] until the bottom of the trench is dense and provides a solid base for the crib wall. The floor of the trench shall be [as shown in the drawings] [of uniform grade across the trench width]. The trench shall be keyed into the stream bank for a distance of 2 m 6 feet. Material removed from the key trenches shall be used as compacted backfill in the key trenches. Sediment excavated from the trench shall be [removed from the site and replaced with select fill] [used as compacted backfill]. Depressions in the trench floor shall be filled with compacted material to raise these areas to design grade and areas above grade shall be reduced to the design grade.

b. The crib wall shall be framed with [untreated straight 300 mm 12-inch square by 2.5 m 8 feet long beams] [200 to 300 mm 8 to 12 inch diameter by 2.5 m 8 feet long straight logs harvested from local sources. These logs shall be cut normal to the trunk and the logs shall have all branches stripped from the trucks]. The header adjacent to the stream shall be placed parallel to the toe of the slope at the design alignment of the wall and shall extend the full width of the trench. The header adjacent to the bank shall be placed parallel to and 2 m 6 feet from the stream side header in the direction of the bank. Headers shall be placed end-to-end and in line at splices between the members. Wood posts shall be driven vertically into the streambed 150 mm 6 inches from the splices on both sides of the header.

c. Stretchers shall be 2 m 6 feet in length. Each stretcher shall be placed normal to the headers and between the vertical poles at the splices between the headers. The stretchers shall be spaced [every 1.2
m 4 feet] [mid distance] between the vertical poles and shall extend a minimum of 100 mm 4 inches beyond the outer edge of the stream side header face. The rear butt of the stretcher shall be placed on top of the header near the bank and shall [extend 100 mm 4 inches beyond the outer face of the header] [be firmly placed against the exposed bank]. The stretcher shall be attached to the header with binding products wrapped three times in a criss cross pattern and secured with a non-raveling knot. A 13 mm 1/2-inch diameter hole shall be drilled vertically through the stretcher and header. A 600 mm 24 inch long, 16 mm 5/8-inch diameter [non-galvanized steel spike] [steel rebar] [hard wood dowel] shall be driven into the hole and set flush to the top of the stretcher. The open area between the inner face of the stream side header and the inner face of the landward header shall be backfilled with compacted [sediment removed from the trench excavation] [select fill] to the middle of the stretchers. Live cuttings 19 to 38 mm 3/4 to 1.5 inches in diameter shall be placed in a criss cross manner on the top of the compacted backfill with the cut ends pushed into the backfill near the landward header. The growth tips of the cuttings shall extend 600 mm 2 feet beyond the face of the stream side header. Backfill shall be placed and lightly compacted on top of the cuttings to the top of the stretchers. Additional headers, stretchers, backfill, and cuttings shall be placed until only the final lift remains. The centerlines of stream side headers shall be off set 50 mm 2 inches towards the bank relative to the lower headers to provide an incline to the face of the structure. Select fill shall be placed in the area between the face of the landward header and the slope of the bank. The fill shall be placed in lifts of the same thickness as the lifts on backfill in the interior of the structure. Each lift shall be compacted to at least 90 percent dry density.

d. The top stream side headers shall be 100 mm 4 inches larger in diameter than the headers used for wall construction. The vertical poles shall be cut flush with the top of the final headers. A header shall be placed at the midpoint between the outer headers and secured with binders and [spikes] [rebar] [dowels] to the underlying stretchers. The lift of backfill immediately below the completion headers shall be filled with a tightly packed brush mat composed of live [and dead] cuttings that are placed in an alternating rectilinear grid pattern. Each layer of brush shall be covered with a thin layer of lightly compacted backfill. [Rounded clean natural stone from 300 to 600 mm 12 to 24 inches in diameter] [Excavated sediment] shall be placed from the top of the packed brush to the top of the final headers [to the grade shown in the drawings]. [Live stakes shall be driven vertically on 600 mm 2 feet centers into the backfill at the top of the structure.] [Large natural stone armor 600 mm 2 feet thick shall be placed on the banks and against the ends of the structure for a distance of 3 m 10 feet upstream and down stream from the structure. Live stakes shall be planted in the joints between the stones.] The key trenches shall be filled with [large natural stone] [quarry rock] to the design grade.

3.13 IRRIGATION

Irrigation of the structure shall be started immediately after installing erosion control products and vegetation. Water shall be applied to supplement rainfall at a sufficient rate to ensure moist soil conditions to a minimum 300 mm 12-inch depth. Run-off and puddling shall be prevented. Watering trucks shall not be driven over turf areas, unless otherwise directed. Watering of other adjacent areas or plant material not related
to work efforts shall be [prevented] [as specified by the Contracting Officer]. Water shall be applied to trenches immediately before placement of live vegetation. Water shall be placed on the completed structure at the end of each day, as needed to control dust and to prevent excessive drying of vegetation, and at the completion of the structure. [The structure shall be irrigated after installation for 3 months until the end of the first year growing season.] [Structures in arid climates shall be irrigated for a period of 3 years.] [Daily irrigation of the structure and work site shall not exceed 20 minutes [each day] [twice a day] [3 times per week] and shall be sufficient to support the survival and growth of planted vegetation. Irrigation shall never exceed limits that could impair the stability of the structure and shall be adjusted to compensate for additions or deficits to soil moisture caused by precipitation or evaporation.]

3.14 FERTILIZER, PESTICIDE, HERBICIDE

**************************************************************************
NOTE: Edit this section as required. Fertilizer, pesticide, and herbicide may be required for the construction, establishment, and maintenance of bioengineered structures. Provide methods for application, frequency of use, safety precautions for humans and the environment in the section below.
**************************************************************************

3.15 FIELD QUALITY CONTROL

The work site shall be inspected by the Contracting Officer prior to final acceptance of work. A punch list noting deficiencies shall be compiled by the Contracting Officer and provided to the Contractor. Perform, repair, adjust, align, or otherwise comply with the specified work on the punch list to the satisfaction of the Contracting Officer. Notify the Contracting Officer at least 14 days prior to the inspection that work shall be ready for inspection. Work will not be accepted until all punch list items are resolved and all work meets or exceeds contract requirements. Final acceptance of work shall not be provided by the Contracting Officer until all defects or deficiencies are corrected. Final Acceptance shall occur only after all corrective actions and supplemental viable plantings are complete and the structure meets performance standards and all contract requirements. Comply with necessary repairs to the structure and vegetation as stated in the warranty.

3.16 CLEAN-UP

Excess material, debris, and waste materials shall be disposed of offsite at an approved landfill or recycling center. Adjacent paved areas shall be cleared. The site shall be restored to preexisting conditions to the extent reasonably possible and to the satisfaction of the Contracting Officer.

3.17 PROTECTION

Immediately upon the start of the installation in an area, the area shall be protected against traffic or other use by erecting barricades and providing signage as required, or as directed. Signage shall be [in accordance with Section 10 14 00.10 EXTERIOR SIGNAGE] [as shown on the drawings]. Protect the work site and vegetation from damage and vandalism and free of trash and debris until final acceptance by the Contracting Officer.
3.18 DOCUMENTATION

Establish and maintain documentation for bioengineering practices to record the desired information and to assure compliance with contract requirements, including, but not limited to, the following:

3.18.1 Maintenance Records

Visit, inspect, and document site conditions after the completion of construction every week for the first year and every two weeks thereafter until the end of the second year. Documentation shall include written reports on site structure and vegetation conditions, damage, plant loss, and the like, to fully describe site conditions at the time of the visits and changes observed since previous visits. Photographs of the site and areas of growth, defects, or damage shall be obtained and included with the records. Records shall be submitted to the Contracting Officer within [48] [_____] hours after the completion of the site visit.

3.18.2 Final Project Report

The Final Project Report shall specify and summarize all construction activities and problems plus information included in the construction and maintenance records as submitted throughout the project. The report shall summarize the work rather than repeat the items in the individual reports.

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for geogrid reinforcement to enhance the veneer soil stability for landfill liners and covers.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1 GENERAL

NOTE: Geometric requirements such as slope length, and construction limits should be shown on the drawings.

1.1 MEASUREMENT AND PAYMENT

The unit of measurement for soil slope reinforcement will be square meters (SM) yards (SY). Overlaps for splices (if allowed) and for the Contractor's convenience will not be measured for payment. Payment will be made at the respective unit price listed on the bidding schedule. Payment will be full compensation for furnishing all material, labor, equipment, supplies and incidentals to complete the work.

SECTION 31 35 19.13 Page 2
1.2 REFERENCES

**************************************************************************
NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.
**************************************************************************

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

ASTM INTERNATIONAL (ASTM)

ASTM D4355/D4355M (2014) Deterioration of Geotextiles from Exposure to Light, Moisture and Heat in a Xenon-Arc Type Apparatus

NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy, Air Force, and NASA projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy, Air Force and NASA projects, or choose the second bracketed item for Army projects.

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

**SD-02 Shop Drawings**
1.4 QUALITY ASSURANCE

Submit a summary of the manufacturer's qualifications and [_____] copies of the manufacturer's quality control (QC) manual a minimum of 7 days prior to delivery of geogrid to the site. The reinforcement manufacturer shall provide a qualified and experienced representative to be available on an as-needed basis during construction. The representative shall visit the site for consultation [at least once during construction] [as requested by the Contracting Officer].

1.5 DELIVERY, STORAGE, AND HANDLING

Check products upon delivery to ensure that the proper material has been received and is dry and undamaged. Protect the materials from damage and exposure following the guidelines presented in ASTM D4873/D4873M.

1.5.1 Labeling

Label each roll with the manufacturer's name, product identification, roll dimensions, lot number, and date manufactured.

1.5.2 Handling

Handle and unload geogrid rolls by hand, or with load carrying straps, a fork lift with a stinger bar, or an axial bar assembly. Geosynthetic rolls shall not be dragged, lifted by one end, lifted by cables or chains, or dropped to the ground.

1.5.3 Storage

Protect geogrid from deleterious materials, chemicals, sparks and flames, temperatures in excess of 70 degrees C 160 degrees F, and any other environmental condition that may degrade the physical properties. If stored outdoors, the rolls shall be elevated from the ground surface. Protect geogrids, except for extruded grids, with an opaque waterproof
NOTE: Polyester is susceptible to hydrolysis in alkaline conditions. A high molecular weight and low carboxyl end group number limit the hydrolysis. Normally, a mill certificate or certification of these properties is adequate. The molecular weight of polyester geosynthetics is determined from GSI GRI GG6, "Determination of the Number Average Molecular Weight of Polyethylene Terephthalate (PET) yarns Based on a Relative Viscosity Value", and ASTM D4603, "Determining Inherent Viscosity of Poly(Ethylene Terephthalate) (PET) by Glass Capillary Viscometer." The carboxyl end group number is determined from GSI GRI GG7, "Carboxyl End Group Content of Polyethylene Terephthalate (PET) Yarns."

The geogrid sample is intended to be for visual demonstration prior to product delivery. Conformance testing samples, if required, should be obtained from material actually delivered to the job. If testing is to be performed for prequalification, the minimum sample size should be 1 meter (36 inches) in length and the full roll width. Although 1 square meter (yard) will provide enough material for testing, the full roll width should be sampled since it provides a better selection of specimen locations, it clearly shows the machine and cross directions, and the difference in waste and shipping costs is negligible.

Submit one properly identified 600 by 600 mm 24 by 24 inches minimum size geogrid sample with the fasteners proposed for use. Provide a geogrid that is a geosynthetic manufactured for reinforcement applications and a regular network of integrally connected polymer tensile elements with aperture geometry sufficient to permit significant mechanical interlock with the surrounding soil, aggregate, or other fill materials.

a. Submit manufacturer's certified raw and roll material test reports including ultimate strength performed in accordance with ASTM D6637 or ASTM D4595 (modified). Test results not meeting the requirements in Table 1 or in the approved Manufacturer's Quality Control Manual will result in rejection of applicable rolls. Provide certified test reports a minimum of 7 days prior to delivery of geogrid to the site.

b. The geogrid structure shall be dimensionally stable and able to retain its geometry under manufacture, transport and installation. The geogrid shall be manufactured with 100 percent virgin resin consisting of polyethylene, polypropylene, polyester, or other approved material and with a maximum of 5 percent in-plant regrind material. Polyester resin shall have a minimum molecular weight of 25,000 and a carboxyl end group number less than 30. Polyethylene and polypropylene shall be stabilized with long term antioxidants.
c. Submit **Certificates of Compliance** for the materials provided and results of conformance testing. Submit an affidavit certifying raw and roll material test results submitted are accurate and that the reinforcement meets the requirements of the project specifications. The affidavit shall be signed by an official authorized to certify on behalf of the manufacturer. [If the affidavit is dated after award of the contract and/or is not specific to the project, the supplier shall attach a statement certifying that the affidavit addressed to the wholesale company is representative of the material supplied.] The documents shall include a statement confirming that all purchased resin used to produce reinforcement is virgin resin. Provide affidavit a minimum of 7 days prior to delivery of geogrid to the site.

2.1.1 Geogrid Reinforcement Properties

The reinforcement shown on the contract drawings shall meet the property requirements listed in Table 1. Reinforcement strength requirements represent minimum average roll values in the machine direction.

<table>
<thead>
<tr>
<th>PROPERTY</th>
<th>REQUIREMENT</th>
<th>TEST DESIGNATION</th>
</tr>
</thead>
<tbody>

<tr>
<td>Interface Friction at [Peak] [Residual], Degrees</td>
<td>[_____]</td>
<td>ASTM D5321/D5321M</td>
</tr>
</tbody>
</table>

*Submit the coefficient of interaction for pull-out resistance of the proposed geogrid in a soil of similar gradation and texture to the material that will be used for fill in the reinforced zone. Establish the coefficient of interaction in accordance with ASTM D6706. Provide certified test results a minimum of 7 days prior to delivery of geogrid to the site.

2.1.1.1 Allowable Strength

Submit Geogrid allowable strength calculated in accordance with GSI GRI GG4a or GSI GRI GG4b. The calculations shall itemize each reduction factor. Account for splice efficiency in the calculations. Provide calculations a minimum of 7 days prior to delivery of geogrid to the site. Allowable strength is based on reduction factors for installation damage, durability, and creep that are applicable to site specific conditions. Determine reduction factors in accordance with the test procedures documented in GSI GRI GG4a or GSI GRI GG4b. The minimum reduction factor for durability shall be 1.1 for polyethylene and polypropylene geogrids and 1.15 for coated polyester geogrids. The minimum reduction factor for installation damage shall be 1.1 for all polymers. The reduction factor for creep shall be based on testing performed in accordance with ASTM D5262 at the strain specified in Table 1.
2.1.1.2 **Interface Friction Testing**

**************************************************************************

NOTE: If the geogrid will not be placed in an anchor trench, interface friction testing should be conducted to determine the runout length for the geogrid. All potential slip interfaces beneath the geogrid need to be tested in computing the required runout length. Normal stresses specified should be representative of anticipated field conditions. Selection of peak versus residual values should be based on anticipated interface displacements.

**************************************************************************

Submit certified laboratory interface friction test results including description of equipment and test method, a minimum of 7 days prior to delivery of geogrid to the site. Conduct laboratory interface friction tests on the following interfaces: [______]. The frequency of testing for each interface shall be at a rate of [1] [______] per project. Conduct tests in accordance with ASTM D5321/D5321M. Use normal stresses of [______], [______], and [______] kPa [______], [______], and [______] psi along with a displacement rate of [5.0] [______] mm [0.2] [______] inches per minute. Orient geosynthetics such that the shear force is parallel to the down slope orientation of these components in the field.

2.2 **SPLICES**

Splices shall consist of a standard method or device recommended by the manufacturer of the geogrid. Splices will not be allowed unless identified on the approved layout drawings. Splices shall be at least 75 percent efficient. Demonstrate the splice efficiency through tests performed in accordance with GSI GRI GG4a or GSI GRI GG4b. Splicing may consist of overlaps, fusion wedge welding, sewing, or bodkin connections. Splicing methods that are dependent on installer experience and skill level, such as hot air and torch-applied open flame, are not acceptable. Construct overlap splices by placing a minimum of 50 mm 2 inches of soil between the layers of geogrid.

PART 3 EXECUTION

3.1 **INSTALLATION**

Submit Geogrid layout plan along with anchorage and joint details, sequencing and construction procedures, a minimum of 7 days prior to geogrid placement.

3.1.1 **Subgrade Preparation**

**************************************************************************

NOTE: For landfill slope reinforcement applications, geogrids are typically placed directly on the underlying geosynthetic surface.

**************************************************************************

Immediately prior to placement of the geogrid, the surface on which the geogrid will be placed shall be free of rock and other material that could damage the geogrid or the underlying geosynthetics.
3.1.2 Anchor Trench

**************************************************************************
NOTE: Delete this paragraph if an anchor trench is not required. Anchor trench dimensions need to be determined on a site specific basis.

Anchor trench dimensions must be computed based on the pull-out resistance of the geogrid. However, pull-out resistance tests (ASTM D6706) are typically not performed due to the cost and complexity of this test procedure. Data bases of interaction coefficients for different geogrids, soils, and loading conditions are kept by geogrid manufacturers. Information from these data bases should be used to design the anchorage system.
**************************************************************************

Place the anchor trench a minimum of [610] [_____] mm [24] [_____] inches back from the edge of the slope to be covered. The anchor trench shall be a minimum of [610] [_____] mm [24] [_____] inches deep and [610] [_____] mm [24] [_____] inches wide. Remove ponded water from the anchor trench while the trench is open. Trench corners shall be rounded to avoid sharp bends in the geogrid. Remove loose soil, rocks larger than [51] [_____] mm [2] [_____] inches in diameter, and any other material which could reduce the effectiveness of the geogrid from the surfaces of the trench. Extend the geogrid down the front wall and across the bottom of the anchor trench. Perform backfilling and compaction of the anchor trench in accordance with Section 31 00 00 EARTHWORK.

3.1.3 Placement

Install the geogrid in accordance with the Manufacturer's recommendations. Unroll the geogrid in the direction of reinforcement. After a layer of geogrid has been placed, use suitable means, that do not damage the underlying geosynthetics, to hold the geogrid flat and in place until cover soil can be placed. Geogrid damaged during placement and covering shall be removed and replaced at no additional cost to the Government.

3.1.4 Overlaps and Fasteners

**************************************************************************
NOTE: Adjacent rolls of uniaxial geogrid should not be overlapped. The plastic-to-plastic contact has reduced frictional resistance.
**************************************************************************

Adjacent rolls of geogrid shall be positioned edge-to-edge and loosely fastened to maintain alignment during fill placement. Adjacent rolls shall not be overlapped. Use fastener type and spacing as recommended by the manufacturer and approved by the Contracting Officer. Metallic fasteners will not be allowed.

3.1.5 Splices

Submit test data showing splice efficiency. Provide certified test results a minimum of 7 days prior to delivery of geogrid to the site. Locate splices, if allowed, within the bottom one-third of the slope. Limit splicing to only one splice per reinforcing strip and no two consecutive
reinforcing strips shall include a splice. Individual reinforcing lengths less than **3 meters 10 feet** shall not be used. Splices in geogrid reinforcement shall be pulled and held taut during cover soil placement.

3.1.6 Penetrations

For small penetrations through geogrids, only transverse members of the geogrid shall be cut. The load-carrying longitudinal (machine direction) members shall be spread around the penetration. For larger penetrations, additional geogrid shall be placed on each side of the penetration and spliced to the adjacent geogrid to compensate for any longitudinal tensile members that must be cut.

3.2 COVER SOIL PLACEMENT

**************************************************************************
NOTE: The maximum acceptable particle size of cover soil is a function of the minimum aperture size of the geogrid and the acceptable maximum particle size against the underlying geosynthetic layer. The book titled "Designing with Geosynthetics" by Dr. Robert Koerner provides guidance on computing the acceptable maximum particle size of cover soil material based on the apperature size of the geogrid.
**************************************************************************

Cover geogrid with soil within [5] [_____] calendar days of acceptance. Keep the geogrid smooth and taut during placement of cover materials. Cover soil shall not be dropped onto the geogrid from a height greater than 1 m 3 feet. The soil shall be pushed out over the geogrid in an upward tumbling motion. Place soil from the bottom of the slope upward. The initial loose soil lift thickness shall be [350] [_____] mm [12] [_____] inches. Use equipment with ground pressures less than 50 kPa 7 psi to place the first lift over the geogrid. A minimum of [460] [610] [915] [_____] mm [18] [24] [36] [_____] inches of soil shall be maintained between construction equipment with ground pressures greater than 50 kPa 7 psi and the geogrid. Equipment placing cover soil shall not stop abruptly, make sharp turns, spin their wheels, or travel at speeds exceeding [2.2] [_____] m/s [5] [_____] mph. Additional cover soil material and placement requirements are described in Section 31 00 00 EARTHWORK.

3.3 OVERSIGHT

Keep a QA Representative present at all times during geogrid installation.

3.4 CONFORMANCE TESTING

**************************************************************************
NOTE: Conformance testing is performed to verify quality control test results submitted by the manufacturer, to detect degradation during shipping and storage, and to verify the correct product is supplied. Verification of quality control by the manufacturer and detecting degradation during shipping and storage is not economically justified for small jobs. Unlike reinforcing steel for concrete, geosynthetics are difficult to identify in the field, and even experienced personnel can sometimes mistake the product identity of unlabeled...
material. Testing after delivery to verify the correct product was supplied may be advisable for critical structures. The strength is usually the most critical property to verify.

Submit results of conformance testing. Conformance testing expenses are the responsibility of the Contractor. Perform testing using a commercial testing laboratory selected by the Contractor and approved by the Contracting Officer. The laboratory shall be accredited via the Geosynthetic Accreditation Institute's Laboratory Accreditation Program (GAI-LAP) for the tests the laboratory will be required to perform. The Contracting Officer reserves the right to direct the location and select the material for samples. Conformance test results shall equal or exceed results reported on the Manufacturer's certified roll material test reports.

<table>
<thead>

</tbody>
</table>

Modify ASTM D4595 for geogrids considering recommendations in GSI GRI GG6. Express the tensile strength on a unit length basis by substituting $n*a$ for $W_s$, where:

- $W_s =$ specimen width, (mm inches)
- $n =$ number of ribs in the sample (must be a whole number)
- $a =$ nominal rib spacing for the product tested, (mm inches)

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for the procurement and installation of steel wire mesh gabion and mattress units used as a measure of protection against erosion forces of stream flow in water courses and slope instability. This section was originally developed for USACE Civil Works projects.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1 GENERAL

1.1 SUMMARY

The work under this specification includes furnishing, assembling, filling and tying open wire mesh rectangular compartmented gabions [and mattresses] placed on a prepared surface of [filter material] [geotextile], [geotextile and filter materials], as specified, and in accordance with the lines, grades, and dimensions shown or otherwise established in the field.

a. Gabions[ and mattresses] are wire mesh containers of variable sizes, uniformly partitioned into internal cells, interconnected with other similar units, and filled with stone at the project site to form
flexible, permeable, monolithic structures. Gabions and mattresses shall be manufactured with all components mechanically connected at the production facility with the exception of the mattress lid, which is produced separately from the base. The supply to the jobsite of unassembled individual wire mesh components (panels) forming gabions and mattresses will not be permitted.

b. Definitions of terms specific to this specification and to all materials furnished on the jobsite, with the exception of the rock to fill the baskets and the filter material, shall refer and be in compliance with ASTM A975 for double twisted wire mesh Gabions and Revet mattresses, or with ASTM A974 for welded wire fabric Gabions and Gabion Mattresses. [For ease of reference, the term "mattress" will be used in this specification in place of Revet mattress and/or Gabion mattress, where the statement is of general nature and it is not specific to the double twisted or welded wire mesh products.]

1.2 UNIT PRICES

**************************************************************************
NOTE: For small projects, the district may opt to use lump sum payment.

Double twisted wire mesh gabions manufactured in SI (metric) units are different in size from those manufactured in English (inch-pound) units.

Sizes for double twisted wire mesh gabions and mattresses in SI (metric) units must refer to Tables 3 and 5 on ASTM A975. Sizes for double twisted wire mesh gabions and mattresses in English (inch-pound) units must refer to Tables 4 and 6 on ASTM A975. Sizes for welded wire mesh gabions and mattresses both in SI (metric) and English (inch-pound) units must refer to Table 1 on ASTM A974.

This note also applies to the subparagraphs below titled Unit of Measure.
**************************************************************************

1.2.1 Filter Material

1.2.1.1 Payment

Payment will be made for costs for filter material, including furnishing, hauling, placing, and maintenance of the filter layers until placement of the gabion [and mattress] cover is completed and accepted. No payment will be made for excess thickness of filter layers or for material required to replace material lost by rain wash, wind erosion, or otherwise, except for additional filter material ordered in writing.

1.2.1.2 Measurement

Filter material will be measured for payment based upon computations made from the theoretical filter thickness as specified or shown, and the areas acceptably placed where shown or staked in the field.
1.2.1.3 Unit of Measure

Unit of measure is cubic meter cubic yard.

1.2.2 Gabion [and Mattress] Protection

1.2.2.1 Payment

Payment will be made for costs associated with gabion [or mattress protection], including the costs of furnishing, assembling, and placing the wire baskets, the stone fill, and all other materials, labor, equipment, tools, supplies, and incidental costs in connection with completing this item of work.

1.2.2.2 Measurement

Gabions [or mattresses] meeting the requirements of these specifications and acceptably placed within the limits indicated on the drawings or otherwise established in the field, will be measured for payment by the cubic meter cubic yard of stone filled gabions [or mattresses] in place.

1.2.2.3 Unit of Measure

Unit of measure will be cubic meter cubic yard.

1.3 REFERENCES

**************************************************************************

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

ASTM INTERNATIONAL (ASTM)

Stainless Steel Spring Wire

ASTM A370  (2021) Standard Test Methods and Definitions for Mechanical Testing of Steel Products

ASTM A428/A428M  (2021) Standard Test Method for Weight (Mass) of Coating on Aluminum-Coated Iron or Steel Articles

1.4 DEFINITIONS

1.4.1 Rate of Aggressiveness

The determination of the rate of aggressiveness (non-aggressive, moderately, or highly aggressive) shall be made on a project-to-project basis, due to the many variables involved and the lack of criteria of general validity. It is normally recommended for the choice to be based on all the available data and on the experience of existing gabion structures in similar environments.

1.4.2 Double Twisted Wire Mesh Gabions[ and Mattresses]

Classified according to the wire coating, which is applied prior to manufacturing the mesh. Coating styles are as follows:

1.4.2.1 Style 1

Wire mesh made from wire which is zinc coated before being double twisted into mesh. Fasteners, lacing wire, and stiffeners are produced from zinc-coated wire. Style 1 for the wire coating is normally recommended for:

1.4.2.1.1 Permanent

Gabion[ or mattress] structures, for works installed in non-aggressive or non-polluted environments, and this condition remains unaltered over time.

1.4.2.1.2 Temporary

Gabion[ or mattress] structures, for works in moderately aggressive environments, depending on the minimum design life of the structure.
1.4.2.2  Style 2

Wire mesh made from wire which is coated with Zn-5Al-MM before being double twisted into mesh. Fasteners, lacing wire, and stiffeners are also produced from Zn-5Al-MM coated wire. Style 2 for the wire coating is normally recommended for:

1.4.2.2.1  Permanent

Gabion[ or mattress] structures, for works installed in moderately aggressive environments.

1.4.2.2.2  Temporary

Gabion[ or mattress] structures, for works in aggressive environments, depending on the minimum design life of the structure.

1.4.2.3  Style 3

Wire mesh, lacing wire, and stiffeners as Style 1 and overcoated with PVC. Fasteners shall be of stainless steel wire. Style 3 for the wire coating is normally recommended for both permanent and temporary gabion structures, for works installed in aggressive or polluted environments, or when the aggressiveness of the site is moderately unpredictable or variable from low to high.

1.4.2.4  Style 4

Wire mesh made from wire which is aluminum-coated before being double twisted into mesh. Fasteners, lacing wire, and stiffeners are also produced from aluminum-coated wire. Style 4 for the wire coating is very seldom used in the gabion industry. Its life expectancy shall be adequately documented to guarantee its consistency and reliability.

1.4.3  Welded Wire Fabric Gabions[ and Mattresses]

Classified according to wire coating styles as follows:

1.4.3.1  Style 1

Welded wire fabric made from wire which is zinc coated before being welded into fabric. Spiral binders, lacing wire, and stiffeners are produced from zinc-coated wire. Style 1 for the wire coating is normally recommended for temporary gabion[ or mattress] structures, for works in non-aggressive or non-polluted environments.

1.4.3.2  Style 2

Welded wire fabric which is made from uncoated wire and the fabric is subsequently zinc-coated after fabrication. Spiral binders, lacing wire, and stiffeners are produced from zinc-coated wire. Style 2 for the wire coating is normally recommended for permanent gabion[ or mattress] structures, for works installed in non-aggressive or non-polluted environments, and this condition remains unchanged over time.

1.4.3.3  Style 3

Welded wire fabric made from wire which is coated with zinc-5 percent aluminum-mischmetal alloy (Zn-5Al-MM) before being welded into fabric.
Spiral binders, lacing wire, and stiffeners are also produced from zinc-5 percent aluminum-mischmetal alloy (Zn-5Al-MM) coated wire. Style 3 for the wire coating is normally recommended for:

1.4.3.3.1 Permanent

Gabion[ or mattress] structures, for works installed in moderately aggressive environments.

1.4.3.3.2 Temporary

Gabion[ or mattress] structures, for works in aggressive environments, depending on the minimum design life of the structure.

1.4.3.4 Style 4

Welded wire fabric made from wire which is aluminum-coated before being welded into fabric. Spiral binders, lacing wire, and stiffeners are also produced from aluminum-coated (aluminized) wire. Style 4 for the wire coating is very seldom used in the gabion industry. Its life expectancy shall be adequately documented to guarantee its consistency and reliability.

1.4.3.5 Style 5

Welded wire fabric, spiral binders, lacing wire, and stiffeners as Styles 1, 2, 3, or 4, and overcoated with PVC. Style 5 for the wire coating is normally recommended for both permanent and temporary gabion structures, for works installed in aggressive or polluted environments, or when the aggressiveness of the site is moderately unpredictable or variable from low to high.

1.5 SUBMITTALS

**************************************************************************

NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy, Air Force, and NASA projects.
The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy, Air Force and NASA projects, or choose the second bracketed item for Army projects.

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-04 Samples
   Gabions or Mattresses
   Alternative Wire Fasteners

SD-06 Test Reports
   Gabions or Mattresses
   Alternative Wire Fasteners; G[, [_____]]

SD-07 Certificates
   Stone Fill
   Filter Material

1.6 QUALITY ASSURANCE

1.6.1 Samples

Furnish samples of materials used to fabricate the gabions or mattresses to the Contracting Officer 60 days prior to start of installation. Samples will be tested in accordance with specification and either ASTM A974 or ASTM A975 depending on which system is being furnished by the Contractor. The Government reserves the right to test additional samples to verify the submitted test records at the Government's expense. When the first test results indicate that the fasteners do not meet the specified requirements, the additional test will be at the Contractor's expense. The fasteners will be rejected after two tests failing to meet the requirements.

1.6.2 Test Report or Documents

Copies of all test results shall be furnished to the Technical Representative of this specification, USACE District, Vicksburg, 4155 Clay St., Vicksburg, MS 39183-3435, Attn: Dale Goss (ED-GI).

1.7 DELIVERY, STORAGE, AND HANDLING

******************************************************************************
NOTE: Delivery to the jobsite of unassembled units will not be permitted, due to the increased labor and onsite supervision time, and to the fact that
assembly is made on the jobsite and not in the quality-controlled manufacturer's facility.

Moreover, unassembled units delivered to the jobsite increase the likelihood to perform the construction by attaching units with a missing end panel rather than using entirely pre-assembled baskets. This will lower the structural integrity of the system, its strength at the connections and its overall resistance to the earth pressures.

It will be the responsibility of the manufacturer to guarantee that gabions are manufactured and delivered with all components mechanically attached, as required in ASTM A975 (Section 6.4) and ASTM A974 (Section 6.5).

Gabions [and mattresses] shall be delivered with all components mechanically connected at the production facility [with the exception of the mattress lid, which is produced separately from the base]. All gabions [and mattresses] are supplied in the collapsed form, either folded or bundled or rolled, for shipping. Bundles are banded together at the factory for ease of shipping and handling. [Mattress bases and lids may be packed in separate bundles].

a. Mattress lids may be supplied either as individual units (bundled) or in roll form. Lacing wire shall be shipped in coils with a diameter of the coil approximately 0.60 m (2 feet). Fasteners shall be shipped in boxes. Preformed stiffeners shall be shipped in bundles.

b. Deliver gabions [and mattresses] to the jobsite labeled in bundles. Labels show the dimensions of the gabions [or mattresses] included, the number of pieces and the color code.

PART 2   PRODUCTS

2.1   MATERIALS

NOTE: The use of the most appropriate Style for the wire coating in double twisted and welded wire gabions [and mattresses] is determined by the minimum required design life of the structure in relationship with the aggressiveness of the surrounding environment (air and water quality).

2.1.1 Double twisted wire mesh Gabions [and Mattresses]

Double twisted wire mesh gabions [and mattresses] shall be [Style 1], [Style 2], [Style 3], [and] [Style 4] manufactured with a non-raveling mesh made by twisting continuous pairs of wires through three half turns (commonly called double twisted) to form a hexagonal-shaped opening. Gabion [and mattress] sizes, wire diameters, mesh opening sizes, and tolerances shall comply with the requirements of ASTM A975 (Tables 1, 3, 4, 5, 6, and Sections 9). Gabions [and Mattresses] shall meet the following test requirements:
2.1.1.1 Metallic Coating

The coating weights shall conform to the requirements of [ASTM A641/A641M, Class 3 (Style 1)], [ASTM A856/A856M (Style 2)], [ASTM A90/A90M] or [ASTM A428/A428M] as applicable, and [ASTM A809 (Style 4)].

2.1.1.2 PVC for Coating

The PVC coating shall show no cracks or breaks after the wires are twisted in the fabrication of the mesh. The initial properties of PVC coating material shall have a demonstrated ability to conform to the following requirements:

2.1.1.2.1 Specific Gravity

In the range from 1.30 to 1.35 dN/dm³, when tested in accordance with test method ASTM D792

2.1.1.2.2 Tensile Strength

Not less than 20.6 MPa 2985 psi when tested in accordance with test method ASTM D412

2.1.1.2.3 Modulus of Elasticity

Not less than 18.6 MPa 2700 psi when tested in accordance with test method ASTM D412

2.1.1.2.4 Hardness

Shore "D" between 50 and 60, when tested in accordance with test method ASTM D2240

2.1.1.2.5 Brittleness Temperature

Not higher than -9 degrees C 15 degrees F, or lower temperature when specified by the purchaser, when tested in accordance with test method ASTM D746.

2.1.1.2.6 Resistance to Abrasion

The percentage of the weight loss shall be less than 12 percent

2.1.1.2.7 Salt Spray Exposure and Ultra Violet Light Exposure

The PVC shall show no effect after 3,000 h of salt spray exposure in accordance with ASTM B117. The PVC shall show no effect of exposure to ultra violet light with test exposure of 3,000 h, using apparatus Spectral Irradiance of Open Flame Carbon Arc with Daylight Filters and 63 degrees C 145 degrees F, when tested in accordance with practice ASTM D1499 and ASTM G152

2.1.1.2.8 Evaluation of Coating After Salt Spray and Ultraviolet Exposure Test

After the salt spray test and exposure to ultraviolet light, the PVC coating shall not show cracks nor noticeable change of color, or blisters or splits. In addition, the specific gravity, tensile strength, hardness and resistance to abrasion shall not change more than 6 percent.
percent, and 10 percent respectively, from their initial values.

### 2.1.1.3 Wire Tensile Strength

The tensile strength of the wire used for the double twisted mesh, lacing wire, and stiffener, when tested in accordance with Test Methods and definitions ASTM A370, shall be in accordance with the requirements of [ASTM A641/A641M (Style 1)], [ASTM A809 (Style 4)], and [ASTM A856/A856M (Style 2)], for soft temper wire.

### 2.1.1.4 Mesh Strength and Panel to Panel Joint Strength

The minimum strength requirements of the mesh, selvedge wire to mesh connection, panel to panel connection, and punch test, when tested in accordance with ASTM A975 Section 13.1, shall be as shown in Table 1. The strength values reported in kN/m lb/ft are referred to the unitary width of the specimen. The panel to panel test shall demonstrate the ability of the fastening system to achieve the required strength, and indicate the number of wire revolutions for the lacing wire or the ring spacing for ring fasteners used. The same number of wire revolutions or ring spacing shall be used in the field installation. Pleating the based panel to obtain internal panels is prohibited.

### 2.1.2 Welded Wire Fabric Gabions[ and Mattresses]

Welded wire fabric gabions[ and mattresses] shall be [Style 1], [Style 2], [Style 3], [Style 4], and [Style 5] manufactured with a welded wire mesh composed of a series of longitudinal and transverse steel wires arranged substantially at right angles to each other, and welded together at the points of intersection by electrical resistance welding to form fabricated sheets. Gabion [and mattress] sizes, wire diameters, mesh opening sizes, physical properties of the PVC for coating, and tolerances shall comply with the requirements of ASTM A974 (Tables 1, 2, 3, and Sections 9). Gabions [and Mattresses] shall meet the following test requirements:

#### 2.1.2.1 Metallic Coating

The coating weights shall conform to the requirements of [ASTM A641/A641M, Class 3 (Style 1)], [ASTM A856/A856M (Style 2)], [ASTM A90/A90M] or [
ASTM A428/A428M] as applicable, and [ASTM A809 (Style 4)].

2.1.2.2 PVC for Coating

PVC adhesion test shall be PVC coating shall show no cracks or breaks after the wires are twisted in the fabrication of the mesh. The initial properties of the PVC coating on the wire and welded wire fabric shall have a demonstrated ability to conform to the following requirements:

2.1.2.2.1 Adhesion

The PVC coating shall adhere to the wire such that the coating breaks rather than separates from the wire, in accordance with test method ASTM A974 Section 13.3;

2.1.2.2.2 Mandrel Bend

The PVC-coated wire when subjected to a single 360° bend at -18 degrees C 0 degrees F around a mandrel ten times the diameter of the wire, shall not exhibit breaks or cracks in the PVC coating;

2.1.2.2.3 Specific Gravity

In the range from 1.20 to 1.40 dN/dm3, when tested in accordance with test method ASTM D792;

2.1.2.2.4 Tensile Strength

Not less than 15.7 MPa 2275 psi when tested in accordance with test method ASTM D638;

2.1.2.2.5 Modulus of Elasticity

Not less than 13.7 MPa 1980 psi at 100 percent strain, when tested in accordance with test method ASTM D638;

2.1.2.2.6 Hardness

Shore "A" not less than 75, when tested in accordance with test method ASTM D2240;

2.1.2.2.7 Brittleness Temperature

Not higher than -9 degrees C 15 degrees F, or lower temperature when specified by the purchaser, when tested in accordance with test method ASTM D746.

2.1.2.2.8 Resistance to Abrasion

The percentage of the weight loss shall be less than 12 percent;

2.1.2.2.9 Salt Spray Exposure and Ultra Violet Light Exposure

The PVC shall show no effect after 3,000 h of salt spray exposure in accordance with ASTM B117. The PVC shall show no effect of exposure to ultra violet light with test exposure of 3,000 h, using apparatus Spectral Irradiance of Open Flame Carbon Arc with Daylight Filters and 63 degrees C 145 degrees F, when tested in accordance with practice ASTM D1499 and ASTM G152;
2.1.2.2.10 Evaluation of Coating After Salt Spray and Ultraviolet Exposure Test

After the salt spray test and exposure to ultraviolet light, the PVC coating shall not show cracks nor noticeable change of color, or blisters or splits. In addition, the specific gravity, tensile strength, hardness and resistance to abrasion shall not change more than 6 percent, 25 percent, and 10 percent respectively, from their initial values.

2.1.2.3 Wire Tensile strength

The tensile strength of the wire used for the welded wire fabric, spiral binders, lacing wire and stiffeners shall be soft medium in accordance with ASTM A641/A641M (Style 1), ASTM A856/A856M (Style 3), and ASTM A809 (Style 4) or hand drawn in accordance with ASTM A853 (Style 2). The cross-sectional area of the test specimen shall be based on the diameter of the metallic coated wire. All the wires used in the fabrication of gabions [and mattresses] must use the same temper wire in accordance with given order.

2.1.2.4 Weld Shear Strength

2.1.2.4.1 Minimum Average Shear Value

The minimum average shear value in Newtons pounds-force shall be 70 percent of the breaking strength of the wire or as indicated in the table as follows, whichever is greater, when tested in accordance with ASTM A974 Section 13.4. Typical minimum average shear strengths as specified are as follows:

<table>
<thead>
<tr>
<th>Wire diameter (mm/inch)</th>
<th>Min. Av. Shear Strength (Nlbs)</th>
<th>Min. Shear Strength (Nlbs)</th>
</tr>
</thead>
<tbody>
<tr>
<td>2.200.087</td>
<td>1300292</td>
<td>1000225</td>
</tr>
<tr>
<td>2.700.106</td>
<td>2100472</td>
<td>1600360</td>
</tr>
<tr>
<td>3.050.120</td>
<td>2600584</td>
<td>2000450</td>
</tr>
</tbody>
</table>

The material shall be deemed to conform with the requirements for weld shear strength if the average of the test results of the first four specimens or if the average of the test results for all welds tested comply with TABLE 2.

2.1.2.4.2 Panel to Panel Joint Strength

The minimum strength of the joined panels, when tested as described in ASTM A974 Section 13.5, shall be as follows:
TABLE 3
Panel to panel joint strength for welded gabions

| Test Description          | Gabions, metallic coated (kN/mlb/ft) | Gabions, PVC coated (kN/mlb/ft) | [Revet mattresses] 
|---------------------------|--------------------------------------|---------------------------------|-------------------
| Connection to selvedges   | 20.41400                             | 17.51200                        | 10.2700           |
| Panel to panel (using lacing wire or ring) | 20.41400                             | 17.51200                        | 10.2700           |

The strength values reported in kN/m lb/ft are referred to the unitary width of the specimen. The panel to panel test shall demonstrate the ability of the fastening system to achieve the required strength, and indicate the number of wire revolutions for the lacing wire used. The same number of wire revolutions shall be used in the field installation.

2.1.3 Alternative Wire Fasteners for Gabions[ and Mattresses]

**************************************************************************
NOTE: The use of steel rings is normally accepted in ASTM A975, for woven wire gabions and mattresses. Stainless steel rings will be used on PVC coated gabions or mattresses which meet the requirements of ASTM A313/A313M. Accepted alternative wire fasteners for welded wire gabions and mattresses are spiral binders, according to ASTM A974. The inclusion of rings for welded gabions is allowed only if proper guarantees over the pull apart, connection strength and long term durability (salt spray) are provided.
**************************************************************************

Subject to approval of the Contracting Officer, alternative fastening systems may be used in lieu of lacing wire. Alternative fasteners to lacing wire recommended for woven wire gabions and mattresses, according to ASTM A975, are steel ring fasteners for metallic coated gabions and mattresses, or stainless steel rings for PVC coated gabions and mattresses. For each shipment of wire gabions or mattresses delivered to the site, furnish the Contracting Officer, in duplicate, test reports or records that have been performed during the last year on all material contained within the shipment meets the composition, physical, and manufacturing requirements stated in this specification. Ring fasteners for woven wire gabions and mattresses shall comply with the minimum requirements indicated in paragraph Ring Fasteners below, and they shall develop a minimum panel to panel joint strength as indicated in TABLE 1. Alternative fasteners to lacing wire for welded wire gabions and mattresses, according to ASTM A974, are spiral binders. Spiral binders for welded wire gabions and mattresses shall comply with the minimum requirements indicated in paragraph Spiral Binders below. Ring fasteners may alternatively be used for welded wire gabions or mattresses, provided that they comply with the minimum specified requirements (salt spray and pull-apart resistance). Connections panel to panel for welded gabions and mattresses with ring fasteners shall develop a minimum joint strength as indicated in TABLE 3. Provide a complete description of the fastener system and a description of a properly installed fastener, including drawings or photographs if necessary. Provide test results that demonstrate that the alternative-fastening system meets the requirements of the specifications, according to the following criteria:
a. That the proposed fastener system can consistently produce a panel to panel joint strength as indicated in the TABLE 1 for double twisted wire mesh gabions and TABLE 3 for welded wire mesh gabions;
b. That the proposed fastener system does not cause damage to the protective coating on the wire;
c. That the Contractor has the proper equipment and trained employees to correctly install the fasteners;
d. That proper installation can be readily verified by visual inspection.

Samples of wire fasteners with their certified test records shall be submitted at least 60 days in advance to the Contracting Officer for approval. The Government reserves the right to test additional samples to verify the submitted test records at the Government's expense. When the first test results indicate that the fasteners do not meet the specified requirements, the additional test will be at the Contractor's expense. The fasteners will be rejected after two tests failing to meet the requirements.

2.1.3.1 Ring Fasteners

The tensile strength of the zinc-coated steel wire, zinc-5 percent aluminum coated mischmetal alloy-coated steel wire and aluminum-coated steel wire used for fasteners shall be in accordance with the requirements of ASTM A764, Type A, B, or C, Table 2 or Table 3. The tensile strength of stainless steel wire used for fasteners shall be in accordance with the requirements of ASTM A313/A313M, Type 302, Table 2. Any fastener system shall give the number of fasteners required to comply with TABLE 1, in accordance with ASTM A975 (Section 13.1.2) for woven wire gabions and mattresses, and TABLE 3, in accordance with ASTM A974 (Section 7.3), for welded wire gabions and mattresses. Ring fasteners shall not be installed more than 100 mm 4 inches apart. Each fastener type shall be closed and the free ends of the fastener shall overlap a minimum of 25 mm 1 inch. The manufacturer or supplier shall state the number of fasteners required for all vertical and horizontal connections for single and multiple basket joining. Approved ring fasteners including fasteners made of stainless steel shall be subject to the salt spray test and pull-apart resistance test and shall be documented by actual testing of panel to panel connections within the last year by validated laboratories.

2.1.3.1.1 Salt Spray Test

A set of two identical rectangular gabion panels, each with a width about 10-1/2 mesh openings along a selvedge wire, shall be joined by properly installed wire fasteners along the two selvedge wires so that each fastener confines two selvedge and two mesh wires. If the fasteners are also to be used to joint two individual empty gabion baskets, two additional selvedge wires which are each mechanically wrapped with mesh wires shall be included so that each fastener confines four selvedge and four mesh wires. The set of the jointed panels shall be subject to salt spray test, ASTM B117, for a period of not less than 48 hours. At the end of the test, the fasteners, the selvedge, or mesh wires confined by the fasteners shall show no rusty spots on any part of the surface excluding the cut ends. A properly installed fastener shall meet the following requirements:

a. Each interlocking fastener shall be in a locked and closed position.
b. Each ring fastener shall be closed, and the free ends of the fastener shall overlap a minimum of 25 mm 1 inch.

2.1.3.1.2 Pull-Apart Resistance Test

A new set of the jointed panels, which are prepared by the same method as specified in the salt spray test but without being subject to the 48-hour salt spray test, shall be mounted on a loading machine with grips or clamps such that the panels are uniformly secured along the full width. The grips or clamps shall be designed to transmit only tension forces. The load will then be applied at a uniform rate of 220 N/s 50 lbs/sec until failure occurs. The failure is defined as when the maximum load is reached and a drop of strength is observed with subsequent loading or the opening between any two closest selvedge wires, applicable to a fastener confining either two or four selvedge wires, becomes greater than 50 mm 2 inches at any place along the panel width. The strength of the jointed panels at failure shall have a minimum as indicated in TABLE 1 or TABLE 3.

2.1.3.2 Spiral Binders

Spiral binders are defined as a length of metallic coated steel wire or metallic coated steel wire with PVC coating preformed into a spiral, used to assemble and interconnect empty gabion and/or mattress units, and to close and secure stone-filled units. Spiral binders shall be fabricated with the same wire and coating style as the wire mesh. Test requirements for spiral binders shall refer to TABLE 3 regarding Metallic Coating, PVC for coating, Tensile Strength, and Panel to Panel Joint Strength.

2.1.4 Testing

Test records made within one year by certified laboratories and Government agencies will be used to determine the acceptability of the fastening system. Samples of wire fasteners and samples of material for fabricating the gabions and mattresses with their certified test records shall be submitted at least 60 days in advance to the Contracting Officer for approval. The Government reserves the right to test additional samples to verify the submitted test records at the Government's expense. When the first test results indicate that the fasteners do not meet the specified requirements, the additional test will be at the Contractor's expense. The fasteners will be rejected after two tests failing to meet the requirements.

2.1.5 Stone Fill

Submit a certificate or affidavit signed by a legally authorized official of the supplier of the stone fill and the supplier of the natural filter material (see next main paragraph below) that it meets the quality required and gradation limits specified.

2.1.5.1 General

**************************************************************************
NOTE: Stones having a lower unit (not less than 2240 kg/m3 140 lb/ft3) may be approved by the Contracting Officer, provided that the design is performed on the selected unit weight and the stone has a performance record to prove its durability.

If stone sources are not listed in the bid documents, the District must ensure that these
sources contain stone with required quality and quantity. It is the Contractor's responsibility to determine that the selected source is capable of supplying the quantities and gradation needed and at the rate needed. Acceptance of a source of stone does not imply acceptance of all material from the source, when such materials are unsuitable as determined by the Contracting Officer.

For gabions[ and mattresses], the ability to function properly depends upon their stability, which is partly depending upon the rocks filling them. Rock sizes should be chosen to prevent them from falling through the mesh of the gabions [or mattresses]. The rock has also to withstand natural weathering processes during the life of the project that would cause it to breakdown to sizes smaller than the wire mesh opening dimensions. Rock to fill gabions[ and mattresses] shall be durable and of suitable quality to ensure permanence in the structure and climate in which it is to be used.

2.1.5.1.1 Delivery

Deliver rock to the work site in a manner to minimize its reduction in sizes (breakdown) during the handling of the rock, and place and secure within the assembled and interconnected gabion[ or mattress].

2.1.5.1.2 Sources

The sources from which the Contractor proposes to obtain the material shall be selected well in advance of the time when the material will be required in the work. The inclusion of more than 5 percent by weight of dirt, sand, clay, and rock fines will not be permitted. Rock may be of a natural deposit of the required sizes, or may be crushed rock produced by any suitable method and by the use of any device that yields the required size limits chosen in TABLE 4.

2.1.5.1.3 Properties

Rocks shall be hard, angular to round, durable and of such quality that they shall not disintegrate on exposure to water or weathering during the life of the structure. [Selected stone from the required excavation may be used if satisfying all requirements as to quality and dimensions.] [All stone shall be obtained from one of the [sources listed below][sources listed at the end of this section]].

2.1.5.1.4 Non-Listed Source

As an option, propose to furnish stone from one non-listed source. The Government [will][may] make such investigations and tests as necessary to determine whether acceptable stone can be produced from the proposed source. Suitable samples of stone fill material shall be collected in the presence of a Government representative and submitted to the Contracting Officer for approval prior to delivery of any such material to the work site. Unless otherwise specified, all test samples shall be obtained and delivered at the Contractor's expense to [_____] at least 60 days in advance of the time when placing of the stone-filled gabions [or mattresses] is expected to begin. Suitable tests and/or service records will be used to determine the acceptability of the stone. In the event suitable test reports and service records are not available, as in the case of newly operated sources, the material may be subjected to petrography.
analysis, specific gravity, absorption, wetting and drying, freezing and thawing, and such other tests as may be considered necessary to demonstrate to the satisfaction of the Contracting Officer that the materials are acceptable for use in the work. All tests will be made by or under the supervision of the Government and at its expense.

2.1.5.2 Stone Quality

Stone fill, crushed stone, shall meet the quality requirements of ASTM C33/C33M, and freezing and thawing requirements of [ASTM D5312/D5312M][COE CRD-C 144] for the region of the United States in which the structure will be constructed.

2.1.5.3 Gradation

Gradation of stone for gabions shall be performed every 1000 tons placed under this contract in accordance with ASTM C136/C136M. Sizes of rock to fill gabions and mattresses are chosen on the basis of the mesh sizes, the structure's thickness, and within the limits shown in TABLE 4. Within each range of sizes, the rock shall be large enough to prevent individual pieces from passing through the mesh openings. Each range of sizes may allow for a variation of 5 percent oversize rock by weight, or 5 percent undersize rock by weight, or both.

2.1.5.3.1 Oversize Rock

In all cases, the sizes of any oversize rock shall allow for the placement of three or more layers of rock within each gabion compartment[and two or more layers of rock within each mattress compartment dependent upon the height of the mattress].

2.1.5.3.2 Undersize Rock

In all cases, undersize rock shall be placed within the interior of the gabion or mattress compartment and shall not be placed on the exposed surface of the structure. There shall be a maximum limit of 5 percent undersize or 5 percent oversize rock, or both, within each gabion[or mattress] compartment. The required rock gradation is reported in Table 4.

2.1.6 Filter Material

**************************************************************************
NOTE: When a filter layer is required beneath the gabion or mattress foundation, care must be taken to ensure that the minimum thickness is achieved evenly
across the surface to be protected. To assure sufficient relative permeability and drainage, to prevent the migration of slope materials into the filter layer, and for the retention of filter materials by the overlying gabion units, the particle size distribution of the filter material should conform to "Filter Design," Appendix E of EM 1110-2-1913."

Stone-filled units have a potential for becoming impermeable. For extreme cases of long protected slope distances, or any application where large volumes of seepage or captured runoff is anticipated, design consideration should be given to the carrying capacity of the filter material and the need for providing pipe drains through the gabion units.

Although the provision of a pervious filter layer beneath gabion slope protection is preferred, particularly for slopes steeper than 1V on 2H, construction economy may be achieved in some cases through the use of geotextile. The specifications for the geotextile should be in accordance with the instructions contained in Section 31 05 19.13 GEOTEXTILES FOR EARTHWORK.

The material shall meet the quality requirements of ASTM C33/C33M for the region in which the structure is located. The gradation test shall be performed in accordance with ASTM C136/C136M. Filter material shall consist of sand and gravel or crushed stone, well graded between the prescribed limits listed below.

[Filter fabrics shall meet the provisions of Section 31 05 19.13 GEOTEXTILES FOR EARTHWORK].

PART 3 EXECUTION

3.1 FOUNDATION PREPARATION

Foundation preparation [may] [shall not] take place on frozen or snow-covered ground. After excavation or stripping, to the extent indicated on the drawings or as directed by the Contracting Officer, all remaining loose or otherwise unsuitable materials shall be removed. All depressions shall be carefully backfilled to grade. If pervious materials are encountered in the foundation depressions, the areas shall be backfilled with free-draining materials. Otherwise, the depressions shall be backfilled with suitable materials from adjacent required excavation, or other approved source, and compacted to a density at least equal to that of the adjacent foundation. Any debris that will impede the proper installation and final appearance of the gabion layer shall also be removed, and the voids carefully backfilled and compacted as specified above. Immediately prior to placing the material, the Contracting Officer
shall inspect the prepared foundation surface, and no material shall be placed thereon until that area has been approved.

3.2 FILTER PLACEMENT

Filter material shall be spread uniformly on the prepared foundation surface in a manner satisfactory to the Contracting Officer, and to the slopes, lines, and grades as indicated on the drawings or as directed. Placing of filter material by methods, which will tend to segregate particle sizes, will not be permitted. Any damage to the foundation surface during the filter placement shall be repaired before proceeding with the work. Compaction of the filter materials will not be required, but it shall be finished to present a reasonably even surface free from mounds or windrows.

3.3 ASSEMBLY

3.3.1 Double twisted wire mesh Gabions

The gabions shall be opened and unfolded one by one on a flat, hard surface. Gabion units over 1.82 m 6 foot in length usually have an extra shipping fold, which must be removed. The sides, ends and diaphragms shall be lifted up into a vertical position to form an open box shape. The back and the front panels of the gabion shall be connected to the end panels and center diaphragms. The top corner of the end panels and center diaphragms have a selvedge wire extending approximately 100 mm 4 inches out from the corner edge. The end panels and the diaphragms shall be raised to a vertical position and the selvedge wire shall be wrapped around the edge wire of the top and back panels.

3.3.2 Double Twisted Wire Mesh Revet Mattresses

***************

NOTE: Remove this paragraph if not needed.

***************

The mattress shall be laid on a flat, hard surface. When the units are unfolded for assembly, depending on their length, they will have one or two shipping folds, which must be removed. The double flap of the side panel shall be folded in and wired to the diaphragm. At the corners, the end flaps shall be folded along the sides and the joint laced up. Each Revet mattress shall be assembled individually, by erecting the sides, ends and diaphragms, ensuring that all creases are in the correct position and the tops of all sides are level.

3.3.3 Welded Wire Fabric Gabions[ and Gabion Mattresses]

The gabions[ or gabion mattresses] shall be opened and unfolded on a flat, hard surface. The units shall be rotated into position and the edges joined with fasteners for assembly. Where spiral fasteners are used, the ends shall be crimped to secure them in place. Where lacing wire is used, the wire shall be wrapped with alternating double and single loops with spacings not to exceed 150 mm 6 inches. Ends shall be secured with two complete revolutions and finished with a one-half hitch. The same fastening procedures shall be used to secure interior diaphragms and end panels. When two gabions are placed side by side, the two end panels may be connected along the vertical edges with a single spiral fastener.
3.4 LACING OPERATIONS

3.4.1 Double Twisted Wire Mesh Gabions[ and Mattresses]

Either lacing wire or ring fasteners are permitted to lace double twisted wire mesh gabions[ or revet mattresses].

3.4.1.1 Lacing Wire

When using lacing wire, a piece of wire 1.2 to 1.5 times the length of the edge to be laced shall be cut off. If the edge of the basket is 0.91 m 3 foot long, no more than 1.2 to 1.5 m 4 to 5 feet of wire should be used at a time to lace. For vertical joints, starting at the bottom end of the panel, the lacing wire shall be twisted and wrapped two times around the bottom selvedge and double and single loops shall be alternated through at intervals not bigger than 100 to 150 mm 4 to 6 inches. The operation shall be finished by looping around the top selvedge wire. The use of pliers to assemble the units with lacing wire is normally recommended.

3.4.1.2 Steel Wire Ring Fasteners

When steel wire ring fasteners are used, the rings shall be installed at the top and bottom connections of the end and center diaphragms. The ring spacing shall be based on the minimum pull apart strength as specified in TABLE 1. In any case, the maximum ring spacing along the edges shall not exceed 0.15 m 6 inches. The use of either a mechanical or a pneumatic fastening tool for steel wire ring fasteners is required. Ring fasteners shall be galvanized, stainless steel or Zn-5 percent aluminum-mischmetal alloy coated.

3.4.2 Welded Wire Mesh Gabions[ and Mattresses]

Either lacing wire or spiral binders are permitted to lace welded wire mesh gabions[ or gabion mattresses]. The empty units shall be placed on the foundation and interconnected with the adjacent unit along the top, bottom and vertical edges using spiral fasteners. Lacing wire may be used in lieu of spiral binders for the interconnection of gabions[ or mattresses] as specified above. The connection with lacing wire or spiral binders shall be based on the minimum panel to panel joint strength as specified in TABLE 3. Spiral binders shall be screwed along the connecting edges, and then each end crimped to secure the spiral in place. Each layer of gabions[ or mattresses] shall be interconnected to the underlying layer along the front, back and sides.

3.5 INSTALLATION AND FILLING

Empty gabion[ and mattress] units shall be assembled individually and placed on the approved surface to the lines and grades as shown or as directed, with the sides, ends, and diaphragms erected in such a manner to ensure the correct position of all creases and that the tops of all sides are level. All gabion units shall be properly staggered [horizontally][ and vertically] as shown in the construction drawings. Finished gabion[ or mattress] structures shall have no gaps along the perimeter of the contact surfaces between adjoining units. All adjoining empty gabion units shall be connected along the perimeter of their contact surfaces in order to obtain a monolithic structure. All lacing wire terminals shall be securely fastened. All joining shall be made through selvedge-to-selvedge or selvedge-to-edge wire connection; mesh-to-mesh or selvedge-to-mesh wire connection is prohibited except in the case where baskets are offset or
stacked and selvedge-to-mesh or mesh-to-mesh wire connection would be necessary. As a minimum, a fastener shall be installed at each mesh opening at the location where mesh wire meets selvedge or edge wire.

a. The initial line of basket units shall be placed on the prepared [filter layer surface] [foundation] and adjoining empty baskets set to line and grade, and common sides with adjacent units thoroughly laced or fastened. They shall be placed in a manner to remove any kinks from the mesh and to a uniform alignment. The basket units then shall be partially filled to provide anchorage against deformation and displacement during the filling operation. The stone shall be placed in the units as specified in paragraph Stone Fill, subparagraph Gradation, part b.

b. Undue deformation and bulging of the mesh shall be corrected prior to further stone filling. Care shall be taken, when placing the stone by hand or machine, to assure that the PVC coating on gabions will not be damaged. All visible faces shall be filled with some hand placement to ensure a neat and compact appearance and that the void ratio is kept to a minimum.

c. Uniformly overfill gabions [and mattresses] by about 25 to 50 mm 1 to 2 inches to compensate for future rock settlements. Gabions [and mattresses] can be filled by any kind of earth-filling equipment, such as a backhoe, gradall, crane, etc. The maximum height from which the stones may be dropped into the baskets shall be 0.91 to 1.20 m 3 to 4 feet. If PVC coated materials are used, no work shall take place unless the ambient temperature is above -7 degrees C 20 degrees F.

3.5.1 Double Twisted Wire Mesh Gabions

After the foundation has been prepared, the pre-assembled gabions shall be placed in their proper location to form the structure. Gabions shall be connected together and aligned before filling the baskets with rock. All connections (panel-to-panel) and basket-to-basket shall be already carried out as described in paragraph ASSEMBLY. Stone fill shall have a gradation of 0.10 to 0.20 m 4 to 8 inches, as described in paragraph Gradation, and shall be placed in 0.30 m 1 foot lifts. Cells shall be filled to a depth not exceeding 0.30 m 1 foot at a time. The fill layer should never be more than 0.30 m 1 foot higher than any adjoining cell. Stiffeners or internal cross ties shall be installed in all front and side of the gabions at 1/3 and 2/3 of the height for 0.91 m 3 feet or higher gabions, as the cell is being filled. Stiffeners shall be installed in the center of the cells. In 0.46 m 1.5 foot high units, stiffeners or internal crossties are not required. Internal cross ties, or alternatively the preformed stiffeners, shall be looped around three twisted wire mesh openings at each basket face and the wire terminals shall be securely twisted to prevent their loosening. The number of voids shall be minimized by using a well-graded stone in order to achieve a dense, compact stone fill. All corners shall be securely connected to the neighboring baskets of the same layer before filling the units. When more than one layer of gabions is required, in order for the individual units to become incorporated into one continuous structure, the next layer of gabions shall be connected to the layer underneath after this layer has been securely closed. Gabions shall be uniformly overfilled by about 25 to 50 mm 1 to 2 inches to compensate for future rock settlements.

SECTION 31 36 00 Page 25
[3.5.2 Double Twisted Wire Mesh Revet Mattresses

**************************************************************************
NOTE: Remove this paragraph if not needed.
**************************************************************************

After being assembled, the revet mattresses shall be placed in their proper location and securely attached to the adjacent units. For structural integrity, all adjoining empty units shall be connected by means of lacing wire or ring fasteners along the edges of their contact surfaces in order to form a monolithic structure. Revet mattresses shall be placed and securely connected while empty. The filling shall be done unit by unit; however, several units can be pre-assembled prior to filling the units. Revet mattress units shall be filled with hard, durable, clean stone having a gradation as indicated in paragraph Gradation. Care shall be taken to ensure that diaphragm tops are accessible for wiring. On slopes, the Revet mattress shall be laid with the 1.83 m 6 foot dimension (width) longitudinally to the slope and progressing up the slope, except for small ditches or where otherwise specified in the project. When the installation is performed on a slope, the filling of the baskets shall start from the lower side of the bank. Where Revet mattresses are to be placed on steep slopes (3H to 2V), the units shall be secured by hardwood pegs driven into the ground just below the upper end panel, at 1.83 m 6 foot centers, or as specified in the project. When the Revet mattress is to be placed over a geotextile, care shall be taken to ensure that any projecting ends of wire are bent upward to avoid puncturing or tearing the cloth. Lids shall be securely connected to the ends of the mattress and to the top sides and diaphragms using alternate double and single loops, or steel wire ring fasteners, as indicated in paragraph FOUNDATION PREPARATION. In case that more adjacent bases are to be covered at one time, mesh rolls shall be used in place of unit size lids. Revet mattresses shall be uniformly overfilled by about 25 to 50 mm 1 to 2 inches to compensate for future rock settlements.

3.5.3 Welded Wire Fabric Gabions

After the foundation has been leveled, the assembled gabions shall be placed in their proper location to form the structure. Care shall be taken to ensure that the top of the diaphragms are aligned correctly. The diaphragms shall be securely connected by either spiral binders or lacing wire. Gabions shall be connected together and aligned before filling them with 100 to 200 mm 4 to 8 inch diameter rocks. Rock filling material shall be as specified in paragraph Gradation and shall be placed in 0.30 m 1 foot lifts. The fill layer shall be carefully hand-packed and braced to prevent bulging. Stiffeners shall be provided every 0.30 m 12 inch levels for 0.91 m 3 foot or higher gabions. Stiffeners shall be formed from lacing wire and placed across the corners at 0.30 m 12 inches from the corner, providing a diagonal bracing. Preformed hooked stiffeners can be utilized. Care shall be taken to ensure the number of voids is minimized by using a well-graded stone and avoiding large rocks in order to achieve a dense, compact compartment. After each 0.30 m 1 foot lift has been placed, it shall be leveled for the next lift. Almost all gabion structures consist of more than one course of gabions; in order that the individual gabions may become incorporated into one continuous structure, they shall be wired to neighboring gabions and the course below, before filling. Gabions shall be uniformly overfilled by about 25 to 50 mm 1 to 2 inches to compensate for future rock settlements.
3.5.4 Welded Wire Fabric Gabion Mattresses

**************************************************************************
NOTE: Remove this paragraph if not needed.
**************************************************************************

After being assembled, the Gabion mattresses shall be placed in their proper location and securely attached to the adjacent units. For structural integrity, all adjoining empty units shall be connected by means of lacing wire or spiral binders along the edges of their contact surfaces in order to form a monolithic structure. Gabion mattresses shall be placed and securely connected while empty. The filling shall be done by unit; however, it is recommended that several units be pre-assembled prior to filling the units. Gabion mattress units shall be filled with hard, durable, clean stone having a gradation as indicated in paragraph Gradation. Care shall be taken to ensure that diaphragm tops are accessible for wiring.

a. On slopes, the Gabion mattress shall be laid with the 1.83 m 6 foot dimension (width) longitudinal to the bank, with the exception of small ditches or when otherwise specified in project. When the installation is performed on a slope, the filling of the units shall start from the lower side of the bank. Where Gabion mattresses are to be placed on steep slopes (3H to 2V), the units shall be secured by galvanized pipes driven into the ground inside the upper end panel, at 1.83 m 6 foot centers, or as specified in the project.

b. When the Gabion mattress is to be placed over a geotextile, care shall be taken to ensure that any projecting ends of wire are bent upward to avoid puncturing or tearing the cloth.

c. Lids shall be securely connected to the ends of the mattress and to the sides and diaphragms using alternate double and single loops, or steel wire ring fasteners, as indicated in paragraph FOUNDATION PREPARATION. In case that more adjacent bases are to be covered at one time, mesh rolls can be used in place of unit size lids. Gabions mattresses shall be uniformly overfilled by about 25 to 50 mm 1 to 2 inches to compensate for future rock settlements.

3.5.5 Non-Rectangular Shapes

Gabion units can conform to bends up to a radius of curvature of 18 to 21 m 60 to 70 feet without alterations. Units shall be securely connected together first, and be placed to the required curvature, holding them in position by staking the units to the ground with hardwood pegs before filling. For other shapes, bevels and miters can be easily formed by cutting and folding the panels to the required angles.

3.6 CLOSING

Lids shall be tightly secured along all edges, ends and diaphragms in the same manner as described for assembling. Adjacent lids may be securely attached simultaneously. The panel edges shall be pulled to be connected using the appropriate closing tools where necessary. Single point leverage tools, such as crowbars, may damage the wire mesh and shall not be used. All end wires shall then be turned in.

NOTE: This guide specification covers the requirements for metal sheet piling. This section was originally developed for USACE Civil Works projects. Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1 GENERAL

NOTE: Permanent earth retaining structures made with steel sheet piling such as caissons, quay walls, and retaining walls are covered by this section. Temporary structures such as shoring and sheeting are the responsibility of the Contractor and unless required by conditions of the project, are not to be covered by this section. The extent and location of the work to be accomplished should be indicated on the project drawings.

The following information must also be shown on the project drawings:
1. Location of piles.
2. Soil data, where required.
3. Pile shape.
4. Pile size and weight.
5. Length or tip and cut-off elevations.

1.1 DESCRIPTION

Design, furnish, install and test metal sheet piles at the locations indicated on the drawings and specified herein. [Assume test pile[s] will be directed to be placed in [a] location[s] that can be incorporated into the work.]

1.2 REFERENCES

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

AMERICAN WELDING SOCIETY (AWS)

AWS D1.1/D1.1M (2020; Errata 1 2021) Structural Welding Code - Steel
AWS D1.5M/D1.5 (2020; Errata 1 2022) Bridge Welding Code

ASTM INTERNATIONAL (ASTM)

1.3 BASIS OF BID

**************************************************************************
NOTE: Select one of the following options.
**************************************************************************

**************************************************************************
NOTE: Use "Lump Sum" paragraph below for lump (principal) sum bidding of piles. Use this in all projects except those where exact pile lengths cannot be practically determined prior to the actual work. Clearly show number of piles, pile capacity, pile locations, and tip and cutoff elevations on the drawings.

Use "Unit Price" paragraph for unit price bidding of piles. Specify unit price bid items for piles only for projects where exact quantities cannot be practically determined prior to the actual work. Lengths of piles must be determined as accurately as possible, prior to bidding, since the unit price per meter (foot) of the piles varies as the length.

SECTION 31 41 16  Page 6

Whenever sheet piling section properties greater than required by design are acceptable, "(Min.)" should be indicated after the applicable value shown in this specification or on the drawings.

1.3.1 Contractor's Geotechnical Consultant

Hire the services of an independent, Registered Professional Geotechnical Engineer, experienced in soil mechanics and Pile Dynamic Analysis, to observe test pile installation and production pile installation as specified herein. The Contractor's Geotechnical Consultant must be independent of the Contractor and must have no employee of employer relationship which could constitute a conflict of interest.

1.3.2 Lump Sum Payment

Base bids upon providing the number, size, capacity, and length of piles as indicated on the [drawings.] [following Table I:

<table>
<thead>
<tr>
<th>Location</th>
<th>Number</th>
<th>Section</th>
<th>[Section Modulus]*</th>
<th>[Moment of Inertia]*</th>
<th>Length (tip to cut-off)</th>
<th>[_____]</th>
<th>[_____]</th>
</tr>
</thead>
</table>

*Section properties should be detailed per foot of wall, in$^3$ per ft.
**Section properties should be detailed per foot of wall, in$^4$ per ft.*

Include the cost of all necessary equipment, tools, material, labor, and supervision required to: deliver, handle, install, cut-off, dispose of any cut-offs, pullout, and meet the applicable contract requirements. Include mobilization, pre-drilling, and redriving heaved piles. If, in redriving, it is found that any pile is not of sufficient length to provide the requirements specified, notify the Contracting Officer, who reserves the right to increase or decrease the total length of piles to be provided and installed by changing the pile locations or elevations, requiring the installation of additional piles, or directing the omission of piles from the requirements shown and specified. If total number of piles or number of each length vary from that specified as the basis for bidding, an adjustment in the contract price or time for completion, or both, will be made in accordance with the contract documents. Payment for piles will be based on successfully installing piles to both the minimum tip elevation and satisfying the acceptance criteria identified herein. No additional payment will be made for: damaged, rejected, or misplaced piles; withdrawn piles; any portion of a pile remaining above the cut-off elevation; backdriving; cutting off piles; splicing; build-ups; any cut-off length of piles; or other excesses beyond the assumed pile length indicated for which the Contractor is responsible. Include payments for vibration monitoring, sound monitoring and precondition construction surveys.]
1.3.3 Unit Prices

**************************************************************************
NOTE: If Section 01 20 00 PRICE AND PAYMENT PROCEDURES is included in the project specifications, this paragraph title (UNIT PRICES) should be deleted from this section and the remaining appropriately edited subparagraphs below should be inserted into Section 01 20 00.
**************************************************************************

1.3.3.1 Steel Sheet Piling, Type [____], Grade [____]

1.3.3.1.1 Payment

Payment for sheet piling quantities will be made at the applicable contract price per linear meter foot for furnished and installed sheet piling. Payment will cover all cost of furnishing, handling, storing and installing piling including placing, driving, cutting holes and other materials, and work incident thereto.

1.3.3.1.2 Measurement

The length of sheet piling installed [and removed] will be measured to the nearest tenth of a linear meter foot. For installed pilings directed to be cut off before reaching the penetration depth shown, the portion cut off will be measured for payment as the difference between the total length of piling shown on the plans for that location and the length of piling installed below the point of cut-off.

1.3.3.1.3 Unit of Measure

Linear meter foot.

1.3.3.2 Steel Fabricated Sections, Type[s] [____], Grade [____]

1.3.3.2.1 Payment

Payment for sheet piling quantities will be made at the applicable contract price per linear meter foot for furnished and installed sheet piling. Payment will cover all cost of furnishing, handling, storing and installing piling including placing, driving, cutting holes and other materials and work incident thereto [except the cost of furnishing piling will not be included in the contract price for Government furnished piling].

1.3.3.2.2 Measurement

The length of sheet piling installed [and removed] will be measured to the nearest tenth of a linear meter foot. For installed pilings directed to be cut off before reaching the penetration depth shown, the portion cut off will be measured for payment as the difference between the total length of piling shown on the plans for that location and the length of piling installed below the point of cut-off.

1.3.3.2.3 Unit of Measure

Linear meter foot.
1.3.3.3  Steel Sheet Piling - Government Furnished

1.3.3.3.1  Payment

Payment for sheet piling quantities will be made at the applicable contract price per linear meter foot for furnished and installed sheet piling. Payment will cover all cost of furnishing, handling, storing and installing piling including placing, driving, cutting holes and other materials and work incident thereto [except the cost of furnishing piling will not be included in the contract price for Government furnished piling].

1.3.3.3.2  Measurement

The length of sheet piling installed [and removed] will be measured to the nearest tenth of a linear meter foot. For installed pilings directed to be cut off before reaching the penetration depth shown, the portion cut off will be measured for payment as the difference between the total length of piling shown on the plans for that location and the length of piling installed below the point of cut-off.

1.3.3.3.3  Unit of Measure

Linear meter foot.

1.3.3.4  Aluminum Sheet Piling, Type [____]

1.3.3.4.1  Payment

Payment for sheet piling quantities will be made at the applicable contract price per linear meter foot for furnished and installed sheet piling. Payment will cover all cost of furnishing, handling, storing and installing piling including placing, driving, cutting holes and other materials and work incident thereto [except the cost of furnishing piling will not be included in the contract price for Government furnished piling].

1.3.3.4.2  Measurement

The length of sheet piling installed [and removed] will be measured to the nearest tenth of a linear meter foot. For installed pilings directed to be cut off before reaching the penetration depth shown, the portion cut off will be measured for payment as the difference between the total length of piling shown on the plans for that location and the length of piling installed below the point of cut-off.

1.3.3.4.3  Unit of Measure

Linear meter foot.

1.3.3.5  Aluminum Fabricated Sections, Type[s] [____]

1.3.3.5.1  Payment

Payment for sheet piling quantities will be made at the applicable contract price per linear meter foot for furnished and installed sheet piling. Payment will cover all cost of furnishing, handling, storing and installing piling including placing, driving, cutting holes and other materials and work incident thereto [except the cost of furnishing piling will not be included in the contract price for Government furnished piling].
1.3.3.5.2 Measurement

The length of sheet piling installed [and removed] will be measured to the nearest tenth of a linear meter foot. For installed pilings directed to be cut off before reaching the penetration depth shown, the portion cut off will be measured for payment as the difference between the total length of piling shown on the plans for that location and the length of piling installed below the point of cut-off.

1.3.3.5.3 Unit of Measure

Linear meter foot.

1.3.3.6 Aluminum Sheet Piling - Government Furnished

1.3.3.6.1 Payment

Payment for sheet piling quantities will be made at the applicable contract price per linear meter foot for furnished and installed sheet piling. Payment will cover all cost of furnishing, handling, storing and installing piling including placing, driving, cutting holes and other materials and work incident thereto [except the cost of furnishing piling will not be included in the contract price for Government furnished piling].

1.3.3.6.2 Measurement

The length of sheet piling installed [and removed] will be measured to the nearest tenth of a linear meter foot. For installed pilings directed to be cut off before reaching the penetration depth shown, the portion cut off will be measured for payment as the difference between the total length of piling shown on the plans for that location and the length of piling installed below the point of cut-off.

1.3.3.6.3 Unit of Measure

Linear meter foot.

1.3.7 Cut-Offs

1.3.7.1 Payment

When pilings which have not been driven to penetration depths shown are directed to be cut off, except for cut-offs due to excessive battering, a lump sum payment will be made for cutting off each piling.

1.3.7.2 Measurement

An additional sum will be paid for each linear meter foot of the portion cut off and measured for payment. For installed pilings directed to be cut off before reaching the penetration depth shown, the portion cut off will be measured for payment as the difference between the total length of piling shown on the plans for that location and the length of piling installed below the point of cut-off at the rate of 50 percent of the applicable contract unit price. [No payment will be made for cut-off portions of Government furnished pilings.]

1.3.7.3 Unit of Measure

Each.
1.3.3.8 Splices

1.3.3.8.1 Payment

Payment will be made for each piling spliced at the direction of the Contracting Officer to drive the piling to a depth greater than shown and extend it up to the required top elevation. An additional sum will be paid for each linear meter foot of the piling extension at the applicable contract unit price.

1.3.3.8.2 Measurement

Splices will be measured for payment for each piling spliced.

1.3.3.8.3 Unit of Measure

Each.

1.3.3.9 Pulled Pilings

1.3.3.9.1 Payment

The Contractor furnished pilings which have been installed and are pulled at the direction of the Contracting Officer and found to be in good condition will be paid for at the applicable contract unit price for furnishing and installing the pilings in their initial position plus the applicable contract unit price for the cost of pulling.

1.3.3.9.2 Measurement

When such pulled pilings are redriven, an additional amount equal to 50 percent of the applicable contract unit price for furnishing and driving the pilings will be paid for redriving the pilings. This additional price constitutes payment for redriving only. The cost of furnishing, initial driving, and pulling the pilings is to be paid for as specified.

a. Government furnished pilings which are pulled at the direction of the Contracting Officer and found to be in good condition will be paid for at the applicable contract unit price for installing the pilings in their initial position plus an equal amount for the cost of pulling. Such piling when redriven will be paid for at the applicable contract unit cost for installing the pilings.

b. When pilings are pulled and found to be damaged no payment will be made for the initial furnishing and driving or for the pulling of such pilings. Pilings replacing damaged pilings will be paid for at the applicable contract unit prices.

1.3.3.9.3 Unit of Measure

Each.

1.3.3.10 Removal of Sheet Pilings

1.3.3.10.1 Payment

Payment will be made for costs associated with removal of sheet pilings. Payment will cover cost of pulling, cleaning the interlock, sorting,
inventorying and storing.

1.3.3.10.2 Measurement

Removal of sheet piling will be made at the applicable contract price per linear meter foot for the removal of sheet pilings.

1.3.3.10.3 Unit of Measure

Linear meter foot.

1.4 NAVY PROJECT PRICE AND PAYMENT PROCEDURES

**************************************************************************
NOTE: Select the applicable paragraph(s) from the following.
**************************************************************************

1.4.1 Basis of Bids

**************************************************************************
NOTE: Use this option for fixed-price contracts.
**************************************************************************

Base bids on pile sections and lengths as indicated. Should the total number of piles or the number of each length vary from that specified as the basis for bidding, an adjustment in the contract price and time for completion will be made. No additional payment will be made for withdrawn, damaged, rejected, or misplaced piles; for any portion of a pile remaining above the cut-off elevation; for backdriving; for cutting off piles, or for any cut off length of piles.

1.4.2 Measurement and Payment

1.4.2.1 NAVFAC PAC Projects

For unit price bid, see SF 1442, "Solicitation, Offer and Award" and "Schedule of Bid Items."

1.4.2.2 NAVFAC LANT Projects

Payment will be at the contract unit price per length, multiplied by the total length of acceptable piles actually installed. Base bids on the number of piles with pile length from tip to cutoff, as indicated, and on the total length of piling from tip to cutoff as specified in the document titled "Instructions to Bidders." Include in bid a unit price per unit length piling based on the quantity stated in the document titled "Instructions to Bidders." If the Contracting Officer requires an increase or a decrease in length of piles furnished and installed, the contract price will be adjusted in accordance with the Contract Clauses of the contract. The unit price bid will be used for upward or downward adjustment of the quantity subject to provisions of FAR 52.211-18, Variation in Estimated Quantities.

1.5 ESTIMATED QUANTITIES

The estimated quantities of sheet piling listed in the unit price schedule of the contract, as to be furnished by the Contractor, are given for bidding purposes only. Sheet piling quantities for payment will consist of
the linear meters feet of piling acceptably installed [and removed]. Installed quantities will consist of all piling including fabricated sections driven between the required top and bottom elevations of pilings plus any additions thereto resulting from changes in design or alignment as provided in paragraph DRIVING. [Removed quantities will consist of the lengths of piling pulled from below the ground level.]

1.6 SUBMITTALS

******************************************************************************

NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy, Air Force, and NASA projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy, Air Force and NASA projects, or choose the second bracketed item for Army projects.

Interlock joint tension strength requirements should be deleted except for flat, or straight web, pilings used in radial or transverse tension applications.

******************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

1.7 DELIVERY, STORAGE, AND HANDLING

Conform all delivery, storage, and handling of materials to the requirements specified herein. Develop and submit plans for the delivery, storage, and handling of piles. Submit delivery, storage, and handling
plans for piles at least 30 days prior to delivery of piles to the job site.

1.7.1 Delivery and Storage

Materials delivered to the site must be new and undamaged and must be accompanied by certified test reports. Provide the manufacturer's logo and mill identification mark on the sheet piling as required by the referenced specifications. Store and handle sheet piling in the manner recommended by the manufacturer to prevent permanent deflection, distortion or damage to the interlocks; as a minimum, support on level blocks or racks spaced not more than 3 m 10 feet apart and not more than 0.60 m 2 feet from the ends. Storage of sheet piling should also facilitate required inspection activities and prevent damage to coatings and corrosion protection prior to installation.

1.7.2 Handling

Lift piles to ensure that the maximum permissible curvature is not exceeded. Holes may be burned above the cutoff length for lifting piles into the leads. If there is evidence of pile damage during driving due to the holes, Contracting Officer may forbid the burning of holes. Do not damage piles when dragging piles across the ground or barge deck.

Inspect piles for excessive curvature and for damage before transporting them from the storage area to the driving area and immediately prior to placement in the driving leads. Curvature in the pile must be measured with the pile laying on a flat surface and is the distance between the pile at the mid-length of the pile and the flat surface. Straightness of the sections of piles must conform to AWS D1.5M/D1.5, Section 3.5.1.1. Piles having excessive curvature will be rejected.

1.7.3 Damaged Piles

Inspect each pile for straightness and structural damage before transporting them to the project site and immediately prior to placement in the driving leads. Bring any damage to the attention of the Contracting Officer. Piles which are damaged during delivery, storage, or handling to the extent they are rendered unsuitable for the work, in the opinion of the Contracting Officer, will be rejected and removed from the project site, or may be repaired, if approved, at no cost to the Government.

Any pile damaged by reason of internal defects or by improper driving must be corrected by one of the following methods approved by the Engineer for the pile in question:

a. The pile is withdrawn, if practicable, and replaced by a new and, if necessary, longer pile.

b. One or more replacement piles are driven adjacent to the defective pile.

c. A Pile Dynamic Analysis and/or low integrity testing must be performed by the Contractor's Geotechnical Consultant to assess the structural integrity of the driven pile(s).

A pile driven below the specified butt elevation must be corrected by one of the following methods approved by the Engineer:

a. The pile is spliced (if approved).
b. A sufficient portion of the footing is extended down to properly embed the pile.

A pile driven out of its proper location or out of plumb as approved by the Engineer, must be corrected by one of the following methods approved by the engineer:

a. One or more replacement piles are driven next to the pile in question.

b. As directed by the structural engineer.

1.8 MATERIAL CERTIFICATES

For each shipment, submit certificates identified with specific lots prior to installing piling. Include in the identification data piling type, dimensions, chemical composition, mechanical properties, section properties, heat number, and mill identification mark.

1.9 INTERLOCKED JOINT TENSION TEST

**************************************************************************
NOTE: Include this paragraph only when the design utilizes straight web metal sheet piles, such as a cellular cofferdam. This should not be included for Z-type sheet piles.
**************************************************************************

Submit, for approval, the procedure for testing the tension strength of piling interlocks prior to testing sheet piling.

]PART 2 PRODUCTS

2.1 METAL SHEET PILING

**************************************************************************
NOTE: ASTM A328/A328M covers one grade of steel sheet piling for general use. ASTM A572/A572M covers three grades (yield strengths of 290, 345, 414 MPa 42, 50, 55, 60 and 65 ksi) of steel available for high strength steel sheet piling, with ASTM A572/572M grade 345MPa 50ksi being the most common. ASTM A690/A690M covers one grade of steel available for high strength steel sheet piling for use where greater resistance to marine splash zone conditions is required. Availability of sheet piling sizes and grades should always be verified as part of the design. Each of the ASTM Specifications contains "Supplementary Requirements" for use when desired by the purchaser. Some of these are provided for and described in the individual ASTM specification; others are standardized, and are indicated only by number and title, with their description found in ASTM A6/A6M.

Hot-rolled straight web steel sheet piling sections are suitable for applications where interlocked joint strength in tension or section stability is a primary design requirement. Section stability (Biaxial Stress) is a consideration in highly
stressed applications only. Cold-formed straight web steel sheet piles should not be used.

Hot-rolled z-type steel sheet pile sections have tighter interlocks and are suitable for applications where reduced permeability through the wall is a primary design requirement.

Cold-formed steel sheet pile sections are suitable for applications where the permeability through the wall is not a primary design requirement. Cold-formed sheet piles typically have a hook and grip interlock which typically has the highest permeability rates. Cold formed sheet piling will not be used in I-walls that act as a flood barrier. This is due to the much greater permeability of the lapped connections between the sheets compared to the ball-and-socket interlock connections in hot rolled sheet piling.

Higher section modulus and stiffness (moment of inertia) of a z-type steel sheet pile improves integrity during driving and allows forces to be redistributed laterally along the wall at changes in wall alignment, in weak soil zones or when the I-wall undergoes wave loadings that vary along the length of the wall. The additional strength also provides some redundancy to sections that must bridge across localized weak zones in the foundation material.

For applications in salt or brackish water use the most economical of a ASTM A690/A690M steel sheet piling which offers greater corrosion resistance or a ASTM A328/A328M steel sheet piling with a protective coating in the splash zone. A protective coating should be applied to a ASTM A690/A690M sheet piling in the splash zone of waterway bulkheads located in salt or brackish water.

Corrosion protection should be provided where piling is exposed to an adverse environment. Choose system(s) based on economics and potential hazards due to sheet piling system failure; more than one system may be necessary depending on conditions above and below the splash zone. While ASTM A690/A690M is suggested for marine environments, its use alone without protective measures may not be effective enough.

Aluminum sheet piling sections are suitable for use in applications requiring moderate bending resistance and minimal design interlocked joint strength in tension. Non-draining, clay-muck soils and soils and water with a ph outside the range of 4.5 to 8.5 and containing chlorides, sulfates or heavy metals (copper, lead, tin, mercury and cobalt) are corrosive to aluminum and should be avoided. Protective coatings or cathodic protection can be
used to provide longer service life to aluminum piling in corrosive environments.

Submit detail drawings for sheet piling, including fabricated sections, showing complete piling dimensions and details, driving sequence and location of installed piling.

a. Include in the drawings details of top protection, special reinforcing tips, tip protection, lagging, splices, fabricated additions to plain piles, cut-off method, corrosion protection, and dimensions of templates and other temporary guide structures for installing piling. Provide details of the method for handling piling to prevent permanent deflection, distortion or damage to piling interlocks.

b. Metal sheet piling must be [hot-rolled steel sections conforming to [ASTM A328/A328M, Grade [_____], Type [_____]] [, interlocked joint strength in tension as shown]] [ASTM A690/A690M [, interlocked joint strength in tension as shown (for flat web sheet piles)]] [hot-rolled, light-duty steel sections conforming to ASTM A572/A572M, Grade [42, [55, [60, [or 65].]]] [cold-formed steel sections formed from hot-rolled steel meeting the chemical and mechanical requirements of [ASTM A328/A328M, ASTM A572/A572M, Grade [_____], Type [_____]] [ASTM A690/A690M]] [cold-formed steel sections conforming to ASTM A577/A577M, Grade [_____]] [extruded aluminum sections fabricated from aluminum conforming to [ASTM B221M ASTM B221,] [ASTM B308/B308M,] Alloy 6061, Temper T6.]

c. For protection of sheet piling, coat it in accordance with Section [09 97 13.26 COATING OF STEEL WATERFRONT STRUCTURES, ZERO VOC, (SZC) SPLASH ZONE COATING] [09 97 02 PAINTING: HYDRAULIC STRUCTURES] [and] [provide cathodic protection in accordance with Section [26 42 13 GALVANIC (SACRIFICIAL) ANODE CATHODIC PROTECTION (GACP) SYSTEM] [26 42 17 IMPRESSED CURRENT CATHODIC PROTECTION (ICCP) SYSTEM] [_____]].

2.1.1 Interlocks

The interlocks of sheet piling must be free-sliding, provide a swing angle suitable for the intended installation but not less than 5 degrees when interlocked, and maintain continuous interlocking when installed.

2.1.2 General Requirements

NOTE: Designers should contact suppliers to verify current availabilities and lead times. Based upon the design requirements for each piling section select the most suitable corresponding section from manufacturer's product specification tables or other commercial sources and place the pertinent section properties of this section on the drawings as minimum requirements.

Z-type sheet pile develop a maximum resistance to bending per unit weight and are particularly adapted to cantilever and anchored type retaining walls.

Straight-Web (S) sections have their interlocks designed for maximum flexibility and tensile
strength and are particularly adapted to cellular retaining walls and cellular cofferdam construction.

Take consideration of which section properties are crucial to the design of the wall. Properties such as section modulus, moment of inertia, and minimum thickness can be listed.

Interlock types for z-type sheet piles, such as larssen or ball and socket, can also be specified if it is crucial to the performance of the design of the wall. Cold formed sheet piles generally have the highest permeability rates with their hook and grip interlocks.

**************************************************************************

Provide sheet piles with minimum section modulus, moment of inertia, shape, and size as specified in the [drawings] [plans] [contract document] [design]. Sheet piling [including special fabricated sections] must be [full-length] sections of the dimensions shown. [Provide fabricated sections conforming to the requirement and the piling manufacturer's recommendations for fabricated sections.] [Fabricated sections connecting cofferdam cells and adjacent arcs composed of pilings from different manufacturers must be Y-sections fabricated from the respective manufacturer's pilings.] [Fabricated tees, wyes and cross pieces must be fabricated of piling sections with a minimum web thickness of 13 mm 1/2 inch.] [Straight web sheet piling to be placed in a circular cell or a connecting arc must be of the same manufacture.] Provide sheet piling with standard lifting holes. Metalwork fabrication for sheet piling must be as specified and in Section 05 50 14 STRUCTURAL METAL FABRICATIONS.

2.2 APPURTENANT METAL MATERIALS

Provide metal plates, shapes, bolts, nuts, rivets and other appurtenant fabrication and installation materials conforming to manufacturer's standards and to the requirements specified in the respective sheet piling standards and in Section 05 50 15 CIVIL WORKS FABRICATIONS.

2.3 TESTS, INSPECTIONS, AND VERIFICATIONS

Requirements for material tests, workmanship and other measures for quality assurance must be as specified and in Section 05 50 14 STRUCTURAL METAL FABRICATIONS. Provide manufacturer's steel plant certificate for Government review and approval.

2.3.1 Materials Tests

Submit certified materials tests reports showing that sheet piling and appurtenant metal materials meet the specified requirements, for each shipment and identified with specific lots prior to installing materials. Material test reports must meet the requirements of ASTM A6/A6M. Perform materials tests conforming to the following requirements. Sheet piling and appurtenant materials must be tested and certified by the manufacturer to meet the specified chemical, mechanical and section property requirements prior to delivery to the site. Testing of sheet piling for mechanical properties must be performed after the completion of all rolling and forming operations. Testing of sheet piling must meet the requirements of ASTM A6/A6M.
2.3.2 Interlocked Joint Strength in Tension Test

**************************************************************************
NOTE: This is for straight web sheet pile only.
This is not be included for z-type sheet pile.
**************************************************************************

Submit the procedure for testing sheet piling interlocked joint strength in tension, prior to testing piling. [The interlocked joint strength in tension test must conform to the piling manufacturer's standard test, include testing at least two 75 mm 3 inch long coupons taken randomly from different as-produced pilings of each heat and must be approved.] Submit a certified report showing results based on approved testing procedures.

2.4 PILE DRIVING EQUIPMENT

Submit complete descriptions of sheet piling driving equipment including hammers, [jetting equipment,] extractors, protection caps and other installation appurtenances, prior to commencement of work. Descriptive information includes manufacturer's name, model numbers, capacity, rated energy, hammer details, cushion material, helmet, and templates. Provide pile driving equipment conforming to the following requirements. Submit descriptions of pile driving equipment, including hammers, power packs, driving helmets, hammer cushions, pile cushions, leads, extractors, jetting equipment, and preboring equipment at least 30 days prior to commencement of work.

2.4.1 Driving Hammers

**************************************************************************
NOTE: Insert desired energy ratings in this paragraph. Hammers with energy ratings between 11,860 and 21,700 J 8,750 and 16,000 foot pounds are recommended.
**************************************************************************

Hammers must be steam, air, or diesel drop, single-acting, double-acting, differential-acting[, or vibratory][or press-in] type. The driving energy of the hammers must be between [_____] and [_____] J foot-pounds as recommended by the manufacturer for the piling weights and subsurface materials to be encountered. Repair damage to piling caused by use of a pile hammer with excess delivered force or energy.

2.4.2 Jetting Equipment

Jetting [may be used at no additional cost to the Government] [will not be permitted]. [Jetting equipment must have not less than two removable or fixed jets of the water or combination air-water type. Water jets must be designed so that the discharge volume and pressure are sufficient to freely erode the material under and adjacent to the piling.]

PART 3 EXECUTION

3.1 PRELIMINARY WORK

3.1.1 Pile Length Markings

Mark each pile prior to driving with horizontal lines at 305 mm one foot intervals. Mark the interval number on pile every 1.52 m 5 feet from pile
3.2 EARTHWORK

Perform in accordance with Section 31 00 00 EARTHWORK. Pre-excavation [will] [will not] [be permitted.] [permitted to a maximum depth [of [_____] meters feet] below [_____] [as indicated]]. Backfill as indicated.

3.3 INSTALLATION

3.3.1 Placing and Driving

3.3.1.1 Placing

**************************************************************************
NOTE: When long piles are being driven, templates are of value. Long piles are very flexible and damage easily. Use templates to keep piles vertical.
**************************************************************************

Submit a written description of the site specific pile installation procedures for Government review and approval. Pile placement installation drawings and details must also be provided.

Any excavation required within the area where sheet pilings are to be installed must be completed prior to placing sheet pilings. Pilings properly placed and driven must be interlocked throughout their length with adjacent pilings to form a continuous diaphragm throughout the length or run of piling wall.

[a. Pilings to be placed in cofferdam cells and connecting arcs must be picked up and completely threaded to demonstrate that they slide freely in interlock.]

[a.][b.] Pilings must be carefully located as [indicated] [or directed.] Pilings must be placed plumb with out-of-plumbness not exceeding [10] [22] mm per meter [1/8] [1/4] inch per foot of length and true to line. Place the pile so the face will not be more than 150 mm 6 inches from vertical alignment at any point. Top of pile at elevation of cut-off must be within 13 mm 1/2 inch horizontally and 50 mm 2 inches vertically of the location indicated. Manipulation of piles to force them into position will not be permitted. Check all piles for heave. Re-drive all heaved piles to the required tip elevation.

[b.][c.] Provide temporary wales, templates, [master pilings] [current deflectors] or guide structures to ensure that the pilings are placed and driven to the correct alignment. Use a system of structural framing sufficiently rigid to resist lateral and driving forces and to adequately support the sheet piling until design tip elevation is achieved. Use two templates, at least, when placing each piling [at third points] [not less than 6 m 20 feet apart]. Templates must not move when supporting sheet piling. Fit templates with wood blocking to bear against the web of each alternate sheet pile and hold the sheet pile at the design location alignment. Provide outer template straps or other restraints as necessary to prevent the sheets from warping or wandering from the alignment. Mark template for the location of the leading edge of each alternate sheet pile. If in view, also mark the second level to assure that the piles are vertical and in position. If
two guide marks cannot be seen, other means must be used to keep the sheet pile vertical along its leading edge.

[c.] [d.] Master pilings must be used to maintain plumbness and proper configuration in placing cofferdam cells over 27 m 90 feet in height in water flowing at a velocity of more than 1.2 m/s 4 feet per second.

3.3.1.2 Driving

**************************************************************************

NOTE: When hard driving or driving through rocky soil or debris is anticipated, require addition of tip protection to prevent damage to sheet piling.

Jetting should generally not be permitted for:

1. Piles dependent on side friction in fine-grained low permeability soils (high clay or silt content) where considerable time is required for the soil to reconsolidate around the piles.

2. Piles subject to uplift.

3. Piles adjacent to existing structures.

4. Piles in closely spaced clusters unless the load capacity is confirmed by tests and unless all jetting is done before final driving of any pile in the cluster.

Pre-augering or spudding should generally not be permitted for piles dependent on side friction in fine-grained, low permeability soils (high clay or silt content) where considerable time is required for the soil to reconsolidate around the piles.

The press-in pile driving method can be used for reduction of noise and/or vibration associated with sheet pile driving; however, site and soil conditions will need to be considered.

**************************************************************************

Submit records of the completed sheet piling driving operations, including a system of identification which shows the disposition of approved piling in the work, driving equipment performance data, piling penetration rate data, piling dimensions and top and bottom elevations of installed piling. [The format for driving records must be as directed.] [Prior to driving pilings in water, paint a horizontal line on both sides of each piling at a fixed distance from the bottom so that it will be visible above the water line after installation. This line must indicate the profile of the bottom elevation of installed pilings and potential problem areas can be identified by abrupt changes in its elevation.] Drive pilings with the proper size hammer and by approved methods so as not to subject the pilings to damage and to ensure proper interlocking throughout their lengths.

a. Maintain driving hammers in proper alignment during driving operations by use of leads or guides attached to the hammer. [Caution must be taken in the sustained use of vibratory hammers when a hard driving condition is encountered to avoid interlock-melt or damages.
Discontinue the use of vibratory hammers and impact hammers employed when the penetration rate due to vibratory loading is 300 mm one foot or less per minute.}

b. Employ a protecting cap in driving when using impact hammers to prevent damage to the tops of pilings. [Use cast steel shoe to prevent damage to the tip of the sheet piling. Submit pile shoe installation details and material data for Government review and approval prior to use in the field.] Remove and replace pilings damaged during driving or driven out of interlock at the Contractor's expense. [Store Government furnished pilings, damaged during driving, at the site as directed.]

c. Drive pilings without the aid of a water jet [unless otherwise authorized]. [Perform authorized jetting on both sides of the pilings simultaneously; discontinue it when the pile tip is approximately 1.5 m 5 feet above the ["calculated"] [indicated] pile tip elevation and make the final 1.5 m 5 feet of penetration by driving. Before commencing the driving of the final 1.5 m 5 feet, firmly seat the pile in place by the application of a number of reduced energy hammer blows.]

d. Take adequate precautions to ensure that pilings are driven plumb. Where possible, drive Z-pile with the ball end leading. If an open socket is leading, a bolt or similar object placed in the bottom of the interlock will minimize packing material into it and ease driving for the next sheet. If at any time the forward or leading edge of the piling wall is found to be out-of-plumb in the plane of the wall the piling being driven must be driven to the required depth and tapered pilings must be provided and driven to interlock with the out-of-plumb leading edge or other approved corrective measures must be taken to insure the plumbness of succeeding pilings. The maximum permissible taper for any tapered piling must be 10 mm per meter 1/8 inch per foot of length.

e. Pilings in each run or continuous length of piling wall must be driven alternately in increments of depth to the required depth or elevation. No piling will be driven to a lower elevation than those behind it in the same run except when the pilings behind it cannot be driven deeper. Incrementally sequence driving of individual piles such that the tip of any sheet pile must not be more than 1.2 m 4 feet below that of any adjacent sheet pile. When the penetration resistance exceeds five blows per 25 mm inch, the tip of any sheet pile must not be more than 0.6 m 2 feet below any adjacent sheet pile. [For cofferdam cells the driving increments must be such that no piling leads the adjacent piling by more than [_____] mm feet and the direction of advancing the driving hammer must be reversed after each pass around the cell.] If the piling next to the one being driven tends to follow below final elevation it may be pinned to the next adjacent piling.

f. If obstructions restrict driving a piling to the specified penetration, the obstructions must be removed or penetrated with a chisel beam. If the Contractor demonstrates that removal or penetration is impractical, make changes in the design alignment of the piling structure as directed to ensure the adequacy and stability of the structure. Pilings must be driven to depths shown and must extend up to the elevation indicated for the top of pilings. [Piling driven to rock must be seated individually on the rock.] A tolerance of [_____] mm inches above the indicated top elevation will be permitted. [At least the first two sheets of the connecting arcs adjacent to the main cells must be driven in the cofferdam cells prior to filling the cells.]
Pilings must not be driven within 30 m 100 feet of concrete less than 7 days old.

g. Pre-augering or spudding of piles [may be used at no additional cost to the Government] [will not be permitted]. [Discontinue pre-augering or spudding approximately [_____] meters feet above the [calculated] [indicated] pile tip elevation. Drive the pile the final [_____] meters feet of penetration].

3.3.2 Cutting-Off and Splicing

Pilings driven to refusal or to the point where additional penetration cannot be attained and are extending above the required top elevation in excess of the specified tolerance must be cut off to the required elevation. Pilings driven below the required top elevation and pilings damaged by driving and cut off to permit further driving must be extended as required to reach the top elevation by splicing when directed at no additional cost to the Government. Submit procedure for insufficient pile length. Provide pile splicing information and details for Government review and approval prior to installation in the field. [If directed, pilings must be spliced as required to drive them to depths greater than shown and extend them up to the required top elevation.]

a. Pilings adjoining spliced pilings must be full length unless otherwise approved. [If splices are allowed in adjoining pilings, the splices must be spaced at least [_____] m feet apart in elevation.] Splicing of pilings must be as indicated. Ends of pilings to be spliced must be squared before splicing to eliminate dips or camber. Pilings must be spliced together with concentric alignment of the interlocks so that there are no discontinuities, dips or camber at the abutting interlocks. Spliced pilings must be free sliding and able to obtain the maximum swing with contiguous pilings. Welding of splices must conform to the requirements of Section 05 50 14 STRUCTURAL METAL FABRICATIONS. Shop and field welding, qualification of welding procedures, welders, and welding operators must be in accordance with AWS D1.1/D1.1M. Submit welding certifications for all welders and welding operators for Government review and approval.

b. The tops of pilings excessively battered during driving must be trimmed when directed, at no cost to the Government. Piling cut-offs [except for Government furnished pilings] will become the property of the Contractor and must be removed from the site.

c. Cut holes in pilings for bolts, rods, drains or utilities in a neat and workmanlike manner, as shown or as directed. Use a straight edge in cuts made by burning to avoid abrupt nicks. Bolt holes in steel piling must be drilled or may be burned and reamed by approved methods which will not damage the surrounding metal. [Bolt holes in aluminum pilings must be drilled.] Holes other than bolt holes must be reasonably smooth and the proper size for rods and other items to be inserted. [All holes in steel pilings on the wet side of cofferdams must be made watertight by welding steel plates over the holes after the piling installation is completed.] Do not use explosives for cutting.

3.3.3 Inspection of Driven Piling

Perform continuous inspection during pile driving. Inspect all piles for compliance with tolerance requirements. Bring any unusual problems which may occur to the attention of the Contracting Officer. Inspect the
interlocked joints of driven pilings extending above ground. Pilings found to be out of interlock must be removed and replaced at the Contractor's expense. [Use divers to inspect underwater interlocked joints of cofferdam sheet piling. Government divers may also inspect the interlocked joints. The inspection of cofferdams must be performed after driving is completed, prior to filling each cell and connecting arc, and within 48 hours after filling each cell and arc.]

3.3.4 Pulling and Redriving

Submit the proposed method of pulling sheet piling, prior to pulling any piling. Pull, as directed, selected pilings after driving to determine the condition of the underground portions of pilings. Any piling so pulled and found to be damaged, to the extent that its usefulness in the structure is impaired, must be removed and replaced at the Contractor's expense. Pilings pulled and found to be in satisfactory condition must be redriven when directed. [Government furnished pilings pulled and not redriven must be stored as directed.]

[3.3.5 Testing Agency Qualifications]

Engage an independent testing agency qualified according to ASTM C1077 and ASTM E329 for testing indicated, as documented according to ASTM E548, and approved by the Contracting Officer.

3.3.6 Survey Data

After the driving of each pile group is complete and before superimposed concrete is placed, provide the Contracting Officer with an as-driven survey showing actual location and top elevation of each pile. Submit an as-driven survey showing actual location and top elevation of each [production pile] [test pile] within [7][_____] calendar days of completing the pile installation. Do not proceed with placing concrete until the Contracting Officer has reviewed the survey and verified the safe load for the pile group driven. Present a survey in such form that it gives deviation from plan location in two perpendicular directions and elevations of each pile to nearest 13 mm half inch. Survey must be prepared and certified by a land surveyor licensed in [____].

3.4 DRAINAGE

**************************************************************************
NOTE: Include this paragraph in cases where sheet pile walls are not designed to retain saturated soils and drainage behind the sheet pile wall is required.
**************************************************************************

Backfill material behind the sheet piling must be free draining and in accordance with Section 31 00 00 EARTHWORK.[ Install drainage system and weep holes as shown in the [contract documents] [plans].]

3.5 ANCHORS

**************************************************************************
NOTE: Include this paragraph only when tiebacks (anchors) are required to support sheet pile wall.
**************************************************************************
Conform to Section 31 68 13 SOIL AND ROCK ANCHORS.

3.6 REMOVAL

The removal of sheet pilings must consist of pulling, sorting, cleaning the interlocks, inventorying and storing previously installed sheet pilings as shown and directed.

3.6.1 Pulling

The method of pulling piling must be approved. Provide pulling holes in pilings, as required. Extractors must be of suitable type and size. Exercise care during pulling of pilings to avoid damaging piling interlocks and adjacent construction. If the Contracting Officer determines that adjacent permanent construction has been damaged during pulling, the Contractor will be required to repair this construction at no cost to the Government. Pull pilings one sheet at a time. Pilings fused together must be separated prior to pulling, unless the Contractor demonstrates, to the satisfaction of the Contracting Officer, that the pilings cannot be separated. The Contractor will not be paid for the removal of pilings damaged beyond structural use due to proper care not being exercised during pulling.

3.6.2 Sorting, Cleaning, Inventorying and Storing

Pulled pilings must be sorted, cleaned, inventoried and stored by type into groups as:

a. Piling usable without reconditioning.
b. Piling requiring reconditioning.
c. Piling damaged beyond structural use.

3.7 INSTALLATION RECORDS

Maintain a pile driving record for each sheet pile driven. Indicate on the installation record: installation dates and times, type and size of hammer, rate of operation, total driving time, dimensions of driving helmet and cap used, blows required per meter foot for each meter foot of penetration, final driving resistance in blows for final 150 mm 6 inches, pile locations, tip elevations, ground elevations, cut-off elevations, and any reheading or cutting of piles. Record any unusual pile driving problems during driving. Submit complete records to the Contracting Officer.

3.8 VIBRATION CONTROL

**************************************************************************
NOTE: Include this paragraph when vibration monitoring is required. Add any additional criteria or requirements as necessary to the particular project.
**************************************************************************

Perform vibration monitoring at the locations [shown in the plan] [decided by the Contracting Officer] during the pile driving operations. Perform vibration monitoring [using] [seismographs] [and geophones] within a distance of 61 meters 200 feet from the pile driving activity. [Engage the services of a qualified, independent vibration consultant, acceptable to
the Government, to conduct the vibration monitoring. The vibration consultant must have minimum of [five] years of experience in vibration monitoring. A minimum of [28] days before the installation of vibration monitors, submit to the Government the name of the vibration consultant and a list of at least [three] previously completed projects of similar scope and purpose.

Prior to the pile driving activities, obtain baseline readings of ambient vibrations. The vibration during the pile driving activities must be limited to [a peak particle velocity of not more than 5 cm 2 inches per second] [the limits mentioned in the [contract documents]]. [Determine appropriate vibration limits as per [US Bureau of Mines] [American Association of State Highway and Transportation Officials (AASHTO)] guidelines. ]During pile driving activities, monitor the vibrations to ensure the limits are not exceeded. If the limits are exceeded, cease the pile driving activity causing the vibration until [the Vibration consultant and the Contracting Officer] are on site to observe the structures nearest to the vibration monitor which has exceeded the limits.

The Contractor must be responsible for all damages resulting from the pile driving operations and must take whatever measures necessary to maintain peak particle velocity within the specified limit. After completion of the project, remove the vibration monitors off the site and off Government property and restore the monitoring locations back to their original condition.

] [3.9 NOISE CONTROL

**************************************************************************

NOTE: Include this paragraph when noise monitoring is required. Add any additional criteria, references or requirements as necessary to the particular project.
**************************************************************************

Perform noise monitoring at the locations [shown in the plan] [decided by the Contracting Officer] [at noise sensitive public areas] during the pile driving operations. [Perform noise monitoring using [noise meters][, and][______]]. [Engage the services of a qualified, independent noise consultant, accept able to the Government, to conduct the noise monitoring. The noise consultant must have minimum of [five] years of experience in noise monitoring. A minimum of [28] days before the installation of noise monitors, submit to the Government the name of the noise consultant and a list of at least [three] previously completed projects of similar scope and purpose.]

Prior to the pile driving activities, obtain baseline readings of ambient noise levels. [The noise limits are mentioned in the [plan] [contract documents]]. [Determine appropriate noise limits as per [local agency] [Occupation Safety and Health Administration] guidelines]. During pile driving activities, monitor the noise to ensure the limits are not exceeded. If the limits are exceeded, cease the pile driving activity and install noise mitigation measures.

The Contractor must be responsible for all damages resulting from the pile driving operations and must take whatever measures necessary to maintain noise within the specified limit. After completion of the project, remove the noise monitors off the site and off Government property and restore the monitoring locations back to their original condition.
[3.10  PRECONSTRUCTION CONDITION SURVEY

**************************************************************************
NOTE: Add any additional criteria, references or requirements as necessary to the particular project.
**************************************************************************

Perform preconstruction condition survey of [structures] [and utilities] [within 61 meters 200 feet of the pile driving activity] [specified in the plans] [decided by the Contracting Officer]. Perform outreach to the owner of the structures [28] days before performing the preconstruction condition survey. The Contractor must obtain written permission from the owner of the structure prior to accessing the structure. The preconstruction condition survey must include video and photographic documentation of the exterior and interior of above ground structures and of the interior of underground structures. Video documentation must be in high definition, and show existing conditions and highlight, where possible, existing cracks, deteriorated concrete, exposed and corroded reinforcement, cracked or broken brick or mortar, and other signs of distress. For utilities, perform the survey when the greatest extent of the interior is exposed. Provide supplementary artificial lighting as needed. The video must include annotation with location and structure nomenclature which describes any areas of distress over the video and time code superimposed on the video. Photographs must be accompanied by sketches or descriptions that indicate the location and direction of each photograph. For each structure surveyed, provide a Pre-Construction Condition Survey Report following completion of the survey. The report must contain all documentation associated with the survey including DVD copies. In the report, include notes, sketches, photographs, and videos. Provide general information, such as location details and structure type, as well as particular information on materials, condition, existing damage, aperture and persistence of cracks, and disrepair observed during visual survey. Provide a graphical depiction of locations of damage or other features of concern. Submit the Preconstruction Condition Survey Reports no later than [28] days before the commencement of pile driving activity. Accept responsibility for damages to existing adjacent or adjoining structures created by pile driving work, and repair any damages to these structures without cost to the Government.

[3.11 CONSTRUCTION INSTRUMENTATION AND MONITORING PROGRAM

**************************************************************************
NOTE: Include this section if instrumentation is to be installed due to concerns about vibration, settlement, lateral movement, etc. during pile driving activities. Instrumentation should be specified and included in the specification. This section can be deleted if there are no instrumentation requirements. Add any additional criteria or requirements as necessary for the particular project.
**************************************************************************

Prepare a geotechnical instrumentation program to monitor settlement [and lateral movement] of temporary and permanent structures, utilities, [embankments] [and excavations] during pile driving. The design and distribution of instrumentation must demonstrate an understanding of the need, purpose and application of each proposed type.[ Perform noise and
vibration monitoring in accordance with NOISE CONTROL and VIBRATION CONTROL
sections.)

Monitoring must extend before, during and for a period after completion of
construction activities related to pile driving when long-term performance
issues are a concern. The monitoring plan must be designed to protect
adjacent structures and utilities against damage due to the pile driving
activities. Establish limiting values of vertical [and horizontal]
movement [and angular distortion] [and vibration] for each structure and
utility within the zone of influence, subject to review by the Government.

Prepare a report detailing the proposed program of instrumentation and
monitoring, establishing threshold values of monitored parameters, and
describing the response plans that will be implemented when threshold
parameters are exceeded. The report must include details about
instrumentation consultant's experience, appropriate types, quantities,
locations and monitoring frequencies of the instruments.

Upon acceptance of the instrumentation and monitoring program, provide,
install and monitor the instrumentation and interpret the data. Submit
instrumentation data reports not less than every [_____] days after the
monitoring program has begun. Take corrective actions, as necessary, based
on the field instrumentation data and as defined in the instrumentation and
monitoring program.

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for drilling exploratory holes; drilling drain holes; drilling, washing and pressure testing grout holes; making grout connections; furnishing, handling, transporting, storing, mixing and injecting the grouting materials; patching the finished grout holes; care and disposal of drill cuttings, waste water and waste grout; clean-up grout galleries and shafts and areas upon completion of the work and all such other operations as are incidental to the drilling and the grouting. This section was originally developed for USACE Civil Works projects.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1 GENERAL

NOTE: This guide specification has been prepared as a section in a general construction specification for concrete dams. By rewording as necessary, this specification may be adapted to other types of
foundation treatment, such as under power plants, locks, cutoff trenches, tunnels, and others.

Methods for listing subdivided items are described in Paragraph 52.2/9109(g) "Variations in Estimated Quantities - Subdivided Items" of Engineer Federal Acquisition Regulation Supplement (EFARS). However, effectiveness of the use of subdivided items in grouting has been questioned as being more hazardous than helpful and that FAR 52.211-16 Variation in Quantity should be used.

Provisions are made for the use of a sanded grout but should generally be limited to those formations where quantities in excess of one cubic foot of grout per linear foot of hole are anticipated. The information contained in EM 1110-2-3506, "Grouting Technology" and EM 1110-2-1302, "Cost Estimates - Government Estimate of Fair and Reasonable Cost to Contractor" should be used as a guide in estimating quantities.

Computer Application of Geotechnical Engineering (CAGE):

a. The CAGE Grouting Task Group has developed a microcomputer program for documentation of grouting operations and graphics for rapid display of data for better field control. Some of the highlights of the program include optional data entry by a laptop or hand held computer in the field, technical review and quality control, preparation of Contractors pay schedules, and preparation of foundation reports. The User's Guide "Microcomputer Grouting Data Package (Multiple Zone and Stage Version for PC and Hand Held Computer)" is available from the U.S. Army Engineer Waterways Experiment Station (USACE-WES-GL). Use of this CAGE package will not require contractual or technical additions to the contract specifications unless the computer equipment, other facilities, or personnel for data entry are to be Contractor supplied. In such case the proper provisions should be included. This program is also an attractive tool for use in grouting operations by Corps of Engineers personnel. Use of this program should be strongly considered for any grouting operation.

b. Computer-aided control and monitoring of the grout injection has recently been used by the U.S. Bureau of Reclamation (USBR) on several of their projects. Their system is appropriate for use on large grouting projects. Use of their system will necessitate certain contractual and technical additions to the specifications which are not included in this guide specification. If interested in this type system for a large grout program more information can be obtained by contacting the CAGE grout task group and the USBR.
Chemical or other specialty grouting applications have not been specifically addressed in this guide specification as most of the CE grouting in rock foundations for concrete structures, cutoff trenches, locks and powerhouses use cement grout. However, the specification may be used as a general outline for chemical or other specialty grouting applications by insertion of the proper equipment, materials, and procedures in the appropriate paragraphs and by modification and deletion of other paragraphs. Engineer Manuals 1110-2-3504, "Chemical Grouting", and 1110-2-3506, "Grouting Technology", should be used as guides when the use of chemical grouts and other specialty grouting applications are being considered. The manufacturer of those systems that meet the potential job requirements should be contacted for verification. Also, consideration should be given to conducting laboratory and field tests and evaluations of the system or systems being considered for a given applications. There may be occasions when the engagement of a consultant would be appropriate and advantageous to assist in the planning, selecting, and evaluating of a system under consideration. Engineer Manual 1110-2-2901, "Tunnels and Shafts in Rock", should be referred to when planning tunnel grouting and the guide specification for Tunnel and Shaft Grouting should be used in the preparation of project specifications.

If grouting is anticipated during extreme temperatures, alteration of certain field procedures may be necessary and should be included in the specifications. Generally, for cold weather grouting, the grout should be maintained at temperatures above 10 degrees C, 50 degrees F until injected, and storage of the grouting materials should be at temperatures above freezing. Temperature controls for grouting surface rocks should be specified based on specific site conditions anticipated. Insulation, heated enclosures, water heaters or other equipment or procedures may be required. Grouting in extremely hot weather may also require extra precautions.

1.1 SUMMARY

**********************************************************************************************

NOTE: If no separate section on "CONCRETE" is used, the appropriate paragraphs applicable to sampling and testing in SECTION 03 70 00 MASS CONCRETE should be inserted in the following paragraphs in lieu of the section reference given below. If a "CONCRETE" section, other than SECTION 03 70 00 MASS CONCRETE is used, the Designer should ensure that the applicable sampling and testing is included in that section.

**********************************************************************************************
a. This section covers drilling exploratory holes; drilling drain holes; drilling, washing and pressure testing grout holes; making grout connections; furnishing, handling, transporting, storing, mixing and injecting the grouting materials; backfilling holes; patching the finished grout holes; care and disposal of drill cuttings, waste water and waste grout; clean up of [grout galleries and shafts][the areas] upon completion of the work and all other such operations as are incidental to the drilling and grouting. The work contemplated consists of [constructing a grout curtain and a drainage curtain][area grouting], the approximate locations, limits, and details which are indicated. Perform Government preconstruction sampling and testing as specified below:

b. Perform sampling and testing of sand, cementitious materials, and admixtures in accordance with Section [03 70 00 MASS CONCRETE][03 30 00 CAST-IN-PLACE CONCRETE].

c. Perform sampling and testing of grout materials in accordance with Section [03 70 00 MASS CONCRETE][03 30 00 CAST-IN-PLACE CONCRETE].

1.2 UNIT PRICES

******************************************************************************
NOTE: If Section 01 20 00 PRICE AND PAYMENT PROCEDURES is included in the project specifications, this paragraph title (UNIT PRICES) should be deleted from this section and the remaining appropriately edited subparagraphs below should be inserted into Section 01 20 00.
******************************************************************************

1.2.1 Mobilization and Demobilization

1.2.1.1 Payment

Payment will be made for costs for assembling all plant and equipment at the site, preparatory to initiating the work and for removing it therefrom when the drilling and grouting program has been completed. Sixty (60) percent of the contract lump sum price for mobilization and demobilization will be paid following completion of moving onto the site, including complete assembly, in working order, of all equipment necessary to perform the required drilling and grouting operations. The remaining forty (40) percent of the contract lump sum price will be paid when all equipment has been removed from the site.

1.2.1.2 Unit of Measure

Unit of measure: lump sum.

1.2.2 Drilling Grout Holes

******************************************************************************
NOTE: Delete the bracketed phrase if pay item "Pressure Washing and Pressure Testing" is retained as a pay item.
******************************************************************************
1.2.2.1 Payment

Payment will be made for costs associated with drilling and redrilling grout holes; [washing and pressure testing of grout holes; ] care and disposal of waste water and waste grout; clean-up of the site; furnishing, handling, transporting and storing of grout materials; and for furnishing all labor and supplies incidental to the work. This price is subject to the cost limitation imposed by[ Section 31 43 13.13 CONCRETE PRESSURE GROUTING,] paragraph PIPE FOR FOUNDATION GROUTING AND DRAINAGE, but only in those locations where pipe is specified. No payment will be made for grout, or the material constituents thereof, wasted due to improper anchorage of grout pipe or connections, or which is wasted due to negligence on the part of the Contractor, nor for grout which is rejected by the Contracting Officer because of improper mixing. Payment will be made at the applicable contract unit prices for materials contained in grout which are wasted, where the wasting is not due to negligence on the part of the Contractor.

1.2.2.2 Measurement

Drilling of grout holes will be measured for payment on the basis of the linear feet of holes actually drilled in concrete or rock, as shown or as directed, including all intermediate holes at locations where pipe was not installed.

1.2.2.3 Unit of Measure

Unit of measure: linear meter foot.

1.2.3 Drilling Drain Holes

1.2.3.1 Payment

Payment will be made for costs associated with drilling of drain holes actually drilled in concrete or rock, as shown or as directed. This price is subject to the cost limitation imposed by[ Section 31 43 13.13 CONCRETE PRESSURE GROUTING,] paragraph PIPE FOR FOUNDATION GROUTING AND DRAINAGE.

1.2.3.2 Measurement

Drilling of drain holes will be measured for payment on the basis of the linear meter feet of holes actually drilled in concrete or rock, as shown or as directed.

1.2.3.3 Unit of Measure

Unit of measure: linear meter foot.

1.2.4 Drilling Exploratory Holes

******************************************************************************************************************************************
NOTE: If a portion of exploratory drilling is to be done through overburden, a separate pay item should be included for this portion.
******************************************************************************************************************************************

1.2.4.1 Payment

Payment will be made for costs associated with drilling of exploratory
holes.

1.2.4.2 Measurement

Drilling of exploratory holes will be measured for payment on the basis of the linear meters feet of holes actually drilled in concrete or rock, as directed by the Contracting Officer.

1.2.4.3 Unit of Measure

Unit of measure: linear meter foot.

[1.2.5 Pressure Washing and Pressure Testing

[1.2.5.1 Payment

Payment will be made for pressure washing and pressure testing of grout holes, which includes the cost of making and breaking connections incidental to the work. Payment will be based upon the total amount of time required for pressure washing and pressure testing, determined by reducing the total number of minutes of operation to the nearest whole hour. No payment will be made for time lost due to fault or negligence of the Contractor, or due to defective equipment furnished by the Contractor. Time will be measured cumulatively to the next whole minute of operations.

[1.2.5.2 Measurement

Pressure washing and pressure testing will be measured for payment on the basis of the actual time water pumps are operating. Pressure washing and pressure testing will be measured from the time pumping is begun on a hole or section of a hole until the time pumping is completed on the hole or section of the hole as determined by the Contracting Officer. Operation time will be determined by rounding 30 or more minutes of operation up to the nearest whole hour, and rounding 29 or less minutes of operation down to the nearest whole hour. Fractional time will be measured cumulatively to the next whole minute of operation.

[1.2.5.3 Unit of Measure

Unit of measure: nearest whole hour.

[1.2.6 Steel Pipe and Fittings

1.2.6.1 Payment

Payment will be made for costs associated with grout and drain hole pipe and fittings remaining in the permanent work.

1.2.6.2 Measurement

Pipe and fittings will be measured for payment on the basis of the actual weight of satisfactorily installed pipe and fittings left in place as shown. No additional allowance will be made because of differences in pipe size or length, or the number of pipes required.

1.2.6.3 Unit of Measure

Unit of measure: kilogram pound.
1.2.7 Portland Cement in Grout

1.2.7.1 Payment

Payment will be made for costs associated with Portland cement in grout.

1.2.7.2 Measurement

Portland cement in grout will be measured for payment on the basis of the number of cubic meters (42.6 kilograms) feet (94 pounds) of cement used in the grout satisfactorily placed in grout holes and in exploratory holes, or wasted when such wasting is not due to the Contractor's negligence.

1.2.7.3 Unit of Measure

Unit of measure: cubic meter (42.6 kilograms) foot (94 pounds).

1.2.8 Pozzolans (Fly Ash) in Grout

1.2.8.1 Payment

Payment will be made for costs associated with fly ash in grout.

1.2.8.2 Measurement

Fly ash in grout will be measured for payment on the basis of the number of cubic meters (33.6 kilograms) feet (74 pounds) of fly ash used in the grout satisfactorily placed in grout holes.

1.2.8.3 Unit of Measure

Unit of measure: cubic meter foot.

1.2.9 Sand in Grout

1.2.9.1 Payment

Payment will be made for costs associated with sand in grout.

1.2.9.2 Measurement

Sand in grout will be measured for payment on the basis of the number of cubic meters feet of sand[,] dry rodded measurement[,] used in the grout satisfactorily placed in grout holes or in exploratory holes.

1.2.9.3 Unit of Measure

Unit of measure: cubic meter foot.

1.2.10 Fluidifier in Grout

1.2.10.1 Payment

Payment will be made for costs associated with fluidifier in grout, including full allowance for the payment by the Contractor of all required royalties.
1.2.10.2 Measurement

Fluidifier in grout will be measured for payment on the basis of the number of kilograms pounds of fluidifier used in the grout satisfactorily placed in grout holes.

1.2.10.3 Unit of Measure

Unit of measure: kilogram pound.

1.2.11 Bentonite in Grout

1.2.11.1 Payment

Payment will be made for costs associated with bentonite in grout.

1.2.11.2 Measurement

Bentonite in grout will be measured for payment on the basis of the number of kilograms pounds of bentonite actually used in grout mixtures satisfactorily placed in grout holes.

1.2.11.3 Unit of Measure

Unit of measure: kilogram pound.

1.2.12 Placing Grout

******************************************************************************************
NOTES: Select appropriate Alternative.

Under certain conditions it may be desirable to include a pay item for standby time for Government directed suspension of drilling or grouting operations.
******************************************************************************************

1.2.12.1 Payment

Payment will be made for costs associated with satisfactorily placing grout in grout holes[, which includes full compensation for proportioning the mix as directed and mixing and injecting the grout as specified[ in Section 31 43 13.13 CONCRETE PRESSURE GROUTING]. Separate payment will be made for all materials used in grout as provided in unit price pay item(s) "Portland Cement in Grout", "Pozzolans (Fly Ash) in Grout", "Sand in Grout", "Fluidifier in Grout", and "Bentonite in Grout"][]. No payment will be made for time lost due to fault or negligence of the Contractor or due to defective equipment furnished by the Contractor.]

1.2.12.2 Measurement

Placing grout will be measured for payment on the basis of [the number of cubic meters feet of materials, satisfactorily placed, exclusive of water [and fluidifier] and regardless of the proportions of the mixes, measured individually as specified in unit price pay items "Portland Cement in Grout", "Pozzolans (Fly Ash) in Grout", and "Sand in Grout".][the actual time grout pumps begin pumping on a hole or portion of hole and continuing until the time pumping is completed on that hole or portion of hole, as determined by the Contracting Officer. Time for satisfactory placement of
grout will be determined by rounding 30 or more minutes of placement time up to nearest whole hour, and rounding 29 or less minutes of placement time down to the nearest whole hour. Fractional placement time will be measured cumulatively to the next whole minute of operation.

1.2.12.3 Unit of Measure

Unit of measure: [cubic meter foot.] [nearest whole hour.]

1.2.13 Connections to Grout Holes

**************************************************************************
NOTE: The price to be inserted in this paragraph should be determined on the basis of the estimated cost to the Contractor for the operation of moving the grout supply line onto the hole. This price should not include any allowance for pipe or other materials used in making the connections. This unit price pay item may be optional for grout payment on an hourly basis.
**************************************************************************

1.2.13.1 Payment

[Payment will be made for costs associated with connections to grout holes at a rate of [_____] dollars per connection. Where stop grouting method is used [payment for at least one connection will be made for each packer setting in a hole].][Payment for only one connection will be made for each hole regardless of the number of settings.]

1.2.13.2 Measurement

Connections to grout holes will be measured for payment per connection for each time the grout supply line is connected to a grout hole for the purpose of injecting grout regardless of the number of times connections are made per hole or the amount of grout actually injected.

1.2.13.3 Unit of Measure

Unit of measure: each.

1.3 REFERENCES

**************************************************************************
NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically
The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

**AMERICAN SOCIETY OF MECHANICAL ENGINEERS (ASME)**

**ASME B16.3** (2021) Malleable Iron Threaded Fittings, Classes 150 and 300

**ASTM INTERNATIONAL (ASTM)**

**ASTM C618** (2019) Standard Specification for Coal Fly Ash and Raw or Calcined Natural Pozzolan for Use in Concrete

**ASTM C937** (2016) Grout Fluidifier for Preplaced-Aggregate Concrete

**U.S. ARMY CORPS OF ENGINEERS (USACE)**

**COE CRD-C 100** (1975) Method of Sampling Concrete Aggregate and Aggregate Sources, and Selection of Material for Testing

### 1.4 DEFINITIONS

#### 1.4.1 Zone

A zone is a predetermined partial depth of curtain. The first zone extends [_____] m feet downward from [the contact between the concrete and the rock] [the bottom of the cutoff trench] [overburden and the top of rock] overburden and elevation [_____] . The second zone extends [_____] m feet downward from the bottom of the first zone. The third zone extends [_____] m feet downward from the bottom of the second zone. [Define additional zones as needed]. All grouting in a given zone and section shall be finished before work is started in the next [higher] [lower] zone.
1.4.2 Section

A section is a reach along the grout curtain, not more than [_____] feet in length in which grouting operations will not be permitted at the same time that drilling is in progress. Insofar as practicable, the grout curtain will be subdivided into sections in a manner which will facilitate the Contractor's operations.

1.4.3 Stage

A stage is one complete operational cycle of drilling, cleaning, pressure washing, pressure testing, pressure grouting, and grout cleanout within a zone. The actual depth of a stage depends upon geologic conditions encountered in drilling. It may vary from a fraction to the full depth of the zone, and is marked by the loss or gain of drill water in appreciable amounts.

1.4.4 Stop

A stop is a predetermined depth at which the expanding plug or packer is positioned.

1.4.5 Split Spacing

Split spacing is the procedure of locating an additional grout hole midway between two previously drilled and grouted holes.

1.5 SUBMITTALS

**************************************************************************

NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy, Air Force, and NASA projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL

SECTION 31 43 13.13  Page 14
PROCEDURES.

Choose the first bracketed item for Navy, Air Force and NASA projects, or choose the second bracketed item for Army projects.

**************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-03 Product Data

Drilling Equipment

Grouting Equipment

Grout Plant; G[, [_____]]

1.6 DELIVERY, STORAGE, AND HANDLING

**************************************************************************

NOTE: If no separate section on "CONCRETE" is used, the appropriate paragraphs applicable to material delivery, storage, and handling in SECTION 03 70 00 MASS CONCRETE should be inserted in this paragraph in lieu of the section reference given below. If a "CONCRETE" section, other than SECTION 03 70 00 is used, the Designer should ensure that the applicable material delivery, storage, and handling paragraphs are included in that section.

**************************************************************************

Transportation and storage of materials shall be in accordance with section [03 70 00 MASS CONCRETE][03 30 00 CAST-IN-PLACE CONCRETE]. A sufficient quantity of cement shall be stored at or near the site of the work to insure that grouting operations will not be delayed by shortage of cement. In the event the cement is found to contain lumps or foreign matter of a nature and in amounts which, in the opinion of the Contracting Officer, may be deleterious to the grouting operations, screening through a standard 100 mesh screen may be required. No payment will be made for such screening.

1.7 PROJECT/SITE CONDITIONS

The program shown and described is based on currently available information. Conditions encountered during construction may require additions or deletions. The grouting program shall not be modified or curtailed as a construction expediency. It is a required part of design and shall not become secondary to any time or scheduling restrictions. Grouting mixes, pressures, injection rate and the sequence in which the holes are drilled and grouted will be determined in the field and shall be as directed.
2.1 GROUTING MATERIAL

Provide grout composed of water and cement, [pozzolans, admixtures, and fillers]. The grout mixes will be designed by the Contracting Officer and will be varied to meet the characteristics of each hole as determined by conditions encountered. The various materials to be furnished shall conform to the specifications listed in paragraphs below.

2.1.1 Water

[The water used in the grout shall be furnished by the Contractor. It shall be fresh, clean and free from injurious amounts of sewage, oil, acid, alkali, salts, or organic matter.] [Water suitable for use in the work will be furnished by the Government. It shall be the responsibility of the Contractor to provide any necessary connections and extensions to the Government supply line shown.]

2.1.2 Cement

**************************************************************************
NOTE: Avoid specifying the use of air entrained cement, except on rare occasions when grout may be exposed to severe freezing and thawing conditions.
**************************************************************************

Cement used in grout shall conform to the requirements of ASTM C91/C91M and ASTM C150/C150M. The use of bulk cement will be permitted provided the Contractor employs methods of handling, transporting, and storage that are satisfactory to the Contracting Officer, otherwise only cement furnished in cloth or paper bags will be accepted to use in the work. Storage of cement shall be in accordance with paragraph DELIVERY, STORAGE, AND HANDLING.

2.1.3 Pozzolans

Pozzolans shall be fly ash [or other raw or calcined natural pozzolans] conforming to ASTM C618. Sampling will be done by an authorized representative of the Government. All tests will be made by and at the expense of the Government. Pozzolans may be furnished in paper sacks or in bulk. It shall be transported, handled, and stored so as to avoid damage, waste, or absorption of moisture.

2.1.4 Admixtures

**************************************************************************
NOTE: Refer to EM 1110-2-3506, "Grouting Technology", for discussions of properties, characteristics and limitations for principal admixture and filler materials. Only the more commonly used are included here.
**************************************************************************

Admixtures shall be added to the grout immediately before or during its mixing and will consist of [accelerators, retarders, water reducers, aluminum powder, and fluidifiers].
2.1.5 Fluidifier

Fluidifier shall be a compound possessing characteristics which will increase the flowability of the mixture, assist in dispersal of the cement grains, and neutralize the setting shrinkage of the grout. The quality of the material shall meet the requirements specified in ASTM C937. Sampling of fluidifier shall be done by an authorized representative of the Contracting Officer. Trial mixtures should be tested prior to using the materials in field work. All tests will be made by and at the expense of the Government. Fluidifier shall be furnished in moisture-resistant paper sacks shipped in sealed containers and shall be handled and stored so as to avoid absorption of moisture, damage or waste. Material which has become caked due to moisture absorption will be rejected.

2.1.6 Bentonite

Bentonite shall be sodium (Na) cation, powdered montmorillonite. It shall be added to the cement grout 2 percent to 5 percent by weight of cement. The percentage shall be adjusted as directed by the Contracting Officer. A separate colloidal bentonite mixer is required to mix the bentonite and water to ensure fully dispensing and hydrating the bentonite before adding to the grout mixer. The bentonite shall be handled and stored so as to avoid absorption of moisture, damage, or waste. Bentonite which has become caked due to moisture absorption will be rejected. A sufficient quantity of bentonite shall be stored at or near the site of the work to insure that grouting operations will not be delayed by shortage of bentonite.

2.1.7 Sand

a. Sand for grout shall be clean and consist of hard, tough, durable, uncoated particles with no more than [_____] percent passing the No. 200 sieve. The shape of the particles shall be generally rounded or cubical (and shall not contain more than [_____] percent of flat or elongated pieces having a maximum dimension in excess of five times the minimum dimension). The sand shall be generally well graded from fine to coarse in accordance with ASTM C136/C136M with 100 percent passing the [No. 8][_____] sieve.

b. Subject the sand to such tests as are necessary to determine its acceptability. Perform sampling of sand in accordance with the applicable sampling provisions contained in COE CRD-C 100 or as directed. Unless otherwise directed, all test samples shall be taken under the supervision of the Contracting Officer and shall be delivered to a designated point, at the expense of the Contractor, at least [_____] days in advance of the time when sand will be required at the site of work. All tests will be made by the Government at its expense. The tests to which the sand will be subjected will include specific gravity, absorption, soundness in magnesium sulfate, petrographic analyses, and any other tests that are necessary to demonstrate that grout of adequate durability can be produced.

c. The percentage of surface moisture in terms of the saturated surface-dried sand will be determined in accordance with ASTM C70, or other method giving comparable results.

d. Store sand in such a manner as to avoid the inclusion of any foreign materials in the grout. All sand shall remain in free draining storage for at least 72 hours prior to use.
2.2 METAL PIPE AND FITTINGS

Metal pipe and fittings required for constructing grout, drainage and exploratory holes shall be furnished, cut, threaded, and fabricated by the Contractor.

2.2.1 Pipe

Pipe will be black steel of the diameter and in the location indicated. The pipe shall conform to ASTM A53/A53M.

2.2.2 Fittings

The fittings shall be black, malleable iron in accordance with ASME B16.3.

PART 3 EXECUTION

3.1 EQUIPMENT

**************************************************************************
NOTE: For jobs where the estimated quantity of solids is between zero and 30 cubic meters 1,000 cubic feet, a pumping capacity of 950 cm³/s 15 gpm is recommended; from 30 to 1400 cubic meters 1,000 to 50,000 cubic feet, a 1900 cm³/s 30 gpm pump; and for jobs greater than 1400 cubic meters 50,000 cubic feet, a 3800 cm³/s 60 gpm pump. Also, for jobs where large grout quantities are anticipated it may be desirable to specify an automated batching plant with batch tickets for all items in the mix.
**************************************************************************

The use of internal combustion engines within dam galleries for operation of drilling and grouting equipment will not be permitted. Submit details and data on the drilling and grouting equipment.

3.1.1 General

All drilling [including exploratory hole drilling] and grouting equipment used shall be of a type, capacity and mechanical condition suitable for performing the work, as determined by the Contracting Officer. The power and equipment and the layout thereof shall meet all applicable requirements of local, State, and Federal regulations and codes, both safety and otherwise.

3.1.2 Drilling Equipment

Standard drilling equipment of the rotary [or percussion] type shall be used to perform the drilling as specified in paragraphs GROUT HOLE DRILLING, DRAIN HOLE DRILLING, COMPLETION OF GROUTING AND DRAIN HOLE DRILLING, and EXPLORATORY HOLE DRILLING. Use [water] [air] for removing cuttings from the hole during drilling operations. Air driven drills used in galleries shall be equipped with suitable mufflers. Supplies shall include all bits, drill rods, tools, casing, piping, pumps, water, and power to accomplish the required drilling. All drilling rigs and pumps will be equipped with pressure gages.
3.1.3 Grouting Equipment

The grout plant shall be capable of supplying, mixing, stirring and pumping the grout and additives, to the satisfaction of the Contracting Officer. Submit a detailed plan showing equipment and grout plant layout proposed for mixing and placing grout. The plant shall have a minimum capacity of $[_____] \text{mL/s} [_____] \text{cm}^3/\text{s} [_____] \text{gpm} [_____] \text{cfm}$ of grout injected at a pressure not greater than $[_____] \text{kPa} [_____] \text{psi}$. It shall be maintained at all times and any grout hole that is lost or damaged due to mechanical failure of equipment or inadequacy of grout supply shall be replaced by another hole, drilled by the Contractor, at its expense. The amount of grouting equipment shall be as necessary to perform the work specified herein. The type to be furnished shall include the following:

a. A progressive cavity pump capable of passing particles up to a top size of $[_____] \text{mm} [_____] \text{inches}$, generating pressures up to $[_____] \text{kPa} [_____] \text{psi}$ and pumping a maximum of $[_____] \text{mL/s} [_____] \text{cm}^3/\text{s} [_____] \text{gpm} [_____] \text{cfm}$. In no case will the pump be separated by more than $[_____] \text{meters feet}$ of grout line from the header of a hole being grouted. Where grout lines are more than $[_____] \text{meters feet}$ long, an additional pump shall be placed in the line within $[_____] \text{meters feet}$ of the header.

b. A [colloidal] [paddle] type grout mixer having a minimum drum capacity of approximately $[_____] \text{cubic meters feet}$ with a mix batch of $[_____] \text{cubic meters feet}$. Mixing time shall be approximately $[_____] \text{seconds}$ per batch.

c. A separate colloidal mixer for mixing and hydrating bentonite.

d. A mechanically agitated sump having a minimum capacity of $[_____] \text{cubic meters feet}$.

e. A circulating grout header with control valves and a pressure gage with protector as shown on the plans. Control valves shall be connected to the return line and header. The header shall be joined directly to the riser pipe at the hole by means of a quick connector union.

f. A water storage tank or suitable source of clean auxiliary water for use in washing, pressure testing and flushing operations.

g. A water meter graduated in cubic meters feet and tenths having a direct reading totalizer and capable of conveniently being set back to zero.

h. Such valves, packers, pressure gages, pressure hose, supply lines, and small tools as may be necessary to provide a continuous supply of grout at accurately controlled pressures as specified. The inside diameter of the pressure hose and grout supply line shall be not less than $[_____] \text{mm inches}$. An accurately calibrated, high precision pressure gage shall be used to check the accuracy of all gages used in the grouting. Gages shall be checked at least every 24 hours, or more frequently if the Contracting Officer so determines. When defects are found, grouting operations will be stopped until calibration of gages has been obtained.

3.2 GROUT, DRAINAGE AND EXPLORATORY HOLES

All holes for grouting, drainage or exploration shall be drilled at the locations, in the direction, angle, and to the depths indicated or as
A maximum tolerance for deviation in angle and direction shall be [_____].. The first series of holes to be drilled and grouted shall be at [_____] meter foot intervals and hereinafter are referred to as primary holes. The location of secondary and succeeding series (intermediate) holes shall be determined by the split spacing method as defined in paragraph SPLIT SPACING. The number of grout holes shall be increased, progressively, by the split spacing method as defined in paragraph SPLIT SPACING. The number of grout holes shall be increased, progressively, by the split spacing method as deemed necessary by the Contracting Officer until the amount of grout used indicates that the foundation is tight. Each hole drilled shall be protected from becoming clogged or obstructed by means of a cap or other suitable device on the collar and any hole that becomes clogged or obstructed due to fault of the Contractor before completion of operations shall be cleaned out in a manner satisfactory to the Contracting Officer or another hole provided by and at the expense of the Contractor. That portion of holes which penetrates concrete of the dam shall be [formed by embedding pipes in the concrete at the time of its placement] [drilled] as specified in paragraph PIPE FOR FOUNDATION GROUTING AND DRAINAGE. Payment will be made for such partial depth of holes at the unit contract price for [Item No. [_____] "Steel Pipe and Fittings"], [Item No. [_____] "Drilling Grout Holes"], [Item No. [_____] "Drilling Drain Holes"], [Item No. [_____] "Drilling Exploratory Holes"].

3.2.1 Pipe for Foundation Grouting and Drainage

All metal pipe and fittings required for constructing grout, drainage and exploratory holes shall be embedded. The pipe and fittings shall be cleaned thoroughly of all dirt, grease, oil, grout and mortar immediately before embedment. All joints shall be made up snug and the assembly held firmly in position and protected from damage or displacement while the concrete is being placed. Take all necessary precautions to prevent any pipe from becoming clogged or obstructed from any cause and any pipe which becomes clogged shall be cleaned out in a manner satisfactory to the Contracting Officer at the Contractor's expense. The presence of tramp metal such as nails, wire, bolts, nuts and other foreign material in the pipes through which diamond drilled holes are to be drilled shall be considered as obstructions. As an option, substitute percussion or diamond drilled holes through the concrete in lieu of pipe, provided that the method proposed meets with the approval of the Contracting Officer and provided further that such substitution does not result in any increased cost to the Government.

3.2.2 Grout Hole Drilling

a. Drill grout holes with standard rotary [or percussion] drilling equipment. No core recovery will be required and the type bit used shall be optional with the Contractor. [The hole shall be of sufficient diameter to allow use of an expansion plug or packer with an effective inside diameter of not less than 13 mm 1/2 inch]. The minimum diameter of hole shall be [35] [_____] mm [1 3/8] [_____] inches at the point of maximum penetration. No grout hole will be drilled at an angle greater than [_____] degrees measured from the vertical nor to a depth greater than [_____] meters feet measured from the collar of the hole. If, as the work progresses, it is determined that holes to depths greater than indicated are necessary, drilling to such greater depth will be ordered in writing, and the drilling to depths in excess of [_____] meters feet will be paid for at a negotiated unit price.
b. Perform drilling in accordance with the applicable grouting method hereinafter described. Whenever as much as [_____] percent of the drill water is lost or the cumulative total of successive water losses is estimated to amount to [_____] percent loss, or artesian flow is encountered, the drilling operations shall be stopped, the hole washed, pressure tested and grouted before drilling operations are resumed in such hole. The grout so injected remaining in a partially completed hole shall be removed therefrom by washing or other methods before it has set sufficiently to require redrilling. Redrilling required because of the Contractor's failure to clean out a hole before the grout has set shall be performed at the Contractor's expense except that where the grout has been allowed to set by direction of the Contracting Officer, the redrilling will be paid for at the contract price for drilling the grout hole. Upon completion of drilling of any hole and prior to pressure testing, all drill cuttings and slurry shall be removed by applying water to the bottom of the hole [through open end rods] and returning the wash water through the hole to the surfaces until the return water is clear. No separate payment will be made for this washing.

3.2.3 Drain Hole Drilling

Drill drain holes with standard diamond drilling equipment, but no core recovery will be required and the Contractor may elect to use coring or noncoring bits. The minimum diameter of hole shall be [72] [_____] mm [2 7/8] [_____] inches, measured at the point of maximum penetration. No drain hole will be drilled at an angle greater than [_____] degrees from the vertical nor to a depth greater than [_____] meters feet, measured from the collar of the hole. Drainage holes shall not be drilled in any location until all adjacent grout holes within a minimum distance of 50 meters 150 feet have been drilled and grouted to full depth.

3.2.4 Completion of Grouting and Drain Hole Drilling

All grouting operations and all drain hole drilling shall be completed and in proper working condition prior to the time of impounding water. At that time all work in the [grouting and drainage galleries] [tunnels] shall be completed, all drain holes shall be uncovered and unobstructed, and the [galleries and their gutters] [tunnels] shall be free of all construction debris. Nipples for grout hole drilling will be removed from the [gallery] [cutoff trench] and disposed of and the finished grout holes will be patched.

3.2.5 Exploratory Hole Drilling

a. Perform such exploratory drilling as may be required to determine the condition of the rock prior to grouting or the effectiveness of the grouting operations during or after grouting. All exploratory drilling shall be performed with rotary drilling equipment using coring type bits. Since the maximum recovery of unpredictable soft or friable materials is of prime importance, make every effort to recover 100 percent of the core by use of the appropriate equipment and drilling procedures.

b. The holes may be required to be drilled to varying depths, with a maximum depth of [_____] meters feet. No exploratory hole will be drilled at an angle greater than [_____] degrees measured from the vertical.
c. Special care should be exercised to obtain cores in as good condition as possible. Keep, in a manner satisfactory to the Contracting Officer, an accurate Driller's Log of all exploratory holes drilled. The log shall include a nontechnical description of all materials encountered in the drilling, their location in the holes and the location of special features such as seams, open cracks, soft or broken rock, points where abnormal loss or gain of drill water occurred, and any other items of interest in connection with the purpose for which the exploratory drilling is required.

d. Wooden or other approved core boxes will be furnished by [the Government] [the Contractor], and place the cores in the boxes in the correct sequence and separated accurately by wooden blocks, according to the measured distances in the hole. No box shall contain cores from more than one hole. The covers shall be fastened securely to the core boxes and delivered in the vicinity of the work as directed.

e. Exploratory holes shall be grouted under pressure, if conditions so indicate, by [stop grouting] [grouting to full depth in one operation] and backfilled in accordance with paragraph BACKFILLING OF HOLES.

3.3 PROCEDURES FOR DRILLING AND GROUTING

3.3.1 General

The drilling and grouting shall be accomplished in single or multiple lines as shown. The drilling and the grouting shall be done by [zones, using the split spacing, stage grouting method] [split spacing, stop grouting method] as described herein.

3.3.2 Stage Grouting

Perform stage grouting of progressively deeper zones in stages with the placement of a grout curtain by drilling and grouting in successive operations in accordance with the following general procedure.

3.3.2.1 Primary Holes

Primary holes for foundation grouting shall be drilled to their first stage of depth within the first zone. The depths will be governed by the foundation conditions.

a. The holes thus drilled shall be washed and pressure tested, and then grouted, except that when pressure testing indicates a relatively tight hole, the Contracting Officer may direct that the grouting of that hole be omitted for that stage and the hole be left open for drilling and grouting of the next stage.

b. After the grouting of any hole, the grout within the hole shall be [removed by washing or by other methods before it has set sufficiently to require redrilling][allowed to set and subsequently the holes shall be redrilled].

c. After the interval of time as specified in paragraph SECOND STAGE, the primary holes not already drilled to the limit of the first stage shall be drilled as directed to additional depths not exceeding the zone limit.

d. The primary holes thus deepened shall again be washed and pressure
tested and then grouted at higher pressures as directed. Again, the grout within the hole shall be removed as described above.

e. The process of successively drilling primary holes to additional depths and grouting at higher and higher pressures in stages, as directed, shall be repeated until all of the primary holes on the maximum spacing (see paragraph GROUT, DRAINAGE AND EXPLORATORY HOLES) have been completely drilled and grouted to the depth of the first zone in that section of the grout curtain.

3.3.2.2 Successive Holes

After the primary holes in the first zone have been completed in any section as specified above, the second and succeeding series of holes, as determined by the "split spacing method," shall be drilled and grouted to the depth of the first zone in like manner until the first zone of that section is completely grouted as directed.

3.3.2.3 Completion of Section

The process of successively drilling to additional depths and grouting at higher and higher pressures in stages for the first series of holes and then for succeeding series of holes shall be repeated for the second and subsequent zones of that section. Other sections along the grout curtain shall be grouted in like manner until grouting of the foundation is completed to the satisfaction of the Contracting Officer. As the drilling and grouting work progresses, it may develop that conditions are such that all or parts of the foundation already grouted require additional grouting. In such event, the equipment shall be returned and additional holes shall be drilled and grouted as directed.

3.3.3 Stop Grouting

Stop grouting is a method whereby each hole is drilled to a final depth and grouted by stops through an expansion plug or packer which is set at successively shallower depths. It involves the placement of a grout curtain by drilling and grouting in accordance with the following general procedure:

a. Drill hole to the full depth and wash as specified in paragraph GROUT HOLE DRILLING.

b. The holes thus drilled and washed shall be pressure tested, and pressure washed as specified in paragraph PRESSURE WASHING AND PRESSURE TESTING.

c. The expansion plug, or packer, shall be placed in the hole at the top of the interval to be grouted blocking off the higher portion of the holes, and the interval is grouted. The lowest zone is grouted first. In no case will the Contractor be required to set the packer deeper than [_____] meters feet.

d. After placing the grout at the pressure and mix directed by the Contracting Officer, the expansion plug, or packer, shall be left in place until the grout pressure drops to that pressure required for the next higher stop or as directed by the Contracting Officer.

e. The expansion plug, or packer, shall then be moved to the next higher stop and grout placed at the lower pressure as directed by the
Contracting Officer.

f. The procedures described in subparagraphs "d" and "e" above shall be repeated until grouting of the hole is complete.

g. After the primary holes in the first zone have been completed in any section as specified above, the second and succeeding series of holes, as determined by the "split spacing method" shall be grouted in like manner until all zones of that section are completely grouted as directed.

h. Other sections along the grout curtain shall be grouted in like manner until grouting of the foundation is completed to the satisfaction of the Contracting Officer.

i. As the drilling and grouting work progresses, it may develop that conditions are such that all or parts of the foundation already grouted require additional grouting. In such event, the equipment shall be returned and additional holes for grouting shall be drilled and grouted as directed and no allowance above contract unit prices will be made for drilling and grouting such holes or for the expense of any movement of equipment necessary to the performance of such work.

3.3.4 Pressure Washing and Pressure Testing

Immediately before the pressure grouting operation, the hole shall be thoroughly washed under pressure and pressure tested. All intersected rock seams and crevices containing clay or other washable materials shall be washed with water [and air] under pressure to remove as much of these materials as possible. If practicable, as determined by the Contracting Officer, such material shall be ejected from one or more holes by introducing water [and air] under pressure into an adjacent hole. In no case shall such pressure exceed the maximum grouting pressure as directed. All grout holes shall be tested with clean water under continuous pressure up to the maximum grouting pressure as directed. All holes sufficiently tight to build up the maximum required pressure shall be washed at such pressure and the washing shall continue as long as there is any increase in the rate at which water is taken, such increase indicating the fractures are being opened by the washing operation. Open holes in which no pressure can be built up shall be washed for a period of 5 minutes, with the pump operating at full capacity, or for such period of time as fracture-filling is being removed, as evidenced by the escape of muddy water through surface openings or other grout holes.

3.3.5 Stage Grouting Procedures

3.3.5.1 First Stage

Perform the first stage, or low-pressure, shallow-curtain grouting by washing and grouting holes at locations indicated or as directed, using the "split spacing" method described in paragraph SPLIT SPACING. Similar stages of drilling and grouting are repeated as necessary to reach the bottom of the first zone. Before grouting is begun in any hole of a given series in any section, at least the nearest two holes in advance of each such hole in that series shall be completely drilled for the same stage and the adjacent hole completely washed to facilitate washing and flushing out of any intervening clay-filled seams, fractures, or solution channels. No hole beneath any portion of the dam shall be grouted until all concrete within [35] [_____] meters [100] [_____] feet has been placed to [full
3.3.5.2 Second Stage

After all first stage grouting in any section has been completed, as specified above, proceed, when so directed, with second stage drilling and grouting in accordance with the procedure outlined herein but in no case shall the deepening of any hole preparatory to grouting be commenced before the previously placed grout has set: nor shall second stage grouting be conducted within a distance of approximately 35 meters 100 feet of any hole in which a previous stage of grouting has been completed until the grout in such previous stage hole has [taken its set] [set for a period of 24-hours]. Grouting at subsequent stages shall conform to the same requirements as to minimum time and distance. Upon completion of all holes to the bottom of the first zone, and after the waiting period the primary holes are drilled to the next stage in the second zone and grouted at higher pressures. The process of drilling, washing, pressure testing, pressure washing, and grouting at progressively higher pressures are continued until the ground is satisfactorily tight to the required depth.

3.3.6 Stop Grouting Procedures

3.3.6.1 Stop Grouting of Grout Holes

Perform the grouting by washing and grouting holes at locations indicated or as directed. Before grouting is begun in any hole of a given series in any section, at least the nearest two holes in the advance of each such hole in that series shall be completely drilled and the adjacent hole completely washed to facilitate washing and flushing out of any intervening clay-filled seams, fractures, or solution channels.

3.3.6.2 Grouting of Existing Exploratory Holes

Existing exploratory holes or portions of holes more than five feet deep after excavation shall be cleaned [pressure-tested], and [pressure grouted] [gravity grouted] as specified for grout holes. Holes less than 1.5 meters five feet deep shall be back-filled with grout mixed in proportions directed by the Contracting Officer. Gravity grouting or backfilling shall be done in accordance with paragraph BACKFILLING OF HOLES.

3.3.7 Grouting Pressures

**************************************************************************
NOTE: Refer to EM 1110-2-3506, "Grouting Technology" for discussions of grouting pressures as an aid in selecting allowable pressures under different conditions.
**************************************************************************

Grouting pressures to be used in the work will vary with conditions encountered in the respective holes and pressures used shall be as directed. It is anticipated that pressures will range from [_____] kPa psi to [_____] kPa psi but in no event will pressures in excess of [_____] kPa psi be required or allowed.

3.3.8 Grouting

All pressure grouting operations shall be performed in the presence of the [Contracting Officer] [Government Inspector], and shall be in accordance

SECTION 31 43 13.13 Page 25
with the following general procedures.

3.3.8.1 Grout Mixes

**************************************************************************

NOTE: Appropriate additives will be used for specific cases.
**************************************************************************

Mixes shall be in the proportions directed by the Contracting Officer who will, from time to time, direct changes to suit the conditions found to exist in the particular grout hole. [The cement grout will include 2 percent to 5 percent (by weight of cement) of sodium bentonite]. The water/cement ratio by volume will be varied to meet the characteristics of each hole as revealed by the grouting operation and will range between [_____] and [_____]. The types of grout shall be as follows:

[a. Cement Grout shall consist of cement, (bentonite) and water.]

[b. Mortar Grout shall consist of cement, (bentonite), sand, and water.]

3.3.8.2 Grout Injection

a. In general, if pressure tests indicate a tight hole, grouting shall be started with a thin mix. If an open hole condition exists, as determined by loss of drill water or inability to build up pressure during washing operations, then grouting shall be started with a thicker mix and with a grout pump operating as nearly as practicable at constant speed at all times; the ratio will be decreased, if necessary, until the required pressure has been reached. [If this procedure does not produce the desired pressure, mortar grout shall be used and the mix varied as necessary to produce the desired results.]

b. When the pressure tends to rise too high, the water/cement ratio shall be increased [and/or the mix of mortar grout changed or discontinued] as may be required to produce the desired results. If necessary to relieve premature stoppage, periodic applications of water under pressure shall be made. Under no conditions shall the pressure or rate of pumping be increased suddenly as either may produce a water-hammer effect which may promote stoppage.

c. The grouting of any hole shall not be considered complete until [that hole refuses to take any grout whatever at three-fourths of the maximum pressures required for that stage] [that hole takes grout at the rate of one cubic foot of grout or less in ten minutes measured over at least a five minute period at the pressure required for that portion of the hole being grouted.]

d. Should grout leaks develop, caulk such leaks when and as directed, the cost thereof being included in the contract price for unit price pay item "Placing Grout", in accordance with Section 01 20 00 PRICE AND PAYMENT PROCEDURES.

e. If, due to size and continuity of fracture, it is found impossible to reach the required pressure after pumping a reasonable volume of grout at the minimum workable water/cement ratio [or mortar grout with the maximum volume of sand at the minimum water/cementing materials ratio] the speed of the pumping shall be reduced or pumping shall be stopped.
temporarily and intermittent grouting shall be performed, allowing sufficient time between grout injections for the grout to stiffen. Following such reduction in pumping speed, if the desired result is not obtained, grouting in the hole shall be discontinued when directed. In such event, the hole shall be cleaned, the grout allowed to set, and additional drilling and grouting shall then be done in this hole or in the adjacent areas as directed, until the desired resistance is built up.

f. After the grouting of any [stage] [stop] of a hole is finished, the pressure shall be maintained by means of a stop-cock or other suitable device until the grout has set to the extent that it will be retained in the hole.

g. Grout that cannot be placed, for any reason, within two hours after mixing shall be wasted. If such grout is mixed at the direction of the Contracting Officer or with his knowledge and consent, such wasted grout, except as specified in Section 01 20 00 PRICE AND PAYMENT PROCEDURES, shall be paid for at the contract unit prices for the materials contained therein.

3.3.8.3 Backfilling of Holes

Holes shall be backfilled with grout proportioned as directed by the Contracting Officer and generally having a water/cement ratio less than 1.0. The backfilling shall be accomplished by injection of grout through a tremie pipe or hose inserted to full depth of hole. When grout vents at the surface, the tremie shall be gradually withdrawn, maintaining grout in pipe or hose until completely removed. Holes containing freshly injected grout shall not be backfilled until the injected grout has set. No separate payment will be made for backfilling holes; however, grout will be paid for at the contract unit price for the Portland cement therein.

3.3.8.4 Equipment Arrangement and Operation

The arrangement of the grouting equipment shall be such as to provide a continuous circulation of grout throughout the system and to permit accurate pressure control by operation of a valve on the grout return line, regardless of how small the grout take may be. The equipment and lines shall be prevented from becoming fouled by the constant circulation of grout and by the periodic flushing out of the system with water. Flushing shall be done with the grout intake valve closed, the water supply valve open, and the pump running at full speed.

3.3.8.5 Protection to Work and Cleanup

[Except as otherwise specified, no grouting will be permitted within [_____] meters feet of installed perforated pipe or gravel filters for foundation drains. Where permitted in such locations, maintain a flow of water through the drains likely to be affected, to serve as tell-tales. In case leakage of grout into drains does occur immediately stop the grouting operations and remove all grout from the drains affected by washing to the satisfaction of the Contracting Officer. Payment for washing will be in accordance with unit price pay item "Pressure Washing and Pressure Testing" in [this Section] [Section 01 20 00 PRICE AND PAYMENT PROCEDURES]. Such stopping of grouting operations and washing of drains shall be repeated as often as required to complete the curtain grouting.] During grouting operations take such precautions as may be necessary to prevent drill cuttings, equipment exhaust oil, wash water, and grout, from defacing or
damaging the permanent structure. Daily maintenance may be required along grout lines, in order to offer better inspection of interconnected holes and breakouts. The Contractor will be required to furnish such pumps as may be necessary to care for waste water and grout from his operations. Upon completion of these operations, clean up all waste resulting from his operations that is unsightly or would interfere with the efficient operation of the project as anticipated by the original design.

3.3.9 Records

The Contracting Officer will keep records of all grouting operations, such as a log of the grout holes, results of washing and pressure testing operations, time of each change of grouting operation, pressure, rate of pumping, amount of cement for each change in water/cement ratio, and other data as deemed by him to be necessary. Furnish all necessary assistance and cooperation to this end.

3.3.10 Communications

When, for its own convenience, the Contractor has the individual elements of the plant so located that communication by normal voice between these elements is not satisfactory, the Contracting Officer may require him to install a satisfactory mechanical means of communications, such as a telephone or other suitable device.

NOTE: This guide specification covers the requirements for constructing a soil-bentonite slurry trench at both conventional and hazardous waste projects.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1  GENERAL

NOTE: In using this guide specification, the designer should realize that the requirements for the bentonite, backfill, and construction procedure are highly dependent on the intended purpose of the slurry trench and the environment in which it is to be used.

The primary considerations for S-B slurry trenches are blowout requirements, permeability, strength, and compressibility.

The S-B backfill should be designed to prevent possible blowout or piping of the S-B backfill into
the surrounding foundation material due to the hydraulic gradient acting across the slurry trench. Design criteria are presented in Chapter 9, Corps of Engineers (COE) EM 1110-2-1901.

The permeability for S-B slurry trenches is usually in the order of 10^-6 to 10^-8 cm/sec. The actual permeability of the slurry trench is dependent on both the filter cake, which forms on the sides of the trench and the S-B backfill. The contributions of both are dependent on the relative permeability and thickness of the two materials. For design purposes, however, it is recommended that the permeability of the slurry trench be based only on the S-B backfill. For permanent or critical temporary projects, laboratory permeability tests should be utilized in establishing the mix design.

When design requirements dictate, both shear strength and compressibility of the S-B backfill should be analyzed by conducting laboratory testing.

Since chemical contaminants commonly associated with hazardous waste sites may increase the permeability of S-B backfill, a compatibility testing program must be undertaken prior to constructing a slurry trench. If the trench is to be excavated through contaminated material, consider performing compatibility testing using two potential backfill materials; soils to be excavated from the trench and an uncontaminated borrow source. It should be noted that compatibility testing can take from 2 to 6 months to complete. For this reason, it is generally recommended that compatibility testing be completed during the design phase of the project.

A recommended compatibility testing program consists of:

1. Free swell (ASTM D5890) and filter cake permeability tests of several bentonites using contaminated site ground water and site mixing water that will be used during construction to determine acceptable bentonites for use on the project.

2. Mix design optimization tests to determine the most economical mix of soils, dry bentonite, and bentonite slurry to produce the required permeability. This consists of short-duration (48-72 hours) permeability tests varying the amount of dry bentonite added (0, 2, and 4 percent) and if necessary the amount of additional fines added (0, 10, 20 percent) using site mixing water as the permeant.

3. Long-term flexible wall permeameter testing of at least 3 S-B backfill samples: the optimum mix design with site mixing water only as the permeant (control); the optimum mix design with contaminated
site ground water as the permeant (after 1 pore volume of site mixing water permeant to ensure a good test setup); and a bentonite content 2 percent greater than the optimum determined in step 2 with contaminated site ground water as the permeant (after 1 pore volume of site mixing water permeant). It is recommended that 3 pore volumes of ground water permeant pass through the S-B backfill samples. This typically takes at least 2 months.

To approximate field conditions in the lab, it is important to obtain contaminated ground water and mixing water from the site. The site mixing water used during compatibility testing shall be the water used to make the bentonite slurry during construction.

For laboratory testing, consider requiring a permeability of one-half an order of magnitude less than the required field permeability (for example, 5x10^-8 cm/sec in the lab for 1x10^-7 cm/sec in the field).

1.1 MEASUREMENT AND PAYMENT

NOTE: Delete this paragraph when work is covered by lump sum contract price.

1.1.1 Measurement

Measurement for S-B Slurry Trench shall be based on the area in square meters feet of completed slurry trench measured in a vertical plane through the centerline of the slurry trench, from the top of the working surface to the bottom of the excavated trench, and vertical lines at each corner of the full depth of the excavated trench. Measurement shall be based on surveys and soundings taken at the site as directed and approved.

1.1.2 Payment

Payment for S-B Slurry Trench will be made at the contract unit price per square meter foot. Such price will include costs incurred for the construction and completion of the slurry trench. No separate payment will be made for material, equipment, handling and cleaning the slurry, quality control testing, record keeping, and site preparation including construction of the working surface.

1.2 DEFINITIONS

NOTE: Remove items not required in the project.

The terms used in this Section are defined as follows:
1.2.1 Slurry Trench

The slurry trench is a [___] [900] mm [3] feet minimum width trench excavated through the existing ground or prepared working surface using the slurry method of excavation and backfilled with S-B backfill material, to form a low permeability cutoff wall.

1.2.2 Slurry Method of Excavation

The slurry method of excavation consists of excavating a vertical walled trench and at the same time keeping the trench filled with a bentonite slurry mixture. The purpose of the slurry is to support the walls of the trench and prevent movement of ground water.

1.2.3 Bentonite

Bentonite is an ultrafine natural clay whose principal mineral constituent is sodium cation montmorillonite.

1.2.4 Slurry

Slurry is a colloidal mixture of bentonite and water.

1.2.5 Soil Bentonite (S-B) Backfill

S-B backfill is a homogeneous mixture of material produced by mixing soil with bentonite slurry [and additional dry bentonite], which is placed into the excavated trench to complete the soil-bentonite slurry trench.

1.2.6 Ground Water Level

The ground water level is the piezometric level of the ground water as determined from piezometers and wells.

1.2.7 Working Surface

The working surface is the top of the [stripped and/or prepared natural ground] [or] [the surface of previously compacted fill] from which the slurry trench shall be constructed.

1.2.8 Confining Stratum

The confining stratum is the soil stratum or rock unit to or into which the bottom of the slurry trench is excavated.

NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy, Air Force, and NASA projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy, Air Force and NASA projects, or choose the second bracketed item for Army projects.

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-01 Preconstruction Submittals

Preconstruction Testing Plan; G[, [_____]]
Slurry Trench Implementation Plan; G[, [_____]]
Blasting Plan; G[, [_____]]

SD-02 Shop Drawings

As-Built Profile

SD-04 Samples

Bentonite; G[, [_____]]
1.5 OTHER SUBMITTAL REQUIREMENTS

Submit the following:

a. Plan describing the general work sequence and layout of operations. The layout of operations shall include scale drawings, which depict slurry and S-B backfill preparation and storage areas. The plan shall describe Contractor qualifications, equipment, method of trench excavation, [blasting,] use or disposal of excavated material, bottom cleaning, slurry preparation and maintenance, S-B backfill preparation and placement, and site clean-up.

b. Plan describing quality control equipment and test procedures, sample test forms for reporting test results, and the offsite laboratory proposed for use.

c. Data on the equipment to be used in the construction of the slurry trench; equipment to be used to obtain [bedrock] [impervious stratum] samples; [equipment to be used to obtain record control samples of the completed slurry trench;] and equipment to be used in the Contractor's quality control testing.

d. A copy of the test results from the bentonite manufacturer for each lot shipped to the site and a certificate of compliance stating that the bentonite complies with applicable standards.

1.6 QUALITY ASSURANCE

The Government may perform quality assurance testing on representative samples obtained by the [Contractor] [Government] of the bentonite slurry and S-B backfill using the laboratory and equipment furnished by the Contractor. The Government testing will in no way relieve the Contractor of the responsibility of performing tests necessary to meet the Construction Quality Control (CQC) requirements. Provide the equipment and laboratory space to government personnel on demand and these services will be considered a subsidiary obligation of the soil bentonite slurry trench construction. Make all routine testing procedures available for inspection by the Contracting Officer at any time.

1.6.1 Qualifications

**************************************************************************
NOTE: Remove subparagraphs not required in the project.

SECTION 31 56 13.13 Page 9
1.6.1.1 Contractor

Successfully installed a minimum area of [_____] 100,000 square meters 1,000,000 square feet. The qualifications and experience of personnel who shall be responsible for conducting the operations shall include references (name and telephone number) of the owners of the Contractor's previous slurry trench construction projects.

1.6.1.2 Slurry Trench Specialist

The slurry trench specialist shall be an individual who has had experience with at least [_____] [5] projects in all aspects of slurry trench construction which includes, but is not limited to:

a. The use, testing, and control of bentonite slurries,

b. The mixing methods required to properly mix the slurry and backfill materials as required,

c. Trench excavation and backfilling procedures, and

d. A thorough knowledge of construction equipment and material testing required for slurry trench construction.

1.6.1.3 Slurry Trench Excavation Equipment Operator

The slurry trench excavation equipment operator shall have experience using similar slurry trench excavation equipment to be used for this contract in a minimum of [_____] [2] projects of similar or greater magnitude (depth).

1.7 DELIVERY, STORAGE, AND HANDLING

Protect materials delivered and placed in storage from the weather, dirt, dust or other contaminants.

1.8 GEOTECHNICAL SITE CONDITIONS

1.8.1 Exploratory Borings

NOTE: In most cases, the exploratory borings along the alignment should be obtained during design. However, in some cases, it may be necessary to have the Contractor obtain exploratory borings to determine or verify the depth or characteristics of the key stratum. This should be performed well in advance of slurry trench installation to prevent delays. If additional drilling is required, it is recommended that a separate specification be prepared for that work.

Subsurface exploratory borings have been obtained by the Government to determine the character of materials to be excavated. Locations of the borings are shown on the drawings and the logs of those borings, which fall within the area of this contract, are included in [_____] for the convenience of the Contractor. The Government assumes no responsibility.
for interpretation or deductions made from the logs and borings. Local minor variations may exist in the subsurface materials between boring locations and, if encountered, will not be considered as being materially different within the purview of this contract [_____] . Soils classifications shown on the logs are the result of [field visual classifications] [laboratory classifications] in accordance with the Unified Soil Classifications System. [The results of all laboratory testing, including rock and soil, are available for review by the Contractor in the [_____] .] [Attention is invited to FAR 52.236-4 Physical Data in the Special Contract [Clauses] [Requirements] for availability of core borings and soil samples for inspection.]

1.8.2 Subsurface Conditions

**************************************************************************
NOTE: A general description of the conditions to be encountered during the excavation should be provided. Also, provide a description of the stratum or formation into which the slurry trench will be keyed.
**************************************************************************

[____].

1.8.3 Ground Water

**************************************************************************
NOTE: Provide a discussion of the ground water that could affect the slurry trench construction.
**************************************************************************

[____].

1.8.4 [Embankment Conditions]

**************************************************************************
NOTE: When a slurry trench is installed through an existing embankment, a description of the embankment materials to be excavated should be provided.
**************************************************************************

[____].

PART 2 PRODUCTS

2.1 MATERIALS

2.1.1 Bentonite

**************************************************************************
NOTE: Bentonites for use may conform to either Section 4 or Section 5 of API Spec 13A, provided the desired permeability is obtained during pre-construction mix design and compatibility testing. Bentonites, which conform to Section 4 of API Spec. 13A, have typically been treated with small amounts of polymers. Bentonites, which conform to Section 5 of API Spec 13A, have not been chemically treated. For this specification, the
values shown in Table 1 for bentonite, reflect the requirements of API Spec 13A, Section 5. Values in Table 1 should be modified accordingly for Section 4 bentonites.

In the event no bentonites conforming to either Section 4 or 5 of API Spec 13A can produce the desired permeability due to contaminants in ground water, bentonites or other materials with substantial chemical alterations or additives may be used. Use of these materials will depend upon the successful completion of a compatibility testing program and the concurrence of all appropriate State and Federal regulatory agencies. These materials should be used with caution due to the general lack of long-term performance data. These materials may be proprietary products. Modify appropriate sections of this guide specification according to manufacturer's recommendations.

The bentonite shall be sodium cation base montmorillonite powder that conforms to API Spec 13A, Section 4, and Table 1, located at the end of this section. [Chemically treated bentonite will not be allowed.] [Other chemically treated bentonites may be considered provided the required permeability values can not be obtained with bentonites conforming with Section 4 or Section 5 of API Spec 13A.] No bentonite from the bentonite manufacturer shall be used prior to acceptance by the Contracting Officer. Bentonite not meeting specifications shall be promptly removed from the site at the Contractor's expense. Bentonite shall be protected from moisture during transit and storage. Submit a minimum of 4.5 kg 10 pounds of the proposed bentonite at least 1 month prior to use.

2.1.2 Water

The [Contractor shall] [Government will] supply [and condition] water required for mixing with bentonite to produce slurry. The water shall be clean, fresh, and comply with the standards specified in Table 1. Submit water quality test results for water used for mixing the bentonite slurry to assure conformance to these standards. Submit a record of the water source and associated chemical analysis.

2.1.3 Backfill Material

NOTE: For backfill materials with a low percentage of fines (less than 20 percent), it may be necessary to add supplemental fines from an additional borrow area to achieve the desired permeability.

If offsite borrow material is selected for use as the backfill material, it should be tested to ensure that it is uncontaminated. It may be possible to use material excavated from the trench as backfill material, even if it is slightly contaminated. If contaminated material is being considered for use, it must be verified that the material can be safely handled in the field.
The gradation requirements below should be modified to fit the chosen backfill material. In general, no particles greater than 76 mm 3 inches should be in the mix, and a minimum fines content of 20 percent is always recommended.

**************************************************************************

The backfill material shall be obtained from [material excavated from the slurry trench] [a Government furnished borrow area] [an offsite borrow area]. Thirty days prior to utilization of any off-site borrow, the site shall be identified and a minimum of 22.5 kg 50 pounds of each type of proposed borrow soil, at least [1] [_____] month prior to use of each type of material, shall be submitted to the Contracting Officer for QA testing. Backfill shall be free of [contamination] [_____], roots, debris, brush, sod, organic or frozen material. [Material passing the 75 micrometer No. 200 sieve shall have a liquid limit greater than [30] [_____] and a plasticity index greater than [10] [_____]]. Materials shall be thoroughly blended prior to mixing with bentonite slurry and shall conform to the following gradation requirements:

<table>
<thead>
<tr>
<th>Screen Size or Number (U.S. Standard)</th>
<th>Percent Passing by Dry Weight</th>
</tr>
</thead>
<tbody>
<tr>
<td>[75 mm 3 inch] [_____]</td>
<td>[100] [_____]</td>
</tr>
<tr>
<td>[4.76 mm No. 4] [_____]</td>
<td>[40-80] [_____]</td>
</tr>
<tr>
<td>[0.42 mm No. 40] [_____]</td>
<td>[25-60] [_____]</td>
</tr>
<tr>
<td>[75 micrometer No. 200] [_____]</td>
<td>[20-40] [_____]</td>
</tr>
</tbody>
</table>

2.2 EQUIPMENT

Furnish all necessary plant and equipment for use on this project.

2.2.1 Trench Excavation Equipment

Equipment for excavating the slurry trench shall be any type or combination of excavating equipment capable of performing the work as specified and shown on the drawings. [The equipment shall be capable of excavating the required minimum width of trench in a single pass of the excavating equipment.] The buckets utilized with such equipment may be perforated, tapered and equipped with bottom-side cutter teeth protruding no more than 150 mm 6 inches. The bucket shall be designed to maintain the width of the trench and to minimize raveling of the trench sides during use. The equipment shall be able to reach at least [_____] 1500 mm 5 feet deeper than the maximum depth shown on the drawings.

2.2.2 Slurry Mixing and Cleaning Equipment

The slurry mixing plant shall be equipped with a high-speed/high-shear, colloidal mixer or a high-velocity/high pressure venturi jet mixer used in conjunction with a high-speed/high-shear centrifugal pump. The plant shall be equipped with a mechanically or hydraulically agitated sump and shall include pumps, valves, hoses, supply lines, tools, and other equipment and materials required to prepare the slurry and deliver it in a continuous supply from the hydration pond [or tanks] to the slurry trench. Mixers shall be capable of achieving complete dispersion of bentonite and
additives, and shall be capable of continually mixing the slurry to provide and maintain a uniform blended slurry. Provide sufficient ponds [or tanks] for storage of hydrated bentonite slurry. [Slurry cleaning equipment shall be available to reduce sand, sediment, or other solids as necessary to maintain the sand content or density requirements of the slurry in the trench. Slurry cleaning equipment may include but not be limited to vibratory shaker screens, centrifugal sand separators, or stilling ponds.]

2.2.3 Field Laboratory Equipment

The field laboratory shall contain as a minimum the following equipment:

<table>
<thead>
<tr>
<th></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Mold and rod for slump test</td>
</tr>
<tr>
<td>2</td>
<td>Marsh funnel sets</td>
</tr>
<tr>

<td>pH [meter] [paper]</td>
</tr>
<tr>
<td>2</td>
<td>Sand content sets</td>
</tr>
<tr>
<td>1</td>
<td>101.6 mm 4 inch Cylindrical mold</td>
</tr>
</tbody>
</table>

2.3 BENTONITE SLURRY MIXES

2.3.1 Initial Bentonite Slurry Mixture

******************************************************************************
NOTE: For most bentonites, 4 to 6 percent by weight should produce a slurry that will meet all the specified requirements. Other mixtures may be determined to be acceptable during pre-construction tests. S-B backfill mix designs should be determined during pre-construction testing. Results from the tests should be used in Table 1.
******************************************************************************

The initial bentonite slurry mixture shall conform to the standards specified in Table 1.

2.3.2 Trench Bentonite Slurry Mixture

The trench bentonite slurry mixture shall conform to the standards
specified in Table 1.

2.3.3 Additional Bentonite

If directed by the Contracting Officer, thicken the slurry to a more viscous condition than the limits specified above. Use additional bentonite, as directed.

2.3.4 Additives

Peptizing agents and bulking agents shall not be mixed with the slurry. Approved thinners or dispersants and flocculants of the types used in the control of oil field drilling muds, may be used to control standard properties of the slurry such as apparent viscosity, pH and filtration characteristics.

2.3.5 S-B Backfill

The S-B backfill, consisting of [backfill material and bentonite slurry] [backfill material, bentonite slurry, and a minimum of [2] [____] percent dry bentonite] shall be thoroughly mixed and shall conform to the standards specified in Table 1 just prior to placement in the trench.

PART 3 EXECUTION

3.1 GENERAL REQUIREMENTS

The slurry trench shall be constructed to the elevations, lines, grades, and cross-sections shown and in accordance with these specifications, unless otherwise directed. The Government may modify the dimensions and quantities of the work as determined necessary. Submit a Slurry Trench Implementation Plan for approval, a minimum of [_____] weeks prior to the start of construction.

3.2 WORKING SURFACE

******************************************************************************
NOTE: The maximum slurry trench surface slope along the slurry trench alignment during construction should be 1 percent. For sites with grades greater than 1 percent, the working surface should be designed to achieve the 1 percent slope. If contaminated, it is common practice to remove the top 300 mm 12 inches of the working surface after completion of the slurry trench. Most excavation equipment requires 6 meters 20 feet of clearance to swing around; therefore, a minimum working surface width of 12 meters 40 feet is recommended. Some equipment may require wider work platforms in order to negotiate trench corners. At sites where S-B backfill will be mixed beside the trench, instead of at a central mixing area, a wider working surface may be required. The slurry trench alignment is not required to be in the centerline of the working surface.
******************************************************************************

Slurry trench construction shall be accomplished from the working surface, as shown on the drawings. If the Contractor's operations require a wider
working surface, the reason for the change shall be submitted. If approved, a wider working surface may be constructed at no additional cost to the Government. Working surface material and compaction requirements are described in Section [______]. In the event that the static ground water table is encountered at a depth of [_____] 1 m 3.0 foot or less below the designated working surface, at the direction of the Contracting Officer, raise the working surface to a height of [_____] [1] m [3] feet above the measured static ground water level with approved fill material. The working surface thus constructed shall be utilized as a basis for measurement for payment.

3.3 SLURRY TRENCH EXCAVATION

**************************************************************************
NOTE: For shallow (less than 15 m 50 feet) slurry walls, most excavation equipment can round trench corners with a 30 m 100 foot turning radius. For trenches deeper than 15 m 50 feet, consult with Contractors about the required turning radius.
**************************************************************************

The excavation shall begin from the working surface and shall provide a vertical (within 2 percent) continuous [_____] 900 mm 3 foot minimum width trench to the required depth along the centerline of the excavation. [The slurry trench shall key [_____] 600 mm 2 feet into the [_____] stratum.]

The Contracting Officer may direct the Contractor to modify the trench depth based on examination of bucket cuttings or drive samples. The toe of the slope of the trench excavation shall not precede the toe of the S-B backfill slope by less than [_____] 9 meters 30 feet or more than [_____] 30 meters 100 feet. At the intersection of 2 straight line segments, the trench excavation shall extend a minimum of [_____] 1500 mm 5 feet beyond the outside of the intersection at all depths. If trench excavation overlaps into previously completed slurry trench, the excavation shall extend a minimum of [_____] 3 meters 10 feet into the previously placed S-B backfill at all depths. Any removed section of completed slurry trench shall be refilled with S-B backfill at no additional expense to the Government.

3.3.1 Confining Stratum Excavation

**************************************************************************
NOTE: If the confining stratum is a competent low permeability bedrock, a very small penetration into the bedrock may be satisfactory. High costs may result by requiring a 600 mm 2 foot key into competent bedrock. Remove this paragraph if not required in the project.
**************************************************************************

The confining stratum shall be excavated the full trench width to the depths shown [or to the depth of refusal] [or as otherwise directed]. [Any [sandstone] [_____] lenses encountered at the minimum excavation depth shall be removed for the full width of the trench and into the underlying confining stratum.] The confining stratum shall then be sampled in accordance with paragraph SAMPLES OF CONFINING STRATUM. Termination of excavation will be approved by the Contracting Officer.
### 3.3.2 Blasting Plan

**NOTE:** Blasting, if necessary, may cause unanticipated adverse effects in the subsurface. The designer should carefully evaluate the need for blasting to remove or loosen subsurface materials. Other methods such as chiseling or modification of slurry trench alignment or depths should be considered prior to implementation of any blasting. Remove this paragraph if not required in the project.

Any blasting shall be approved. Blasting shall be conducted in accordance with an approved blasting plan. The blasting plan shall include hole spacing and depths, loading, delay sequence, type of explosives, safety program, and any other pertinent information that will be necessary for the Contracting Officer's evaluation. Explosive materials shall be stored on the site. A drawing showing the top and bottom elevations of the sandstone at each blasting drill hole shall be submitted. Submit a blasting plan, as specified, for approval.

### 3.4 SLURRY PLACEMENT AND TESTING

**NOTE:** Sand content of the in-trench slurry is highly dependent upon the soils through which the trench is excavated. In many cases, typical values for sand content can be as high as 30 percent without impacting the quality of the installation. It should be noted that higher sand contents also lead to a higher density slurry. Adjustments should be made in Table 1 regarding slurry density and sand content limits according to site conditions. The main concern is to ensure that sand is not dropping out of the in trench slurry to the bottom of the trench in amounts so as to affect performance of the slurry trench.

### 3.4.1 Slurry Placement

Introduce slurry into the trench at the time excavation begins. The level of the slurry in open trenches shall be maintained a minimum of 900 mm 3 feet above ground water level and no more than 600 mm 2 feet below the top of the working surface until the placement of S-B backfill is complete.

[If the density or sand content of the slurry in the trench does not conform to the standards specified in Table 1, the excess solids shall be removed from the slurry using approved methods or the slurry shall be replaced with fresh slurry.] Slurry shall not be diluted by surface water. Conditioning of the slurry may require recirculation through a shaker screen or the addition of approved additives. Provide sufficient personnel, equipment, slurry storage areas, and prepared slurry materials ready to raise the slurry level at any time in the excavated trench, weekends and holidays included.
3.4.2 Slurry Testing

The bentonite slurry in the trench shall be sampled a minimum of 2 times each [_____] [8] hour shift (near the beginning and end of each shift), at two depths; approximately 600 mm 2 feet below the slurry surface and approximately 600 mm 2 feet above the bottom of the trench. These samples shall be taken within 1500 mm 5 feet of the toe of the S-B backfill slope. Additional samples shall be obtained at the request of the Contracting Officer.

3.5 EXCAVATED MATERIAL

Material excavated from the trench [shall] [shall not] be used as backfill. [Excavated material to be used as backfill shall be stockpiled for subsequent processing in approved areas.] [Excavated trench material not used as backfill shall be placed [in the waste disposal area] [as directed].]

3.6 STABILITY

**************************************************************************
NOTE: A stability analysis should be performed during design to determine required minimum slurry densities or levels, and to determine if any restrictions will be required regarding stockpile placement or other loading situations. Any site specific restrictions should be described below.
**************************************************************************

The Contractor is responsible for ensuring and maintaining the stability of the excavated trench at all times, for its full length and depth, and for maintaining slurry densities and levels within specified limits. Control surcharges from all excavation and backfilling equipment, waste, berm construction, backfill stockpiles, and any other loading situations that may affect trench stability. It is the Contractor's sole responsibility to ensure that the mixing of S-B backfill and any stockpiles do not affect the open trench stability. In the event of failure of the trench walls prior to completion of backfilling, re-excavate the trench, remove all material displaced into the trench, and take corrective action to prevent further deterioration, at the Contractor's expense.

3.7 TRENCH CLEANING

**************************************************************************
NOTE: The initial cleaning of the trench bottom can be accomplished with an excavator bucket. This method of trench cleaning will generally be sufficient for final cleaning of most projects. It is generally recommended to limit the distance between the excavated face and the toe of the S-B backfill, as required in Paragraph SLURRY TRENCH EXCAVATION, in order to assure trench stability. In some cases, the air-lift pump method may be the only way to clean certain reaches of the trench. However, the air-lift pump method can slow production, is somewhat difficult to maneuver in the trench, and may not clean the trench bottom effectively in many cases.
**************************************************************************
Cleaning of the S-B backfill face can be difficult since the materials are very soft and may require the excavator to track over portions of the trench that are not yet backfilled. This procedure should only be specified when required to meet project needs.

At a minimum, unless otherwise approved, the trench bottom shall be cleaned at the start of each [_____] [day]. (If S-B backfill placement operations have ceased for longer than [24] [_____] hours, the face of the S-B backfill slope shall be cleaned prior to the placement of additional S-B backfill.) The trench bottom shall be probed for any deposits or sloughed materials prior to cleaning. The trench bottom shall be cleaned by using an [excavator bucket,] [air lift pump] or other approved equipment to ensure removal of sand, gravel, sediment, and other material left in the trench during excavation or which has settled out of the slurry. Cleaning equipment shall not remove material from the walls of the trench. The Contracting Officer may require more frequent cleaning. [After the trench bottom has been cleaned, sample the trench bottom with a [drive tube] [split tube] [_____] sampler approved by the Contracting Officer. Rock surfaces that cannot be penetrated by a [drive tube] [split spoon] sampler shall not be required to be sampled. After examining the samples, the Contracting Officer will either approve the excavation at the points checked or require additional cleaning. If additional cleaning is required, then additional samples shall be furnished as specified above.]

3.8 S-B BACKFILL MIXING AND PLACEMENT

3.8.1 Mixing

NOTE: It may be preferable to mix the S-B backfill in a separate mixing area rather than along the side of the trench, particularly in contaminated areas, or where off-site borrow is used for backfill materials. Other mixing methods may include the utilization of a batch plant or pugmill operation to blend materials. Although more expensive, these procedures may minimize operations in a contaminated area.

The S-B backfill shall be thoroughly mixed via diskimg, harrowing, bulldozing, blading, or other approved methods into a homogeneous mass, free from large lumps or clods of soil or pockets of fines, sand, or gravel. Occasional lumps of up to [_____] [75] mm [3] inches in their largest dimension will be permitted. All particles shall be coated with slurry. The S-B backfill may be sluiced with slurry during the mixing operations. Sluicing with water is not permitted. The S-B backfill shall be mixed [in a separate mixing location as shown on the drawings] [along the side of the trench]. [When mixing the S-B backfill along the side of the trench, heavy equipment such as bulldozers shall not operate in a back and forth fashion, paralleling the open trench, closer than 5 meters 15 feet from the lip of the trench. Excess slurry may be allowed to flow back into the trench].

SECTION 31 56 13.13  Page 19
3.8.2 Placement

Initial S-B backfill placement shall be by one of the following methods:
(1) Placement by lowering S-B slurry to the bottom of the trench with crane and clamshell bucket, or tremie methods until the surface of the S-B backfill rises above the surface of the slurry trench at the end of the trench; (2) Construct a lead-in trench [1H:1V] [_____] or flatter at a point outside of the limits of work to allow a S-B backfill face to form prior to reaching the full depth of the required slurry trench. No payments will be made for the portions of trenches which lie outside of the limits of work. Placement operations shall proceed in such a manner that the slope of the initially placed S-B backfill is maintained. Free dropping of S-B backfill through the slurry is not permitted. The S-B backfill shall be placed so that it will slide down the forward face of the S-B backfill slope. The S-B backfill shall be placed in the excavated trench so that no pockets of slurry are trapped and that a constant slope is maintained. Placement shall be continuous from the beginning of the trench in the direction of the excavation to the end of the trench.

3.8.3 Mixing and Placing During Cold Weather

No mixing or placing of the S-B backfill shall be performed when the air temperature is below \(-7\) degrees C \(20\) degrees F. Frozen S-B backfill shall not be placed in the trench and backfill material containing frozen lumps shall not be used to mix S-B backfill.

3.8.4 Testing

When required, additional samples for permeability testing shall be taken at [___] intervals for the [___] [full depth] of the completed slurry trench using \(75\) mm \(3\) inch thin wall (Shelby) tubes. [If test results do not meet the requirements listed in Table 1, corrective action, as determined by the Contracting Officer, shall be taken.]

3.9 SOUNDINGS

Take excavation and S-B backfill soundings every [____] 6 meters 20 feet along the trench centerline using a weighted tape, cable, or other approved device. Submit a record of soundings and measurements taken during construction of the slurry trench. Soundings shall be measured to the nearest \(30\) mm \(0.1\) ft. The soundings shall measure the following:

3.9.1 Elevation of Top of Confining Stratum

The top of the confining stratum shall be determined based on examination of samples taken as described under paragraph SAMPLES OF CONFINING STRATUM. This elevation shall be subject to approval.

3.9.2 Elevation of Trench Bottom Prior to Backfilling

Determine the elevation of the trench bottom after the trench has been cleaned and approved as described under paragraph Trench Cleaning. This sounding shall not precede the toe of the S-B backfill slope more than [____] 15 meters 50 feet. This elevation is subject to approval by the Contracting Officer.

3.9.3 Profile of S-B Backfill Slope and Trench Bottom

The S-B backfill slope and trench bottom shall be sounded at the beginning
3.10  **AS-BUILT PROFILE**

An as-built profile of the trench bottom and S-B backfill slopes, including descriptions of materials encountered in the trench bottom, shall be continuously maintained. This profile shall indicate extent of excavation and the S-B backfill profile at the end of each work day [and after each S-B backfill batch is placed in the trench as determined from soundings]. [The S-B backfill batch numbers shall appear on the profile with the limits of each batch of material delineated as placed.] Submit a scale drawing providing a log of the subsurface materials excavated from the trench, and a profile of the completed slurry trench. [The limits of each batch of S-B backfill shall be delineated as placed.]

3.11  **TREATMENT OF TOP OF SLURRY TRENCH**

******************************************************************************

**NOTE:** For heavy equipment crossings, it is recommended the upper portion of the S-B backfill be excavated and a clay plug be placed under the compacted trench cover. Additional support may be necessary to support the anticipated loads.

******************************************************************************

Prior to placement of the compacted trench cover, a temporary [non-compacted soil] [plastic sheeting] cover shall be placed over the trench to prevent desiccation. The temporary cover material shall be placed within [2] [--] days after S-B backfill placement is completed over each 30 meter 100 foot reach. If any depression develops within the completed slurry trench area, it shall be repaired by placing and compacting additional trench cover soil. After a minimum [two] [--] weeks, the temporary trench cover shall be removed and replaced by a final compacted trench cover. A final compacted trench cover [--] mm feet wide and [--] mm ft deep shall be placed [as specified in Section [--]] [to a dry density of [--] 90 percent of maximum density at optimum moisture to plus 3 percent in accordance with ASTM D698]. Heavy construction equipment and machinery shall only be driven over the slurry trench at approved heavy equipment crossing points.

3.12  **QUALITY CONTROL TESTING**

Provide Quality Control Inspectors as necessary for bentonite slurry preparation and maintenance, trench excavation, and S-B backfill preparation and placement. Submit all test results.

3.12.1  Bentonite Tests

A minimum of 1 test for each specified requirement shall be performed for each truck or rail car shipment delivered to the site.

3.12.2  Water Tests

******************************************************************************

**NOTE:** Acceptable slurries can generally be made from most water sources; however, any suspect water should be tested during pre-construction tests.

Water with high hardness
A minimum of [_____] test[s] for each specified requirement shall be performed for each water source used. Testing shall be performed as specified in Table 1.

3.12.3 Backfill Material Tests

One set of backfill material tests, as specified in Table 1, shall be performed for every [_____] 500 cubic meters yards used.

3.12.4 Slurry Properties

NOTE: It is generally recommended that after high shear mixing, the slurry be allowed to hydrate for 8 hours before use in the trench. This process assures that the bentonite is fully hydrated and is uniform throughout. Shorter hydration times may be allowed if it can be shown that the prepared slurry meets or exceeds project requirements.

[Slurry shall be required to hydrate a minimum of [8] [_____] hours prior to use.] The initial bentonite slurry shall be tested prior to placing in the trench and a minimum of 2 times each [_____] [8] hour shift per mixing plant. Submit a record of bentonite slurry mix quantities, proportions of additives utilized, and adjustments for each batch.

3.12.5 S-B Backfill Tests

NOTE: The confining pressure used to perform permeability testing should be representative of site conditions. To simulate site conditions, the confining pressure specified should be representative of the upper quarter to one-half of the wall depth.

Shelby tube, split spoon, or other sampling devices may be pushed into the completed slurry trench to obtain samples for quality control testing; however, it can be difficult to obtain quality samples of many S-B backfills, especially if there are coarse materials in the S-B backfill. As a result, samples of S-B backfill obtained just prior to placement in the trench are used for QA/QC, and samples of the S-B backfill from the completed wall, if taken, may be used for QA or for information only. The designer should determine what samples are necessary to meet project requirements. It should be noted that permeability tests may take several days before results are known.

Sampling and testing shall be performed, in accordance with the approved Preconstruction Testing Plan, just prior to placing S-B backfill in the trench as shown in Table 1. [The density of the S-B backfill shall be calculated using a 101.6 mm 4 inch cylindrical mold as described in]
Paragraph 6 of ASTM D698.  S-B backfill shall be placed in the mold and rodded 10 times.  Additional S-B backfill shall then be added to fill the mold.  The weight and volume of the molded S-B backfill shall then be used to determine the density.] [The density of the S-B backfill shall be determined using a mud balance.] Density shall be determined at a rate of 1 test for every [_____] [1000] cubic meters yards.  A sample of S-B backfill for permeability testing shall be taken just prior to placement in the trench for every [1000] [_____] cubic meters yards.  Submit a Plan providing a list of test equipment, procedures, and materials to be used to [verify] [develop] the mix design for the S-B backfill and an S-B Backfill Test Report containing the results of the tests performed, a report summarizing the procedures and results of the Pre-construction S-B backfill mix tests.  The report shall include a description of mix proportions, gradations, slumps, densities, permeabilities, and moisture contents of [_____] 3 samples of the final S-B backfill mix using the bentonite and backfill materials proposed for use.  Submit a minimum of 22.5 kg 50 pounds of each type of proposed borrow soil at least [1] [_____] month prior to use.

[3.12.6  Samples of Confining Stratum]

**************************************************************************
NOTE: This paragraph is to be used if the slurry trench is to be keyed into a confining stratum.  Samples of the confining stratum can be based on examination of samples taken from bucket cuttings or drive tube samplers.  In many cases, examination of bucket cuttings alone will be sufficient to determine when the confining stratum has been reached.  If required, samples can be obtained with drive tube samples.  Drive tubes can be pushed with the excavator bucket or a drill rig.  Remove this paragraph if not needed in the project.
**************************************************************************

Samples of the confining stratum shall be taken at [_____] meter foot horizontal intervals and at additional intervals or depths as directed.  Samples shall be obtained from [either] [excavator bucket cuttings] [drive tube samples].  [The sampler shall be a [_____] mm inch I.D., or larger, [drive tube sampler] with a minimum length of [_____] m feet.  Samples shall be obtained by advancing the sampler a minimum of [_____] mm inches into the confining stratum.  The samples shall have a minimum length [recover] of [_____] mm inches.] After examining these samples, the Contracting Officer will either approve the termination of excavation at the sample points or require additional excavation.  If additional excavation is required, then additional samples shall be furnished as specified above.  All samples shall be properly identified and labeled, placed in sealed plastic containers and stored in a location designated by the Contracting Officer.

]3.13  CLEAN-UP

Excavation spoil, unused S-B backfill, and excess slurry shall be removed following completion of S-B backfill placement.  These materials shall be disposed of [in the waste disposal area] [at the direction of the Contracting Officer] [_____].

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for procurement, installation, and testing of cast-in-place concrete piles, steel casing.

Adhere to *[UFC 1-300-02](#)* Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a *[Criteria Change Request (CCR)](#)*.

NOTE: Requirements for materials and procedures for special or unusual design should be added as necessary to fit specific projects. It is expected that cast-in-place concrete will be used elsewhere on the project and therefore Section 03 30 00 CAST-IN-PLACE CONCRETE will be a part of the specification.

NOTE: The following information shall be shown on the project drawings:

1. Locations, dimensions, shape, length, and design strength of piles.
2. Locations and lengths of test piles and load tests, if either is required.

3. Soil data, where required.

PART 1   GENERAL

1.1 REFERENCES

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

AMERICAN WELDING SOCIETY (AWS)

AWS D1.1/D1.1M (2020; Errata 1 2021) Structural Welding Code - Steel

ASTM INTERNATIONAL (ASTM)

1.2 REQUIREMENTS

NOTE: Select the applicable paragraph(s) from the following:

1.2.1 [Pile Lengths and Quantity]

NOTE: Use this option for lump-sum contracts. This
method should be used in all but special cases. Fill in Table 1 as required selecting columns applicable to project. Generally, pile capacity, location, and tip elevation are shown on the plans.

Base bids upon the [number, size, capacity, and length of piles as indicated.] [following Table 1:]

<table>
<thead>
<tr>
<th>Location</th>
<th>Number</th>
<th>Size</th>
<th>Capacity</th>
<th>Length</th>
</tr>
</thead>
</table>

When the total number of piles or the number of each length vary from that specified as the basis for bidding, an adjustment in the contract price or time for completion will be made in accordance with Contract Clause, "changes." Adjustments in the contract will not be made for [pile splices;] cutting off piles; for a portion of a pile remaining above the cut-off elevation; or for broken, damaged, or rejected piles.

1.2.2 Measurement and Payment

See SF 1442, "Solicitation, Offer and Award" and "Schedule of Bid Items."

NOTE: For NAVFAC LANT projects, use the following.

[Payment will be for the total length of completed and accepted piling, measuring from tip elevation to cutoff elevation. Payment will be by the contract unit price for furnishing labor, materials, tools, equipment, and incidentals, and for doing the work involved in furnishing and driving piling. Driving piling includes furnishing and driving piling including [test piles] [jetting or drilling] [pile splices] [excavation and backfill around piling] pile cutoff, [redriving, and replacement of broken, or rejected piles]. [Payment will be separate contract unit price for furnishing labor, materials, tools, equipment, and incidentals for doing the work involved in performing load tests on piles.]]

1.3 SUBMITTALS

NOTE: Review Submittal Description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G". Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the
Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy, Air Force, and NASA projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy, Air Force, and NASA projects, or choose the second bracketed item for Army projects.

**************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-02 Shop Drawings

Piles and pile cap

Show placement of steel. Show casing details, closures, and splices. [Show placement of and calculations for reinforcement.]

SD-04 Samples

Test piles

SD-06 Test Reports

Test pile data

[Load tests]

**************************************************************************

NOTE: Delete sentence in brackets when test piles are not driven.

**************************************************************************

For load tests, submit test data and results. [Submit test pile data from steel cased cast-in-place concrete test piles, from which the Government will determine and list the "calculated" tip elevations and the driving resistances for all piles. Use this list as the basis for ordering piles. Do not order piles until list is provided by the Government.]

SD-07 Certificates

**************************************************************************

NOTE: Mill certificates are generally required only
Pipe piles
Concrete testing results

[Steel shell casings]

Show name and location of steel mill and fabricating plant for pipe piles.

Data on pile driving equipment

Include in data for driving equipment, make, model, and type of pile hammer; manufacturer's specification sheet on pile hammer; and detail drawings of driving helmets, hammer cushion or capblock with records of successful use.

SD-11 Closeout Submittals
Pile driving records

1.4 QUALITY ASSURANCE
1.4.1 Welding

Shop and field welding, qualification of welders, and inspection of welds shall be in accordance with AWS D1.1/D1.1M.

1.5 EQUIPMENT
1.5.1 Pile Hammers

NOTE: Insert driving energy of hammer. Select hammer based on results of wave equation analysis such that hammer is compatible with pile type and capacity and hammer/cushion/pile system are capable of obtaining required capacity.

Furnish a hammer having a capacity at least equal to the hammer manufacturer's recommendation for the total weight of pile and character of subsurface material to be encountered. Obtain required driving energy of hammer, except for diesel hammers, by use of a heavy ram and a short stroke with low impact velocity. [For driving use the same type pile hammer, operated at same rate and in same manner, as that used for driving testing piles.]

1.5.2 Driving Helmets (Caps) and Cushion (Capblocks)

Use a hammer cushion or capblock between the helmet, driving cap or driving head and hammer ram. Driving cap and hammer cushion combination shall be capable of protecting head of pile, minimizing energy absorption and dissipation, and transmitting hammer energy uniformly to top of pile. When driving helmet or cap is used, it shall fit loosely around top of pile so
that the pile may rotate slightly without binding within helmet or cap. [During test pile period demonstrate to satisfaction of the Contracting Officer that equipment to be used on the project performs the above function.] Hammer cushion or capblock may be a solid hardwood block at least 150 mm 6 inches thick with grain parallel to pile axis and enclosed in a close-fitting steel housing or may consist of aluminum and micarta (or equal) discs stacked alternately in a steel housing. Use steel plates at the top and bottom of the capblock assembly. Under no circumstances will use of wood blocks, wood chips, rope or other material permitting excessive loss of hammer energy be permitted.

PART 2    PRODUCTS
2.1    PILING
2.1.1    Casings

**************************************************************************
NOTE: There are generally three types of casing or pipe used. Open-end and closed-end structural casings (usually steel pipe) and a closed-end non-structural casing (usually light gage shells). Non-structural casings must be driven with a mandrel. Specify the minimum thickness for any structural casing. Thickness of non-structural casings (light gage shells) is the responsibility of the Contractor as the shell is simply a form for the concrete. Ensure minimum nominal diameter at tip and two-third points above tip are indicated on drawings. In general, use closed-end casings except in the following conditions where open-end structural casings should be considered:

1. It is important to avoid soil displacement as in piles driven adjacent to existing structures.

2. Soil condition indicate a dense or clayey soil, or extremely coarse granular soil is present, such as gravel.
**************************************************************************

Provide a circular cross section throughout casing length whether or not modified by helical corrugations or flutings. Leave casing permanently in place. Provide casing with closed tips [, except for steel pipe casings conforming to ASTM A252 that may be open-end driven]. Provide watertight joint and tip connections. [Provide non-mandrel driven casings of steel with a wall thickness of [_____] mm [_____] inches.] Provide any one of the following types or combination of types of casings [, but provide only one type or combination of casing throughout the project].

2.1.1.1    Uniform Taper

Diameter shall increase from tip to cut-off at a uniform rate. Minimum nominal diameter at tip and two-third points above tip shall be as indicated.

2.1.1.2    Step-Taper

Section increments shall increase in diameter uniformly. Minimum nominal
diameter at tip and two-third points above tip shall be as indicated.

2.1.1.3 Constant Section

Diameter shall be constant from tip to cut-off. Steel pipe piles, conforming to ASTM A252, Grade 2, may be used in lieu of casings of constant-diameter section. Minimum nominal diameter shall be as indicated.

2.1.1.4 Combination Type

Combination type cast-in-place concrete piles, steel casing, may be any of the following combinations.

a. Steel pipe lower section with metal casing taper or constant-diameter upper section.

b. Constant-diameter or tapered lower section with tapered upper section.

c. Tapered lower section with constant-diameter upper section.

2.1.2 Piling

Provide steel cased cast-in-place concrete piles.

2.1.3 Reinforcement

**************************************************************************
NOTE: Ensure that reinforcing steel size is always indicated. Length must be indicated if less than full pile length.
**************************************************************************

Materials shall conform to the requirements of Section 03 30 00 CAST-IN-PLACE CONCRETE.

2.1.4 Concrete

**************************************************************************
NOTE: Normal usage would reference all concrete work to Section 03 30 00 CAST-IN-PLACE CONCRETE. If a mix design for this piling section is not or will not be specified in one of these sections, add the optional sentence to provide the required mix design. Insert the ultimate compressive strength required by the design. Fill in blank for slump if different values are required by mix design or pile diameter.
**************************************************************************

Material shall conform to the requirements of Section 03 30 00 CAST-IN-PLACE CONCRETE.[ Provide concrete with a minimum compressive strength of [_____] MPa [_____] psi at 28 days, a slump of [from [100 to 150 mm] [4 to 6 inches] [______], and a maximum aggregate size of 19 mm 3/4 inch].]
3.1 DRIVING

3.1.1 Driving Casing

NOTE: Delete items in brackets when test piles or load tests are not used.

Drive casing to or below the ["calculated"] tip elevation [to reach a driving resistance in accordance with the schedule which the Government will prepare from the test-pile driving data]. When a pile fails to reach the ["calculated"] tip elevation, [or when a pile reaches the ["calculated"] tip elevation without reaching the required driving resistance,] notify the Government and perform corrective measures as directed by the Contracting Officer.

3.1.2 Tolerance in Driving

NOTE: Pile butt tolerance may be increased if the design allows. Location within 100 mm 4 inches of indicated position is a strict tolerance.

Drive casing with a variation of not more than 21 mm per meter 0.25 inch per foot of pile length from the required axial alignment. Locate butts within [100] [_____] mm [4] [_____] inches of position indicated. Do not force casings into position. Check casings for heave after all piles are driven in a cluster within a 4.50 meters 15 foot radius. Redrive to required tip elevation or penetration resistance those casings found to have heaved. Maintain center of gravity of each group of footing piles with templates or other approved means. Where casings are damaged, mislocated, or driven out of alignment, replace or drive additional casing as directed.

3.1.3 Jetting or Predrilling of Casings

NOTE: Drilling may be used, providing the drill diameter is at least 50 mm 2 inches in diameter smaller than the pile, and the Contractor can demonstrate a procedure that will not detract from the carrying capacity of the pile. Jetting or predrilling should generally not be permitted in the following conditions:

1. For piles dependent on side friction in fine-grained, low-permeability soils (high clay or silt content) where considerable time is required for soil to reconsolidate around the piles;

2. For piles subject to uplift;

3. For piles adjacent to existing structures;

4. For piles in closely spaced clusters unless the
load capacity is confirmed by test and unless all jetting is done before final driving of any pile in the cluster.

[Jetting or predrilling of pile casing [will] [shall not] be permitted.] Discontinue jetting or predrilling approximately 1.5 meters 5 feet above the [bearing stratum] [calculated] [pile tip elevation]. Drive casing [the final 1.5 meters 5 feet of penetration] [to calculated pile tip elevation]. Before starting [final] driving firmly seat casing in place by application of a number of reduced energy hammer blows.

3.2 SPICING AND CUTTING

3.2.1 Splicing of Load Bearing Casings

NOTE: Restrict number of splices where design indicates splicing will cause structural weakness. In general uplift piles using a structural casing should have as few splices as possible.

Splices may be used when approved by the Contracting Officer. [Do not use more than two splices per full length of casing]. Splices shall be able to transmit vertical and lateral forces, and in addition, shall develop 100 percent of the flexural capacity of the ordinary pile casing cross section. Make lateral joints with a full penetration groove weld in a butt joint in accordance with AWS D1.1/D1.1M or as approved by the Contracting Officer.

3.2.2 Cut-Off

Cut-off casings by oxyfuel cutting, sawing or other means approved by the Contracting Officer, to within 25 mm one inch of the designated cut-off elevation.

3.3 CONCRETING

Cast-in-place concrete is included in Section 03 30 00 CAST-IN-PLACE CONCRETE.

3.3.1 Preparation

NOTE: Insert the radius distance 3 to 6 meters 10 to 20 feet. Where open end casings are required, do not place concrete until all soil, water, and foreign material is removed.

Do not place concrete in a pile casing until all other casings within a radius of [_____] meters [_____] feet or within heave range have been driven and inspected. Clean inside of casing by removing soil and other foreign material. Remove free water until the maximum depth of water in the casing is 100 mm 4 inches. Inspect each casing after installation and before placing [reinforcement and] concrete. Verify the integrity of the casing throughout its length. Verify the absence of distortion and that any reduction of area does not exceed 10 percent.
3.3.2 Reinforcement

Reinforce unsupported sections of piles, uplift or tension piles [throughout their entire length] [as indicated], piles exposed to high bending stresses not resisted by batter piles, and between top of pile and pile cap or slab. Assemble and place reinforcement in casing as a preassembled unit. Secure reinforcement prior to placement of concrete.

3.3.3 Concrete

Deposit concrete in casing in a continuous operation by means of a funnel or hopper.

3.4 FIELD QUALITY CONTROL

3.4.1 Test Piles

**************************************************************************
NOTE: Indicate location of test piles on plans or insert the numbers of appropriate soil boring test holes.
**************************************************************************

**************************************************************************
NOTE: Drilling may be used, providing the drill diameter is at least 50 mm 2 inches in diameter smaller than the pile, and the Contractor can demonstrate a procedure that will not detract from the carrying capacity of the pile. Jetting or predrilling should generally not be permitted in the following conditions:

1. For piles dependent on side friction in fine-grained, low-permeability soils (high clay or silt content) where considerable time is required for soil to reconsolidate around the piles;

2. For piles subject to uplift;

3. For piles adjacent to existing structures;

4. For piles in closely spaced clusters unless the load capacity is confirmed by test and unless all jetting is done before final driving of any pile in the cluster.
**************************************************************************

Use test piles of the type, and drive in the manner specified for all piling elsewhere in this section. The Government will use test pile data to determine the "calculated" pile tip elevation and required driving resistance. Drive test piles [at the locations indicated] [in the vicinity of soil boring test holes Nos. [____], [____], and [____]]. Drive test piles to [indicated tip elevation] [indicated bidding lengths]. Drive piles driven one day an additional 150 mm 6 inches using full rated driving energy hammer on the next work day, unless refusal is encountered. Record an increase or decrease in driving resistance. When there is a decrease in driving resistance, a load test, at the expense of the Government, may be required by the Contracting Officer. Use test piles, when located properly and offering adequate driving resistance in the finished work. [Jetting is
permitted when test piles clearly establish the validity of its use, as directed by the Contracting Officer.]

3.4.2 [Load Tests

**************************************************************************

NOTE: If pile load tests are required, specify number of piles. Select method of load test. Permit methods using anchor piles, see ASTM D1143, only if approved by EFD Code 411, Geotechnical Branch or in EFD's with no Code 411, EFD Code 402, Structural Branch or EFD Code 405, Civil Branch. Insert figures (tons) corresponding to 200 percent of the design load. Select the appropriate acceptance criterion. The first method (offset) is generally recommended for normal size piles. The second method (slope) and the third method (net-settlement) can be combined into one criterion.

**************************************************************************

Perform load tests on [_____] piles. Load tests shall be in accordance with ASTM D1143/D1143M as modified herein. [The use of anchor piles is not permitted.] Provide apparatus for applying the vertical loads as required by the method, either for load supported directly by the pile or load from weighted box or platform [or reaction frame attached to sufficient uplift piles to take safely the required load] applied to the pile by hydraulic jack. Increase the load in increments until rapid progressive settlement takes place or until a total load of [_____] metric tons [_____] tons has been applied. Consider the load test satisfactory when [after one hour at full test load the gross settlement of the pile butt is not greater than the gross elastic pile compression plus 4 mm 0.15 inches plus one percent of the pile tip diameter or width in millimeters inches.] [the slope of the gross load-settlement curve under the full test load does not exceed 1.4 mm per metric ton 0.05 inches per ton.] [the net settlement after removal of test loads does not exceed 19 mm 3/4 inches.] Make load tests at locations shown on driven test piles. Additional load tests, at the expense of the Government, may be required by the Contracting Officer. [Loading, testing, and recording and analysis of data must be under the direct supervision of a registered professional engineer provided and paid for by the Contractor.]

]3.4.3 Concrete Testing

**************************************************************************

NOTE: The following table is recommended for use in determining the number of test cylinders required in relation to the size of each lot of piles to be tested.

<table>
<thead>
<tr>
<th>Pile Lot</th>
<th>Number of Test Cylinders</th>
</tr>
</thead>
<tbody>
<tr>
<td>25</td>
<td>2</td>
</tr>
<tr>
<td>100</td>
<td>48</td>
</tr>
<tr>
<td>1,000</td>
<td>20*</td>
</tr>
</tbody>
</table>
Sample and test concrete in accordance with Section 03 30 00 CAST-IN-PLACE CONCRETE. Take specimens for every [_____] piles with at least 4 specimens for any one day's operation. Take specimens from a batch chosen at random.

3.4.4 Pile Records

NOTE: Omit reference to load test when not required in project.

For each pile, keep a record of the number of blows required for each meter foot of penetration and number of blows for the last 150 mm 6 inches of penetration or fraction thereof for test piles, penetration in blows per meter foot for job piles [as required for the "calculated" driving resistance]. Include in record the beginning and ending times of each operation during driving of each pile, type and size of hammer used, rate of operation, stroke or equivalent stroke for diesel hammers, type of driving helmet, and type and dimensions of hammer cushion (capblock) and pile cushion used. Record retap data and any unusual occurrence during pile driving. Notify Contracting Officer 10 days prior to driving of [test] piles [and load test].

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for precast, prestressed piles.

Adhere to **UFC 1-300-02** Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a **Criteria Change Request (CCR)**.

NOTE: The extent and location of the work to be accomplished should be indicated on the project drawings or included in the project specification.

NOTE: Show the following information on the drawings:

1. Locations and design loads of piles. If both tension and compression piles are contained in
design, identify by type.

2. Size, shape, and length of piles.

3. Locations, sizes, and number of prestressing steel strands. Unit stresses for prestressing strands.

4. Details of reinforcement.

5. Details of splices, if required.

6. Locations of test piles, if required.

7. Soil data, where required.

8. Identify piles as vertical or battered.

------------------------------------------------------------------------------------------------------------------------

PART 1   GENERAL

------------------------------------------------------------------------------------------------------------------------

NOTE: Structural engineer must confirm the structural capacity of piles and provide specific bending moments, lateral loads and other design requirements for pile design.

------------------------------------------------------------------------------------------------------------------------

1.1 DESCRIPTION

Design, furnish, install and test precast prestressed concrete piles at the locations indicated on the drawings and specified herein. [Assume test pile[s] will be directed to be placed in [a ]location[s] that can be incorporated into the work.][Test piles that meet performance requirements can be incorporated into the permanent work.]

1.2 REFERENCES

------------------------------------------------------------------------------------------------------------------------

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

Subsurface soil data logs are [indicated][appended to the special contract requirements][provided on the project drawings].[ The subsoil investigation report may be examined at [______].]

]1.4 BASIS OF BID

**************************************************************************
NOTE: Select one of the following options:
NOTE: Use "Lump Sum" paragraph below for lump (principal) sum bidding of piles. Use this in all projects except those where exact pile lengths cannot be practically determined prior to the actual work. Clearly show number of piles, pile capacity, pile locations, and tip and cutoff elevations on the drawings.

Use "Unit Price" paragraph for unit price bidding of piles. Specify unit price bid items for piles only for projects where exact quantities cannot be practically determined prior to the actual work. Lengths of piles must be determined as accurately as possible, prior to bidding, since the unit price per meter foot of the piles varies as the length increases or decreases. Refer to Standard Test Method for High-Strain Dynamic Testing of Deep Foundations (ASTM D4945).

1.4.1 Production Pile Acceptance Criteria

Safe design capacity for piles is [_____] KN [_____] kips. Drive piles to [minimum tip elevation] [a minimum depth of [_____] m [_____] feet below cut-off elevation], and to such additional depth as required to obtain a bearing capacity of not less than [_____] KN [_____] kips. The Contractor's Geotechnical Consultant will determine the terminal driving criteria based on results of [dynamic pile driving tests at end of drive or restrike] [static load tests] [wave equation analysis].

The following formulas can be used in cases where allowable pile loads are less than 355 KN 80 kips (determined using a factor of safety of 3 for individual piles and 4 for pile groups) and are presented only as a guide to aid in establishing the controlling penetration per blow, which, together with the minimum depth of penetration will serve to determine the required minimum depth of penetration of each individual pile:

For double acting hammers:

\[ R = \frac{2E}{S + 0.1} \]

For single acting hammers:

\[ R = \frac{2WH}{S + 0.1} \]

Where R is the approximate allowable pile load in kips; E equals the energy in foot-kips per blow based on an acceptable certified statement from the manufacturer of the hammer; W equals the weight of the hammer or ram in kips; H equals the height of fall of the hammer or ram in feet; and S equals the average inches of penetration per blow for the last three blows. An allowance will be made for reduced penetration caused by shock absorption of the cushion or cap blocks.

1.5 LUMP SUM PAYMENT

NOTE: Use this paragraph for lump-sum contracts, consult with Contracting Officer's Technical
Representative (Geotechnical Branch) on applicability of use prior to selection. This paragraph will be typically used when there are 1) relatively small quantity of piles, 2) allowable pile loading is less than 355 kN (80 kips), and 3) the subsurface conditions are well defined. Fill in Table I as required selecting columns applicable to project. Generally, pile capacity, location, and minimum tip elevation are shown on plans. Test piles and load tests are not incorporated on lump sum contracts. Delete this paragraph for unit-price contracts.

**************************************************************************

Base bids upon providing the number, size, capacity, and length of piles as indicated on the [drawings.] [following Table I:

<table>
<thead>
<tr>
<th>[Location]</th>
<th>Number</th>
<th>Size</th>
<th>Capacity</th>
<th>Length (tip to cut-off)</th>
<th>[Maximum Bending Moment]</th>
<th>[Maximum Shear Force]</th>
</tr>
</thead>
</table>

Include the cost of all necessary equipment, tools, material, labor, and supervision required to: deliver, handle, install, cut-off, dispose of any cut-offs, and meet the applicable contract requirements. Include mobilization, pre-drilling, and redriving heaved piles. If, in redriving, it is found that any pile is not of sufficient length to provide the capacity specified, notify the Contracting Officer, who reserves the right to increase or decrease the total length of piles to be provided and installed by changing the pile locations or elevations, requiring the installation of additional piles, or directing the omission of piles from the requirements shown and specified. If total number of piles or number of each length vary from that specified as the basis for bidding, an adjustment in the contract price or time for completion, or both, will be made in accordance with the contract documents. Payment for piles will be based on successfully installing piles to both the minimum tip elevation and satisfying the acceptance criteria identified herein. No additional payment will be made for: damaged, rejected, or misplaced piles; withdrawn piles; any portion of a pile remaining above the cut-off elevation; backdriving; cutting off piles; splicing; build-ups; any cut-off length of piles; or other excesses beyond the assumed pile length indicated for which the Contractor is responsible. Include payments for vibration monitoring, sound monitoring and precondition construction surveys.

[1.6 UNIT PRICE

**************************************************************************

NOTE: This paragraph is tailored for Navy.

Delete this paragraph for lump-sum contracts.

For NAVFAC PAC projects: Where there is unit pricing for piles, use this paragraph and edit applicable attachments for inclusion in Standard Form 1442, "Solicitation, Offer and Award" and "Schedule of Bid Items." Select first bracketed text.
For NAVFAC Southeast projects, where there is a need for unit pricing of piles, include this paragraph. Refer to NAVFAC SE Instruction 00010, "Instructions for Preparing Basis of Bid Statement With Unit-Priced Items," for method of specifying unit price bid items. Select first bracketed text.

**************************************************************************
[ For unit price bid, see SF 1442, "Solicitation, Offer and Award" and "Schedule of Bid Items."
]
**************************************************************************

NOTE: For NAVFAC LANT projects, use the following paragraph for measurement and payment and subsequent sub-parts.

**************************************************************************
Requirements of FAR 52.211-18 Variation in Estimated Quantity do not apply to payment for piling. Each pile and test pile acceptably provided will be paid for at the bid unit price per unit length, which will include items incidental to furnishing and driving the piles including mobilization and demobilization, jetting, predrilling, probing, redriving uplifted piles, an additional 1.5 m 5 feet in furnished length for any test pile not driven beyond estimated pile length, and cutting off piles at the cut-off elevation. Include the cost for additional length for the test piles in the total unit price cost for the job. Payment will be made for production and test piles at the bid unit price for the length of pile, from tip to final cut-off, actually provided, excluding buildups and splices directed by the Contracting Officer to be made. If the actual cumulative pile length driven (tip to cut-off) vary more than 25 percent from the total pile length specified as a basis for bidding, at the direction of the Contracting Officer, the unit price per unit length will be adjusted in accordance with provisions of FAR 52.236-2 Differing Site Conditions. Include payments for vibration monitoring, sound monitoring, construction instrumentation and monitoring, and precondition construction surveys.]

] [1.7 PAYMENT

**************************************************************************
NOTE: This paragraph is tailored for Army.
Delete this paragraph for lump-sum contracts.

If Section 01 20 00 PRICE AND PAYMENT PROCEDURES is included in the project specifications, this paragraph title (UNIT PRICES) should be deleted from this section and the remaining appropriately edited subparagraphs below should be inserted into Section 01 20 00 PRICE AND PAYMENT PROCEDURES.

**************************************************************************
1.7.1 Furnishing and Delivering Prestressed Concrete Piles

1.7.1.1 Payment

Payment will be made for costs associated with furnishing and delivering the required lengths of permanent prestressed concrete piles, [including H-pile extensions,] which includes costs of furnishing and delivering piles to the work site. No payment will be made for the driving head or lengths of piles exceeding required lengths. No payment will be made for piles damaged during delivery, storage, or handling to the extent that they are rendered unsuitable for the work, in the opinion of the Contracting Officer.

1.7.1.2 Measurement

Furnishing and delivering permanent prestressed concrete piles will be measured for payment by the linear meter foot of piles required below the cut-off elevation as [determined by the Contracting Officer and furnished to the Contractor] [indicated].

1.7.1.3 Unit of Measure

Unit of measure: linear meter foot.

1.7.2 Driving Prestressed Concrete Piles

1.7.2.1 Payment

Payment will be made for costs associated with driving permanent prestressed concrete piles, which includes costs of handling, driving, [and splicing of piles,] [performing dynamic testing, interpreting data and submitting reports,] measuring heave, redriving heaved piles, removal of [build-ups] driving heads or cutting off piles at the cut-off elevation and removing from the work site, compiling and submitting pile driving records, backfilling voids around piles, and any other items incidental to driving piles to the required elevation.

1.7.2.2 Measurement

Permanent prestressed concrete piles will be measured for payment for driving on the basis of lengths, to the nearest hundredth tenth of a linear meter foot, along the axis of each pile acceptably in place below the cut-off elevation shown.

1.7.2.3 Unit of Measure

Unit of measure: linear meter foot.

1.7.3 Pulled Prestressed Concrete Piles

1.7.3.1 Payment

Payment will be made for costs associated with piles pulled at the direction of the Contracting Officer and found to be undamaged. The cost of furnishing and delivering pulled and undamaged piles will be paid for at the applicable contract unit price for payment item "Furnishing and Delivering Prestressed Concrete Piles". The cost of driving pulled and undamaged piles will be paid for at the applicable contract unit price for payment item "Driving Prestressed Concrete Piles". The cost of pulling undamaged piles will be paid for at twice the applicable contract unit.
price for payment item "Driving Prestressed Concrete Piles", which includes
backfilling any remaining void. The cost of redriving pulled and undamaged
piles will be paid for at the applicable contract unit price for payment
item "Driving Prestressed Concrete Piles". No payment will be made for
furnishing, delivering, driving, pulling, and disposing of piles, including
pile driving points, pulled and found to be damaged and backfilling voids.
New piles replacing damaged piles will be paid for at the applicable
contract unit price for payment items "Furnishing and Delivering
Prestressed Concrete Piles" and "Driving Prestressed Concrete Piles".

1.7.3.2 Measurement

Furnishing and delivering pulled and undamaged permanent prestressed
concrete piles will be measured for payment as specified in paragraph UNIT
PRICES, subparagraph FURNISH AND DELIVER PRESTRESSED CONCRETE PILES.
Pulling undamaged prestressed concrete piles will be measured for payment
as specified in paragraph UNIT PRICES, subparagraph DRIVING PRESTRESSED
CONCRETE PILES. Redriving pulled undamaged prestressed concrete piles will
be measured for payment as specified in paragraph UNIT PRICES, subparagraph
DRIVING PRESTRESSED CONCRETE PILES. New piles replacing damaged piles will
be measured for payment as specified in paragraph UNIT PRICES,
subparagraphs FURNISH AND DELIVER PRESTRESSED CONCRETE PILES and DRIVING
PRESTRESSED CONCRETE PILES.

1.7.3.3 Unit of Measure

Unit of measure: linear meter foot.

1.7.4 Prestressed Concrete Pile Driving Tests

1.7.4.1 Payment

Payment will be made for costs associated with furnishing, delivering,
driving, pulling, and disposing of driven test piles, including pile driving
points and splices; conducting pile driving tests; backfilling voids around piles; compiling pile driving test records; performing dynamic testing; interpreting data; and submitting reports.

1.7.4.2 Measurement

Prestressed concrete pile driving tests will be measured for payment on the
basis of the applicable contract unit price per pile driving test.

1.7.4.3 Unit of Measure

Unit of measure: each.

1.7.5 Prestressed Concrete Piles for Load Tests

1.7.5.1 Payment

Payment will be made for costs associated with furnishing, delivering,
driving, pulling, and disposing of load test piles, including pile driving
points and splices; backfilling voids around piles; compiling pile driving records; furnishing, fabricating, and mounting of strain rods and protective assembly; furnishing, fabricating, and mounting of inclinometer and inclinometer protective assembly; performing dynamic testing; interpreting data; and submitting reports. No additional payment will be made for load test piles incorporated in the permanent work other...
1.7.5.2 Measurement

Prestressed concrete piles for load tests will be measured for payment on the basis of the applicable contract unit price per load test pile.

1.7.5.3 Unit of Measure

Unit of measure: each.

1.7.6 Prestressed Concrete Pile Static Axial Compressive Load Tests

1.7.6.1 Payment

Payment will be made for costs associated with prestressed concrete pile static axial compressive load tests in accordance with ASTM D1143/D1143M, including material and labor for fabricating and furnishing load frames; calibrating load cells and hydraulic jacks; furnishing specified test equipment; installing strain rods; placing and removing test loads and test equipment; recording, reducing, and submitting test data; and compiling and submitting pile static axial load test reports. No payment will be made for rejected pile compressive load tests.

1.7.6.2 Measurement

Prestressed concrete pile static axial compressive load tests will be measured for payment on the basis of the applicable contract unit price per load test.

1.7.6.3 Unit of Measure

Unit of measure: each.

1.7.7 Prestressed Concrete Pile Static Tensile Load Tests

1.7.7.1 Payment

Payment will be made for costs associated with prestressed concrete pile static tensile load tests in accordance with ASTM D3689/D3689M, including material and labor for fabricating and furnishing load frames; calibrating load cells and hydraulic jacks; furnishing specified test equipment; installing strain rods; placing and removing test loads and test equipment; recording, reducing, and submitting test data; and compiling and submitting pile load test reports. No payment will be made for rejected pile static tensile load tests.

1.7.7.2 Measurement

Prestressed concrete pile tensile load tests will be measured for payment on the basis of the applicable contract unit price per number of tensile load test.

1.7.7.3 Unit of Measure

Unit of measure: each.
1.7.8 Prestressed Concrete Pile Lateral Load Tests

1.7.8.1 Payment

Payment will be made for costs associated with prestressed concrete pile lateral load tests in accordance with ASTM D3966/D3966M, including material and labor for fabricating and furnishing load frames; calibrating load cells and hydraulic jacks; furnishing specified test equipment; installing inclinometers; placing and removing test loads and test equipment; recording, reducing, and submitting test data; and compiling and submitting pile load test reports. No payment will be made for rejected pile lateral load tests.

1.7.8.2 Measurement

Prestressed concrete pile lateral load tests will be measured for payment on the basis of the applicable contract unit price per lateral load test.

1.7.8.3 Unit of Measure

Unit of measure: each.

1.7.9 Pulled Load Test Prestressed Concrete Piles

1.7.9.1 Payment

Payment will be made for costs associated with load test prestressed concrete piles pulled prior to load testing at the direction of the Contracting Officer and found to be undamaged. The cost of furnishing, delivering, driving, and pulling undamaged load test piles will be paid for at the applicable contract unit price for payment item "Prestressed Concrete Piles for Load Tests". The cost of pulling undamaged load test piles the second time after redriving and testing will be paid for at twice the applicable contract unit price for payment item "Driving Prestressed Concrete Piles". The cost of redriving pulled undamaged load test piles will be paid for at the applicable contract unit price for payment item "Driving Prestressed Concrete Piles". No payment will be made for furnishing, delivering, driving, pulling, and disposing of load test piles pulled at the direction of the Contracting Officer and found to be damaged. New load test piles replacing damaged piles will be paid for at the applicable contract unit price for payment item "Prestressed Concrete Piles for Load Tests".

1.7.9.2 Measurement

Pulled undamaged load test prestressed concrete piles will be measured for payment as specified in paragraph UNIT PRICES, subparagraph PRESTRESSED CONCRETE PILES FOR LOAD TESTS. Pulling undamaged load test prestressed concrete piles the second time after redriving and testing will be measured for payment as specified in paragraph UNIT PRICES, subparagraph DRIVING PRESTRESSED CONCRETE PILES. Redriving pulled undamaged prestressed concrete piles will be measured for payment as specified in paragraph UNIT PRICES, subparagraph DRIVING PRESTRESSED CONCRETE PILES. New load test prestressed concrete piles replacing damaged piles will be measured for payment as specified in paragraph UNIT PRICES, subparagraph PRESTRESSED CONCRETE PILES FOR LOAD TESTS.
1.7.9.3 Unit of Measure

Unit of measure: as specified in paragraph UNIT PRICES, subparagraphs DRIVING PRESTRESSED CONCRETE PILES and PRESTRESSED CONCRETE PILES FOR LOAD TESTS, respectfully.

1.7.10 Pile Driving Shoes

1.7.10.1 Payment

Payment will be made for costs associated with pile driving shoes, including furnishing, delivering, and installing.

1.7.10.2 Measurement

Pile driving shoes will be measured for payment on the basis of the number of pile driving shoes required.

1.7.10.3 Unit of Measure

Unit of measure: each.

1.7.11 Prestressed Concrete Pile Splices

1.7.11.1 Payment

Payment will be made for costs associated with prestressed concrete pile splices, including all plant, labor, and material required to make the splice.

1.7.11.2 Measurement

Prestressed concrete pile splices will be measured for payment on the basis of the applicable contract unit price per pile splice.

1.7.11.3 Unit of Measure

Unit of measure: each.

1.7.12 Vibration Monitoring

1.7.12.1 Payment

Payment will be made for costs associated with vibration monitoring.

1.7.12.2 Measurement

Vibration monitoring will be measured for payment on the basis of the applicable contract unit price per vibration monitoring point.

1.7.12.3 Unit of Measure

Unit of measure: each.

1.7.13 Sound Monitoring

1.7.13.1 Payment

Payment will be made for costs associated with sound monitoring.
1.7.13.2 Measurement

Sound monitoring will be measured for payment on the basis of the applicable contract unit price per vibration monitoring point.

1.7.13.3 Unit of Measure

Unit of measure: each.

1.7.14 Preconstruction Condition Survey

1.7.14.1 Payment

Payment will be made for costs associated with preconstruction condition surveys.

1.7.14.2 Measurement

Preconstruction condition survey will be measured for payment on the basis of the applicable contract unit price per structure to be surveyed.

1.7.14.3 Unit of Measure

Unit of measure: each.

1.7.15 Construction Instrumentation and Monitoring

1.7.15.1 Payment

Payment will be made for costs associated with construction instrumentation and monitoring.

1.7.15.2 Measurement

Construction instrumentation and monitoring will be measured as a single pay item.

1.7.15.3 Unit of Measure

Unit of measure: one.

1.8 SUBMITTALS

**************************************************************************

NOTE: Review Submittal Description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets
following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy, Air Force, and NASA projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy, Air Force, and NASA projects, or choose the second bracketed item for Army projects.

******************************************************************************
Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

1.9 DELIVERY, STORAGE, AND HANDLING

Store, handle, and transport piles in accordance with PCI MNL-116 except as follows. Use methods for handling and storage of piles such that the piles are not subjected to excessive bending stress, cracking, spalling, or other damage. Follow the lifting instructions of the precaster.
1.9.1 Damaged Piles

Inspect each pile for sweep and structural damage such as cracking and spalling before transporting them to the project site and immediately prior to placement in the driving leads. Bring any cracks (cracks other than crazing, surface drying, shrinkage cracks and end cracks) to the attention of the Contracting Officer. Piles which are damaged during delivery, storage, or handling to the extent they are rendered unsuitable for the work, in the opinion of the Contracting Officer, will be rejected and removed from the project site, or may be repaired, if approved, at no cost to the Government.

Any pile damaged by reason of internal defects or by improper driving must be corrected by one of the following methods approved by the Engineer for the pile in question and the project Structural Engineer:

- The pile is withdrawn, if practicable, and replaced by a new and, if necessary, longer pile.
- One or more replacement piles are driven adjacent to the defective pile.
- A Pile Dynamic Analysis and low integrity testing must be performed by the Contractor's Geotechnical Consultant to assess the structural integrity of the driven pile(s).

A pile driven below the specified butt elevation must be corrected by one of the following methods approved by the Engineer:

- The pile is spliced (if approved).
- A sufficient portion of the footing is extended down to properly embed the pile.

A pile driven out of its proper location or out of plumb as approved by the Engineer, must be corrected by one of the following methods approved by the engineer:

- One or more replacement piles are driven next to the pile in question.
- As directed by the structural engineer.

1.9.2 Repairable Cracks

Reject or repair piles with cracks equal to or greater than $0.15 \text{ mm}$ or $0.006 \text{ inches}$ but less than $1.5 \text{ mm}$ or $0.06 \text{ inches}$. As an alternate to pile rejection, the Contractor may submit a proposal to repair deficient piles, which must be restored prior to driving to provide its required design capacity, perform its intended function in the structure, and take into consideration long term durability in corrosive environment.

1.9.3 Non-Repairable Cracks

Piles with cracks equal to or greater than $1.5 \text{ mm}$ or $0.06 \text{ inches}$ will be rejected.

******************************************************************************

NOTE: Sweep and camber typically apply to steel piles. In special cases, this paragraph may apply to precast/pre-stressed concrete piles.
[1.9.4  Pile Sweep

Limit sweep to 3 mm per 3 M 1/8 inch per 10 feet over the length of the pile. Piles having excessive sweep will be rejected.

]1.10  QUALITY CONTROL

1.10.1  Piles

Prepare in accordance with ACI SP-66. Indicate placement of reinforcement including tendons. Indicate location of special embedded or attached lifting devices, employment of pick-up points, support points other than pick-up points, and any other methods of pick-up. Provide certification of a Professional Engineer registered in any jurisdiction of the U.S. or its territories, that layout and details of reinforcement and tendons conform with that shown on the structural design drawings.

1.10.2  Quality Control Procedures

Submit the precasting manufacturer's quality control procedures and inspection records established in accordance with PCI MNL-116.

1.10.3  Installation Procedures

a. Submit information on the type of equipment proposed to be used, proposed methods of operation, pile driving plan including proposed sequence of driving, and details of all pile driving equipment and accessories.

b. Provide details of pile driving equipment and a Wave Equation Analysis of pile drivability for selection of the hammer along with a statement of driving procedures. The Wave Equation Analysis is to be completed by the Contractor's Geotechnical Consultant for each test pile location where different subsurface conditions exist and is to include the following information pertaining to the proposed pile driving equipment:

(1) Complete Pile and Driving Equipment Data Form, (which can be downloaded at: http://www.wbdg.org/ffc/dod/unified-facilities-guide-specifications-ufgs/forms-graphics-tables) for each proposed pile hammer and pile type combination.

(2) Copies of computer input and output sheets and graphs showing soil resistance versus blow count as well as maximum tension and compression stresses versus blow count. Analysis must be run at the estimated tip elevation as well as other required elevations to define maximum stress levels in the pile during driving.

c. Provide detailed procedures for conducting the dynamic pile load test and equipment to be used for conducting the load test. The detailed description must explain how specific information of pile performance will be evaluated.

][1.10.4  Contractor's Geotechnical Consultant Documentation

Hire the services of an independent, Registered Professional Geotechnical Engineer, experienced in soil mechanics and Pile Dynamic Analysis, to observe test pile installation and production pile installation as
specified herein. The Contractor's Geotechnical Consultant must be independent of the Contractor and must have no employee of employer relationship which could constitute a conflict of interest.

Provide instructions and procedures on how the Contractor will assist the Government in the processes of Dynamic Pile Testing, Inspection and Monitoring of piles during installation and testing.

1.10.5 Concrete Mix Design

Certify, using a Government-approved independent commercial testing laboratory, that proportioning of mix is in accordance with ACI 211.1 or ACI 318M ACI 318 for specified strength and is based on aggregate data which has been determined by laboratory tests during last twelve months. Submit a complete list of materials including type; brand; source and amount of cement, fly ash, pozzolan, ground slag, and admixtures; and applicable reference specifications. Submit additional data regarding concrete aggregates if the source of aggregate changes. Submittal must clearly indicate where each mix design will be used when more than one mix design is submitted. Submit a concrete mix design before concrete is placed, for each type of concrete used for the piles. Submit concrete cylinder compressive strength test results.

1.10.6 Load Test Supporting Data

Submit Jack calibration records, a testing arrangement description and diagram, and the proposed loading sequence.

1.10.7 Silica Fume Manufacturer's Representative

Provide statement that the manufacturer's representative will be present at plant to ensure proper mix, including high range water reducer (HRWR), and batching methods.

PART 2 PRODUCTS

2.1 PILE REQUIREMENTS

******************************************************************************
NOTE: Delete sentence in brackets when test piles are not required. Government requires the Contractor to employ a Geotechnical Consultant to determine the calculated tip elevation and provide oversight of piling installation and testing.
******************************************************************************

Provide precast prestressed concrete piles per PCI Journal Volume 38, Number 2 (PCI JR-382). Production of piles must be in accordance with PCI MNL-116.[ Order test piles [3] [_____] meters [10] [_____] feet longer in length than production piles.[ Drive the additional test pile length only when based upon the recommendation of the Contractor's Geotechnical Consultant and approved by the Contracting Officer.] The [Contractor's Geotechnical Consultant][Contracting Officer] will use test pile data to determine "calculated" pile tip elevation and necessary driving resistance. This information will be given to the Contractor no later than 7 days from receipt of complete test data. Use this list as the basis for ordering the piles. Do not order piles until list is provided by the [Contractor's Geotechnical Consultant][Contracting Officer].][ Provide test piles [1.5] [_____] meter [5] [_____] feet longer than the bid length.]
2.2 MATERIALS

2.2.1 Cementitious Materials

Cementitious materials must be portland cement, blended cement or portland cement in combination with natural pozzolan or fly ash or ground granulated blast furnace slag and conforms to appropriate specifications listed below.

2.2.1.1 Cement

**************************************************************************
NOTE: Insert type of cement required. Generally, Types II, or I/II, is preferred. Type I, or Type III with 8 percent maximum C3A and "low alkali", may be used. Do not use Type III in conjunction with silica fume. In very special cases, Type V, "low alkali," which has limited availability, may be used.
**************************************************************************
**************************************************************************
NOTE: Cement type and quantity of cement required in mix design is dependent upon the environment, soil conditions, need for corrosion protection, and location of piling:

(a) CHLORIDE PROTECTION:

Normal Use. In fresh water or air environment, specify Type I or Type II cement. Type III may be permitted provided tricalcium aluminate (C3A) content is limited to 8 percent and it is low alkali.

Marine Use. In soil or water environments, subject to chlorides above 1,000 ppm, within about 300 m 1000 feet of the ocean or tidal water, specify Type II or Type III (with a maximum tricalcium aluminate (C3A) content of 8 percent and low alkali) cement, a minimum cementitious materials content of 335 kilograms per cubic meter 564 pounds per cubic yard and a maximum water to cementitious materials ratio of 0.40.

Seawater Exposure. In direct contact with ocean water, specify Type II or Type III (with a maximum tricalcium aluminate (C3A) content of 8 percent and low alkali) cement, a minimum cementitious materials content of 390 kilograms per cubic meter 658 pounds per cubic yard and a maximum water to cementitious materials ratio of 0.40.

(b) SULFATE RESISTANCE minimum cementitious materials content of 335 kilograms per cubic meter 564 pounds per cubic yard is recommended.

Normal Use. In soils with negligible amount of sulfate, specify Type I or Type II cement. Type III cement may be permitted provided tricalcium

SECTION 31 62 13.20 Page 24
aluminate (C3A) content is limited to 8 percent and it is low alkali.

Moderate Sulfate Exposure. In exposures with moderate sulfate content (between 0.10 and 0.20 percent in soil and less than 1500 ppm in water), specify Type II or Type III (with a maximum tricalcium aluminate (C3A) content of 8 percent and low alkali) cement and a maximum water to cementitious materials ratio of 0.40. Do not use Class C fly ash, blast furnace slag, or silica fume for cement replacement.

Severe Sulfate Exposure. In exposures with high sulfate content (exceeds 0.20 percent in soil or 1500 ppm in water), specify Type V or Type II (with a maximum tricalcium aluminate content of 5 percent) cement, and a maximum water to cementitious materials ratio of 0.40. Do not use Class C fly ash, blast furnace slag, or silica fume for cement replacement.

Alkali-Silica Reactivity. When alkali-silica reactivity is a concern, it is recommended to limit the maximum alkali content of cement to 0.40 or 0.50, when it is locally available, otherwise use 0.60.

**************************************************************************

ASTM C150/C150M, [Type I, II, or III [_____] with a maximum alkali content of [0.40] [0.60] percent][; or] [ASTM C595/C595M, Type [IP(MS) or IS(MS)] [_____] ] blended cement except as modified herein. The blended cement must consist of a mixture of ASTM C150/C150M cement (with alkali content not exceeding [0.40] [0.60] percent) and one of the following materials: ASTM C618 pozzolan or fly ash, or ASTM C989/C989M ground iron blast-furnace slag, or ASTM C1240 silica fume. Use cement with a maximum of 0.60 percent alkali if no satisfactory test results are available (made within the past six months) to prove that the cement alkali content is less than 0.40 percent. Cement certificates must include test results in accordance with ASTM C150/C150M, including equivalent alkalies indicated in the optional chemical requirements.[ Use cement with a tricalcium aluminate (C3A) content of less than [8] [5] percent.] Do not use Type III cement in conjunction with silica fume.

**************************************************************************

NOTE: Fly ash, pozzolan, and ground iron blast-furnace slag increase durability. They may produce uneven discoloration of the concrete during the early stages of construction, depending upon the type of curing provided. Use Fly ash/pozzolan (loss on ignition not exceeding 3 percent) for frost areas to reduce carbon interference with air entraining admixture. Straight replacement with fly ash or natural pozzolan beyond 15 percent may decrease the concrete's strength gain rate. The following options can help mitigate this slower gain rate: (1) a lower water/cement ratio may be used, (2) partial cement replacement can be completed, e.g., one sack of cement can be replaced by 1.5 sacks of fly ash.
as long as the final replacement ratio meets the requirements, and (3) very fine fly ashes or pozzolans (e.g. with average particle sizes below 5 microns) can be used.

2.2.1.2 Fly Ash and Pozzolan

NOTE: Loss on ignition greater than 3 percent may result in significant variations in air content. The air entrainment admixture content may need to be varied often to maintain the same level of entrained air.

ASTM C618, Class N, or F except that the maximum total alkalies must be 3.0 percent, and the maximum allowable loss on ignition must be [3] 6 percent. If the aggregates are reactive, the maximum calcium oxide content must be 13.0 percent. Do not use Class C.

2.2.1.3 Ground Iron Blast-Furnace Slag

ASTM C989/C989M, Grade 120.

2.2.1.4 Silica-Fume

NOTE: Use silica fume concrete for marine structures where low permeability and enhanced durability are necessary. The silica fume and HRWR additive should be from the same manufacturer. The Contractor and batch plant may need help from the manufacturer. Select weight percentage based on performance required. If used, a replacement of 7 percent is recommended.

NOTE: Use for high durability and low permeability. The initial cost of the concrete will increase, and supervision at the batch plant, finishing, and curing is necessary. A HRWR must be used with silica fume. The slump can be increased 50 to 125 mm 2 to 5 inches without reducing strength. Finishing may be more difficult. Proper curing is essential because there is a tendency for plastic shrinkage cracking.

ASTM C1240, provide silica fume that is a by-product of silicon or ferrosilicon production. Provide percent by weight of the total cementitious materials as indicated in the table below.

2.2.1.5 Supplemental Cementitious Materials (SCM) Content

The concrete mix must contain one of the SCMs listed below, or a linear combination thereof.
### SUPPLEMENTARY CEMENTITIOUS MATERIALS CONTENT

<table>
<thead>
<tr>
<th>SCM</th>

### 2.2.2 Water

Water must be fresh, clean, and potable; free from injurious amounts of oils, acids, alkalis, salts, organic materials, or other substances deleterious to concrete or steel.

### 2.2.3 Aggregates

NOTE: For exposed piles in areas where reactive aggregates are likely to be supplied, provide for additional tests and certification to insure that reactive aggregates will not be used. While not wholly conclusive, petrographic examination (ASTM C295/C295M), chemical test (ASTM C289/C289M), and mortar bar method (ASTM C227) are valuable indicators.

While more reliable, the concrete prism test (ASTM C1293) takes 1 to 2 years to complete and is not practical. The accelerated mortar bar method (ASTM C1260) is similarly reliable and takes only 16 days to yield results. In areas where reactive aggregates can not be avoided, specify use of low alkali cement, and cements modified to mitigate alkali-silica reactivity. Service records of concrete made with these materials along with tests should be used in evaluating these materials.

NOTE: Include modification to ASTM C33/C33M when reactive aggregates could be encountered. More modifications may be required. Additional tests and certifications may be required in the submittal paragraphs.
ASTM C33/C33M[, except as modified herein. Provide aggregate free from any
substance which may be deleteriously reactive with alkalis in cement in an
amount sufficient to cause excessive expansion of concrete]. Do not mix,
store in same stockpile, or use fine aggregates from different sources of
supply in same concrete mix or same structure without approval. The
fineness modulus of fine aggregate must be not less than 2.40 or greater
than 3.0. For piles that will be exposed to freezing and thawing, fine and
coarse aggregate subjected to five cycles of the sodium sulfate soundness
test must show a loss not greater than 10 percent. If the selected
aggregates fail the soundness test, the Contractor may use the aggregate
source, provided concrete specimens made with the aggregates to be used for
the piles must have a durability factor of not less than 80 based on 300
cycles of freezing and thawing when tested in accordance with
ASTM C666/C666M. Prior to pile fabrication, submit certified test reports
for the following tests specified in ASTM C33/C33M[, in addition, test the
gradation of each size of aggregate in accordance with ASTM C136/C136M],
twice] [_____] during each shift when the concrete plant is operating:

a. Grading
b. Amount of material finer than 75 micrometers No. 200 sieve
c. Organic impurities
d. Soundness
e. Clay lumps and friable particles
f. Coal and lignite
g. Weight of slag
h. Abrasion of coarse aggregate
i. Fineness modulus
j. Reactive aggregates
k. Freezing and thawing

2.2.3.1 Alkali-Silica Reactivity (ASR)

Evaluate and test fine and coarse aggregates to be used in all concrete for
alkali-aggregate activity.

Separately evaluate the fine and coarse aggregates using ASTM C1260. Test
results of the individual aggregates must have a measured expansion equal
to or less than 0.08 percent at 14 days after casting per ASTM C1260. If
the test data indicates an expansion of greater than 0.08 percent, reject
the aggregate(s) or perform additional testing, using ASTM C1567, as
follows: utilize the Contractor's proposed low alkali portland cement
[blended cement] and SCM in combination with the proposed aggregate for the
test portioning. Determine the SCM quantity that will meet all the
requirements of these specifications and that will lower the ASTM C1567
expansion to equal or less than 0.08 percent at 14 days after casting.

If the above option does not lower the expansion to less than 0.08 percent
at 14 days after casting, reject the aggregate(s) and submit new aggregate
sources for retesting. Submit the results of testing to the Contracting Officer for evaluation and acceptance.

2.2.4 Admixtures

**************************************************************************
NOTE: For guidance in use of either water-reducing admixtures, set retarding admixtures, or combination of admixtures, see ACI 543R-74, "Recommendations for Design, Manufacture, and Installation of Concrete Piles."
**************************************************************************

Chemical admixtures must conform to ASTM C494/C494M, [Type A] [Type B]. Air-entraining admixture must conform to ASTM C260/C260M.] Do not use admixtures containing chlorides.

2.2.5 Prestressing Steel

Use seven-wire stress-relieved or low-relaxation strand conforming to ASTM A416/A416M, Grade 270. Use prestressing steel free of grease, oil, wax, paint, soil, dirt, and loose rust. Do not use prestressing strands or wire having kinks, bends, or other defects.

2.2.6 Reinforcing Steel

**************************************************************************
NOTE: Minimum cover for reinforcing steel in concrete structures is dependent upon the environment, soil conditions, need for corrosion protection, and location of piling. For normal exposure minimum cover is 50 mm 2 inches. For piles exposed to marine conditions (chloride content above 1000 ppm) in or within about 300 m 1000 feet of the ocean or tidal water, use 75 mm 3 inches minimum cover, including the chamfered corners. For additional detailed guidance, see following publications: ACI 543R, "Recommendations for Design, Manufacture and Installation of Concrete Piles" (ACI Manual, Part 3); State of California, Department of Public Works, Design Specifications, Volume 1, Bridge Planning and Design Manual, Chapter 6. Piles to be used in a marine environment may receive a protective coating, particularly if the piles are steam cured. The protective coating should be applied to that portion of pile which remains aboveground or water line. Show areas to be protected on drawings.
**************************************************************************

**************************************************************************
NOTE: Insert grade of reinforcement. Specify ASTM A706/A706M reinforcing where welding or bending of reinforcement bars is important. In addition, ASTM A934/A934M may be specified where extra reinforcement protection is required.
**************************************************************************

ASTM A615/A615M, Grade [300] [420] [40] [60]; [ASTM A706/A706M, Grade [420]
2.2.7 Ties and Spirals

NOTE: If project has been designed for epoxy rebar, add ASTM A934/A934M, "Epoxy-Coated Prefabricated Steel Reinforcing Bars" in this paragraph and in the paragraph REFERENCES.

Steel, ASTM A1064/A1064M for spirals and ASTM A615/A615M [ASTM A706/A706M] for ties.

2.2.8 Anchorages and End Fittings

ACI 318M ACI 318.

2.2.9 Grout

Provide cement grout for prestressed piles using materials conforming to requirements stipulated herein for concrete mixes. Use admixtures, if required, known to have no injurious effects on steel or concrete. Do not use calcium chloride.

2.2.10 Epoxy Coating

[EP-3][_____] conforming to Section [____], "Epoxy-Resin Systems" of [_____]DOT RBS. Coat the top 7500 mm 25 feet of piles.

2.2.11 H-Pile Extensions

Use H-pile extensions for composite prestressed concrete-steel piles of steel conforming to the requirements of [ASTM A36/A36M] [ASTM A572/A572M].

2.2.12 Pile Driving Points

Use pile driving points of steel conforming to the requirements of ASTM A27/A27M or [ASTM A36/A36M] [ASTM A572/A572M], of the [type] [details] indicated.

2.3 CONCRETE MIX DESIGN

NOTE: Insert the minimum 28 day compressive strength required by the design. A minimum of 35 MPa 5000 psi is generally required. Insert aggregate size, either 19 mm 3/4 inch or 25 mm one inch is generally maximum. For marine exposure, (or moderate and severe sulfate exposure) include last bracketed sentence, which limits the water-cement ratio to a maximum of 0.40.

NOTE: Air-entrainment may be considered optional only in regions that do not experience freezing temperatures.
ACI 211.1 or ACI 318M ACI 318, Chapter 4. Concrete must have a minimum compressive strength of [35] [_____] MPa [5000] [_____] psi at 28 days and a maximum size aggregate of [_____] mm inches. Concrete must be air entrained with a minimum of 4.5 percent and a maximum of 7.5 percent. Mix must contain fly ash, ground iron blast furnace slag or silica fume to meet the requirements specified herein to mitigate Alkali-Silica Reactivity (ASR). [For marine exposure, ensure a dense concrete free of shrinkage cracks, with a minimum degree of permeability. The maximum water cement ratio must be 0.40.]

2.4 FABRICATION

2.4.1 Formwork

Formwork and dimensional tolerances must be in accordance with PCI MNL-116, PCI MNL-135, and as specified herein. Provide forms of metal, braced and stiffened against deformation, accurately constructed, watertight, and supported on unyielding casting beds. Forms must permit movement of pile without damage during release of prestressing force. Form precast dowel holes with galvanized flexible metal conduit. [Inside forms or void tubes not to be grouted may be treated cardboard, plywood, or other material.]

2.4.2 Pretensioning

Perform pretensioning in accordance with PCI MNL-116, and as specified herein. Use gage calibrated within last [6 months][_____] by a laboratory approved by Contracting Officer. Provide means for measuring elongation of steel to nearest 3 mm 1/8 inch. Give tensioning steel a uniform prestress prior to being brought to design prestress. Induce same initial prestress in each unit when several units of prestressing steel in a pile are stretched simultaneously.

2.4.3 Casting

2.4.3.1 Conveying

Convey concrete to formwork in accordance with PCI MNL-116, and as specified herein. Clean conveying equipment thoroughly before each run. During placing, make any free vertical drop of the concrete less than 0.91 m 3 feet. Remove concrete which has segregated in conveying or placing.

2.4.3.2 Placing and Casting

**************************************************************************
NOTE: Select the size of chamfer required. Consult with local producers. Where project requires a large quantity of piling a specific value may be specified, otherwise, use a minimum or a range of values.
**************************************************************************

Perform concrete casting within 3 days after pretensioning steel; however, do not deposit concrete in forms until placement of reinforcement and anchorages has been inspected and approved by pile manufacturer's quality control representative. Produce each pile of dense concrete straight with smooth surfaces with reinforcement retained in its proper position during fabrication. Use vibrator with heads smaller than the minimum distance
between steel for pretensioning. Make surface of pile ends perpendicular to axis of pile. Chamfer, (a minimum of 19 mm 3/4 inch,)(______ mm [_____] inch),( between 19 mm and 31 mm 3/4 inch and 1 1/4 inch,) ends of piles and corners of square piles.

2.4.4 Curing of Piles

Cure piles using moist or accelerated curing in accordance with the PCI MNL-116 except as follows. [_____]

2.4.4.1 Moist Curing

Moist cure using moist burlap coverings, plastic sheeting, or membrane curing compound until minimum strength to detension is achieved.

2.4.4.2 Accelerated Curing

After placement of concrete, moist cure for a period of 4 hours. Follow by accelerated curing until concrete has reached specified release strength. Enclose casting bed for accelerated curing with a suitable enclosure. During application of steam or heat, increase the air temperature at a rate not to exceed 22 degrees C 40 degrees F per hour. Cure at a maximum temperature of 65 degrees C 150 degrees F until concrete has reached specified release strength. Reduce temperature at a rate not to exceed 11 degrees C 20 degrees F per hour until a temperature of 11 degrees C 20 degrees F above ambient air temperature is reached. After accelerated curing, moist cure using either water or membrane curing until a total accelerated and moist curing time of 72 hours is achieved.

2.4.5 Detensioning

**************************************************************************
NOTE: Specify "release strength." Release strength of 30 MPa 4000 psi (Design strength) of 35 MPa 5000 psi or 0.8 of the 28 day design strength is desirable; however, some regions use 0.7 of the design strength 25 MPa 3500 psi for design strength of 35 MPa 5000 psi. A minimum release strength of 0.6 of the design strength is required. Check with local pile manufacturers.
**************************************************************************

Perform detensioning in accordance with PCI MNL-116, and as specified herein. Gradually release tension in strands from anchorage. Detension after approval by pile manufacturer's quality control representative. Perform transfer of prestressing force when concrete has reached a minimum compressive strength of [_____] MPa psi.

2.5 PRODUCT QUALITY CONTROL

Where piling is manufactured in a plant with an established quality control program as attested to by a current certification in the PCI "Certification Program for Quality Control" perform product quality control in accordance with PCI MNL-116. Where piling is manufactured by specialists or in plants not currently enrolled in the PCI "Certification Program for Quality Control," set-up a product quality control system in accordance with PCI MNL-116 and perform concrete and aggregate quality control testing using an independent commercial testing laboratory approved by the Contracting Officer in accordance with the following.
2.5.1 Piles

Prepare shop drawings in accordance with ACI SP-66. Indicate placement of reinforcement including tendons. Indicate location of special embedded or attached lifting devices, employment of pick-up points, support points other than pick-up points, and any other methods of pick-up. [Provide certification of a Professional Engineer registered in any jurisdiction of the U.S. or its territories, that layout and details of reinforcement and tendons conform with that shown on the structural design drawings.]

2.5.2 Silica Fume Manufacturer's Representative

Provide statement that the manufacturer's representative will be present at plant to ensure proper mix, including high range water reducer (HRWR), and batching methods.

2.5.3 Aggregate Tests

Take samples of fine and coarse aggregate at concrete batch plant and test. Perform mechanical analysis (one test for each aggregate size) in accordance with ASTM C136/C136M. Tabulate results of tests in accordance with ASTM C33/C33M.

2.5.4 Slump and Strength Tests

Sample concrete in accordance with ASTM C172/C172M at time concrete is deposited for each production line. Perform slump tests in accordance with ASTM C143/C143M. Mold cylinders in accordance with ASTM C31/C31M. Mold at least six cylinders per day or one for every [15] [45] cubic meter [20] [60] cubic yards of concrete placed, whichever is greater. Cure cylinders in same manner as piles and for accelerated curing, place at coolest point in casting bed. Perform strength tests in accordance with ASTM C39/C39M. Test two cylinders of each set at 7 days or 14 days, or at a time for establishing transfer of prestressing force (release strength) and removal of pile from forms. Test remaining cylinders of each set 28 days after molding.

2.5.5 Changes in Proportions

If, after evaluation of strength test results, compressive strength is less than specified compressive strength, make adjustments in proportions and water content and changes in temperature, moisture, and curing procedures as necessary to secure specified strength. Submit changes in mix design to Contracting Officer in writing.

2.5.6 Compressive Strength Test Results

Evaluate compressive strength test results at 28 days in accordance with ACI 214R using a coefficient of variation of 10 percent. Evaluate strength of concrete by averaging test results of each set of standard cylinders tested at 28 days. Not more than 10 percent of individual cylinders tested must have a compressive strength less than specified design strength.

2.5.7 Chloride Ion Concentration

Sampling and determination of water soluble chloride ion content in accordance with ASTM C1218/C1218M. Maximum water soluble chloride ion concentrations in hardened concrete at ages from 28 to 42 days contributed
from the ingredients including water, aggregates, cementitious materials, and admixtures must not exceed 0.06 percent by weight of cement.

2.5.8 Chloride Ion Penetration

Proportion concrete to have the chloride ion penetration test in accordance with ASTM C1202 to ensure the durability of concrete in marine environment, and be below 3000 coulombs for concrete specimens tested at 56 days.

2.5.9 Precasting Manufacturer's Quality Control Procedures

Submit the precasting manufacturer's quality control procedures and inspection records established in accordance with PCI MNL-116.

2.6 MATERIAL SUSTAINABILITY CRITERIA

For materials used, where applicable and to extent allowed by performance criteria, provide and document the following in accordance with Section 01 33 29 SUSTAINABILITY REQUIREMENTS AND REPORTING:

a. Recycled content for fly ash and pozzolan.

b. Recycled content for Ground Iron Blast-Furnace Slag.

c. Recycled content for Silica Fume.

d. Minimum [75 percent] [_____] recycled content for steel used for stressed tendon reinforcing.

2.7 PILE DRIVING EQUIPMENT

Submit descriptions of pile driving equipment, including hammers, power packs, driving helmets, hammer cushions, pile cushions, leads, extractors, jetting equipment, and preboring equipment at least 30 days prior to commencement of work.

Provide Pile Driving Equipment as mentioned in this section.

2.7.1 Pile Hammers

Provide a hammer capable of developing the indicated ultimate pile capacity at blow count less than 100 per 300 mm foot considering hammer impact velocity; ram weight; stiffness of hammer and pile cushions; cross section, length, and total weight of pile; and character of subsurface material to be encountered.[ Use the same pile hammer, operating at the same rate and in the same manner, as that used for driving test piles.] Use wave equation analysis to verify that the hammer will develop stresses within acceptable limits in the piles. At final driving, operate pile hammer in accordance with manufacturer's recommendation. Provide the plant and equipment for air hammers that have sufficient capacity to maintain, under working conditions, the pressure at the hammer specified by the manufacturer. The hose connecting the compressor with the hammer must be at least the minimum size recommended by the Manufacturer. Evaluate hammer performance at the end of driving by measuring blows per minute and comparing with the manufacturer's recommendations. Measure impact velocity of open-end (single acting) diesel hammers at all times during pile driving operations with a device for this purpose. If such a device is not available, obtain the stroke by measuring the speed of operation either manually or with a device that makes the measurement automatically. Equip
closed-end (double acting) diesel hammers with a bounce chamber pressure gauge in good working order, mounted near ground level so as to be easily read by the Contracting Officer. Provide a correlation chart of bounce chamber pressure and potential energy. Equip hydraulic hammers with a system for measurement of ram energy. The system must be in good working order and the results must be easily and immediately available to the Engineer.

2.7.2 Driving Helmets and Cushion Blocks

2.7.2.1 Driving Helmets or Caps and Pile Cushions

Use a steel driving helmet or cap including a pile cushion between top of pile and driving helmet or cap to prevent impact damage to pile. Use a driving helmet or cap and pile cushion combination capable of protecting pile head, minimizing energy absorption and dissipation, and transmitting hammer energy uniformly over top of pile. Provide driving helmet or cap that fits sufficiently loose around top of pile so that pile may be free to rotate without binding within driving helmet.[ During test pile installation, demonstrate to satisfaction of Contracting Officer that equipment to be used on project performs specified function.] Use pile cushion of solid wood or of laminated construction using plywood, softwood or hardwood boards with grain parallel to end of pile. Select the pile cushion thickness placed on the pile head prior to driving by wave equation analysis so that the limiting driving stresses are not exceeded. Replace pile cushion at the start of driving of each pile and when it becomes highly compressed, charred or burned, or has become spongy or deteriorated in any manner. Show details of driving helmets, capblocks (hammer cushions), and pile cushions. Submit 2 weeks prior to [test] pile installation.

2.7.2.2 Hammer Cushion or Capblock

**************************************************************************
NOTE: Select either wood or aluminum/micarta capblock. Delete inappropriate sentences. An aluminum/micarta capblock is recommended because of its consistent elastic properties and long life. If final pile penetration resistance is based on a Wave Equation analysis, the type of capblock used should be the same as that used in the analysis.
**************************************************************************

Use a hammer cushion or capblock between driving helmet or cap and hammer ram consisting of[ a solid hardwood block with grain parallel to the pile axis and enclosed in a close-fitting steel housing][ aluminum and micarta (or equal) discs stacked alternately in a steel housing or a suitable polymer designed for this specific purpose as indicated by the hammer manufacturer]. Use steel plates at top and bottom of capblock (hammer cushion).[ Replace wood capblock (hammer cushion) when it becomes highly compressed, charred or burned or becomes spongy or deteriorated in any manner.][ Replace aluminum, micarta or polymer discs that have become damaged, split or deteriorated in any manner.][ Do not replace wood capblock (hammer cushion) during final driving of any pile.] Do not use small wood blocks, wood chips, rope or other materials that permit excessive loss of hammer energy.
PART 3 EXECUTION

3.1 PRELIMINARY WORK

[3.1.1 Wave Equation Analysis of Pile Drivability

a. Prior to driving any pile, submit a pile Wave Equation Analysis, performed by Contractor's Geotechnical Consultant, for each size pile and distinct subsurface profile condition. These analyses must take into account the proposed hammer assembly, pile cap block and cushion characteristics, the pile properties and estimated lengths and the soil properties anticipated to be encountered throughout the installed pile length based on static capacity analysis with consideration of driving gain/loss factors. Only one specific model of pile hammer may be used for each pile type and capacity.

b. Demonstrate using the Wave Equation Analysis that the piles will not be damaged during driving, must indicate that the driving stresses will be maintained within the limits below and indicate the blow count necessary to achieve the required ultimate static pile capacities.

Allowable Driving Stresses

Concrete

Compression - 0.85 $f'$c minus UPL
Tension - (3 times (the square root of $f'$c)) plus UPL

$f'$c is compressive strength of concrete
UPL = Unit Prestress after Losses
(Obtain values from pile manufacturer)

c. Perform a refined Wave Equation Analysis upon completion of the dynamic and static testing programs outlined in this specification section, taking into consideration the evaluated capacities, gain/loss factors and recommended production pile lengths.[ Develop production pile driving criteria based on the results of the refined Wave Equation Evaluations.]

d. All pile driving equipment provided by the Contractor will be subject to the approval of the Contractor's Geotechnical Consultant. Complete the attached pile and driving equipment data form, including hammer information, in full as part of the submittal of the results of the Wave Equation Analyses.

e. Pay for the cost of performing the Wave Equation Analyses and include in the base bid.

]3.1.2 Pile Length Markings

Mark each pile prior to driving with horizontal lines at 305 mm one foot intervals. Mark the interval number on pile every 1.5 2m 5 feet from pile tip.

3.2 PILE DRIVING

3.2.1 Driving Piles

**************************************************************************

SECTION 31 62 13.20 Page 36
NOTE: Delete bracketed option for foundation excavation when not required. Delete items in brackets dealing with tip elevation and driving resistance when test piles or load tests are not used. Delete item in brackets regarding predrilling or jetting when procedure is not used. If needed, insert maximum hammer energy for no tip resistance. This can be determined by comparing tensile stresses in pile resulting from a Wave Equation Analysis with effective prestress in pile.

Notify Contracting Officer 10 days prior to driving of [test] piles[ and load test]. Stop foundation excavation at 300 mm one foot above foundation grade before piles are driven. Do not drive piles within 30 meter 100 feet of concrete less than 7 days old. Complete excavation to lines and grades shown when pile driving is completed. Piles may be driven when the specified 28-day concrete strength has been achieved but not less than 7 days after casting. The Contractor's Geotechnical Consultant will determine the terminal driving criteria based on results of [dynamic pile driving tests at the end of drive or restrike] [static load tests] [wave equation analysis]. Drive piles to [the terminal driving criteria ] [or below "calculated"] [indicated tip elevation] [to reach a driving resistance established by the [dynamic pile driving tests at the end of drive or restrike] [static load tests] [wave equation analyses (WEAP)] in accordance with the schedule which the [Contractor's Geotechnical Consultant] [Contracting Officer] will prepare from the test-pile driving data. During initial driving and until pile tip has penetrated beyond layers of very soft soil[ or below bottom of predrilled or prejetted holes], use a reduced driving energy of the hammer as required to prevent pile damage. Refusal criteria will be established by the Contracting Officer. If a pile fails to reach ["calculated"] [indicated] tip elevation, [or if a pile reaches ["calculated"] tip elevation without reaching required driving resistance,] notify Contracting Officer and perform corrective measures as directed. Provide hearing protection when noise levels exceed 140 dB. Do not handle or move piles or pile sections in any manner that would result in cracking or permanent damage to the concrete or to the grout surrounding the prestressing cables. Piles may be driven without pile guides or leads providing a hammer guide frame is used to keep the pile and hammer in alignment.

3.2.2 Protection of Piles

NOTE: Delete references to batter piles when not applicable to the project. Use more stringent criteria as necessary based on the application. Confirm with the structural engineer.

Take care to avoid damage to piles during handling, placing pile in leads, and during pile driving operations. Support piles laterally during driving, but allow rotation in leads. Where pile or projecting reinforcement orientation is essential, take precautionary measures to maintain the orientation during driving. Take special care in supporting battered piles to prevent excessive bending stresses in pile. Square top of pile to longitudinal axis of pile. Maintain axial alignment of pile hammer with that of the pile. If the Contractor elects to use a pile head with projecting strands or mild steel reinforcement, prevent direct impact.
forces from being transmitted through the reinforcement, by using a special driving head.

3.2.3 **Pile Placement** and Tolerances in Driving

**************************************************************************
NOTE: Omit references to batter piles when not applicable to the project. Select appropriate tolerances for type of pile.
**************************************************************************

Submit pile placement plans at least 30 days prior to delivery of piles to the job site.

Drive piles with a variation of not more than 2 percent from vertical for plumb piles or more than 4 percent from required angle for batter piles. Maintain and check axial alignment of pile and leads at all times. If subsurface conditions cause pile drifting beyond allowable axial alignment tolerance, notify Contracting Officer and perform corrective measures as directed. Place butts within 100 mm 4 inches of location indicated. Manipulation of piles within specified tolerances will not be permitted, to a maximum of 1 1/2-percent of their exposed length above ground surface or mudline. In addition to specified tolerances, maintain a location to provide a clear distance of at least 125 mm 5 inches from butt to edge of pile cap. If clear distance can not be maintained, then notify Contracting Officer. Check each pile for heave. Redrive heaved piles to required point elevation.

3.2.4 **Rejected Piles**

Withdraw piles damaged or impaired for use during handling or driving, mislocated, or driven out of alignment beyond the maximum tolerance. Replace with new piles or cut-off and abandon damaged or impaired piles and drive new piles as directed. Remove excess cut-off from piles and unacceptable piles from the work site. Perform all work in connection with withdrawing and removing rejected piles from the site at no additional cost to the Government.

3.2.5 **Jetting of Piles**

**************************************************************************
NOTE: Jetting should generally not be permitted for piles:

1. Dependent on side friction in fine-grained low permeability soils (high clay or silt content) where considerable time is required for the soil to reconsolidate around the piles.

2. Subject to uplift or lateral forces.

3. Adjacent to existing structures.

4. In closely spaced clusters unless the load capacity is confirmed by test.
**************************************************************************

Water jets will not be permitted. Use jetting to assist driving piles through strata that cannot be penetrated practicably by use of the hammer.
alone. Restrict driving to a static weight while water is being injected to prevent inducing tensile stresses in the piles which damage the concrete. Discontinue jetting and resume hammer driving after the penetration of the strata requiring jetting has been accomplished. Discontinue jetting when the pile tip is approximately 1.5 m 5 feet above the [calculated] [indicated] pile tip elevation. Drive pile the final 1.5 m 5 feet of penetration or more to meet the required driving criteria. Take adequate measures for collecting and disposing of runoff water. Jetting method and equipment must be approved by the Contracting Officer prior to commencing jetting operation. Before starting final driving, firmly seat piles in place by application of a number of reduced energy hammer blows. Employ measures, including use of a silt curtain, to contain turbid water created by jetting piles.

3.2.6 Predrilling of Piles

******************************************************************************
NOTE: Predrilling should generally not be permitted for piles:
1. Dependent on side friction in fine-grained low permeability soils (high clay or silt content) where considerable time is required for the soil to reconsolidate around the piles.
2. Subject to uplift or lateral forces.
3. Located in cohesionless soils.
4. In closely spaced clusters unless the load capacity is confirmed by test.
******************************************************************************

Predrilling to remove soil or other material representing the bulk of the volume of the pile to be driven will not be permitted. The diameter of the hole must not exceed two-thirds the width of the pile. Predrill only to a depth of [_____] meters feet below cut-off elevation prior to setting piles. Discontinue drilling when the pile tip is approximately 1.5 m 5 feet above the [calculated] [indicated] pile tip elevation. Drive pile the final 1.5 m 5 feet of penetration or more to meet the required driving criteria.

3.2.7 Pile Splices

******************************************************************************
NOTE: Splicing of piles normally should not be permitted except where extremely long or heavy piles are required. If splices are permitted, drawings should indicate splice details. (See PCI standard drawings for typical splice details).
******************************************************************************
[Splicing of piles is not permitted.] Make splices as indicated. Splices must be capable of developing the full strength of the member in compression, tension, shear, and bending. Submit detail drawings of splices and design calculations demonstrating the strength of the splice for approval. Submit information for shop and field pile splices prior to fabrication.]
3.2.8 Build-Ups

**************************************************************************
**NOTE:** Insert compressive strength required by design, usually a minimum of 35 MPa 5,000 psi.
Insert maximum percent of build-ups permitted for project. The percent will depend on criticality of pile failure at build-up; whether the top of the pile is designed as a moment connection; exposure of piles to external physical or corrosive damage.
Normally, for piles supporting piers exposed to seawater, limit percentage of build-ups to 10 percent.
**************************************************************************

Where required, pile section may be extended to cut-off elevation by means of a cast-in-place reinforced concrete build-up. Make build-up in accordance with PCI BDM. Construct build-ups made after completion of driving in accordance with detail "Build-Up Without Driving." Make build-ups to be driven in accordance with detail "Build-Up With Driving."
Have details of means for protecting joints by a suitable mortar or epoxy approved by Contracting Officer. Where build-ups are exposed to water, protect cast-in-place section from water during curing period. Concrete in build-up must have a minimum compressive strength of [_____] MPa psi. Build-ups will not be permitted on more than [_____] percent of total number of piles. If this percent figure is exceeded, or if in the judgment of the Contracting Officer, the clustered location of build-ups is undesirable, withdraw piles of insufficient length and replace with longer piles. Payment for such withdrawal and replacement will be made as an adjustment to the contract price.

3.2.9 Pile Cut-Off

Cut-off piles with a smooth level cut using pneumatic tools, sawing, or other suitable methods approved by Contracting Officer. Use of explosives for cutting is not permitted. Remove cut-off sections of piles from the site and off government property upon completion of the work.

3.2.10 As-Driven Survey

After the driving of each pile group is complete and before concrete is placed, provide the Contracting Officer with an as-driven survey showing actual location and top elevation of each pile. Do not proceed with placing concrete until the Contracting Officer has reviewed the survey and verified the safe load for the pile group driven. Present a survey in such form that it gives deviation from plan location in two perpendicular directions and elevations of each pile to nearest 13 mm half inch. Survey must be prepared and certified by a licensed land surveyor.

3.2.11 Protection of Existing Structures

**************************************************************************
**NOTE:** Include this paragraph only when protection of existing structures from pile driving activities is required.

The designer must indicate on the drawings all structures and facilities for which protection is required. The designer must also provide a project
specific document that details design criteria, requirements for preconstruction condition surveys, post construction condition surveys, geotechnical instrumentation to measure ground movements and any other requirements.

Add any additional requirements as necessary.

Mitigate impact on existing facilities due to pile driving activities in accordance with the [project specific document] [______].

3.2.12 Pile Shoe

Submit details about pile shoe used, if any. Where indicated or directed, securely attach pile shoes of an approved design to the piles in a manner described in the detail drawings.

3.3 FIELD QUALITY CONTROL

3.3.1 Test Piles

NOTE: Select the second bracketed option when soil conditions dictate the use of a test pile longer than production piles. The ordered pile length for test piles should be 1.5 m 5 feet longer than ordered length for production piles to allow additional penetration if driving conditions dictate. Indicate location and number (if required) of test piles on plans, or list appropriate soil boring test hole numbers.

[Use test piles of type, and drive as specified for piling elsewhere in this section. ] [Order test piles [_____] meters feet longer in length than production piles. Drive the additional test pile length only at the direction of the Contracting Officer. ] The [Contractor's Geotechnical Consultant] [Contracting Officer] will use test pile data to determine "calculated" pile tip elevation or necessary driving criteria. Drive test piles [at the locations indicated] [in vicinity of soil boring test holes Nos. [____], [____], and [____]]. Drive test piles to [indicated tip elevation] [indicated bidding lengths] [required driving criteria]. Use test piles, if located properly and offering adequate driving resistance in finished work.[ Pre-drilling or jetting is permitted only when test piles clearly establish validity of its use, or as directed by the Contracting Officer.][ Provide and operate a pile driving analyzer as specified in paragraph DYNAMIC PILE ANALYSIS during the driving of each test pile. Modify driving as required based upon recommendation of [Contractor's Geotechnical Consultant and approval of the Contracting Officer].]

[3.3.2 Dynamic Pile Analysis

Submit a performance report summarizing dynamic test results for test piles within [7][_____] calendar days of completing field work.[ For production piles, submit a performance report within one day of testing. Submit a typed report summarizing the results of dynamic testing of production piles on a monthly basis.]
Dynamic testing provides supplemental information for evaluating pile integrity, hammer and drive system performance, assess pile installation driving stresses, and pile capacities. Perform dynamic testing on [_____] percent of the test piles during the full length of the pile driving and during restrike a minimum of [_____] days after initial driving. Dynamic pile testing must also be performed on [_____] production piles as chosen by the Contracting Officer. Use test piles of type as specified elsewhere in this section. Provide equipment to obtain dynamic measurements, record, reduce and display its data that meet the requirement of ASTM D4945. The equipment must have been calibrated within [6][_____] months prior to the start of the testing operations and thereafter throughout the contract duration. Drive test piles at the locations indicated or at the locations selected by the Contracting Officer. Employ an independent inspection firm, hereinafter referred to as the "Contractor's Geotechnical Consultant", experienced in the pile driving process[, monitoring of test pile installation,] and in the use of the Pile Driving Analyzer and its related equipment. Perform dynamic pile analysis as follows:

3.3.2.1 Pile Analysis

[_____] working days prior to driving the test piles, submit the pile and complete driving equipment data to the Contracting Officer. The Contractor's Geotechnical Consultant must use the submitted information to perform wave equation analyses and must prepare a summary report of the wave equation results. The wave equation analysis using GRLWEAP software by Pile Dynamics, Inc. or equivalent must be used to assess the ability of the proposed driving system to install the pile to the required capacity and desired penetration depth within the allowable driving stresses. Approval of the proposed driving system by the Contracting Officer must be based upon the wave equation analyses indicating that the proposed driving system can develop a pile capacity of [_____] kN kips at a driving resistance not greater than [_____] mm/blow blows per inch within allowable driving stress limits. The hammer must also be sized or adjustable such that the penetration per blow at the required ultimate capacity does not exceed 12 mm 0.5 inches.

3.3.2.2 Pile Drivability

Perform each dynamic pile analysis in two steps. The first step is to check the hammer, pile and soil performance, and to determine the suitability of the proposed hammer for the size, length and type of pile being installed for the soil types encountered as the piles are driven. This initial monitoring must determine whether pre-augering or jetting is appropriate, efficiency of the hammer relative to specified efficiency, effectiveness of cushion, level of compressive and tensile stress in pile and extent/location of any pile damage caused by the initial driving. With each blow of the pile, record the information listed below electronically and analyze the information using the Pile Driving Analyzer:

(1) Blow number
(2) Blow rate per minute and stroke.
(3) Input and reflected values of force and velocity.
(4) Value of upward and downward traveling force wave with time.
(5) Maximum and final transferred energy to pile, hammer system efficiency.

(6) Maximum compressive stress, velocity, acceleration and displacement.

(7) Maximum tensile stress in pile.

(8) Pile structural integrity, damage detection, extent and location.

(9) Bearing capacity of pile by Case method.

If the pile, hammer and soil performance evaluation recommends changes to the hammer stroke, pile cushioning, augering or any other aspect for the pile driving operation, incorporate these changes into production pile driving in an effort to control excessive stresses and pile damage. Replace test piles damaged or broken during installation incorporating driving modifications as determined by the Contractor's Geotechnical Consultant and reviewed and approved by the Contracting Officer. Repeat this procedure until allowable tensile and compressive stresses are achieved in the pile and/or pile damage is minimized. Subject selected initial driving records to rigorous computer analysis by the Case Pile Wave Analysis Program (CAPWAP) for determination of resistance distribution, soil resistance and properties, and estimation of anticipated gain/loss factors.

3.3.2.3 CAPWAP

Signal matching analysis by CAPWAP® software of the dynamic pile testing data must be performed on data obtained from the end of initial driving and the beginning of restrike of all control piles. CAPWAP analyses must be performed by an engineer who has achieved Advanced Level or better on the PDI / PDCA Dynamic Measurement and Analysis Proficiency Test for Providers of PDA Testing Services.

Upon completion of[ test] pile driving, allow the piles to set-up for at least [72 hours][_____] days]. After evaluation of pile, hammer and soil performance by the Contractor's Geotechnical Consultant, the second step of the dynamic pile analysis may proceed. This portion of the evaluation requires striking the set-up piles a minimum of 20-50 times, or as directed by the Contractor's Geotechnical Consultant using the same hammer which was used for the[ test] pile driving and which will be used for production pile driving. "Warm up" the hammer and make it optimally ready prior to restriking, in order to avoid capacity losses during evaluation of restrike data. Apply maximum hammer energy during restrike in order to fully mobilize the soil resistance. However, exercise care so as to not overstress the pile. In addition to those items listed above, selected restrike driving records (as directed by the Contractor's Geotechnical Consultant are to be subjected to rigorous computer analysis by the Case Pile Wave Analysis Program (CAPWAP) for determination of resistance distribution, soil resistance and properties, and plot of applied load vs. average pile displacement based on the calculated soil properties.

3.3.2.4 Dynamic Load Test Reporting

Upon satisfactory completion of each dynamic load test, submit[ a minimum of three copies of] a Pile Performance Report for the Contractor by the Contractor's Geotechnical Consultant. The submittal must be prepared and sealed by a Professional Engineer registered in [____].
The report for the Dynamic Pile Analysis must contain the following information:

a. Capacity of pile from Case Pile Wave Analysis Program (CAPWAP). Information resulting from analysis of a selected restrike blow.

b. Maximum and final transferred energy, hammer system efficiency during pile installation.

c. Maximum compressive stress, velocity, acceleration and displacement.

d. Maximum tensile stress in pile.

e. Pile structural integrity, damage detection, extent and location.

f. Blows per minute and blow number.

g. Input and reflection values of force and velocity, upward and downward traveling force wave with time.

h. Pile skin friction and toe resistance distribution.

i. Maximum energy transferred to pile.

The maximum allowable pile design load must be proposed by the Contractor's Geotechnical Consultant based upon the results of a satisfactory pile load test conducted on a pile driven as specified herein and must include the effects of load transfer to the soil above the foundation stratum.

Use either a model 8G or PAX Pile Driving Analyzer as manufactured by Pile Dynamics, Inc., of Cleveland Ohio or approved equivalent, for dynamic testing of the pile hammer and for dynamic load testing of the test pile. All equipment necessary for the dynamic monitoring such as sensors, cables or wireless transmitters, etc., must be furnished by the Contractor's Geotechnical Consultant. The equipment must conform to the requirements of ASTM D4945.

Pay for all services of the Contractor's Geotechnical Consultant. The Contractor's Geotechnical Consultant must be available throughout the pile driving operation to consult with the Contracting Officer when required by the Contracting Officer. The cost of changes in the Contractor's procedure, as required by evaluation of the results of the Pile Driving Analysis, will be at the Contractor's expense.

3.3.3 Static Load Tests

**************************************************************************
NOTE: If pile load tests are required and approved by the Contracting Officer, specify number and location of piles. Select method of load test. In ASTM D1143/D1143M, permit anchor piles only if approved by the Contracting Officer's Technical Representative (Geotechnical Branch). Insert figure kN kips corresponding to 200 percent of the design load. Select appropriate acceptance criteria. The offset method (first option) is usually recommended.
**************************************************************************
Submit test set-up and procedures.

Perform compressive load tests on [_____] test piles in accordance with ASTM D1143/D1143M (standard loading procedure) as modified herein.[ Allow a minimum of [72 hours][_____] days following final test pile driving for pile set-up prior to load testing.] [Do not use anchor piles.] Provide apparatus for applying vertical loads as required by method, using load from weighted box or platform [or reaction frame attached to sufficient uplift piles to safely take required load] applied to pile by hydraulic jack. Increase load in increments until rapid progressive settlement takes place or until application of total compressive load of [_____] kN kips for compressive load tests. Consider load test satisfactory when [after one hour at full test load gross settlement of pile butt is not greater than gross elastic pile compression plus 4 mm 0.15 inch plus one percent of pile tip diameter or width in [_____] mm inches,] [slope of gross load-settlement curve under full test load does not exceed 1.5 mm per metric ton 0.05 inches per ton,] [net settlement after removal of test load does not exceed 19 mm 3/4 inch]. Perform load tests at locations[ as proposed by the Contractor's Geotechnical Consultant and] as directed by the Contracting Officer. Additional load tests, at Government expense, may be required by the Contracting Officer. Perform the loading, testing, and recording and analysis under the direct supervision of a Registered Professional Engineer, registered in the state of project location, and provided and paid for by the Contractor. [Submit test pile records][ and ][load test data] within [7][_____] calendar days of test completion.

[3.3.3.1 Safe Design Capacity

Determine the safe design capacity of a test pile as determined from the results of load tests according to UFC 3-220-01.

][3.3.4 Tensile Load Test

Perform tensile load tests on [_____] test piles in accordance with ASTM D3689/D3689M, as modified [and ]in paragraph LOAD TESTS. Apply a tensile load of [_____] kN kips to each tensile load test pile. In performing the tension load test, apply the ultimate load equal to one and one-half times the safe tension capacity, and employ the Standard Loading Procedure. Perform dynamic measurements on [_____] piles designated as dynamic test piles in accordance with ASTM D4945 during driving. During easy driving, ensure that damaging tension stresses do not develop in the pile. Signal matching must be performed by the Contractor's Geotechnical Consultant on representative data collected at the end of the initial driving and at the beginning of all restrike events. Additional signal matching analysis must be performed as determined by the Engineer.

][3.3.5 Lateral Load Test

Perform lateral load tests on [_____] piles in accordance with ASTM D3966/D3966M, as modified [and ]in paragraph LOAD TESTS. Lateral load tests must consist of jacking two piles apart with a hydraulic jack, with one pile serving as the reaction pile for the other. Apply a lateral load of [_____] kN kips to each pair of lateral load test piles. Record required movement readings for each pile.
3.3.6 Pile Records

**************************************************************************

NOTE: Omit reference to load test when not required in project. Omit reference to test piles and "calculated tip elevation" when test piles are not driven. Where special or unusual soil conditions are expected, consultation with the Contracting Officer's Technical Representative (Geotechnical Branch) regarding special engineering supervision of driving, testing, recording and analysis of data for project may be useful.

**************************************************************************

**************************************************************************

NOTE: The Specifier must attach the specifications pile driving log graphic (for all pile driving projects) and the pile driving equipment data form (for projects using PDA) to the end of this specification section.

**************************************************************************

Submit pile [and test pile] records.[ Submit load test data and results.]

Keep a complete and accurate record of each pile driven. Indicate the pile location, deviations from pile location, cross section shape and dimensions, original length, ground elevation, tip elevation, cut-off elevations, [batter alignment,] number of blows required for each 300 mm foot of penetration and number of blows for the last 150 mm 6 inches penetration or fraction thereof [as required] for the "calculated" [driving resistance]. Include in the record the beginning and ending times of each operation during driving of pile, type and size of hammer used, rate of operation, stroke or equivalent stroke for diesel hammer, type of driving helmet, and type and dimension of hammer cushion (capblock) and pile cushion used. Record retap data and unusual occurrences during pile driving such as redriving, heaving, weaving, splicing, obstructions, [jetting,] and any driving interruptions.[ Install an energy monitor on the hammers and record readings every 250 mm of pile installation.] A preprinted pile driving log for recording pile driving data[ and pile driving equipment data form], which can be downloaded at: http://www.wbdg.org/ffc/dod/unified-facilities-guide-specifications-ufgs/forms-graphics-tables.

3.3.7 Testing Agency Qualifications

Engage an independent testing agency qualified according to ASTM C1077 and ASTM E329 for testing indicated. Submit testing agency qualifications to the Contracting Officer for approval.

3.4 SPECIAL INSPECTION AND TESTING FOR SEISMIC-RESISTING SYSTEMS

**************************************************************************

NOTE: Include this paragraph only when special inspection and testing for seismic-resisting systems is required by the International Building Code (IBC).

This paragraph will be applicable to both new buildings designed and to existing building seismic rehabilitation designs done according to UFC.
UFGS

1-200-01, "General Building Requirements" and UFC
3-310-04, "Seismic Design for Buildings".

The designer must indicate on the drawings all
locations and all features for which special
inspection and testing is required in accordance
with Chapter 17 of the IBC. This includes
indicating the locations of all structural
components and connections requiring inspection.

Add any additional requirements as necessary.

Perform special inspections and testing for seismic-resisting systems and
components in accordance with Section 01 45 35 SPECIAL INSPECTIONS.

][3.5 VIBRATION CONTROL

NOTE: Include this paragraph when vibration
monitoring is required. Add any additional criteria
or requirements as necessary to the particular
project.

Perform vibration monitoring at the locations [shown in the plan] [decided
by the Contracting Officer] during the pile driving operations. Perform
vibration monitoring [using] [seismographs] [and geophones] within a
distance of [61] [_____] meters [200] [_____] feet from the pile driving
activity. Engage the services of a qualified, independent vibration
consultant, acceptable to the Government, to conduct the vibration
monitoring. The vibration consultant must have minimum of [five] [_____] years of experience in vibration monitoring. A minimum of [28] [_____] days before the installation of vibration monitors, submit to the
Government the name of the vibration consultant and a list of at least
[three] [_____] previously completed projects of similar scope and purpose.

Prior to the pile driving activities, obtain baseline readings of ambient
vibrations. The vibration during the pile driving activities must be
limited to [a peak particle velocity of not more than [5] [_____] cm [2.0]
[_____] inches per second.] [the limits mentioned in the [contract
documents] [_____] ]. Determine appropriate vibration limits as per [US
Bureau of Mines] [American Association of State Highway and Transportation
Officials (AASHTO)] guidelines.] During pile driving activities, monitor
the vibrations to ensure the limits are not exceeded. If the limits are
exceeded, cease the pile driving activity causing the vibration until [the
Vibration consultant and the Contracting Officer] [_____] are on site to
observe the structures nearest to the vibration monitor which has exceeded
the limits.

The Contractor must be responsible for all damages resulting from the pile
driving operations and must take whatever measures necessary to maintain
peak particle velocity within the specified limit. After completion of the
project, remove the vibration monitors off the site and off Government
property and restore the monitoring locations back to their original
condition.

][3.6 NOISE CONTROL

NOTE: Include this paragraph when noise monitoring
Perform noise monitoring at the locations [shown in the plan] [decided by the Contracting Officer] [at noise sensitive public areas] during the pile driving operations. Perform noise monitoring using [noise meters][, and][_____.] Engage the services of a qualified, independent noise consultant, acceptable to the Government, to conduct the noise monitoring. The noise consultant must have minimum of [five] [_____] years of experience in noise monitoring. A minimum of [28] [_____] days before the installation of noise monitors, submit to the Government the name of the noise consultant and a list of at least [three] [_____] previously completed projects of similar scope and purpose.

Prior to the pile driving activities, obtain baseline readings of ambient noise levels. The noise limits are mentioned in the [plan] [contract documents]. Determine appropriate noise limits as per [local agency] [Occupation Safety and Health Administration] guidelines. During pile driving activities, monitor the noise to ensure the limits are not exceeded. If the limits are exceeded, cease the pile driving activity and install noise mitigation measures.

The Contractor must be responsible for all damages resulting from the pile driving operations and must take whatever measures necessary to maintain noise within the specified limit. After completion of the project, remove the noise monitors off the site and off Government property and restore the monitoring locations back to their original condition.

[3.7] PRECONSTRUCTION CONDITION SURVEY

Perform preconstruction condition survey of [structures][and utilities] [within [61] [_____] meters [200] [_____] feet of the pile driving activity] [specified in the plans] [decided by the Contracting Officer]. Perform outreach to the owner of the structures [28] [_____] days before performing the preconstruction condition survey. The Contractor must obtain written permission from the owner of the structure prior to accessing the structure. The preconstruction condition survey must include video and photographic documentation of the exterior and interior of above ground structures and of the interior of underground structures. Video documentation must be in high definition, and show existing conditions and highlight, where possible, existing cracks, deteriorated concrete, exposed and corroded reinforcement, cracked or broken brick or mortar, and other signs of distress. For utilities, perform the survey when the greatest extent of the interior is exposed. Provide supplementary artificial lighting as needed. The video must include annotation with location and structure nomenclature which describes any areas of distress over the video and time code superimposed on the video. Photographs must be accompanied by sketches or descriptions that indicate the location and direction of each photograph. For each structure surveyed, provide a Pre-Construction Condition Survey Report following completion of the survey. The report must contain all documentation associated with the survey including DVD copies. In the report, include notes, sketches, photographs, and videos. Provide general information, such as location details and structure type,
as well as particular information on materials, condition, existing damage, aperture and persistence of cracks, and disrepair observed during visual survey. Provide a graphical depiction of locations of damage or other features of concern. Submit the Preconstruction Condition Survey Reports no later than [28] [_____] days before the commencement of pile driving activity. Accept responsibility for damages to existing adjacent or adjoining structures created by pile driving work, and repair any damages to these structures without cost to the Government.

3.8 CONSTRUCTION INSTRUMENTATION AND MONITORING PROGRAM

NOTE: Include this section if instrumentation is to be installed due to concerns about vibration, settlement, lateral movement, etc. during pile driving activities. Instrumentation should be specified and included in the specification. This section can be deleted if there are no instrumentation requirements.

Add any additional criteria or requirements as necessary for the particular project.

Prepare a geotechnical instrumentation program to monitor settlement and lateral movement of temporary and permanent structures, utilities, embankments and excavations during pile driving. The design and distribution of instrumentation must demonstrate an understanding of the need, purpose and application of each proposed type. Perform noise and vibration monitoring in accordance with NOISE CONTROL and VIBRATION CONTROL sections.

Monitoring must extend before, during and for a period after completion of construction activities related to pile driving when long-term performance issues are a concern. The monitoring plan must be designed to protect adjacent structures and utilities against damage due to the pile driving activities. Establish limiting values of vertical and horizontal movement and angular distortion and vibration for each structure and utility within the zone of influence, subject to review by the Government.

Prepare a Instrumentation and Monitoring Program Report detailing the proposed program of instrumentation and monitoring, establishing threshold values of monitored parameters, and describing the response plans that will be implemented when threshold parameters are exceeded. The report must include details about instrumentation consultant’s experience, appropriate types, quantities, locations and monitoring frequencies of the instruments.

Upon acceptance of the instrumentation and monitoring program, provide, install and monitor the instrumentation and interpret the data. Submit instrumentation data reports not less than every [_____] days after the monitoring program has begun. Take corrective actions, as necessary, based on the field instrumentation data and as defined in the instrumentation and monitoring program.

Pile and Driving Equipment Data Form

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for post-tensioned, centrifugally cast cylinder piles and prestressed statically cast cylinder piles. Pile reinforcing specified in this guide specification is for steel, special reinforcement materials (i.e. composite, non-magnetic, etc.) should be added on a project by project basis.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

NOTE: The extent and location of the work to be accomplished should be indicated on the project drawings or included in the project specification.
NOTE: The following information must be shown on the drawings:

1. Locations and design loads on piles. If both tension and compression piles are contained in design, identify by type.

2. Size, shape, and length of piles.

3. Locations, sizes, and number of longitudinal ducts for post tensioned steel. Location, sizes and number of prestressing strands. Unit stresses for post tensioned and prestressing strands or wire.

4. Details of reinforcement and tendons.

5. Details of splices, if required.

6. Locations of test piles, if required.

7. Soil data, where required.

************************************************************************************
PART 1   GENERAL
************************************************************************************

NOTE: Structural engineer must confirm the structural capacity of piles and provide specific bending moments, lateral loads and other design requirements for pile design.

************************************************************************************
1.1 DESCRIPTION

Design, furnish, install and test concrete cylinder piles at the locations indicated on the drawings and specified herein.[ Assume test pile[s] will be directed to be placed in [a] location[s] that can be incorporated into the work.][ Test piles which meet performance requirements may be incorporated into permanent work.]

1.2 REFERENCES

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically
be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

1.3 SUBSURFACE DATA

Subsurface soil data logs are[ indicated][ appended to the special contract requirements][ provided on the project drawings].[ The subsoil investigation report may be examined at [____].]
cut-off elevation], and to such additional depth as required to obtain a bearing capacity of not less than [_____] KN [_____] kips. The Contractor's Geotechnical Consultant will determine the terminal driving criteria based on [results of dynamic pile driving tests at end of drive or restrike] [static load tests] [wave equation analysis].

The following formulas can be used in cases where allowable pile loads are less than 355 KN 80 kips (determined using a factor of safety of 3 for individual piles and 4 for pile groups) and are presented only as a guide to aid in establishing the controlling penetration per blow, which, together with the minimum depth of penetration will serve to determine the required minimum depth of penetration of each individual pile:

\[
\begin{align*}
R &= \frac{2E}{S + 0.1} & \text{For double acting hammers} \\
R &= \frac{2WH}{S + 0.1} & \text{For single acting hammers}
\end{align*}
\]

Where \( R \) is the approximate allowable pile load in kips; \( E \) equals the energy in foot-kips per blow based on an acceptable certified statement from the manufacturer of the hammer; \( W \) equals the weight of the hammer or ram in kips; \( H \) equals the height of fall of the hammer of ram in feet; and \( S \) equals the average inches of penetration per blow for the last three blows. An allowance will be made for reduced penetration caused by shock absorption of the cushion or cap blocks.

[1.5 LUMP SUM PAYMENT]

******************************************************************************
NOTE: Use this paragraph for lump-sum contracts, consult with Contracting Officer's Technical Representative (Geotechnical Branch) on applicability of use prior to selection. This paragraph will be typically used when there are 1) relatively small quantity of piles, 2) allowable pile loading is less than 40 tons, and 3) the subsurface conditions are well defined. Fill in Table I as required selecting columns applicable to project. Generally, pile capacity, location, and minimum tip elevation are shown on plans. Test piles and load tests are not incorporated on lump sum contracts. Delete this paragraph for unit-price contracts.

******************************************************************************

Base bids upon providing the number, size, capacity, and length of piles as indicated on the [drawings.][following Table I:

<table>
<thead>
<tr>
<th>[Location]</th>
<th>Number</th>
<th>Size</th>
<th>Capacity</th>
<th>Length (tip to cut-off)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The contract price for piling must include the cost of all necessary equipment, tools, material, labor, and supervision required to: deliver, handle, install, cut-off, dispose of any cut-offs, and meet the applicable contract requirements. The contract price also includes mobilization,
pre-drilling, and redriving heaved piles. If, in redriving, it is found that any pile is not of sufficient length to provide the capacity specified, notify the Contracting Officer, who reserves the right to increase or decrease the total length of piles to be furnished and installed by changing the pile locations or elevations, requiring the installation of additional piles, or directing the omission of piles from the requirements shown and specified. Should total number of piles or number of each length vary from that specified as the basis for bidding, an adjustment in the contract price or time for completion, or both, will be made in accordance with the contract documents. Payment for piles will be based on successfully installing piles to both the minimum tip elevation and satisfying the acceptance criteria identified herein. No additional payment will be made for: damaged, rejected, or misplaced piles; withdrawn piles; any portion of a pile remaining above the cut-off elevation; backdriving; cutting off piles; splicing; build-ups; any cut-off length of piles; or other excesses beyond the assumed pile length indicated for which the Contractor is responsible.

NOTE: Delete this paragraph for lump-sum contracts.

For NAVFAC PAC projects: Where there is unit pricing for piles, use this paragraph and edit applicable attachments for inclusion in Standard Form 1442, "Solicitation, Offer and Award" and "Schedule of Bid Items."

For NAVFAC Southeast projects, where there is a need for unit pricing of piles, include this paragraph. Refer to NAVFAC SE Instruction 00010, "Instructions for Preparing Basis of Bid Statement With Unit-Priced Items," for method of specifying unit price bid items.

NOTE: For NAVFAC LANT projects, use the following paragraph for measurement and payment and subsequent sub-parts.

Requirements of FAR 52.211-18 Variation in Estimated Quantity do not apply to payment for piling. Each pile and test pile acceptably provided will be paid for at the bid unit price per unit length, which will include items incidental to furnishing and driving the piles including mobilization and demobilization, [jetting][predrilling][probing], redriving uplifted piles, [an additional 1.5 m 5 feet in furnished length for any test pile not driven beyond estimated pile length,] and cutting off piles at the cut-off elevation. [Include the cost for additional length for the test piles in the total unit price cost for the job.] Payment will be made for production [and test piles] at the bid unit price for the length of pile, from tip to final cut-off, actually provided, excluding buildups and splices directed by the Contracting Officer to be made. If the actual cumulative pile length driven (tip to cut-off) vary more than 25 percent
from the total pile length specified as a basis for bidding, at the
direction of the Contracting Officer, the unit price per unit length will
be adjusted in accordance with provisions of FAR 52.236-2 Differing Site
Conditions. [Payments will be made per each at the respective bid unit
price for pile cut-offs, pile build-ups, pile loads tests and pile
splices.][Include payments for vibration monitoring, sound monitoring,
construction instrumentation and monitoring, and precondition construction
surveys].

1.7 PAYMENT

**************************************************************************

NOTE: This paragraph is tailored for Army. If
Section 01 20 00 PRICE AND PAYMENT PROCEDURES is
included in the project specifications, this
paragraph title (UNIT PRICES) should be deleted from
this section and the remaining appropriately edited
subparagraphs below should be inserted into Section
01 20 00 PRICE AND PAYMENT PROCEDURES.
**************************************************************************

1.7.1 Furnishing and Delivering Concrete Cylinder Piles

1.7.1.1 Payment

Payment will be made for costs associated with furnishing and delivering
the required lengths of permanent concrete cylinder piles, which includes
costs of furnishing and delivering piles to the work site. No payment will
be made for the driving head or lengths of piles exceeding required
lengths. No payment will be made for piles damaged during delivery,
storage, or handling to the extent that they are rendered unsuitable for
the work, in the opinion of the Contracting Officer.

1.7.1.2 Measurement

Furnishing and delivering permanent concrete cylinder piles will be
measured for payment by the linear meter foot of piles required below the
cutoff elevation as [determined by the Contracting Officer and furnished to
the Contractor] [indicated].

1.7.1.3 Unit of Measure

Linear meter foot.

1.7.2 Driving Concrete Cylinder Piles

1.7.2.1 Payment

Payment will be made for costs associated with driving permanent concrete
cylinder piles, which includes costs of handling, driving, [and splicing of
piles, ] [performing dynamic testing, interpreting data and submitting
reports, ] measuring heave, redriving heaved piles, removal of [build-ups
] driving heads or cutting off piles at the cutoff elevation and removing
from the work site, compiling and submitting pile driving records,
backfilling voids around piles, and any other items incidental to driving
piles to the required elevation.
1.7.2.2 Measurement

Permanent concrete cylinder piles will be measured for payment for driving on the basis of lengths, to the nearest hundredth of a linear meter tenth of a linear foot, along the axis of each pile acceptably in place below the cutoff elevation shown.

1.7.2.3 Unit of Measure

Linear meter foot.

1.7.3 Pulled Concrete Cylinder Piles

1.7.3.1 Payment

Payment will be made for costs associated with piles pulled at the direction of the Contracting Officer and found to be undamaged. The cost of furnishing and delivering pulled and undamaged piles will be paid for at the applicable contract unit price for payment item "Furnishing and Delivering Concrete Cylinder Piles". The cost of driving pulled and undamaged piles will be paid for at the applicable contract unit price for payment item "Driving Concrete Cylinder Piles". The cost of pulling pulled and undamaged piles will be paid for at twice the applicable contract unit price for payment item "Driving Concrete Cylinder Piles", which includes backfilling any remaining void. The cost of redriving pulled and undamaged piles will be paid for at the applicable contract unit price for payment item "Driving Concrete Cylinder Piles". No payment will be made for furnishing, delivering, driving, pulling, and disposing of piles pulled and found to be damaged and backfilling voids. New piles replacing damaged piles will be paid for at the applicable contract unit price for payment items "Furnishing and Delivering Concrete Cylinder Piles" and "Driving Concrete Cylinder Piles".

1.7.3.2 Measurement

Furnishing and delivering pulled and undamaged permanent concrete cylinder piles will be measured for payment as specified in paragraph PAYMENT, subparagraph FURNISHING AND DELIVERING CONCRETE CYLINDER PILES. Pulling undamaged concrete cylinder piles will be measured for payment as specified in paragraph PAYMENT, subparagraph DRIVING CONCRETE CYLINDER PILES. Redriving pulled undamaged concrete cylinder piles will be measured for payment as specified in paragraph PAYMENT, subparagraph DRIVING CONCRETE CYLINDER PILES. New piles replacing damaged piles will be measured for payment as specified in paragraph PAYMENT, subparagraphs FURNISHING AND DELIVERING CONCRETE CYLINDER PILES and DRIVING CONCRETE CYLINDER PILES.

1.7.3.3 Unit of Measure

Linear meter foot.

[1.7.4 Concrete Pile Driving Tests

1.7.4.1 Payment

Payment will be made for costs associated with furnishing, delivering, driving, pulling, and disposing of driven test piles, [including splices]; conducting pile driving tests; backfilling voids around piles; compiling pile driving test records[; performing dynamic testing; interpreting data; and submitting reports].

SECTION 31 62 13.24  Page 14
1.7.4.2 Measurement

Concrete pile driving tests will be measured for payment on the basis of the applicable contract unit price per pile driving test.

1.7.4.3 Unit of Measure

Each.

][1.7.5 Concrete Cylinder Piles for Load Tests

1.7.5.1 Payment

Payment will be made for costs associated with furnishing, delivering, driving, pulling, and disposing of load test piles[ including splices]; backfilling voids around piles; compiling pile driving records[; furnishing, fabricating, and mounting of strain rods and protective assembly][; furnishing, fabricating, and mounting of instrumentation and instrumentation protective assembly][; performing dynamic testing; interpreting data; and submitting reports]. No additional payment will be made for load test piles incorporated in the permanent work other than as provided.

1.7.5.2 Measurement

Concrete cylinder piles for load tests will be measured for payment on the basis of the applicable contract unit price per load test pile.

1.7.5.3 Unit of Measure

Each.

][1.7.6 Concrete Pile Static Axial Compressive Load Tests

1.7.6.1 Payment

Payment will be made for costs associated with concrete pile static axial compressive load tests in accordance with ASTM D1143/D1143M, including material and labor for fabricating and furnishing load frames; calibrating load cells and hydraulic jacks; furnishing specified test equipment; installing strain rods; placing and removing test loads and test equipment; recording, reducing, and submitting test data; and compiling and submitting pile load test reports. No payment will be made for rejected pile static axial compressive load tests.

1.7.6.2 Measurement

Concrete pile compressive load tests will be measured for payment on the basis of the applicable contract unit price per load test.

1.7.6.3 Unit of Measure

Each.
1.7.7 Concrete Pile Static Tensile Load Tests

1.7.7.1 Payment

Payment will be made for costs associated with concrete pile static tensile load tests in accordance with ASTM D3689, including material and labor for fabricating and furnishing load frames; calibrating load cells and hydraulic jacks; furnishing specified test equipment; installing strain rods; placing and removing test loads and test equipment; recording, reducing, and submitting test data; and compiling and submitting pile load test reports. No payment will be made for rejected pile static tensile load tests.

1.7.7.2 Measurement

Concrete pile static tensile load tests will be measured for payment on the basis of the applicable contract unit price per number of tensile load test.

1.7.7.3 Unit of Measure

Each.

1.7.8 Concrete Pile Lateral Load Tests

1.7.8.1 Payment

Payment will be made for costs associated with concrete pile lateral load tests in accordance with ASTM D3966/D3966M, including material and labor for fabricating and furnishing load frames; calibrating load cells and hydraulic jacks; furnishing specified test equipment; installing inclinometers; placing and removing test loads and test equipment; recording, reducing, and submitting test data; and compiling and submitting pile load test reports. No payment will be made for rejected pile lateral load tests.

1.7.8.2 Measurement

Concrete pile lateral load tests will be measured for payment on the basis of the applicable contract unit price per lateral load test.

1.7.8.3 Unit of Measure

Each.

1.7.9 Pulled Load Test Concrete Cylinder Piles

1.7.9.1 Payment

Payment will be made for costs associated with load test concrete cylinder piles pulled prior to load testing at the direction of the Contracting Officer and found to be undamaged. The cost of furnishing, delivering, driving, and pulling undamaged load test piles will be paid for at the applicable contract unit price for payment item "Concrete Cylinder Piles for Load Tests". The cost of pulling undamaged load test piles the second time after redriving and testing will be paid for at twice the applicable contract unit price for payment item "Driving Concrete Cylinder Piles". The cost of redriving pulled undamaged load test piles will be paid for at the applicable contract unit price for payment item "Driving Concrete Cylinder Piles". No payment will be made for furnishing, delivering,
driving, pulling, and disposing of load test piles pulled at the direction of the Contracting Officer and found to be damaged, unless the pile was damaged due to overdriving at the request of the Engineer. New load test piles replacing damaged piles will be paid for at the applicable contract unit price for payment item "Concrete Cylinder Piles for Load Tests".

1.7.9.2 Measurement

Pulled undamaged load test concrete cylinder piles will be measured for payment as specified in paragraph PAYMENT, subparagraph CONCRETE CYLINDER PILES FOR LOAD TESTS. Pulling undamaged load test concrete cylinder piles the second time after redriving and testing will be measured for payment as specified in paragraph PAYMENT, subparagraph DRIVING CONCRETE CYLINDER PILES. Redriving pulled undamaged concrete cylinder piles will be measured for payment as specified in paragraph PAYMENT, subparagraph DRIVING CONCRETE CYLINDER PILES. New load test concrete cylinder piles replacing damaged piles will be measured for payment as specified in paragraph PAYMENT, subparagraph CONCRETE CYLINDER PILES FOR LOAD TESTS.

1.7.9.3 Unit of Measure

Unit of measure: as specified in paragraph PAYMENT, subparagraphs DRIVING CONCRETE CYLINDER PILES and CONCRETE CYLINDER PILES FOR LOAD TESTS, respectfully.

1.7.10 Concrete Pile Splices

1.7.10.1 Payment

Payment will be made for costs associated with concrete pile splices, including all plant, labor, and material required to make the splice.

1.7.10.2 Measurement

Concrete pile splices will be measured for payment on the basis of the applicable contract unit price per pile splice.

1.7.10.3 Unit of Measure

Each.

1.7.11 Pile Driving Shoes

1.7.11.1 Payment

Payment will be made for costs associated with pile driving shoes, including furnishing, delivering, and installing.

1.7.11.2 Measurement

Pile driving shoes will be measured for payment on the basis of the number of pile driving shoes required.

1.7.11.3 Unit of Measure

Unit of measure: each.
1.7.12 Vibration Monitoring

1.7.12.1 Payment

Payment will be made for costs associated with vibration monitoring.

1.7.12.2 Measurement

Vibration monitoring will be measured for payment on the basis of the applicable contract unit price per vibration monitoring point.

1.7.12.3 Unit of Measure

Each.

1.7.13 Sound Monitoring

1.7.13.1 Payment

Payment will be made for costs associated with sound monitoring.

1.7.13.2 Measurement

Sound monitoring will be measured for payment on the basis of the applicable contract unit price per sound monitoring point.

1.7.13.3 Unit of Measure

Each.

1.7.14 Preconstruction Condition Survey

1.7.14.1 Payment

Payment will be made for costs associated with preconstruction condition surveys.

1.7.14.2 Measurement

Preconstruction condition survey will be measured for payment on the basis of the applicable contract unit price per structure to be surveyed.

1.7.14.3 Unit of Measure

Each.

1.7.15 Construction Instrumentation and Monitoring

1.7.15.1 Payment

Payment will be made for costs associated with construction instrumentation and monitoring.

1.7.15.2 Measurement

Construction instrumentation and monitoring will be measured as a single pay item.
1.8 SUBMITTALS

**************************************************************************
NOTE: Review Submittal Description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy, Air Force, and NASA projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy, Air Force, and NASA projects, or choose the second bracketed item for Army projects.

**************************************************************************
Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

- **SD-01 Preconstruction Submittals**
  - Installation Procedures; G[, [____]]
  - Contractor's Geotechnical Consultant Documentation; G[, [____]]
  - Wave Equation Analysis; G[, [____]]

1.9 DELIVERY, STORAGE, AND HANDLING

Store, handle, and transport piles in accordance with PCI MNL-116 except as follows. Use methods for handling and storage of piles such that the piles are not subjected to excessive bending stress, cracking, spalling, or other damage. Follow the lifting instructions of the precaster.

1.9.1 Damaged Piles

Inspect each pile for sweep and structural damage such as cracking and spalling before transporting them to the project site and immediately prior to placement in the driving leads. Bring any unusual cracks (cracks other than crazing, surface drying, shrinkage cracks and end cracks) to the attention of the Contracting Officer. Piles which are damaged during delivery, storage, or handling to the extent they are rendered unsuitable for the work, in the opinion of the Contracting Officer, will be rejected and removed from the project site, or may be repaired, if approved, at no cost to the Government.

Any pile damaged by reason of internal defects or by improper driving must be corrected by one of the following methods approved by the Engineer for the pile in question and the Structural Engineer of Record:

a. The pile is withdrawn, if practicable, and replaced by a new and, if necessary, longer pile.

b. One or more replacement piles are driven adjacent to the defective pile.

c. A Pile Dynamic Analysis and low integrity testing must be performed by the Contractor’s Geotechnical Consultant to assess the structural integrity of the driven pile(s).

A pile driven below the specified butt elevation must be corrected by one of the following methods approved by the Engineer:

a. The pile is spliced (if approved).
b. A sufficient portion of the footing is extended down to properly embed the pile.

A pile driven out of its proper location or out of plumb as approved by the Engineer, must be corrected by one of the following methods approved by the engineer:

a. One or more replacement piles are driven next to the pile in question.

b. As directed by the structural engineer.

1.9.1.1 Repairable Cracks

Piles with cracks equal to or greater than 0.15 mm 0.006 inches but less than 1.5 mm 0.06 inches must be repaired or rejected at the discretion of the Contracting Officer. As an alternate to pile rejection, the Contractor may submit a proposal to repair deficient piles. Prior to driving, piles must be restored to their required design capacity so that they can perform their intended structural function and achieve long term durability in corrosive environment.

1.9.1.2 Non-Repairable Cracks

Piles with cracks equal to or greater than 1.5 mm 0.06 inches must be rejected.

1.9.2 Pile Sweep

**************************************************************************
NOTE: Sweep and camber typically apply to steel piles. In special cases, this paragraph may apply to precast concrete piles.
**************************************************************************

Sweep must be limited to the tolerances specified in PCI MNL-116 over the length of the pile. Piles having excessive sweep must be rejected. Piles that develop non repairable cracks due to handling and installation must be rejected.

1.10 QUALITY CONTROL

1.10.1 Piles

**************************************************************************
NOTE: When the size and complexity of project warrants certification by a registered engineer, insert requirements; otherwise delete.
**************************************************************************

Prepare in accordance with ACI SP-66. Indicate placement of reinforcement including tendons. Indicate location of special embedded or attached lifting devices, employment of pick-up points, support points other than pick-up points, and any other methods of pick-up. [Provide certification by a professional engineer registered in any jurisdiction, that layout and details of reinforcement and tendons conform with that shown on the structural design drawings.]
1.10.2 Quality Control Procedures

Submit the precasting manufacturer's quality control procedures and inspection records established in accordance with PCI MNL-116.

1.10.3 Installation Procedures

a. Submit information on the type of equipment proposed to be used, proposed methods of operation, pile driving plan including proposed sequence of driving, and details of all pile driving equipment and accessories.

b. Provide details of pile driving equipment and a Wave Equation Analysis of pile drivability for selection of the hammer along with a statement of driving procedures. The Wave Equation Analysis is to be completed by the Contractor's Geotechnical Consultant for each test pile location where different subsurface conditions exist and is to include the following information pertaining to the proposed pile driving equipment:

1. Completed Pile and Driving Equipment Data Form (which can be downloaded at: http://www.wbdg.org/ffc/dod/unified-facilities-guide-specifications-ufgs/forms-graphics-tables), for each proposed pile hammer and pile type combination.

2. Copies of computer input and output sheets and graphs showing soil resistance versus blow count as well as maximum tension and compression stresses versus blow count. Analysis must be run at the estimated tip elevation as well as other required elevations to define maximum stress levels in the pile during driving.

c. Provide detailed procedures for conducting the dynamic pile load test and equipment to be used for conducting the load test. The detailed description must explain how specific information of pile performance will be evaluated.

[1.10.4 Contractor's Geotechnical Consultant Documentation

Hire the services of an independent, Registered Professional Geotechnical Engineer, experienced in soil mechanics and Pile Dynamic Analysis, to observe test pile installation and production pile installation as specified herein. The Contractor's Geotechnical Consultant must be independent of the Contractor and must have no employee of employer relationship which could constitute a conflict of interest.

Provide instructions and procedures on how the Contractor shall assist the Government in the processes of Dynamic Pile Testing and Interior Inspection of Damaged Piles.

1.10.5 Concrete Mix Design

Submit a concrete mix design before concrete is placed, for each type of concrete used for the piles. Certify, using a Government-approved independent commercial testing laboratory, that proportioning of mix is in accordance with ACI 211.1 or ACI 318M ACI 318 for specified strength and is based on aggregate data which has been determined by laboratory tests during last twelve months. Submit a complete list of materials including type, brand, source and amount of cement, fly ash, pozzolan, ground slag, and admixtures; and applicable reference specifications. Submit additional data regarding concrete aggregates if the source of aggregate changes.
Submittal shall clearly indicate where each mix design will be used when more than one mix design is submitted.

[1.10.6 Load Test Supporting Data

Submit Jack calibration records, a testing arrangement description and diagram, and the proposed loading sequence.

[1.10.7 Silica Fume Manufacturer's Representative

Provide statement that the manufacturer's representative will be present at plant to ensure proper mix, including high range water reducer (HRWR), and batching methods.

PART 2 PRODUCTS

2.1 PILE MATERIALS

**************************************************************************
NOTE: Delete sentence in brackets when test piles are not required. Government requires the Contractor to employ a Geotechnical Consultant to determine the calculated tip elevation and provide oversight of piling installation and testing.
**************************************************************************

Provide precast concrete cylinder piles per PCI Journal Volume 38, Number 2 (PCI JR-382). Production of piles must be in accordance with PCI MNL-116.[Order test piles [3] [_____] meters [10] [_____] feet longer in length than production piles.][Drive the additional test pile length only when based upon the recommendation of the Contractor's Geotechnical Consultant and approved by the Contracting Officer.] The [Contractor's Geotechnical Consultant] [Contracting Officer] will use test pile data to determine "calculated" pile tip elevation and necessary driving resistance. This information will be given to the Contractor no later than seven days from receipt of complete test data. Use this list as the basis for ordering the piles. Do not order piles until list is provided by the [Contractor's Geotechnical Consultant] [Contracting Officer].[Provide test piles [1.5] [_____] meters [5] [_____] feet longer than the bid length.]

2.2 MATERIALS

2.2.1 Cementitious Materials

Cementitious materials must be portland cement, [blended cement] or only portland cement in combination with natural pozzolan or fly ash [or ground granulated blast furnace slag] and must conform to appropriate specifications listed below.

2.2.1.1 Cement

**************************************************************************
NOTE: Insert type of cement required. Generally, Types II, or I/II, is preferred. Type I, or Type III with 8 percent maximum C3A and "low alkali" may be used. Do not use Type III in conjunction with silica fume. In very special cases, Type V, "low alkali," which has limited availability, may be used.
**************************************************************************
NOTE: Cement type and quantity of cement required in mix design is dependent upon the environment, soil conditions, need for corrosion protection, and location of piling:

(a) CHLORIDE PROTECTION:

Normal Use. In fresh water or air environment, specify Type I or Type II cement. Type III may be permitted provided tricalcium aluminate (C3A) content is limited to 8 percent and it is low alkali.

Marine Use. In soil or water environments, subject to chlorides above 1,000 ppm, within about 300 m
1000 feet of the ocean or tidal water, specify Type II or Type III (with a maximum tricalcium aluminate (C3A) content of 8 percent and low alkali) cement, a minimum cementitious materials content of 335 kilograms per cubic meter 564 pounds per cubic yard and a maximum water to cementitious materials ratio of 0.40.

Seawater Exposure. In direct contact with ocean water, specify Type II or Type III (with a maximum tricalcium aluminate (C3A) content of 8 percent and low alkali) cement, a minimum cementitious materials content of 390 kilograms per cubic meter 658 pounds per cubic yard and a maximum water to cementitious materials ratio of 0.40.

(b) SULFATE RESISTANCE:

A minimum cementitious materials content of 335 kilograms per cubic meter 564 pounds per cubic yard is recommended.

Normal Use. In soils with negligible amount of sulfate, specify Type I or Type II cement. Type III cement may be permitted provided tricalcium aluminate (C3A) content is limited to 8 percent and it is low alkali.

Moderate Sulfate Exposure. In exposures with moderate sulfate content (between 0.10 and 0.20 percent in soil and less than 1500 ppm in water), specify Type II or Type III (with a maximum tricalcium aluminate (C3A) content of 8 percent and low alkali) cement and a maximum water to cementitious materials ratio of 0.40. Do not use Class C fly ash, blast furnace slag, or silica fume for cement replacement.

Severe Sulfate Exposure. In exposures with high sulfate content (exceeds 0.20 percent in soil or 1500 ppm in water), specify Type V or Type II (with a maximum tricalcium aluminate content of 5 percent) cement, and a maximum water to cementitious
materials ratio of 0.40. Do not use Class C fly ash, blast furnace slag, or silica fume for cement replacement.

******************************************************************************

ASTM C150/C150M, [Type I, II, or III [_____] with a maximum alkali content of 0.60 percent; or] [ASTM C595/C595M, Type [IP(MS) or IS(MS)] [_____] blended cement except as modified herein.] The blended cement must consist of a mixture of ASTM C150/C150M cement (with alkali content not exceeding 0.60 percent) and one of the following materials: ASTM C618 pozzolan or fly ash, or ASTM C989/C989M ground iron blast-furnace slag, or ASTM C1240 silica fume. Cement certificates must include test results in accordance with ASTM C150/C150M, including equivalent alkalies indicated in the optional chemical requirements. [Use cement with a tricalcium aluminate (C3A) content of less than [8] [5] percent.] Type III cement must not be used in conjunction with silica fume.

******************************************************************************

NOTE: Fly ash, pozzolan, and ground iron blast-furnace slag increase durability. They may produce uneven discoloration of the concrete during the early stages of construction, depending upon the type of curing provided. Use Fly ash/pozzolan (loss on ignition not exceeding 3 percent) for frost areas to reduce carbon interference with air entraining admixture. Straight replacement with fly ash or natural pozzolan beyond 15 percent may decrease the concrete's strength gain rate. The following options can help mitigate this slower gain rate: (1) a lower water/cement ratio may be used, (2) partial cement replacement can be completed, e.g., one sack of cement can be replaced by 1.5 sacks of fly ash, as long as the final replacement ratio meets the requirements, and (3) very fine fly ashes or pozzolans (e.g., with average particle sizes below 5 microns) can be used.

******************************************************************************

2.2.1.2 Fly Ash and Pozzolan

******************************************************************************

NOTE: Loss on ignition greater than 3 percent may result in significant variations in air content. The air entrainment admixture content may need to be varied often to maintain the same level of entrained air.

******************************************************************************

ASTM C618, Class N, or F except that the maximum total alkalies must be [3] [6] percent. If the aggregates are reactive the maximum calcium oxide content must be 13.0 percent. Class C must not be used.

2.2.1.3 Ground Iron Blast-Furnace Slag

ASTM C989/C989M, Grade 120.

[2.2.1.4 Silica Fume

******************************************************************************
NOTE: Use silica fume concrete for marine structures where low permeability and enhanced durability are necessary. The silica fume and HRWR additive should be from the same manufacturer. The Contractor and batch plant may need help from the manufacturer. Select weight percentage based on performance required. If used, a replacement of 7 percent is recommended.

**************************************************************************

NOTE: Use for high durability and low permeability. The initial cost of the concrete will increase, and supervision at the batch plant, finishing, and curing is necessary. A HRWR must be used with silica fume. The slump can be increased 50 to 125 mm 2 to 5 inches without reducing strength. Finishing may be more difficult. Proper curing is essential because there is a tendency for plastic shrinkage cracking.

**************************************************************************

ASTM C1240, provide silica fume that is a by-product of silicon or ferrosilicon production. Provide percent by weight of the total cementitious materials as indicated in table below.

2.2.1.5 Supplemental Cementitious Materials (SCM) Content

The concrete mix must contain one of the four SCMs listed below, or a linear combination thereof.

<table>
<thead>
<tr>
<th>SC Munmental</th>

</table>
2.2.2 Water

Water must be fresh, clean, and potable; free from injurious amounts of oils, acids, alkalis, salts, organic materials, or other substances deleterious to concrete or steel.

2.2.3 Aggregates

**************************************************************************
NOTE: For piles in areas where reactive aggregates are likely to be supplied, provide for additional tests and certification to insure that reactive aggregates will not be used. While not wholly conclusive, petrographic examination (ASTM C295/C295M), chemical test (ASTM C289), and mortar bar method (ASTM C227) are valuable indicators. While more reliable, the concrete prism test (ASTM C1293) takes 1 to 2 years to complete and is not practical. The accelerated mortar bar method (ASTM C1260) is similarly reliable and takes only 16 days to yield results. In areas where reactive aggregates can not be avoided, specify use of low alkali cement, and/or cements modified to mitigate alkali-silica reactivity. Service records of concrete made with these materials along with tests should be used in evaluating these materials.
**************************************************************************
**************************************************************************
NOTE: Include modification to ASTM C33 when reactive aggregates could be encountered. More modifications may be required. Additional tests and certifications may be required in the submittal paragraphs.
**************************************************************************

ASTM C33/C33M[, except as modified herein. Provide aggregate free from any substance which may be deleteriously reactive with alkali in cement in an amount sufficient to cause excessive expansion of concrete].[ Dune sand must not be used as fine aggregate.] Do not mix, store in same stockpile, or use fine aggregates from different sources of supply in same concrete mix or same structure without approval. The fineness modulus of fine aggregate must be not less than 2.40 or greater than 3.0. For piles that will be exposed to freezing and thawing, fine and coarse aggregate subjected to five cycles of the sodium sulfate soundness test must show a loss not greater than 10 percent. If the selected aggregates fail the soundness test, the Contractor may use the aggregate source, provided concrete specimens made with the aggregates to be used for the piles must have a durability factor of not less than 80 based on 300 cycles of freezing and thawing when tested in accordance with ASTM C666/C666M. Prior to pile fabrication, submit certified test reports for the following tests specified in ASTM C33/C33M[, in addition, [twice] [_____] during each shift when the concrete plant is operating, the gradation of each size of aggregate must be tested in accordance with ASTM C136/C136M]:

a. Grading

b. Amount of material finer than 75 micrometers No. 200 sieve
c. Organic impurities

d. Soundness

e. Clay lumps and friable particles

f. Coal and lignite

g. Weight of slag

h. Abrasion of coarse aggregate

i. Fineness modulus

j. Reactive aggregates

k. Freezing and thawing

2.2.3.1 Alkali-Silica Reactivity (ASR)

Fine and coarse aggregates to be used in all concrete must be evaluated and tested by the Contractor for alkali-aggregate activity.

The fine and coarse aggregates must be evaluated separately, using ASTM C1260. Test results of the individual aggregates must have a measured expansion equal to or less than 0.08 percent at 16 days after casting. Should the test data indicate an expansion of greater than 0.08 percent, the aggregates(s) must be rejected or additional testing, using ASTM C1567 must be performed as follows: utilize the Contractor's proposed low alkali portland cement [blended cement] and SCM in combination with the proposed aggregate for the test portioning. The SCM quantity must be determined that will meet all the requirements of these specifications and that will lower the ASTM C1567 expansion to equal or less than 0.08 percent at 16 days after casting.

If the above option does not lower the expansion to less than 0.08 percent at 16 days after casting, reject the aggregate(s) and submit new aggregate sources for retesting. Submit the results of testing to the Contracting Officer for evaluation and acceptance.

2.2.4 Admixtures

**************************************************************************

NOTE: For guidance in use of either water-reducing admixtures, set retarding admixtures, or combination of admixtures, see ACI 543R, "Recommendations for Design, Manufacture, and Installation of Concrete Piles.

**************************************************************************

Chemical admixtures must conform to ASTM C494/C494M, [Type A] [Type B]. [Air-entraining admixture must conform to ASTM C260/C260M. ]Do not use admixtures containing chlorides.

2.2.5 Prestressing Steel

Use seven-wire stress-relieved or low-relaxation strand conforming to ASTM A416/A416M, Grade 270. Use prestressing steel free of grease, oil, wax, paint, soil, dirt, and loose rust. Do not use prestressing strands or
2.2.6 Reinforcing Steel

 Minimum cover for reinforcing steel in concrete structures is dependent upon the environment, soil conditions, need for corrosion protection, and location of piling. For normal exposure minimum cover is 50 mm (2 inches). For piles exposed to marine conditions (chloride content above 1000 ppm) in or within about 300 m (1000 feet) of the ocean or tidal water, use 75 mm (3 inches) minimum cover, including chamfered corners. For additional detailed guidance, see following publications: ACI 543R, "Recommendations for Design, Manufacture and Installation of Concrete Piles" (ACI Manual, Part 3); State of California, Department of Public Works, Design Specifications, Volume 1, Bridge Planning and Design Manual, Chapter 6. Piles to be used in a marine environment may receive a protective coating, particularly if the piles are steam cured. The protective coating should be applied to that portion of pile which remains aboveground or water line. Show areas to be protected on drawings.

Insert grade of reinforcement. Specify ASTM A706/A706M reinforcing where welding or bending of reinforcement bars is important. In addition, ASTM A996/A996M may be specified for epoxy coating of reinforcing where extra reinforcement protection is required.

Weld reinforcing steel in accordance with AWS D1.4/D1.4M.

2.2.6.1 Spirals and Ties

 NOTE: If project has been designed for epoxy rebar, add ASTM A934/A934M, "Epoxy-Coated Prefabricated Steel Reinforcing Bars" in this paragraph and in the paragraph REFERENCES.

2.2.7 Grout

Provide cement grout for prestressed piles using materials conforming to requirements stipulated herein for concrete mixes or for post-tensioned piles, PTI M55.1. Use admixtures, if required, known to have no injurious effects on steel or concrete. Do not use admixtures containing calcium.
chloride. Grout must have a minimum compressive strength of 48 MPa 7,000 psi in 28 days, as determined by testing 50 mm by 50 mm by 50 mm 2 inch by 2 inch by 2 inch cubes.

2.2.8 Joint Sealing Material

The abutting joint surfaces of precast segments must be covered by a sealing material of sufficient thickness to fill all voids between the end surface, except at the core holes for the stressing strands and telltale, when brought together under compression as specified. This sealing material must attain a minimum ultimate compressive strength of 48 MPa 7,000 psi in 28 days, and must be as resistant to exposure and weathering as is the concrete.

2.2.9 Epoxy Coating

2.2.10 Pressure Grouting Epoxy

2.2.10.1 Crack Sealer for Pressure Grouting

ASTM C881/C881M, Type IV, Grade 1, Class B or C without filler.

2.2.10.2 Crack Surface Sealer for Pressure Grouting

ASTM C881/C881M, Type IV, Grade 3, Class B or C with mineral filler.

2.2.11 H-Pile Extensions

Use H-pile extensions for composite prestressed concrete-steel piles of steel conforming to the requirements of [ASTM A36/A36M] [ASTM A572/A572M].

2.2.12 Pile Driving Points

Use pile driving points of steel conforming to the requirements of ASTM A27/A27M or [ASTM A36/A36M] [ASTM A572/A572M], of the [type] [details] indicated.

2.2.13 Prestressing/Post Tensioning Tendons

ASTM A416/A416M, Grade [1720 MPa] [1860 MPa] [250 ksi] [270 ksi], uncoated, 7 wire, low-relaxation strand or ASTM A886/A886M, Grade [1860 MPa] [_____] MPa] [270 ksi] [_____] ksi], indented, 7 wire, low-relaxation strand (including supplement).

2.3 CONCRETE

2.3.1 Concrete Mix Design

**************************************************************************
NOTE: Insert the specified compressive strength, f'c. A minimum of 48 MPa 7000 psi is normally specified. Consider reducing average overstrength factor to produce a more economical concrete mix design. ACI 318M ACI 318 may be modified for a specified compressive strength, f'c, over 35 MPa 5000 psi to permit a required average compressive

SECTION 31 62 13.24 Page 31
strength, f'cr, of f'c plus 4.8 MPa 700 psi.
Concrete may be proportioned in accordance with ACI 214R for the probability of one test in 10 falling below the specified compressive strength, f'c, if the mix design reflects actual concrete plant standard deviations and the resulting production concrete conforms to specified requirements. Do not use lightweight or fiber-reinforced concrete.

Concrete must have a minimum specified compressive strength, f'c, of [_____] [7000] psi at 28 days. The minimum cementitious materials content must be 354 kg per cubic meter 600 pounds per cubic yard of concrete. The design must be prepared in accordance with ACI 211.1 and ACI 318M ACI 318. The mix design must be based on current materials previously evaluated by the concrete producer whose established methods of statistical quality control is in conformance with ACI 318M ACI 318. In the absence of such data, the Contractor must sample and test the aggregates for the design of concrete. Calcium Nitrite must be added to the mix at a rate of [10 liters per cubic meter] [2.0 gallons per cubic yard].

2.3.2 Concrete Mix Design Proportioning

a. Water and cement ratio must be equal to or less than 0.40. If fly ash is used, the water and cement ratio must be calculated as the weight of water divided by the weight of cement plus 60 percent of the weight of fly ash. If silica fume is used, the water and cement ratio must be calculated as the weight of water divided by the weight of cement plus the weight of silica fume.

b. Maximum aggregate size must not exceed 19 mm 3/4 inch.

************** Air-entrainment may be considered optional only in regions that do not experience freezing temperatures. **************

c. Air-entrainment must be 4.5 to 7.5 percent. Determine air void structure in accordance with ACI 212.3R. Spacing factor must be less than 2.5 mm 0.01 inch, the specific surface area must be greater than 0.39 square meter per 0.000016 cubic meter 600 square inches per cubic inch of air void volume, and the number of air voids per mm inch of traverse must be significantly greater than the numerical value of the percentage of air in the concrete.

2.3.3 Trial Mixtures

Trial mixtures having proportions and consistencies of the proposed mix design must be made to document the Contractor’s ability to produce workable concrete which does not segregate or show excessive slump loss characteristics.

2.4 FABRICATION

Fabrication of the concrete cylinder piles, including storage and handling of materials, batching and mixing of concrete, stressing, sampling, testing and recording must follow the guidelines set forth in PCI MNL-116 “Manual for Quality Control for Plants and Production of Precast and Prestressed
2.4.1 Manufacturing of Piles and Pile Sections

The aggregates, cement and water must be proportioned batched by calibrated device and mixed thoroughly by suitable mixing plant to produce consistent and homogeneous concrete.

Full length, pretensioned concrete piles and post-tensioned pile sections can be manufactured by the centrifugal casting process. If this process is utilized, individual piles and pile sections must be formed and compacted by centrifugal force in a machine of suitable type so designed that the concrete molds may be revolved at speeds sufficient to ensure even distribution and dense packing of concrete without the creation of voids behind reinforcing steel.

Filling the mold and spinning should be continuous and must all take place before any of the concrete in the mold has taken an initial set. Excess water forced to the center must be drained or removed prior to curing. The section must be cured in the mold until the concrete has attained the indicated strength to prevent deformation or damage during demolding.

Alternatively, concrete cylinder piles can be made by the static cast method. Extruded dry cast method must not be allowed for static cast piles.

Manufacturing by the static cast method must utilize rigid steel forms and be vibrated as necessary to ensure that the concrete is consolidated and homogeneous for the entire pile length.

Filling the mold should be continuous and must be completed for each individual pile before any of the concrete in the mold has taken an initial set. The pile must be cured in the mold until the concrete has attained the indicated strength to prevent deformation or damage during demolding. After initial set has occurred, the top form section may be removed to allow finishing of the pour stop along the exterior top face of the pile.

For both fabrication methods, the wall thickness of the pile sections must be as specified on the plans.

2.4.2 Spiral Reinforcing

*************************************************************************

NOTE: Minimum cover for reinforcing steel in concrete structures is dependent upon the environment, soil conditions, need for corrosion protection, and location of piling. For normal exposure minimum cover is 50 mm 2 inches. For piles exposed to marine conditions (chloride content above 1000 ppm), use 75 mm 3 inches minimum cover except at corners where 100 mm 4 inches of cover should be provided. In normal and marine conditions, 38 mm 1-1/2 inch cover may be used for post-tensioned, centrifugally cast piles using no-slump concrete, with minimum 9.15 sacks of cement per cubic meter 7 sacks cement per cubic yard. For additional detailed guidance, see following publications: ACI
Sections must have a spiral reinforcement cage, arranged and dimensioned as shown on the contract drawings. This reinforcing cage must be securely held in position during the casting or spinning of the concrete.

Center to center spacing of spiral (defined as spiral pitch) must not exceed six times the spiral wire diameter in the portion of the pile extending from the soffit of the pile cap to a location equal to the point of fixity below mudline as shown on the contract drawings.

The spiral steel reinforcing must be outside the prestress bars and must have a minimum concrete cover to the outside surface of the pile section as shown on the contract drawings. [The spiral steel reinforcing must be outside the tendon ducts and must have a minimum concrete cover of 38 mm (1-1/2 inches) to the outside surface of the pile section.]

2.4.3 Arrangement of Strands

The number, size, and arrangement of the prestressing strands must be in accordance with the details shown on the contract drawings.

2.4.4 Curing of Piles

Cure piles using moist or accelerated curing. Curing of piles must be in accordance with the PCI MNL-116 except as follows.

2.4.4.1 Moist Curing

Moist cure using moist burlap coverings, plastic sheeting, or membrane curing compound until minimum strength to detension is achieved.

2.4.4.2 Accelerated Curing

After placement of concrete, moist cure for a period of 4 hours. Accelerated cure until concrete has reached specified release strength. Enclose casting bed for accelerated curing with a suitable enclosure. During application of steam or heat, increase the air temperature at a rate not to exceed 22 C degrees 40 F degrees per hour. Cure at a maximum temperature of 65 degrees C 150 degrees F until concrete has reached specified release strength. Reduce temperature at a rate not to exceed 11 C degrees 20 F degrees per hour until a temperature of 11 C degrees above ambient air temperature is reached. After accelerated curing, moist cure using either water or membrane curing until a total accelerated and moist curing time of 72 hours is achieved.
2.4.5 Handling

Piles must not be demolded or lifted off from casting beds unless the designed lifting strength or minimum works cube strength of 39.3 MPa 5,700 psi (whichever is greater) has been achieved. Lifting device or crane must be such that no shock or impact is imposed on piles.

Care should be taken at all stages or transporting, lifting and handling to ensure the piles are not damaged or cracked. Piles should be stored on firm stable ground not susceptible to settlement under the weight of piles. The piles must be placed on strong supports (hard wood) which are truly level and spaced so as to avoid undue bending stress in the piles. The supports should be vertically above one another.

No pile must be driven before the 28-day strength of concrete has been achieved.

2.5 CONCRETE CYLINDER PILE POST-TENSIONED CENTRIFUGALLY CAST (ALTERNATIVE I)

2.5.1 Anchorages and End Fittings

ACI 318MACI 318, for post-tensioned assemblies.

2.5.2 Forms

Provide forms of metal, braced and stiffened against deformation, accurately constructed, watertight, and supported on unyielding casting beds. Forms must permit movement of pile without damage during release of the prestressing force. Make piles to dimensional tolerances in accordance with PCI MNL-116 and as follows:

a. Location of Reinforcing Steel

(1) Main Reinforcement: 3 to 6 mm 1/8 to 1/4 inch from position designated on drawings.

(2) Spacing of Spiral: Plus or minus 13 mm 1/2 inch from position designated on drawings exclusive of concrete cover requirements.

b. Location of Pipe Sleeves from True Position: Plus or minus 10 mm 3/8 inch.

2.5.3 Longitudinal Reinforcement

The number, size, and arrangement of the longitudinal post tensioned tendons must be in accordance with the details shown on the contract drawings.

The main longitude reinforcement must be fitted symmetrically, equally and continuously spread over the whole length without joint or lap. The main longitudinal post tensioned tendons should be level at the top of the pile and should fit tightly into the pile shoe and end plate.

2.5.4 Spin Casting

The spinning of the whole assembly must follow proven spinning procedure that has been used by the manufacturer in the manufacturing of similar pile sections.
2.5.5 Longitudinal Ducts (holes) for Prestressing Tendons

Details and positioning of ducts (holes) must be in accordance with PCI MNL-116, and as specified herein. Longitudinal ducts for the prestressing tendons must be formed in the walls of the pile sections during casting. The ducts must be 35 mm 1-3/8 inches (nominal diameter) and positioned so that there must be a minimum cover of 38 mm 1-1/2 inches from the edge of the ducts to the outside surface of the pile section.

2.5.6 Concrete Strength

**************************************************************************
NOTE: Specify "assembly strength." Assembly strength of 30 MPa 4000 psi for (Design strength) of 50 MPa 7000 psi or 0.7 of the 28-day design strength is desirable; however, some regions use 0.8 of the design strength. Check with local pile manufacturers.
**************************************************************************

The pile sections must not be assembled together into a pile until the compressive strength of the concrete has reached 30 MPa 4,000 psi as determined by cylinders cured in the same manner as the sections.

2.5.7 Alignment of Sections

Pile sections must be positioned in accurate alignment so that the axis of the pile does not deviate from a straight line more than 3 mm per 3 m 1/8-inch per 10 feet of length. Adjacent sections must be positioned so that the maximum deviation of the outside surface of the joint does not exceed 6 mm 1/4-inch. Where membrane curing is used, remove curing compound from abutting end-surface of sections. The abutting joining surfaces must be covered by a joint sealing material of sufficient thickness to fill voids between end surfaces, except at the core holes for the stressing. The pile section must be brought into contact and held together by a force equivalent to not less than 690 kPa 100 psi on the gross concrete area, until the sealing materials has set.

2.5.8 Post Tensioning

Tendons must be tensioned to an allowable unit stress as indicated on the plans. The specified tension must be measured by the gage pressure of the hydraulic stressing jack and verified by the elongation of the steel strand. Provide jack gage calibrated within past 6 months by a laboratory approved by the Contracting Officer. The variation in the actual elongation and the calculated elongation must not be greater than 5 percent. Tension in the tendons must be maintained by mechanical end-locks or anchors until final stress transfer. Aggregate prestress loss through transfer of stressing force from jack to temporary anchorage must not exceed an average of 10 percent in any one cable or an average of 5 percent for all cables in one pile.

2.5.9 Grouting

After tensioning all tendons, each tendon hole must be cleaned and completely filled with grout, including holes not used for tensioning. The pressure of the grout is to be slowly raised to a minimum of 690 kPa 100 psi but not over 1034 kPa 150 psi and held for at least one minute. While the grout is curing, the pile must not be moved or handled in any manner that
could damage the pile.

2.5.10 Stress Transfer (Detensioning)

Transfer of the post tension force from temporary end locks to grouted tendons must not be done until the grout has reached a compressive strength of 30 MPa, 4,000 psi. Prestressing tendons must be considered to be without slippage from the removal of the end locks when, upon cutting the wires between the end of the pile and the anchor with a burning torch, the wires do not part under stress with a "cup and cone" fracture, but are burned through with the torch. Piles that show evidence of prestressing cable slippage must be rejected.

2.6 CONCRETE CYLINDER PILE PRESTRESSED STATIC CAST (ALTERNATIVE II)

2.6.1 Forms

Use collapsible internal formwork to manufacture piles. Do not use a mandrel to manufacture piles. Provide forms of metal, braced and stiffened against deformation, accurately constructed, watertight, and supported on unyielding casting beds. Forms must permit movement of pile without damage during release of the prestressing force. Make piles to dimensional tolerances in accordance with PCI MNL-116, PCI MNL-135, and as follows:

a. Location of Reinforcing Steel
   (1) Main Reinforcement: 3 to 6 mm, 1/8 to 1/4 inch from position designated on drawings.
   (2) Spacing of Spiral: Plus or minus 13 mm, 1/2 inch from position designated on drawings exclusive of concrete cover requirements.

b. Location of Pipe Sleeves from True Position: Plus or minus 10 mm, 3/8 inch.

2.6.2 Casting

2.6.2.1 Conveying

Convey concrete to formwork in accordance with PCI MNL-116, and as specified herein. Clean conveying equipment thoroughly before each run. During placing, make any free vertical drop of the concrete less than 0.91 m, 3 feet. Remove concrete which has segregated in conveying or placing.

2.6.2.2 Placing and Casting

Perform concrete casting within 3 days after pretensioning steel; however, do not deposit concrete in forms until placement of reinforcement and anchorages has been inspected and approved by pile manufacturer's quality control representative. Produce each pile of dense concrete straight with smooth surfaces with reinforcement retained in its proper position during fabrication. Use vibrator with heads smaller than the minimum distance between steel for pretensioning. Make surface of pile ends perpendicular to axis of pile. Chamfer, a minimum of 19 mm, 3/4 inch, [ends of piles].

2.6.3 Pretensioning

********************************************************************
NOTE: Use minimum nominal level of prestress equal
to 8.3 MPa 1200 psi in the gross pile section, resulting from the combined prestressing force in the strands after all losses.

Pretensioning must be performed in accordance with PCI MNL-116, and as specified herein. Measure tendon to which steel is to be pretensioned by jack pressure read on a calibrated gage and verify by elongation of steel. Use gage calibrated within last 6 months by a laboratory approved by Contracting Officer. Provide means for measuring elongation of steel to nearest 3 mm 1/8 inch. When difference between results of measurement and gage reading is more than 5 percent, determine cause of discrepancy and correct. Give tensioning steel a uniform prestress prior to being brought to design prestress. Induce same initial prestress in each unit when several units of prestressing steel in a pile are stretched simultaneously.

2.6.4 Stress Transfer (Detensioning)

NOTE: Specify "release strength." Release strength of 30 MPa 4000 psi for (Design strength) of 35 MPa 5000 psi or 0.7 of the 28-day design strength is desirable; however, some regions use 0.8 of the design strength. Check with local pile manufacturers.

Perform release of prestressed steel in pretensioned piles in such an order that eccentricity of prestress will be minimized. Gradually release tension in strands from anchorage. Detension after approval by pile manufacturer's quality control representative. Perform transfer of prestressing force when concrete has reached a minimum compressive strength of [_____] MPa [_____] psi.

2.7 FABRICATION TOLERANCES

a. Pile ends must be plane surfaces and perpendicular to the longitudinal axis of the pile with a maximum deviation of 6 mm 1/4-inch per 12 inches at the pile head. End surfaces must also be free of spalls. Any end surface which exhibits more than ten percent of the end surface area spalled to a depth of more than 3 mm 1/8 inch will be rejected.

b. Accumulated deviation from straightness measured along two perpendicular faces of the pile, while not subjected to bending (sweep), must not exceed 3 mm per 1 m 1/8-inch per 10 feet of length.

c. Overall lengths of individual piles must be within 0.3 percent of the overall length specified.

d. The outside diameter of piles is defined as the average of two measurements taken along the axes at right angles to each other on cross section. The wall thickness is defined as the average of four measurements taken along pile axes at right angles to each other in a cross section:

### 2.8 Protection from Freezing

For cylinder piles exposed to freezing, provide precast drain holes through pile wall at approximate ground water elevation and fill pile with free-draining material. For piles standing in open water, place a concrete plug from lowest freeze depth to a minimum of 300 mm (one foot) above maximum high-water level and provide precast drain holes through pile wall just above surface of concrete plug.

### 2.9 Product Quality Control

Where piling is manufactured in a plant with an established quality control program as attested to by a current certification in the PCI "Certification Program for Quality Control" or the QA/QC procedure established under the ISO 9002 certification program, perform product quality control in accordance with PCI MNL-116 or ISO 9002, respectively. Where piling is manufactured by specialists or in plants not currently enrolled in the PCI "Certification Program for Quality Control," or the QA/QC procedure established under the ISO 9002 certification program, set up a product quality control system in accordance with PCI MNL-116 or ISO 9002 and perform concrete and aggregate quality control testing using an independent commercial testing laboratory approved by the Contracting Officer in accordance with the following.

#### 2.9.1 Aggregate Tests

Take samples of fine and coarse aggregate at concrete batch plant and test. Perform mechanical analysis (one test for each aggregate size) in accordance with ASTM C136/C136M. Tabulate results of tests in accordance with ASTM C33/C33M.

#### 2.9.2 Slump and Strength Tests

Sample concrete in accordance with ASTM C172/C172M at time concrete is deposited for each production line. Perform slump tests in accordance with ASTM C143/C143M. Mold cylinders in accordance with ASTM C31/C31M. Mold at least six cylinders per day or one for every [15] [45] cubic meter [20] [60] cubic yards of concrete placed, whichever is greater. Cure cylinders in same manner as piles and for accelerated curing, place at coolest point in casting bed. Perform strength tests in accordance with ASTM C39/C39M. Test two cylinders of each set at 7 days or 14 days, or at a time for establishing transfer of prestressing force (release strength) and removal of pile from forms. Test remaining cylinders of each set 28 days after molding.

#### 2.9.3 Compressive Strength Test Results

Evaluate compressive strength test results at 28 days in accordance with ACI 214R using a coefficient of variation of 10 percent. Evaluate strength of concrete by averaging test results of each set of standard cylinders tested at 28 days. Not more than 10 percent of individual cylinders tested must have a compressive strength less than specified design strength.
2.9.4 Changes in Proportions

If, after evaluation of strength test results, compressive strength is less than specified compressive strength, make adjustments in proportions and water content and changes in temperature, moisture, and curing procedures as necessary to secure specified strength. Submit changes in mix design to Contracting Officer in writing.

2.9.5 Chloride Ion Concentration

Sampling and determination of water-soluble chloride ion content in accordance with ASTM C1218/C1218M. Maximum water soluble-chloride ion concentrations in hardened concrete at ages from 28 to 42 days contributed from the ingredients including water, aggregates, cementitious materials, and admixtures must not exceed 0.06 percent by weight of cement.

2.9.6 Chloride Ion Penetration

To ensure the durability of concrete in marine environment, concrete must be proportioned to have the chloride ion penetration test in accordance with ASTM C1202, and be below 3,000 coulombs for concrete specimens tested at 60 days.[ Alternatively, a ponding test in accordance with AASHTO T 259 may be performed to validate chloride ion penetration in accordance with ASTM C1202.]

2.9.7 Destructive Pile Testing

At the beginning of production, produce three additional piles with the same length as production piles which must be randomly selected by the Contracting Officer for testing by taking core samples. Take three core samples each location at 2.4m 8 feet from head and toe and at mid length of the pile or as directed by the Contracting Officer for a total of 9 core samples per pile. Visually inspect each sample for evidence of segregation and distribution of reinforcements. Test all core samples for compressive strength according to ASTM C42/C42M. The average compressive strength of any three consecutively tested samples must not be less than 85 percent of specified 28-day compressive strength of concrete. If any of the above requirements for segregation, distribution of reinforcement and strength are not met, all production piles produced until the date of testing must be subject to rejection.

In addition to the above, saw cut each pile into three equal length sections. Each section must be inspected for specified dimension, strand placement and clear cover tolerances.

2.10 MATERIAL SUSTAINABILITY CRITERIA

For materials used, where applicable and to extent allowed by performance criteria, provide and document the following in accordance with Section 01 33 29 SUSTAINABILITY REQUIREMENTS AND REPORTING:

a. Recycled content for fly ash and pozzolan
b. Recycled content for Ground Iron Blast-Furnace Slag
c. Recycled content for Silica Fume
d. Minimum [75 percent] [_____] recycled content for steel used for stressed tendon reinforcing
2.11 PILE DRIVING EQUIPMENT

Submit descriptions of pile driving equipment, including hammers, power packs, driving helmets, hammer cushions, pile cushions, leads, extractors, jetting equipment, and preboring equipment at least 30 days prior to commencement of work. Provide Pile Driving Equipment as mentioned in this section.

2.11.1 Pile Hammers

Provide a hammer capable of developing the indicated ultimate pile capacity at blow count less than 100 per 300 mm foot considering hammer impact velocity; ram weight; stiffness of hammer and pile cushions; cross section, length, and total weight of pile; and character of subsurface material to be encountered. Use the same pile hammer, operating at the same rate and in the same manner, as that used for driving test piles. Use wave equation analysis to verify that the hammer will develop stresses within acceptable limits in the piles. At final driving, operate pile hammer in accordance with manufacturer's recommendation. Provide the plant and equipment for air hammers that have sufficient capacity to maintain, under working conditions, the pressure at the hammer specified by the manufacturer. The hose connecting the compressor with the hammer must be at least the minimum size recommended by the Manufacturer. Evaluate hammer performance at the end of driving by measuring blows per minute and comparing with the manufacturer's recommendations. Measure impact velocity of open-end (single acting) diesel hammers at all times during pile driving operations with a device for this purpose. If such a device is not available, obtain the stroke by measuring the speed of operation either manually or with a device that makes the measurement automatically. Equip closed-end (double acting) diesel hammers with a bounce chamber pressure gauge in good working order, mounted near ground level so as to be easily read by the Contracting Officer. Provide a correlation chart of bounce chamber pressure and potential energy. Equip hydraulic hammers with a system for measurement of ram energy. The system must be in good working order and the results must be easily and immediately available to the Engineer.

2.11.2 Driving Helmets and Cushion Blocks

2.11.2.1 Driving Helmets or Caps and Pile Cushions

Use a steel driving helmet or cap including a pile cushion between top of pile and driving helmet or cap to prevent impact damage to pile. Use a driving helmet or cap and pile cushion combination capable of protectingpile head, minimizing energy absorption and dissipation, and transmitting hammer energy uniformly over top of pile. Provide driving helmet or cap that fits sufficiently loose around top of pile so that pile may be free to rotate without binding within driving helmet. During test pile installation, demonstrate to satisfaction of Contracting Officer that equipment to be used on project performs specified function. Use pile cushion of solid wood or of laminated construction using plywood, softwood or hardwood boards with grain parallel to end of pile. Select the pile cushion thickness placed on the pile head prior to driving by wave equation analysis so that the limiting driving stresses are not exceeded. Replace pile cushion at the start of driving of each pile and when it becomes highly compressed, charred or burned, or has become spongy or deteriorated in any manner. Show details of driving helmets, capblocks (hammer cushions), and pile cushions. Submit 2 weeks prior to [test] pile
2.11.2.2 Hammer Cushion or Capblock

**************************************************************************

NOTE: Select either wood or aluminum/micarta capblock. Delete inappropriate sentences. An aluminum/micarta capblock is recommended because of its consistent elastic properties and long life. If final pile penetration resistance is based on a Wave Equation analysis, the type of capblock used should be the same as that used in the analysis.

**************************************************************************

Use a hammer cushion or capblock between driving helmet or cap and hammer ram consisting of a solid hardwood block with grain parallel to the pile axis and enclosed in a close-fitting steel housing; aluminum and micarta (or equal) discs stacked alternately in a steel housing or a suitable polymer designed for this specific purpose as indicated by the hammer manufacturer. Use steel plates at top and bottom of capblock (hammer cushion). Replace wood capblock (hammer cushion) when it becomes highly compressed, charred or burned or becomes spongy or deteriorated in any manner. Replace aluminum, micarta or polymer discs that have become damaged, split or deteriorated in any manner. Do not replace wood capblock (hammer cushion) during final driving of any pile. Do not use small wood blocks, wood chips, rope or other materials that permit excessive loss of hammer energy.

PART 3 EXECUTION

**************************************************************************

NOTE: In some cases, cylinder piles may be advanced using a collapsible auger inside the pile and washing the pile section down. In other cases, large diameter piles have been assembled by stacking precast rings and post tensioning them together.

**************************************************************************

3.1 PRELIMINARY WORK

3.1.1 Wave Equation Analysis of Pile Drivability

a. Prior to driving any pile, submit a pile Wave Equation Analysis, performed by Contractor's Geotechnical Consultant, for each size pile and distinct subsurface profile condition. These analyses must take into account the proposed hammer assembly, pile cap block and cushion characteristics, the pile properties and estimated lengths and the soil properties anticipated to be encountered throughout the installed pile length based on static capacity analysis with consideration of driving gain/loss factors. Only one specific model of pile hammer may be used for each pile type and capacity.

b. Demonstrate using the Wave Equation Analysis that the piles will not be damaged during driving, indicate that the driving stresses will be maintained within the limits below and indicate the blow count necessary to achieve the required ultimate static pile capacities.
<table>
<thead>
<tr>
<th>Allowable Driving Stresses</th>
</tr>

<tbody>
<tr>
<td><strong>Concrete</strong></td>
</tr>
<tr>
<td>Compression</td>
</tr>
<tr>
<td>Tension</td>
</tr>
</tbody>
</table>

$f'c$ is compressive strength of concrete
UPL = Unit Prestress after Losses
(Obtain values from pile manufacturer)

(c) Perform a refined Wave Equation Analysis upon completion of the dynamic and static testing programs outlined in this specification section, taking into consideration the evaluated capacities, gain/loss factors and recommended production pile lengths. Develop production pile driving criteria based on the results of the refined Wave Equation Evaluations.

d) All pile driving equipment provided by the Contractor will be subject to the approval of the Contractor’s Geotechnical Consultant. Complete the attached pile and driving equipment data form, including hammer information, in full as part of the submittal of the results of the Wave Equation Analyses.

e) Pay for the cost of performing the Wave Equation Analyses and include in the base bid.

3.1.2 Pile Length Markings

Mark each pile prior to driving with horizontal lines at 305 mm one foot intervals. Mark the interval number on pile every 1.52 m 5 feet from pile tip.

3.2 PILE DRIVING

3.2.1 Driving Piles

**************************************************************************
NOTE: Delete bracketed option for foundation excavation when not required. Delete items in brackets dealing with tip elevation and driving resistance when test piles or load tests are not used. Delete item in brackets regarding predrilling or jetting when procedure is not used. If needed, insert maximum hammer energy for no tip resistance. This can be determined by comparing tensile stresses in pile resulting from a Wave Equation Analysis with effective prestress in pile.
**************************************************************************

Notify Contracting Officer 10 days prior to driving of test piles and load test.[ Stop foundation excavation at 300 mm one foot above foundation grade before piles are driven. Do not drive piles within 30 meter 100 feet of concrete less than 7 days old. Complete excavation to lines and grades shown when pile driving is completed.] Piles may be driven when the specified 28-day concrete strength has been achieved but not less than 7 days after casting. The Contractor’s Geotechnical Consultant will determine the terminal driving criteria based on results of
Drive piles to [the terminal driving criteria] [or below "calculated"] [indicated tip elevation] [to reach a driving resistance established by the [dynamic pile driving tests at the end of drive or restrike] [static load tests] [wave equation analyses (WEAP)] in accordance with the schedule which the [Contractor's Geotechnical Consultant] [Contracting Officer] will prepare from the test-pile driving data. During initial driving and until pile tip has penetrated beyond layers of very soft soil [or below bottom of predrilled or prejetted holes], use a reduced driving energy of the hammer as required to prevent pile damage. Refusal criteria will be established by the Contracting Officer. If a pile fails to reach ["calculated"] [indicated] tip elevation, [or if a pile reaches ["calculated"] tip elevation without reaching required driving resistance,] notify Contracting Officer and perform corrective measures as directed. Provide hearing protection when noise levels exceed 140 dB. Do not handle or move piles or pile sections in any manner that would result in cracking or permanent damage to the concrete or to the grout surrounding the prestressing cables. Piles may be driven without pile guides or leads providing a hammer guide frame is used to keep the pile and hammer in alignment.

3.2.2 Protection of Piles

**************************************************************************
NOTE: Delete references to batter piles when not applicable to the project.
**************************************************************************

Take care to avoid damage to piles during handling, placing pile in leads, and during pile driving operations. Support piles laterally during driving, but allow rotation in leads. Where pile or projecting reinforcement orientation is essential, take precautionary measures to maintain the orientation during driving. Take special care in supporting battered piles to prevent excessive bending stresses in pile. Square top of pile to longitudinal axis of pile. Maintain axial alignment of pile hammer with that of the pile. If the Contractor elects to use a pile head with projecting strands or mild steel reinforcement, prevent direct impact forces from being transmitted through the reinforcement, by using a special driving head.

3.2.3 Pile Placement and Tolerances in Driving

**************************************************************************
NOTE: Omit references to batter piles when not applicable to the project. Select appropriate tolerances for type of pile. Use more stringent criteria as necessary based on the application. Confirm with the structural engineer.
**************************************************************************

Submit pile placement plans at least 30 days prior to delivery of piles to the job site. Drive piles with a variation of not more than 2 percent from vertical for plumb piles or more than 4 percent from required angle for batter piles. Maintain and check axial alignment of pile and leads at all times. If subsurface conditions cause pile drifting beyond allowable axial alignment tolerance, notify Contracting Officer and perform corrective measures as directed. Place butts within 100 mm 4 inches of location indicated. Manipulation of piles within specified tolerances will not be permitted. Will be permitted, to a maximum of 1-1/2-percent of their
In addition to specified tolerances, maintain a location to provide a clear distance of at least 125 mm (5 inches) from butt to edge of pile cap. If clear distance can not be maintained, then notify Contracting Officer. Check each pile for heave. Redrive heaved piles to required point elevation.

3.2.4 Rejected Piles

Withdraw piles damaged or impaired for use during handling or driving, mislocated, or driven out of alignment beyond the maximum tolerance. Replace with new piles or cut-off and abandon damaged or impaired piles and drive new piles as directed. Remove excess cut-off from piles and unacceptable piles from the work site. Perform all work in connection with withdrawing and removing rejected piles from the site at no additional cost to the Government.

3.2.5 Jetting of Piles

**************************************************************************

NOTE: Jetting should generally not be permitted for piles:

1. Dependent on side friction in fine-grained low permeability soils (high clay or silt content) where considerable time is required for the soil to reconsolidate around the piles.

2. Subject to uplift or lateral forces.

3. Adjacent to existing structures.

4. In closely spaced clusters unless the load capacity is confirmed by test.
**************************************************************************

Water jets will not be permitted. Use jetting to assist driving piles through strata that cannot be penetrated practicably by use of the hammer alone. Restrict driving to a static weight while water is being injected to prevent inducing tensile stresses in the piles which damage the concrete. Discontinue jetting and resume hammer driving after the penetration of the strata requiring jetting has been accomplished. Discontinue jetting when the pile tip is approximately 1.5 m (5 feet) above the [calculated][indicated] pile tip elevation. Drive pile the final 1.5 m (5 feet) of penetration or more to meet the required driving criteria. Take adequate measures for collecting and disposing of runoff water. Jetting method and equipment must be approved by the Contracting Officer prior to commencing jetting operation. Before starting final driving, firmly seat piles in place by application of a number of reduced energy hammer blows. Employ measures, including use of a silt curtain, to contain turbid water created by jetting piles.

3.2.6 Predrilling of Piles

Predrilling to remove soil or other material representing the bulk of the volume of the pile to be driven will be provided. The diameter of the hole must not exceed two-thirds the width of the pile. Predrill only to a depth of [_____] meters feet below cut-off elevation prior to setting piles. Discontinue drilling when the pile tip is approximately 1.5 m (5 feet) above the [calculated][indicated]
pile tip elevation. Drive pile the final 1.5 m 5 feet of penetration or more to meet the required driving criteria.]

3.2.7 Pile Splices

**************************************************************************
NOTE: Splicing of piles normally should not be permitted except where extremely long or heavy piles are required. If splices are permitted, drawings should indicate splice details. (See PCI standard drawings for typical splice details).
**************************************************************************

[Splicing of piles is not permitted.] [Make splices as indicated. Splices must be capable of developing the full strength of the member in compression, tension, shear, and bending. Submit detail drawings of splices and design calculations demonstrating the strength of the splice for approval. Submit information for shop and field pile splices prior to fabrication.]

3.2.8 Build-Ups

**************************************************************************
NOTE: Insert compressive strength required by design, usually a minimum of 35 MPa 5,000 psi. Insert maximum percent of build-ups permitted for project. The percent will depend on criticality of pile failure at build-up; whether the top of the pile is designed as a moment connection; exposure of piles to external physical or corrosive damage. Normally, for piles supporting piers exposed to seawater, limit percentage of build-ups to 10 percent.
**************************************************************************

Where required, pile section may be extended to cut-off elevation by means of a cast-in-place reinforced concrete build-up. Make build-up in accordance with PCI BDM. Construct build-ups made after completion of driving in accordance with detail "Build-Up Without Driving." Make build-ups to be driven in accordance with detail "Build-Up With Driving." Have details of means for protecting joints by a suitable mortar or epoxy approved by Contracting Officer. Where build-ups are exposed to water, protect cast-in-place section from water during curing period. Concrete in build-up must have a minimum compressive strength of [_____] MPa psi. Build-ups will not be permitted on more than [_____] percent of total number of piles. If this percent figure is exceeded, or if in the judgment of the Contracting Officer, the clustered location of build-ups is undesirable, withdraw piles of insufficient length and replace with longer piles. Payment for such withdrawal and replacement will be made as an adjustment to the contract price.

3.2.9 Pile Cut-Off

Cut-off piles with a smooth level cut using pneumatic tools, sawing, or other suitable methods approved by Contracting Officer. Use of explosives for cutting is not permitted. Remove cut-off sections of piles from the site and off government property upon completion of the work.
3.2.10  As-Driven Survey

After the driving of each pile group is complete and before concrete is placed, provide the Contracting Officer with an as-driven survey showing actual location and top elevation of each pile. Do not proceed with placing concrete until the Contracting Officer has reviewed the survey and verified the safe load for the pile group driven. Present a survey in such form that it gives deviation from plan location in two perpendicular directions and elevations of each pile to nearest 13 mm (half inch). Survey must be prepared and certified by a licensed land surveyor.

3.2.11  Protection of Existing Structures

**************************************************************************
NOTE: Include this paragraph only when protection of existing structures from pile driving activities is required.

The designer must indicate on the drawings all structures and facilities for which protection is required. The designer must also provide a project specific document that details design criteria, requirements for preconstruction condition surveys, post construction condition surveys, geotechnical instrumentation to measure ground movements and any other requirements.

Add any additional requirements as necessary.
**************************************************************************

Mitigate impact on existing facilities due to pile driving activities in accordance with the [project specific document] [____].

3.2.12  Pile Shoe

Submit details about pile shoe used, if any. Where indicated or directed, securely attach pile shoes of an approved design to the piles in a manner described in the detail drawings.

3.3  FIELD QUALITY CONTROL

3.3.1  Test Piles

**************************************************************************
NOTE: Select the second bracketed option when soil conditions dictate the use of a test pile longer than production piles. The ordered pile length for test piles should be 1.5 m (5 feet) longer than ordered length for production piles to allow additional penetration if driving conditions dictate. Indicate location and number (if required) of test piles on plans, or list appropriate soil boring test hole numbers.
**************************************************************************

[Use test piles of type, and drive as specified for piling elsewhere in this section.] [Order test piles [_____] meters (feet) longer in length than production piles. Drive the additional test pile length only at the
direction of the Contracting Officer.] The [Contractor's Geotechnical Consultant] [Contracting Officer] will use test pile data to determine "calculated" pile tip elevation or necessary driving criteria. Drive test piles [at the locations indicated] [in vicinity of soil boring test holes Nos. [_____] , [_____] , and [_____] ]. Drive test piles to [indicated tip elevation] [indicated bidding lengths] [required driving criteria]. Use test piles, if located properly and offering adequate driving resistance in finished work. Pre-drilling or jetting is permitted only when test piles clearly establish validity of its use, or as directed by the Contracting Officer. Provide and operate a pile driving analyzer as specified in paragraph DYNAMIC PILE ANALYSIS during the driving of each test pile. Modify driving as required based upon recommendation of [Contractor's Geotechnical Consultant and approval of the Contracting Officer].

3.3.1.1 Dynamic Pile Analysis

Submit a performance report summarizing dynamic test results for [test] piles within [7] [_____] calendar days of completing field work. For production piles, submit a performance report within one day of testing. Submit a typed report summarizing the results of dynamic testing of production piles on a monthly basis.

Dynamic testing provides supplemental information for evaluating pile integrity, hammer and drive system performance, assess pile installation driving stresses, and pile capacities. Perform dynamic testing on [_____] percent of the [test] piles during the full length of the pile driving and during restrike a minimum of [_____] days after initial driving. Dynamic pile testing must also be performed on [_____] production piles as chosen by the Contracting Officer. Use [test] piles of type as specified elsewhere in this section. Provide equipment to obtain dynamic measurements, record, reduce and display its data that meet the requirements of ASTM D4945. The equipment must have been calibrated within [6] [_____] months prior to the start of the testing operations and thereafter throughout the contract duration. Drive [test] piles at the locations indicated or at the locations selected by the Contracting Officer. Employ an independent inspection firm, hereinafter referred to as the "Contractor's Geotechnical Consultant", experienced in the pile driving process[, monitoring of test pile installation,] and in the use of the Pile Driving Analyzer and its related equipment. Perform dynamic pile analysis as follows:

3.3.1.2 Pile Analyzing

[_____] working days prior to driving the [test] piles, submit the pile and complete driving equipment data to the Contracting Officer. The Contractor's Geotechnical Consultant must use the submitted information to perform wave equation analyses and must prepare a summary report of the wave equation results. The wave equation analysis using GRLWEAP software by Pile Dynamics, Inc. or equivalent must be used to assess the ability of the proposed driving system to install the pile to the required capacity and desired penetration depth within the allowable driving stresses. Approval of the proposed driving system by the Contracting Officer must be based upon the wave equation analyses indicating that the proposed driving system can develop a pile capacity of [_____] kN kips at a driving resistance not greater than [_____] blows per mm blows per inch within allowable driving stress limits. The hammer must also be sized or adjustable such that the penetration per blow at the required ultimate capacity does not exceed 12 mm 0.5 inches.
3.3.1.3 Pile Drivability

Perform each dynamic pile analysis in two steps. The first step is to check the hammer, pile and soil performance, and to determine the suitability of the proposed hammer for the size, length and type of pile being installed for the soil types encountered as the piles are driven. This initial monitoring must determine whether pre-augering or jetting is appropriate, efficiency of the hammer relative to specified efficiency, effectiveness of cushion, level of compressive and tensile stress in pile and extent/location of any pile damage caused by the initial driving. With each blow of the pile, record the information listed below electronically and analyze the information using the Pile Driving Analyzer:

a. Blow number
b. Blow rate per minute and stroke.
c. Input and reflected values of force and velocity.
d. Value of upward and downward traveling force wave with time.
e. Maximum and final transferred energy to pile, hammer system efficiency.
f. Maximum compressive stress, velocity, acceleration and displacement.
g. Maximum tensile stress in pile.
h. Pile structural integrity, damage detection, extent and location.
i. Bearing capacity of pile by Case method.

If the pile, hammer and soil performance evaluation recommends changes to the hammer stroke, pile cushioning, augering or any other aspect for the pile driving operation, incorporate these changes into production pile driving in an effort to control excessive stresses and pile damage. Replace test piles damaged or broken during installation, incorporating driving modifications as determined by the Contractor's Geotechnical Consultant and reviewed and approved by the Contracting Officer. Repeat this procedure until allowable tensile and compressive stresses are achieved in the pile and pile damage is minimized. Subject selected initial driving records to rigorous computer analysis by the Case Pile Wave Analysis Program (CAPWAP) for determination of resistance distribution, soil resistance and properties, and estimation of anticipated gain/loss factors.

3.3.1.4 CAPWAP

Signal matching analysis by CAPWAP software of the dynamic pile testing data must be performed on data obtained from the end of initial driving and the beginning of restrike of all control piles. CAPWAP analyses must be performed by an engineer who has achieved Advanced Level or better on the PDI / PDCA Dynamic Measurement and Analysis Proficiency Test for Providers of PDA Testing Services.

Upon completion of [test] pile driving, allow the piles to set-up for at least [72 hours] [_____ days]. After evaluation of pile, hammer and soil performance by the Contractor's Geotechnical Consultant, the second step of the dynamic pile analysis may proceed. This portion of the evaluation
requires striking the set-up piles a minimum of 20-50 times, or as directed by the Contractor's Geotechnical Consultant using the same hammer which was used for the [test] pile driving and which will be used for production pile driving. "Warm up" the hammer and make it optimally ready prior to restriking, in order to avoid capacity losses during evaluation of restrike data. Apply maximum hammer energy during restrike in order to fully mobilize the soil resistance. However, exercise care so as to not overstress the pile. In addition to those items listed above, selected restrike driving records (as directed by the Contractor's Geotechnical Consultant) are to be subjected to rigorous computer analysis by the Case Pile Wave Analysis Program (CAPWAP) for determination of resistance distribution, soil resistance and properties, and plot of applied load vs. average pile displacement based on the calculated soil properties.

3.3.1.5 Dynamic Load Test Reporting

a. Upon satisfactory completion of each dynamic load test, submit[ a minimum of three copies of] a Pile Performance Report for the Contractor by the Contractor's Geotechnical Consultant. The submittal must be prepared and sealed by a Professional Engineer registered in [_____].

b. The report for the Dynamic Pile Analysis must contain the following information:

(1) Capacity of pile from Case Pile Wave Analysis Program (CAPWAP). Information resulting from analysis of a selected restrike blow.

(2) Maximum and final transferred energy, hammer system efficiency during pile installation.

(3) Maximum compressive stress, velocity, acceleration and displacement.

(4) Maximum tensile stress in pile.

(5) Pile structural integrity, damage detection, extent and location.

(6) Blows per minute and blow number.

(7) Input and reflection values of force and velocity, upward and downward traveling force wave with time.

(8) Pile skin friction and toe resistance distribution.

(9) Maximum energy transferred to pile.

c. The maximum allowable pile design load must be proposed by the Contractor's Geotechnical Consultant based upon the results of a satisfactory pile load test conducted on a pile driven as specified herein and must include the effects of load transfer to the soil above the foundation stratum.

Use either a model Model 8G or PAX Pile Driving Analyzer as manufactured by Pile Dynamics, Inc., of Cleveland Ohio or approved equivalent, for dynamic testing of the pile hammer and for dynamic load testing of the test pile. All equipment necessary for the dynamic monitoring such as sensors, cables or wireless transmitters, must be furnished by the Contractor's Geotechnical Consultant. The equipment must conform to the requirements of
ASTM D4945.

Pay for all services of the Contractor's Geotechnical Consultant. The Contractor's Geotechnical Consultant must be available throughout the pile driving operation to consult with the Contracting Officer when required by the Contracting Officer. The cost of changes in the Contractor's procedure, as required by evaluation of the results of the Pile Driving Analysis, will be at the Contractor's expense.

3.3.2 Load Tests

3.3.2.1 Static Load Tests

**************************************************************************
NOTE: If pile load tests are required and approved by the Contracting Officer, specify number and location of piles. Select method of load test. In ASTM D1143/D1143M, permit anchor piles only if approved by the Contracting Officer's Technical Representative (Geotechnical Branch). Insert figure kips kN corresponding to 200 percent of the design load. Select appropriate acceptance criteria. The offset method (first option) is usually recommended.
**************************************************************************

Submit test set-up and procedures. Perform compressive load tests on [_____] test piles in accordance with ASTM D1143/D1143M (standard loading procedure) as modified herein.[ Allow a minimum of [72 hours] [_____] days following final test pile driving for pile set-up prior to load testing.][ Do not use anchor piles.][ Provide apparatus for applying vertical loads as required by method, using load from weighted box or platform[ or reaction frame attached to sufficient uplift piles to safely take required load] applied to pile by hydraulic jack. Increase load in increments until rapid progressive settlement takes place or until application of total compressive load of [_____] KN kips for compressive load tests. Consider load test satisfactory when[ after one hour at full test load gross settlement of pile butt is not greater than gross elastic pile compression plus 4 mm 0.15 inch plus one percent of pile tip diameter or width in [_____] mm inches],[ slope of gross load-settlement curve under full test load does not exceed 1.5 mm per metric ton 0.05 inches per ton],[ net settlement after removal of test load does not exceed 19 mm 3/4 inch.][ Perform load tests at locations[ as proposed by the Contractor's Geotechnical Consultant and] as directed by the Contracting Officer. Additional load tests, at Government expense, may be required by the Contracting Officer. Perform the loading, testing, and recording and analysis under the direct supervision of a Registered Professional Engineer, registered in the state of project location, and provided and paid for by the Contractor.[ Submit test pile records][ and ][load test data] within seven calendar days of conducting the test.

3.3.2.1.1 Safe Design Capacity

Determine the safe design capacity of a test pile as determined from the results of load tests according to UFC 3-220-01.

3.3.2.2 Tensile Load Tests

Perform tensile load tests on [_____] test piles in accordance with ASTM D3689, as modified[ and ]in paragraph LOAD TESTS. Apply a tensile
load of [_____] kN kips to each tensile load test pile. In performing the tension load test, apply the ultimate load equal to one and one-half times the safe tension capacity, and employ the Standard Loading Procedure.

Perform dynamic measurements on [_____] piles designated as dynamic test piles in accordance with ASTM D4945 during driving. During easy driving, ensure that damaging tension stresses do not develop in the pile. Signal matching must be performed by the Contractor's Geotechnical Consultant on representative data collected at the end of the initial driving and at the beginning of all restrike events. Additional signal matching analysis must be performed as determined by the Engineer.

3.3.2.3 Lateral Load Tests

Perform lateral load tests on [_____] piles in accordance with ASTM D3966/D3966M, as modified in paragraph LOAD TESTS. Lateral load tests must consist of jacking two piles apart with a hydraulic jack, with one pile serving as the reaction pile for the other. Apply a lateral load of [_____] kN kips to each pair of lateral load test piles. Record required movement readings for each pile.

3.3.3 Pile Records

Submit pile and test pile records. Submit load test data and results.

Keep a complete and accurate record of each pile driven. Indicate the pile location, deviations from pile location, cross section shape and dimensions, original length, ground elevation, tip elevation, cut-off elevations, [batter alignment, ]number of blows required for each 300 mm foot of penetration and number of blows for the last 150 mm 6 inches penetration or fraction thereof [as required ]for the "calculated" [driving resistance]. Include in the record the beginning and ending times of each operation during driving of pile, type and size of hammer used, rate of operation, stroke or equivalent stroke for diesel hammer, type of driving helmet, and type and dimension of hammer cushion (capblock) and pile cushion used. Record retap data and unusual occurrences during pile driving such as redriving, heaving, weaving, splicing, obstructions, [jetting, ]and any driving interruptions. [Install an energy monitor on the hammers and record readings every 300 mm 12 inches of pile installation.] A preprinted pile driving log for recording pile driving data[ and pile driving equipment data form], which can be downloaded at: https://www.wbdg.org/ffc/dod/unified-facilities-guide-specifications-ufgs/forms-graphics-tables

[3.3.4 Testing Agency Qualifications

Engage an independent testing agency qualified according to ASTM C1077 and ASTM E329 for testing indicated. Submit testing agency qualifications to the Contracting Officer for approval.

][3.4 SPECIAL INSPECTION AND TESTING FOR SEISMIC-RESISTING SYSTEMS

**************************************************************************

NOTE: Include this paragraph only when special inspection and testing for seismic-resisting systems is required by the International Building Code (IBC).

This paragraph will be applicable to both new buildings designed and to existing building seismic
rehabilitation designs done according to UFC 1-200-01, "General Building Requirements" and UFC 3-310-04, "Seismic Design for Buildings".

The designer must indicate on the drawings all locations and all features for which special inspection and testing is required in accordance with Chapter 17 of the IBC. This includes indicating the locations of all structural components and connections requiring inspection.

Add any additional requirements as necessary.

Perform special inspections and testing for seismic-resisting systems and components in accordance with Section 01 45 35 SPECIAL INSPECTIONS.

}[3.5 VIBRATION CONTROL

Perform vibration monitoring at the locations [shown in the plan] [decided by the Contracting Officer] during the pile driving operations. Perform vibration monitoring [using] [seismographs][ and geophones] within a distance of [61] [_____] meters [200] [_____] feet from the pile driving activity. [Engage the services of a qualified, independent vibration consultant, acceptable to the Government, to conduct the vibration monitoring. The vibration consultant must have minimum of [five] [_____] years of experience in vibration monitoring. A minimum of [28] [_____] days before the installation of vibration monitors, submit to the Government the name of the vibration consultant and a list of at least [three] [_____] previously completed projects of similar scope and purpose.]

Prior to the pile driving activities, obtain baseline readings of ambient vibrations. The vibration during the pile driving activities must be limited to [a peak particle velocity of not more than [5] [_____] cm [2.0] [_____] inches per second] [the limits mentioned in the [contract documents]]. [Determine appropriate vibration limits as per [US Bureau of Mines] [American Association of State Highway and Transportation Officials (AASHTO)] guidelines.] During pile driving activities, monitor the vibrations to ensure the limits are not exceeded. If the limits are exceeded, cease the pile driving activity causing the vibration until [the Vibration consultant and the Contracting Officer] [_____] are on site to observe the structures nearest to the vibration monitor which has exceeded the limits.

The Contractor must be responsible for all damages resulting from the pile driving operations and must take whatever measures necessary to maintain peak particle velocity within the specified limit. After completion of the project, remove the vibration monitors off the site and off Government property and restore the monitoring locations back to their original condition.
3.6 NOISE CONTROL

**************************************************************************
NOTE: Include this paragraph when noise monitoring is required. Add any additional criteria, references or requirements as necessary to the particular project.
**************************************************************************

Perform noise monitoring at the locations [shown in the plan] [decided by the Contracting Officer] [at noise sensitive public areas] during the pile driving operations. Perform noise monitoring using [noise meters][, and] [_____] . Engage the services of a qualified, independent noise consultant, acceptable to the Government, to conduct the noise monitoring. The noise consultant must have minimum of [five] [_____] years of experience in noise monitoring. A minimum of [28] [_____] days before the installation of noise monitors, submit to the Government the name of the noise consultant and a list of at least [three] [_____] previously completed projects of similar scope and purpose.

Prior to the pile driving activities, obtain baseline readings of ambient noise levels. The noise limits are mentioned in the [plan] [contract documents]. Determine appropriate noise limits as per [local agency] [Occupation Safety and Health Administration] guidelines. During pile driving activities, monitor the noise to ensure the limits are not exceeded. If the limits are exceeded, cease the pile driving activity and install noise mitigation measures.

The Contractor must be responsible for all damages resulting from the pile driving operations and must take whatever measures necessary to maintain noise within the specified limit. After completion of the project, remove the noise monitors off the site and off Government property and restore the monitoring locations back to their original condition.

3.7 PRECONSTRUCTION CONDITION SURVEY

**************************************************************************
NOTE: Add any additional criteria, references or requirements as necessary to the particular project.
**************************************************************************

Perform preconstruction condition survey of [structures][and utilities] within [61] [_____] meters [200] [_____] feet of the pile driving activity [specified in the plans] [decided by the Contracting Officer]. Perform outreach to the owner of the structures [28] [_____] days before performing the preconstruction condition survey. The Contractor must obtain written permission from the owner of the structure prior to accessing the structure. The preconstruction condition survey must include video and photographic documentation of the exterior and interior of above ground structures and of the interior of underground structures. Video documentation must be in high definition, and show existing conditions and highlight, where possible, existing cracks, deteriorated concrete, exposed and corroded reinforcement, cracked or broken brick or mortar, and other signs of distress. For utilities, perform the survey when the greatest extent of the interior is exposed. Provide supplementary artificial lighting as needed. The video must include annotation with location and structure nomenclature which describes any areas of distress over the video and time code superimposed on the video. Photographs must be accompanied by sketches or descriptions that indicate the location and direction of...
each photograph. For each structure surveyed, provide a Pre-Construction Condition Survey Report following completion of the survey. The report must contain all documentation associated with the survey including DVD copies. In the report, include notes, sketches, photographs, and videos. Provide general information, such as location details and structure type, as well as particular information on materials, condition, existing damage, aperture and persistence of cracks, and disrepair observed during visual survey. Provide a graphical depiction of locations of damage or other features of concern. Submit the Preconstruction Condition Survey Reports no later than [28] [_____] days before the commencement of pile driving activity. Accept responsibility for damages to existing adjacent or adjoining structures created by pile driving work, and repair any damages to these structures without cost to the Government.

[3.8 CONSTRUCTION INSTRUMENTATION AND MONITORING PROGRAM

**************************************************************************
NOTE: Include this section if instrumentation is to be installed due to concerns about vibration, settlement, lateral movement, etc. during pile driving activities. Instrumentation should be specified and included in the specification. This section can be deleted if there are no instrumentation requirements.

Add any additional criteria or requirements as necessary for the particular project.
**************************************************************************

Prepare a geotechnical instrumentation program to monitor settlement[ and lateral movement] of temporary and permanent structures, utilities, [embankments] [and excavations] during pile driving. The design and distribution of instrumentation must demonstrate an understanding of the need, purpose and application of each proposed type.[ Perform noise and vibration monitoring in accordance with NOISE CONTROL and VIBRATION CONTROL sections.]

Monitoring must extend before, during and for a period after completion of construction activities related to pile driving when long-term performance issues are a concern. The monitoring plan must be designed to protect adjacent structures and utilities against damage due to the pile driving activities. Establish limiting values of vertical [and horizontal] movement [and angular distortion] [and vibration] for each structure and utility within the zone of influence, subject to review by the Government.

Prepare an Instrumentation and Monitoring Program Report detailing the proposed program of instrumentation and monitoring, establishing threshold values of monitored parameters, and describing the response plans that will be implemented when threshold parameters are exceeded. The report must include details about instrumentation consultant’s experience, appropriate types, quantities, locations and monitoring frequencies of the instruments.
Upon acceptance of the instrumentation and monitoring program, provide, install and monitor the instrumentation and interpret the data. Submit instrumentation data reports not less than every [_____] days after the monitoring program has begun. Take corrective actions, as necessary, based on the field instrumentation data and as defined in the instrumentation and monitoring program.

NOTE: This guide specification covers the requirements for the installation, testing, and forming of enlarged concrete footings and cylindrical shafts by ramming the concrete into place under a specific energy of impact.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

NOTE: The following information must be shown on the project drawings:

1. Plan of Pressure Injected Footings (PIF) (singles and clusters) and cluster configurations

2. Batter PIF angle

3. Design loads

4. Location of test PIF, unless option to allow direction by Contracting Officer is selected.
PART 1   GENERAL

1.1   DESCRIPTION

Design, furnish, install, and test pressure injected footings (PIF) at the locations indicated on the drawings and as specified herein. Assume test location[s] can be incorporated into the work.

1.2   REFERENCES

**************************************************************************
NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard’s Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard’s Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.
**************************************************************************

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

[1.3 SUBSURFACE DATA]

Subsurface soil data logs are indicated appended to the special contract requirements provided on the project drawings. The subsoil investigation report may be examined at [_____]..

[1.4 BASIS OF BID]

**************************************************************************
NOTE: Select one of the following options:

Use "Lump Sum" paragraph below for lump (principal) sum bidding of PIF. Use this in all projects except those where exact PIF lengths cannot be practically determined prior to the actual work. Clearly show number of PIF, PIF capacity, PIF locations, and tip and cutoff elevations on the drawings.

Use "Unit Price" paragraph for unit price bidding of PIF. Specify unit price bid items for PIF only for projects where exact quantities cannot be practically determined prior to the actual work. Lengths of PIF must be determined as accurately as possible, prior to bidding, since the unit price per meter (foot) of the PIF varies as the length increases or decreases.

**************************************************************************

1.4.1 Production Acceptance Criteria

Safe design bearing capacity for PIF is [_____] KN [_____] kips. Install PIFs to minimum tip elevation a minimum depth of [_____] m [_____] feet below foundation level, and to such additional depth as required to obtain a bearing capacity of not less than [_____] KN [_____] kips. The Contractor's Geotechnical Consultant will determine the terminal driving criteria based on results of static load tests.

**************************************************************************
NOTE: PIF bearing capacity must be computed per formula. In absence of a load test, use K-value from table below: (K-values and Bearing Capacity

Recommended K-Values

N = number of blows from Standard Penetration Test

---

Determine safe bearing capacity by ramming zero-slump concrete, in batches of 0.14 cubic meter 5 cubic feet, into granular soil stratum by drop hammer in accordance with the following formula:

\[
L = \frac{B \times W \times H \times V^{2/3}}{K}
\]

where

L = Safe bearing capacity of PIF in metric tons (tons)
B = Average number of blows of hammer required to inject one cubic meter or one cubic foot of concrete in expanded base, during injection of the last batch.

W = Weight of drop hammer in metric tons or tons.

H = Height of fall of drop hammer in meters or feet.

V = Total volume of concrete in expanded base measured in cubic meters or cubic feet, and

K = [Constant determined from the load test] [_____] [1.4.2] Lump Sum Payment

**************************************************************************
NOTE: Use this paragraph for lump-sum contracts, consult with Contracting Officer's Technical Representative (Geotechnical Branch) on applicability of use prior to selection.
**************************************************************************

Base bids upon providing the number, size, capacity, and length of PIF as indicated on the [drawings.] [following Table I:

<table>
<thead>
<tr>
<th>Location</th>
<th>Number</th>
<th>Size</th>
<th>Bearing Capacity</th>
<th>Length</th>
<th>Maximum Bending Moment</th>
<th>Maximum Shear Force</th>
</tr>
</thead>
</table>

Include the cost of all necessary equipment, tools, material, labor, and supervision required to: install, test, and meet the applicable contract requirements. Include mobilization and pre-drilling. If it is found that any PIF is not of sufficient length to provide the capacity specified, notify the Contracting Officer, who reserves the right to increase or decrease the total length of PIF to be provided and installed by changing the PIF locations or elevations, requiring the installation of additional PIF, or directing the omission of PIF from the requirements shown and specified. If total number of PIF or number of each length vary from that specified as the basis for bidding, an adjustment in the contract price or time for completion, or both, will be made in accordance with the contract documents. Payment for PIF will be based on successfully installing PIF to both the minimum tip elevation and satisfying the acceptance criteria identified herein. No additional payment will be made for: rejected PIF or other excesses beyond the assumed PIF length indicated for which the Contractor is responsible. [ Include payments for vibration monitoring, sound monitoring and precondition construction surveys.]

1.4.3 Unit Price

**************************************************************************
NOTE: Delete this paragraph for lump-sum contracts.
**************************************************************************

For NAVFAC PAC projects: Where there is unit pricing for PIF, use this paragraph and edit applicable attachments in price schedule for.
inclusion in Standard Form 1442, "Solicitation, Offer and Award" and "Schedule of Bid Items."

For NAVFAC Southeast projects, where there is a need for unit pricing of PIF, include this paragraph. Refer to NAVFAC SE Instruction 00010, "Instructions for Preparing Basis of Bid Statement With Unit-Priced Items," for method of specifying unit price bid items.

For unit price bid, see SF 1442, "Solicitation, Offer and Award" and "Schedule of Bid Items."

******************************************************************************

NOTE: For NAVFAC LANT projects, use the following paragraph for measurement and payment and subsequent sub-parts.

******************************************************************************

Requirements of FAR 52.211-18 Variation in Estimated Quantity do not apply to payment for PIF. Each PIF and test PIF acceptably provided will be paid for at the bid unit price per unit length, which will include items incidental to furnishing and driving the PIF including mobilization and demobilization, and [jetting] [preditrilling]. Payment will be made for production [and test PIF] at the bid unit price for the length of PIF, from tip to final cut-off, actually provided, excluding buildups directed by the Contracting Officer to be made. If the actual cumulative PIF length driven (tip to cut-off) vary more than 25 percent from the total PIF length specified as a basis for bidding, at the direction of the Contracting Officer, the unit price per unit length will be adjusted in accordance with provisions of FAR 52.236-2 Differing Site Conditions. [Payments will be made per each at the respective bid unit price for PIF build-ups and loads tests.] [Include payments for vibration monitoring, sound monitoring, construction instrumentation and monitoring, and precondition construction surveys].

1.5 PAYMENT

******************************************************************************

NOTE: Delete this paragraph for lump-sum contracts.

If Section 01 20 00 PRICE AND PAYMENT PROCEDURES is included in the project specifications, this paragraph title (UNIT PRICES) should be deleted from this section and the remaining appropriately edited subparagraphs below should be inserted into Section 01 20 00 PRICE AND PAYMENT PROCEDURES.

******************************************************************************

1.5.1 Mobilization and Demobilization

1.5.1.1 Payment

Payment will be made for costs associated with mobilization and demobilization as a separate single lump sum item.
1.5.1.2 Measurement
Lump sum.

1.5.1.3 Unit of Measure
Lump sum.

1.5.2 Installing PIF

1.5.2.1 Payment
Payment will be made for costs associated with installing PIF, which includes costs of installing PIFs and removing excess waste from the work site, compiling and submitting PIF records, and any other items incidental to installing PIF to the required elevation.

1.5.2.2 Unit of Measure
Linear meter.Foot.

1.5.3 PIF Static Axial Compressive Load Tests

1.5.3.1 Payment
Payment will be made for costs associated with PIF static axial compressive load tests in accordance with ASTM D1143/D1143M, including material and labor for fabricating and furnishing load frames; calibrating load cells and hydraulic jacks; furnishing specified test equipment; installing strain rods; placing and removing test loads and test equipment; recording, reducing, and submitting test data; and compiling and submitting load test reports. No payment will be made for rejected static axial compressive load tests.

1.5.3.2 Measurement
PIF static axial compressive load tests will be measured for payment on the basis of the applicable contract unit price per load test.

1.5.3.3 Unit of Measure
Each.

1.5.4 PIF Static Tensile Load Tests

1.5.4.1 Payment
Payment will be made for costs associated with PIF static tensile load tests in accordance with ASTM D3689, including material and labor for fabricating and furnishing load frames; calibrating load cells and hydraulic jacks; furnishing specified test equipment; installing strain rods; placing and removing test loads and test equipment; recording, reducing, and submitting test data; and compiling and submitting load test reports. No payment will be made for rejected static tensile load tests.

1.5.4.2 Measurement
PIF tensile load tests will be measured for payment on the basis of the applicable contract unit price per number of tensile load test.
1.5.4.3 Unit of Measure

Each.

1.5.5 PIF Lateral Load Tests

1.5.5.1 Payment

Payment will be made for costs associated with PIF lateral load tests in accordance with ASTM D3966/D3966M, including material and labor for fabricating and furnishing load frames; calibrating load cells and hydraulic jacks; furnishing specified test equipment; installing inclinometers; placing and removing test loads and test equipment; recording, reducing, and submitting test data; and compiling and submitting load test reports. No payment will be made for rejected lateral load tests.

1.5.5.2 Measurement

PIF lateral load tests will be measured for payment on the basis of the applicable contract unit price per lateral load test.

1.5.5.3 Unit of Measure

Each.

1.5.6 Vibration Monitoring

1.5.6.1 Payment

Payment will be made for costs associated with vibration monitoring.

1.5.6.2 Measurement

Vibration monitoring will be measured for payment on the basis of the applicable contract unit price per vibration monitoring point.

1.5.6.3 Unit of Measure

Each.

1.5.7 Sound Monitoring

1.5.7.1 Payment

Payment will be made for costs associated with sound monitoring.

1.5.7.2 Measurement

Sound monitoring will be measured for payment on the basis of the applicable contract unit price per vibration monitoring point.

1.5.7.3 Unit of Measure

Each.
1.5.8 Preconstruction Condition Survey

1.5.8.1 Payment

Payment will be made for costs associated with preconstruction condition surveys.

1.5.8.2 Measurement

Preconstruction condition survey will be measured for payment on the basis of the applicable contract unit price per structure to be surveyed.

1.5.8.3 Unit of Measure

Each.

1.5.9 Construction Instrumentation and Monitoring

1.5.9.1 Payment

Payment will be made for costs associated with construction instrumentation and monitoring.

1.5.9.2 Measurement

Construction instrumentation and monitoring will be measured as a single pay item.

1.5.9.3 Unit of Measure

One.

1.6 SUBMITTALS

**************************************************************************

NOTE: Review Submittal Description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy, Air Force, and NASA projects.
The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy, Air Force, and NASA projects, or choose the second bracketed item for Army projects.

**************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-01 Preconstruction Submittals

Designer and Installer's Qualifications; G[, [____]]
Testing Agency Qualifications; G[, [____]]
Contractor's Geotechnical Consultant Documentation

PIF Installation Equipment

Load Test Apparatus

SD-11 Closeout Submittals

PIF Records

1.7 QUALITY CONTROL

1.7.1 PIF Records

Pressure-injected footings (PIF) must consist of an expanded base of concrete, formed by ramming concrete into place, and a [cased ][uncased ][reinforced ]concrete shaft to transmit the superstructure load to the expanded base.

1.7.2 PIF Installation Equipment

Submit descriptions of proposed PIF installation equipment before commencing work. Include details of the rig, hammer type, and available energy.

1.7.3 Load Test Apparatus

**************************************************************************

NOTE: Delete this paragraph if load testing is not required.
**************************************************************************

Submit equipment description lists or catalog cuts and a brief description of the load test procedure, including maximum load and modifications in accordance with the procedure required by ASTM D1143/D1143M before commencing tests.

1.7.4 Contractor's Geotechnical Consultant Documentation

Hire the services of an independent, Registered Professional Geotechnical Engineer, experienced in soil mechanics to observe test PIF installation and production PIF installation as specified herein. The Contractor's Geotechnical Consultant must be independent of the Contractor and must have no employee or employer relationship which could constitute a conflict of interest.

1.8 QUALIFICATIONS

Installation of PIF must be performed by a specialty Contractor experienced and competent in the installation of PIF as specified herein. Submit evidence that the contractor has had similar type projects. The projects must demonstrate proficiency of the designer as applicable to the intent of the project. The Designer must be a Professional Engineer registered in the state where the project is located.
Submit **Designer and Installer's Qualifications** at least 30 calendar days prior to installation.

[1.9  **DESIGN CALCULATIONS**

The installer must submit two sets of detailed design calculations for approval at least 30 calendar days prior to the beginning of construction. A detailed explanation of the design parameters for the calculations must be included in the submittal. Additionally, the quality control test program confirming the design requirements, must be submitted. All calculations and drawings must be prepared and sealed by a Professional Engineer in the State in which the project is constructed.

**PART 2 PRODUCTS**

2.1  **CONCRETE**

**************************************************************************
NOTE: Insert the correlated section number and title or include concrete specification in this section in the blank below in the correct format per UFC 1-300-02.
**************************************************************************

Provide as specified in [_____] except as specified otherwise herein, for minimum 28-day concrete compressive strength of [_____] MPa pounds per square inch, using 19 mm 3/4 inch maximum coarse aggregate. Concrete for base [and for uncased shaft ]must have minimum 3-day compressive strength of [_____] MPa pounds per square inch.[ Cased shaft must have minimum 3-day compressive strength of [_____] MPa pounds per square inch.] The expanded base must be made of zero-slump concrete. Use [zero-slump concrete for uncased shaft][ 75 mm 3 inch slump concrete for cased or uncased shaft][ 100 to 150 mm 4 to 6 inch slump concrete for cased shaft]. Zero-slump concrete must be developed by reducing water in regular-mix concrete in accordance with ACI 211.3R. Submit concrete mix design for approval at least 30 calendar days prior to installation.

2.1.1  **Portland Cement**

Portland cement must confirm to ASTM C150/C150M and Section 03 30 00 CAST-IN-PLACE CONCRETE.

2.1.2  **Water**

Water must be fresh, clean, and free from sewage, oil, acid, alkali, salts, or organic matter.

2.1.3  **Fine Aggregate**

Fine aggregate must meet the requirements of ASTM C33/C33M. The sand must consist of hard, dense, durable, uncoated rock particles and be free from injurious amounts of silt, loam, lumps, soft or flaky particles, shale, alkali, organic matter, mica, and other deleterious substances. If washed, a washing method must be used that will not remove desirable fines, and the sand must subsequently be permitted to drain until the residual-free moisture is reasonably uniform and stable. The sand must be well-graded from fine to coarse, with fineness modulus between 1.30 and 3.40.
2.1.4 **Aggregates**

Aggregate must meet the requirements of **ASTM C33/C33M**, for fine aggregate, except as to gradation. The sand must consist of hard, dense, durable, uncoated rock fragments and must be free from injurious amounts of silt, lumps, loam, soft, or flaky particles, shale, alkali, organic matter, mica, and other deleterious substances. If washed, the method must not remove other desirable fines, and the sand must be permitted to drain until the residual free moisture is reasonably uniform and stable. Sand gradation must be reasonably consistent and must conform to the following requirements as delivered to the grout mixer:

<table>
<thead>
<tr>
<th>Sieve Opening U.S. Standard Sieve Number</th>
<th>Cumulative Percent by Weight Passing</th>
<th>Cumulative Percent by Weight Retained</th>
</tr>
</thead>
<tbody>
<tr>
<td>2.38 mm 8</td>
<td>100</td>
<td>0</td>
</tr>
<tr>
<td>1.19 mm 16</td>
<td>95-100</td>
<td>0-5</td>
</tr>
<tr>
<td>0.600 mm 30</td>
<td>55-80</td>
<td>20-45</td>
</tr>
<tr>
<td>0.300 mm 50</td>
<td>30-55</td>
<td>45-70</td>
</tr>
<tr>
<td>0.150 mm 100</td>
<td>10-30</td>
<td>70-90</td>
</tr>
<tr>
<td>0.075 mm 200</td>
<td>0-10</td>
<td>90-100</td>
</tr>
</tbody>
</table>

The sand must have a fineness modulus of not less than 1.30 nor more than 2.10. The sand gradation shown above may be modified with the approval of the Contracting Officer. Mortar test specimens made with the modified sand must exhibit compressive strength equal to or greater than that exhibited by similar specimens made with sand meeting grading and other requirements shown above.

2.1.5 **Zero-Slump Concrete Sampling**

Various testing agencies have developed special procedures to produce test specimens to mold zero-slump concrete test cylinders. These procedures should be used to mold zero-slump concrete cylinders. One such procedure that has been widely used is described below. Conform to appropriate sections of **ASTM C143/C143M** and **ASTM C172/C172M**.

Obtain approximately **0.08 cubic meter 3 cubic feet** of concrete from the batch to be placed in the PIF. A fresh, moist sample of concrete must be obtained for each cylinder. Record the mix temperature. Assemble the compaction steel mold **150 mm diameter by 300 mm high 6-inch diameter by 12 inch high** and tighten all lugs. Using a US Standard **19 mm 3/4 inch sieve** to screen the mix, place sufficient material in the mold to give a loose lift thickness of **50 mm 2 inches**. Compact the lift using 20 blows of the Marshall hammer **4.53 Kg falling 457 mm 10-lb weight falling 18 inches**, making sure that all blows are evenly spaced over the entire surface. Repeat the procedure for each lift until eight lifts are placed. The material should be passed through a **12.7 mm 1/2 inch sieve** for the last two lifts in order to form a smooth top. The compacted specimen should remain in the reusable mold for 24 hours before removal for additional curing.
2.1.6 Compressive Strength Test Results

Evaluate compressive strength test results at 28 days in accordance with [ACI 214R] using a coefficient of variation of 10 percent. Evaluate strength of concrete by averaging test results of each set of standard cylinders tested at 28 days. Not more than 10 percent of individual cylinders tested must have a compressive strength less than specified design strength.

2.2 REINFORCEMENT

**************************************************************************

NOTE: Insert the correlated section number and title in paragraph REINFORCEMENT or include reinforcement specification in this section, in blank below in proper format per UFC 1-300-02.

Shafts are reinforced only when the shaft is required to withstand tension, moment, or shear. Shaft reinforcement may also be required for compression or lateral loads for battered shafts.

**************************************************************************

Materials, assembly, and placement of reinforcement must conform to the requirements of Section [03 30 00 CAST-IN-PLACE CONCRETE] [______].

2.3 CASINGS

**************************************************************************

NOTE: Delete paragraph UNCASED SHAFT if only cased shafts are used. Delete paragraphs CASINGS and CASED SHAFT if only uncased shafts are used. Do not use uncased shafts in soft clay or silt soils unless:

1. Adjacent PIF are installed in previously bored holes equal to the inside diameter of the driving tubes, or

2. PIF are located more than 2.7 m 9 feet apart.

**************************************************************************

Provide permanent steel casing of sufficient thickness, strength, and rigidity to prevent deformation, collapse, or distortion caused by driving adjacent PIF or by soil or hydrostatic pressure. Casings must be watertight.

2.4 MATERIAL SUSTAINABILITY CRITERIA

For materials used, where applicable and to extent allowed by performance criteria, provide and document the following in accordance with Section 01 33 29 SUSTAINABILITY REQUIREMENTS AND REPORTING:

a. Recycled content for fly ash and pozzolan

b. Recycled content for Ground Iron Blast-Furnace Slag

c. Recycled content for Silica Fume

d. Minimum [75 percent] [_____] recycled content for steel used for stressed tendon reinforcing
PART 3   EXECUTION

3.1   INSTALLATION

3.1.1   General Requirements

Design of the PIF is based upon assumed subsurface elevations to which the PIF must penetrate at various locations and total energy required to drive them. Based upon results of PIF test loadings, the Contracting Officer will specify the actual elevation to which PIF must penetrate and the total energy to be applied to drive the last 0.14 cubic meter 5 cubic feet of concrete into the base.

3.1.2   Placement

Do not place PIF until earthwork has been graded to elevation indicated. Do not place permanent PIF until load test[s] [have][has] been successfully completed. Modifications to pressure-injected footings (PIF) must be approved by the Contracting Officer prior to placement.

3.1.3   Tolerance

Placement tolerance must be a maximum 50 mm 2 inches from plan location for single PIF and 75 mm 3 inches from plan location for PIF in clusters. Except for batter installations, PIF must be a maximum of two percent out of plumb. Batter installations must be within five percent of the indicated required angle. The required angle must not exceed 0.44 rad 25 degrees from the vertical.

PIFs must be monitored for heave immediately after installation and after adjacent PIFs are installed. If PIFs heave more than 13 mm 1/2 inch notify the Contracting Officer.

3.1.4   PIF Damaged, Mislocated, or Out of Alignment

**************************************************************************
NOTE: For PIF installed beyond tolerance, determine actual load to be supported. Reject PIF unless determination shows that overloading does not exceed 10 percent where no load test has been conducted, or 20 percent when load test has been conducted, providing that materials are not stressed beyond allowable limits.
**************************************************************************

Abandon PIF damaged, mislocated, or out of alignment beyond maximum tolerance and place additional PIF where directed without additional cost to the Owner.

3.1.5   As-Driven Survey

After the installation of each PIF group is complete, provide the Contracting Officer with an as-driven survey showing actual location and top elevation of each PIF. Do not proceed with placing concrete until the Contracting Officer has reviewed the survey and verified the safe load for the PIF group driven. Present a survey in such form that it gives deviation from plan location in two perpendicular directions and elevations of each PIF to nearest 13 mm half inch. Survey must be prepared and certified by a licensed land surveyor.
3.1.6 Protection of Existing Structures

**************************************************************************
NOTE: Include this paragraph only when protection of existing structures from pile driving activities is required.

The designer must indicate on the drawings all structures and facilities for which protection is required. The designer must also provide a project specific document that details design criteria, requirements for preconstruction condition surveys, post construction condition surveys, geotechnical instrumentation to measure ground movements and any other requirements.

Add any additional requirements as necessary.
**************************************************************************
Mitigate impact on existing facilities due to PIF installation activities in accordance with the [project specific document] [_____].

3.2 BASE

**************************************************************************
NOTE: Use drive tubes from 508 to 610 mm 20 to 24 inches in diameter for loads 72.6 metric tons 80 tons and greater with energy of 189,840 J 140,000 foot-pounds or use drive tubes from 305 to 406 mm 12 to 16 inches in diameter for loads less than 72.6 metric tons 80 tons with energy of 67,800 to 135,600 J 50,000 to 100,000 foot-pounds.
**************************************************************************
Load steel drive tube of [_____ mm _____ inch] [appropriate] diameter with a plug of 0.14 cubic meter 5 cubic feet of concrete or gravel and force into ground by drop hammer blows on plug at bottom inside of the steel tube. Pre-bore to assist driving if appropriate. Drive tube to predetermined depth of granular soil stratum suitable for forming expanded base. At this depth, expel plug while preventing further penetration of the tube, with sufficient seal maintained to prevent entry of water or soil. During injection of concrete, level of concrete in tube shall be 150 mm 6 inches above bottom of tube.

3.3 SHAFTS

3.3.1 Uncased Shaft

**************************************************************************
NOTE: Delete paragraph UNCASED SHAFT if only cased shafts are used. Delete paragraphs CASINGS and CASED SHAFT if only uncased shafts are used. Do not use uncased shafts in soft clay or silt soils unless:

1. Adjacent PIF are installed in previously bored holes equal to the inside diameter of the driving tubes, or
2. PIF are located more than 2.7 m 9 feet apart.

Ensure continuous and complete contact between concrete shaft and surrounding soil. Form shaft by compacting charges of zero-slump concrete with hammer blows of 20,300 to 27,100 Joules 15,000 to 20,000 foot-pounds of energy and withdraw drive tube in not more than 600 mm 2 foot increments. Concrete level inside drive tube must be higher than bottom of tube at all times. Alternatively, when shaft is reinforced full length, fill drive-tube with 150 to 200 mm 6 to 8 inches of high-slump concrete and withdraw tube, recharging concrete as needed to ensure that final level is at or above cut-off elevation.

3.3.2 Cased Shaft

NOTE: Delete paragraph UNCASED SHAFT if only cased shafts are used. Delete paragraphs CASINGS and CASED SHAFT if only uncased shafts are used. Do not use uncased shafts in soft clay or silt soils unless:

1. Adjacent PIF are installed in previously bored holes equal to the inside diameter of the driving tubes, or

2. PIF are located more than 2.7 m 9 feet apart.

NOTE: Where soil conditions indicate that it may be impractical or difficult to fill the annular space between the shaft and the soil around a single casing, shaft must be supported laterally or PIF must be reinforced. Where a single PIF is used as a foundation and the shaft is cased, shaft must be supported at the top in at least two directions, perpendicular to each other. Where two PIF are used in a group and their shafts are cased, the groups must be supported laterally at the top in a direction perpendicular to a line drawn between centers of the footings. Insert minimum nominal diameter of casings.

Concrete shaft must be cased in a permanent steel casing formed by inserting a steel casing with a minimum diameter of [_____] mm inches into drive tube and embedding in expanded base as required to exclude water or other foreign material. Withdraw drive tube and fill steel casing with 75 mm 3 inch slump concrete to cut-off elevation but not until after all PIF within a 2.7 m 9 foot radius have been installed. Place concrete in continuous flow from bottom to top of shaft, and do not drop through water. Fill spaces between steel casing and surrounding soil with sand by a process of washing sand as the drive tube is withdrawn. Allow shaft to cure 24 hours minimum before constructing additional PIF within a 2.7 m 9 foot radius. Remove mud, water, and other foreign matter before filling casing with concrete. Extract and discard distorted, bent, or damaged casings and drive new casings.

SECTION 31 62 13.26 Page 20
3.4 REINFORCEMENT

**************************************************************************
NOTE: Insert the correlated section number and title in paragraph REINFORCEMENT or include reinforcement specification in this section. Shafts are reinforced only when the shaft is required to withstand tension, moment, or shear. Shaft reinforcement may also be required for compression or lateral loads for battered shafts.
**************************************************************************

Assemble, securely tie together, and place in shaft as a unit. Use spacers to center reinforcement in the shaft and maintain alignment. Reinforce full length of battered shafts and uncased shafts to resist uplift force. Connect shaft to superstructure with reinforcement as indicated. Provide necessary dowels. Submit drawings, details and schedules.

3.5 FIELD QUALITY CONTROL

**************************************************************************
NOTE: Delete these paragraphs if load testing is not required.
**************************************************************************

3.5.1 Load Tests

**************************************************************************
NOTE: This section is applicable to axial compression load tests. Revise accordingly for axial tension load tests (ASTM D3689) or lateral load tests (ASTM D3966/D3966M). The requirement of performing the load test under the direct supervision of a registered professional engineer may be waived at the discretion of the design agency.
**************************************************************************

ASTM D1143/D1143M[, measurement method as recommended by the Contractor]; provide [one] [_____] test PIF[s] conforming to requirements for permanent PIF at location[s] [indicated] [directed by the Contracting Officer]. Place test PIF in same manner specified for permanent PIF. Test PIF indicated or directed to be placed in permanent locations may be incorporated into the final work if load testing is satisfactory. Perform tests and recording of data under the direct supervision of a registered Professional Engineer provided by the [Government] [Contractor]. Load frames, jacks, pumps, and dial gauges must be the responsibility of the Contractor.

3.5.2 Test Measurements

Maintain ultimate test load as per ASTM D1143/D1143M. Determine safe bearing capacity of test PIF from results of load test as approved by the Contracting Officer. Safe bearing capacity must be the lesser of two values computed as follows: (a) one-half the load at which the load vs. total settlement curve exhibits a slope of 1.3 mm per 907 kg 0.05 inches per ton of test load; or (b) one-half the load that causes net settlement
after rebound of not more than 25.4 mm one inch.]

3.6 INSPECTION AND SAFETY

Engage an independent testing agency qualified according to ASTM C1077 and ASTM E329 for testing indicated. Submit testing agency qualifications to the Contracting Officer for approval at least 30 calendar days prior to installation. Provide sufficient light and access for proper inspection of full length of casings. The Contractor must provide safety requirements and access equipment required for proper inspection. Casing must be inspected and approved prior to installing shaft.

3.6.1 Pressure Injected Footing Records

Maintain daily records and make available to the Contracting Officer at all times. Within 15 days after completion of PIF, furnish to the Contracting Officer a complete and accurate record of all PIF installed. Records must include, as a minimum, the following information for each PIF:

a. Reference or identification number

b. Shaft type and method of reinforcing used

c. Diameter, length, location, and elevation of finished concrete at top of shaft

d. Elevation of bottom of base

e. Type and volume of concrete in base

f. Number and magnitude of blows required to drive the last 0.14 cubic meter 5 cubic feet of base concrete

g. Unusual or unexpected conditions encountered during installation

h. Date of construction drilling, driving, concrete placing, high and low temperatures, and weather conditions for each PIF

i. For PIF closer than nine shaft diameters, elevations at adjacent PIF, recorded before and after driving

j. Sequence of placing PIF in groups.

3.7 SPECIAL INSPECTION AND TESTING FOR SEISMIC-RESISTING SYSTEMS

**************************************************************************

NOTE: Include this paragraph only when special inspection and testing for seismic-resisting systems is required by the International Building Code (IBC).

This paragraph will be applicable to both new buildings designed and to existing building seismic rehabilitation designs done according to UFC 1-200-01, "General Building Requirements", UFC 3-301-01 "Structural Engineering", and UFC 3-301-02 "Design of Risk Category V Structures, National Strategic Military Assets".

The designer must indicate on the drawings all
locations and all features for which special inspection and testing is required in accordance with Chapter 17 of the IBC. This includes indicating the locations of all structural components and connections requiring inspection.

Add any additional requirements as necessary.

Perform special inspections and testing for seismic-resisting systems and components in accordance with Section 01 45 35 SPECIAL INSPECTIONS.

[3.8 VIBRATION CONTROL]

NOTE: Include this paragraph when vibration monitoring is required. Add any additional criteria or requirements as necessary to the particular project.

Perform vibration monitoring at the locations[ shown in the plan][ decided by the Contracting Officer] during the PIF installation operations. Perform vibration monitoring [using] [seismographs] [and geophones] within a distance of [61] [_____] meters [200] [_____] feet from the PIF installation activity.[ Engage the services of a qualified, independent vibration consultant, acceptable to the Government, to conduct the vibration monitoring. The vibration consultant must have minimum of [five] [_____] years of experience in vibration monitoring. A minimum of [28] [_____] days before the installation of vibration monitors, submit to the Government the name of the vibration consultant and a list of at least [three] [_____] previously completed projects of similar scope and purpose.]

Prior to the PIF installation activities, obtain baseline readings of ambient vibrations. The vibration during the PIF installation activities must be limited to[ a peak particle velocity of not more than [5] [_____] cm [2.0] [_____] inches per second][ the limits mentioned in the [contract documents] [______]].[ Determine appropriate vibration limits as per [US Bureau of Mines ] [American Association of State Highway and Transportation Officials (AASHTO)] guidelines. During PIF installation activities, monitor the vibrations to ensure the limits are not exceeded. If the limits are exceeded, cease the PIF installation activity causing the vibration until [the Vibration consultant and the Contracting Officer] [_____] are on site to observe the structures nearest to the vibration monitor which has exceeded the limits.

The Contractor must be responsible for all damages resulting from the PIF installation operations and must take whatever measures necessary to maintain peak particle velocity within the specified limit. After completion of the project, remove the vibration monitors off the site and off Government property and restore the monitoring locations back to their original condition.

[3.9 NOISE CONTROL]

NOTE: Include this paragraph when noise monitoring is required. Add any additional criteria, references or requirements as necessary to the particular project.
Perform noise monitoring at the locations [shown in the plan] [decided by the Contracting Officer] [at noise sensitive public areas] during the PIF installation operations. Perform noise monitoring using [noise meters], and _____. Engage the services of a qualified, independent noise consultant, acceptable to the Government, to conduct the noise monitoring. The noise consultant must have minimum of [five] years of experience in noise monitoring. A minimum of [28] days before the installation of noise monitors, submit to the Government the name of the noise consultant and a list of at least [three] previously completed projects of similar scope and purpose.

Prior to the PIF installation activities, obtain baseline readings of ambient noise levels. The noise limits are mentioned in the [plan] [contract documents]. Determine appropriate noise limits as per [local agency] [Occupational Safety and Health Administration] guidelines. During PIF installation activities, monitor the noise to ensure the limits are not exceeded. If the limits are exceeded, cease the PIF installation activity and install noise mitigation measures.

The Contractor must be responsible for all damages resulting from the PIF installation and must take whatever measures necessary to maintain noise within the specified limit. After completion of the project, remove the noise monitors off the site and off Government property and restore the monitoring locations back to their original condition.

3.10 PRECONSTRUCTION CONDITION SURVEY

NOTE: Add any additional criteria, references or requirements as necessary to the particular project.

Perform preconstruction condition survey of [structures] [and utilities] within [61] meters [200] feet of the PIF installation activity [specified in the plans] [decided by the Contracting Officer]. Perform outreach to the owner of the structures [28] days before performing the preconstruction condition survey. The Contractor must obtain written permission from the owner of the structure prior to accessing the structure. The preconstruction condition survey must include video and photographic documentation of the exterior and interior of above ground structures and of the interior of underground structures. Video documentation must be in high definition, and show existing conditions and highlight, where possible, existing cracks, deteriorated concrete, exposed and corroded reinforcement, cracked or broken brick or mortar, and other signs of distress. For utilities, perform the survey when the greatest extent of the interior is exposed. Provide supplementary artificial lighting as needed. The video must include annotation with location and structure nomenclature which describes any areas of distress over the video and time code superimposed on the video. Photographs must be accompanied by sketches or descriptions that indicate the location and direction of each photograph. For each structure surveyed, provide a Pre-Construction Condition Survey Report following completion of the survey. The report must contain all documentation associated with the survey including DVD copies. In the report, include notes, sketches, photographs, and videos. Provide general information, such as location details and structure type, as well as particular information on materials, condition, existing damage,
aperture and persistence of cracks, and disrepair observed during visual survey. Provide a graphical depiction of locations of damage or other features of concern. Submit the Preconstruction Condition Survey Reports no later than [28] [_____] days before the commencement of PIF installation activity. Accept responsibility for damages to existing adjacent or adjoining structures created by PIF installation work, and repair any damages to these structures without cost to the Government.

3.11 CONSTRUCTION INSTRUMENTATION AND MONITORING PROGRAM

**************************************************************************
NOTE: Include this section if instrumentation is to be installed due to concerns about vibration, settlement, lateral movement, etc. during PIF installation activities. Instrumentation should be specified and included in the specification. This section can be deleted if there are no instrumentation requirements.
Add any additional criteria or requirements as necessary for the particular project.
**************************************************************************

Prepare a geotechnical instrumentation program to monitor settlement [and lateral movement] of temporary and permanent structures, utilities, [embankments] [and excavations] during PIF installation. The design and distribution of instrumentation must demonstrate an understanding of the need, purpose and application of each proposed type. Perform noise and vibration monitoring in accordance with NOISE CONTROL and VIBRATION CONTROL sections.

Monitoring must extend before, during and for a period after completion of construction activities related to PIF installation when long-term performance issues are a concern. The monitoring plan must be designed to protect adjacent structures and utilities against damage due to the PIF installation activities. Establish limiting values of vertical [and horizontal] movement [and angular distortion] [and vibration] for each structure and utility within the zone of influence, subject to review by the Government.

Prepare a report detailing the proposed program of instrumentation and monitoring, establishing threshold values of monitored parameters, and describing the response plans that will be implemented when threshold parameters are exceeded. The report must include details about instrumentation consultant's experience, appropriate types, quantities, locations and monitoring frequencies of the instruments.

Upon acceptance of the instrumentation and monitoring program, provide, install and monitor the instrumentation and interpret the data. Submit instrumentation data reports not less than every [_____] days after the monitoring program has begun. Take corrective actions, as necessary, based on the field instrumentation data and as defined in the instrumentation and monitoring program.

UNITED FACILITIES GUIDE SPECIFICATIONS

This guide specification covers the requirements for furnishing all equipment, labor, and materials (except materials specified to be furnished by the Government) and performing all operations in connection with the furnishing, installing and testing of steel pipe piles.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1  GENERAL

NOTE: The structural engineer must confirm the structural capacity of the piles and provide specific requirements for bending moments, lateral loads etc. for the pile design.

1.1 DESCRIPTION

Design, furnish, install and test steel pipe piles at the locations indicated on the drawings and specified herein. Assume test pile[s] will be directed to be placed in [a ]location[s] that can be incorporated into
1.2 REFERENCES

********************************************************************************
NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

********************************************************************************

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

AMERICAN WELDING SOCIETY (AWS)

AWS D1.1/D1.1M (2020; Errata 1 2021) Structural Welding Code - Steel

AWS D1.5M/D1.5 (2020; Errata 1 2022) Bridge Welding Code

ASTM INTERNATIONAL (ASTM)

ASTM A572/A572M (2021; E 2021) Standard Specification for High-Strength Low-Alloy Columbium-Vanadium Structural Steel
1.3 SUBSURFACE DATA

********************************************************************************
NOTE: Section 00 31 32.13 Subsurface Drilling and Sampling Information is not a UFGS. CSI MasterFormat prescribes this section for inclusion of this data.
********************************************************************************

Subsurface soil data logs are [indicated] [appended to the special contract requirements] [provided on the project drawings]. The subsoil investigation report samples of material taken from subsurface
investigations may be examined at [____].

1.4 BASIS OF BID

**************************************************************************

NOTE: Select one of the following options:
**************************************************************************

**************************************************************************

NOTE: Use "Lump Sum" paragraph below for lump (principal) sum bidding of piles. Use this in all projects except those where exact pile lengths cannot be practically determined prior to the actual work. Clearly show number of piles, pile capacity, pile locations, and tip and cutoff elevations on the drawings.

Use "Unit Price" paragraph for unit price bidding of piles. Specify unit price bid items for piles only for projects where exact quantities cannot be practically determined prior to the actual work. Lengths of piles must be determined as accurately as possible, prior to bidding, since the unit price per meter foot of the piles varies as the length increases or decreases. Refer to Standard Test Method for High-Strain Dynamic Testing of Deep Foundations (ASTM D4945)

**************************************************************************

1.4.1 Contractor's Geotechnical Consultant

Hire the services of an independent, Registered Professional Geotechnical Engineer, experienced in soil mechanics and Pile Dynamic Analysis, to observe test pile installation as specified herein. The Contractor's Geotechnical Consultant must be independent of the Contractor and must have no employee of employer relationship, which could constitute a conflict of interest.

1.4.2 Production Pile Acceptance Criteria

Safe design capacity for piles is [____] KN [____] kips. Drive piles to [minimum tip elevation] [a minimum depth of [____] m [____] feet below cut-off elevation], and to such additional depth as required to obtain a bearing capacity of not less than [____] KN [____] kips. The Contractor's Geotechnical Consultant will determine the terminal driving criteria based on results of [dynamic pile driving tests at end of drive or restrike] [static load tests] [wave equation analysis].

The following formulas can be used in cases where allowable pile loads are less than 355 kN 80 kips (determined using a factor of safety of 3 for individual piles and 4 for pile groups) and are presented only as a guide to aid in establishing the controlling penetration per blow, which, together with the minimum depth of penetration will serve to determine the required minimum depth of penetration of each individual pile:

\[
R = \frac{2E}{S + 0.1} \quad \text{For double acting hammers}
\]

\[
R = \frac{2WH}{\text{No text provided}} \quad \text{For single acting hammers}
\]
S plus 0.1

Where $R$ is the approximate allowable pile load in kips; $E$ equals the energy in foot-kips per blow based on an acceptable certified statement from the manufacturer of the hammer; $W$ equals the weight of the hammer or ram in kips; $H$ equals the height of fall of the hammer or ram in feet; and $S$ equals the average inches of penetration per blow for the last three blows. An allowance will be made for reduced penetration caused by shock absorption of the cushion or cap blocks.

[1.4.3] Lump Sum Payment

**************************************************************************

NOTE: Use this paragraph for lump-sum contracts, consult with Contracting Officer's Technical Representative (Geotechnical Branch) on applicability of use prior to selection. This paragraph will be typically used when there are 1) relatively small quantity of piles, 2) allowable pile loading is less than 355 kN 80 kips, and 3) the subsurface conditions are well defined. Fill in Table I as required selecting columns applicable to project. Generally, pile capacity, location, and minimum tip elevation are shown on plans. Test piles and load tests are not incorporated on lump sum contracts. Delete this paragraph for unit-price contracts.

**************************************************************************

Base bids upon providing the number, size, capacity, and length of piles as indicated on the drawings. Following Table I:

<table>
<thead>
<tr>
<th>Location</th>
<th>Number</th>
<th>Size</th>
<th>Capacity</th>
<th>Length (Tip to Cut-Off)</th>
<th>Maximum Bending Moment</th>
<th>Maximum Shear Force</th>
</tr>
</thead>
</table>

Include the cost of all necessary equipment, tools, material, labor, and supervision required to: deliver, handle, install, cut-off, place concrete infill, dispose of any cut-offs, and meet the applicable contract requirements. Include mobilization, pre-drilling, and redriving heaved piles to the required depth of penetration, tip elevation, refusal blow count as directed by the Contractor's Geotechnical Consultant. If, in redriving, it is found that any pile is not of sufficient length to provide the capacity specified, notify the Contracting Officer, who reserves the right to increase or decrease the total length of piles to be provided and installed by changing the pile locations or elevations, requiring the installation of additional piles, or directing the omission of piles from the requirements shown and specified. If total number of piles or number of each length vary from that specified as the basis for bidding, an adjustment in the contract price or time for completion, or both, will be made in accordance with the contract documents. Payment for piles will be based on successfully installing piles to both the minimum tip elevation and satisfying the acceptance criteria identified herein. No additional payment will be made for: damaged, rejected, or misplaced piles; withdrawn piles; any portion of a pile remaining above the cut-off elevation; backdriving; cutting off piles; splicing; build-ups; any cut-off length of

SECTION 31 62 16.13 Page 9
piles; or other excesses beyond the assumed pile length indicated for which the Contractor is responsible. Include payments for vibration monitoring, sound monitoring, construction instrumentation and monitoring, and precondition construction surveys.

][1.4.4 Unit Price

**************************************************************************

NOTE: Delete this paragraph for lump-sum contracts.

For NAVFAC PAC projects: Where there is unit pricing for piles, use this paragraph and edit applicable attachments from price schedule for inclusion in Standard Form 1442, "Solicitation, Offer and Award" and "Schedule of Bid Items."

For NAVFAC Southeast projects, where there is a need for unit pricing of piles, include this paragraph. Refer to NAVFAC SE Instruction 00010, "Instructions for Preparing Basis of Bid Statement With Unit-Priced Items," for method of specifying unit price bid items.

**************************************************************************

NOTE: For NAVFAC LANT projects, use the following paragraph for measurement and payment and subsequent sub-parts.

**************************************************************************

Requirements of FAR 52.211-18 Variation in Estimated Quantity do not apply to payment for piling. Each pile and test pile acceptably provided will be paid for at the bid unit price per unit length, which will include items incidental to furnishing and driving the piles including mobilization and demobilization, [concrete infill,][jetting][predrilling][probing], redriving uplifted piles, [an additional 1.5 m 5 feet in furnished length for any test pile not driven beyond estimated pile length,] and cutting off piles at the cut-off elevation. [Include the cost for additional length for the test piles in the total unit price cost for the job.] Payment will be made for production[and test piles] at the bid unit price for the length of pile, from tip to final cut-off, actually provided, excluding buildups and splices directed by the Contracting Officer to be made. If the actual cumulative pile length driven (tip to cut-off) vary more than 25 percent from the total pile length specified as a basis for bidding, at the direction of the Contracting Officer, the unit price per unit length will be adjusted in accordance with provisions of FAR 52.236-2 Differing Site Conditions.[Payments will be made per each at the respective bid unit price for pile cut-offs, pile build-ups, pile loads tests and pile splices.]

][1.5 PAYMENT

**************************************************************************

NOTE: Delete this paragraph for lump-sum contracts.

If Section 01 20 00 PRICE AND PAYMENT PROCEDURES is included in the project specifications, this
1.5.1 Furnishing and Delivering Steel Pipe Piles

1.5.1.1 Payment

Payment will be made for costs associated with furnishing and delivering the required lengths of permanent steel pipe piles, which includes costs of furnishing and delivering piles to the work site. No payment will be made for the driving head or lengths of piles exceeding required lengths. No payment will be made for piles damaged during delivery, storage, or handling to the extent that they are rendered unsuitable for the work, in the opinion of the Contracting Officer.

1.5.1.2 Measurement

Furnishing and delivering permanent steel pipe piles will be measured for payment by the linear meter foot of piles required below the cut-off elevation as [determined by the Contracting Officer and furnished to the Contractor] [indicated].

1.5.1.3 Unit of Measure

Linear meter foot.

1.5.2 Driving Steel Pipe Piles

1.5.2.1 Payment

Payment will be made for costs associated with driving permanent steel pipe piles, which includes costs of handling, driving, [and splicing of piles,] [performing dynamic testing, interpreting data and submitting reports,] [placing concrete infill] measuring heave, redriving heaved piles, removal of [build-ups ] driving heads or cutting off piles at the cut-off elevation and removing from the work site, compiling and submitting pile driving records, backfilling voids around piles, and any other items incidental to driving piles to the required elevation.

1.5.2.2 Measurement

Permanent steel pipe piles will be measured for payment for driving on the basis of lengths, to the nearest hundredth (tenth) of a linear meter foot, along the axis of each pile acceptably in place below the cut-off elevation shown.

1.5.2.3 Unit of Measure

Linear meter foot.

1.5.3 Pulled Steel Pipe Piles

1.5.3.1 Payment

Payment will be made for costs associated with piles pulled at the direction of the Contracting Officer and found to be undamaged. The cost
of furnishing and delivering pulled and undamaged piles will be paid for at the applicable contract unit price for payment item "Furnishing and Delivering Steel pipe Piles". The cost of driving pulled and undamaged piles will be paid for at the applicable contract unit price for payment item "Driving Steel pipe Piles". The cost of pulling undamaged piles will be paid for at twice the applicable contract unit price for payment item "Driving Steel pipe Piles", which includes backfilling any remaining void. The cost of redriving pulled and undamaged piles will be paid for at the applicable contract unit price for payment item "Driving Steel pipe Piles". No payment will be made for furnishing, delivering, driving, pulling, and disposing of piles, including pile driving points, pulled and found to be damaged and backfilling voids. New piles replacing damaged piles will be paid for at the applicable contract unit price for payment items "Furnishing and Delivering Steel pipe Piles" and "Driving Steel pipe Piles".

1.5.3.2 Measurement

Furnishing and delivering pulled and undamaged permanent steel pipe piles will be measured for payment as specified in paragraph PAYMENT, subparagraph FURNISHING AND DELIVERING STEEL PIPE PILES. Pulling undamaged steel pipe piles will be measured for payment as specified in paragraph PAYMENT, subparagraph DRIVING STEEL PIPE PILES. Redriving pulled undamaged steel pipe piles will be measured for payment as specified in paragraph PAYMENT, subparagraph DRIVING STEEL PIPE PILES. New piles replacing damaged piles will be measured for payment as specified in paragraph PAYMENT, subparagraphs FURNISHING AND DELIVERING STEEL PIPE PILES and DRIVING STEEL PIPE PILES.

1.5.3.3 Unit of Measure

Linear meter foot.

[1.5.4 Steel Pipe Pile Driving Tests

1.5.4.1 Payment

Payment will be made for costs associated with furnishing, delivering, driving, pulling, and disposing of driven test piles, [including [pile driving points][ and ][splices]]; conducting pile driving tests; backfilling voids around piles; compiling pile driving test records[; performing dynamic testing; interpreting data; and submitting reports].

1.5.4.2 Measurement

Steel pipe pile driving tests will be measured for payment on the basis of the applicable contract unit price per pile driving test.

1.5.4.3 Unit of Measure

Each.

][1.5.5 Steel Pipe Piles for Load Tests

1.5.5.1 Payment

Payment will be made for costs associated with furnishing, delivering, driving, pulling, and disposing of load test piles[ including [pile driving points][ and ][splices]]; backfilling voids around piles; compiling pile
driving records; furnishing, fabricating, and mounting of strain rods and protective assembly; furnishing, fabricating, and mounting of inclinometer and inclinometer protective assembly; performing dynamic testing; interpreting data; and submitting reports. No additional payment will be made for load test piles incorporated in the permanent work other than as provided.

1.5.5.2 Measurement
Steel pipe piles for load tests will be measured for payment on the basis of the applicable contract unit price per load test pile.

1.5.5.3 Unit of Measure
Each.

1.5.6 Steel Pipe Pile Static Axial Compressive Load Tests

1.5.6.1 Payment
Payment will be made for costs associated with steel pipe pile static axial compressive load tests in accordance with ASTM D1143/D1143M, including material and labor for fabricating and furnishing load frames; calibrating load cells and hydraulic jacks; furnishing specified test equipment; installing strain rods; placing and removing test loads and test equipment; recording, reducing, and submitting test data; and compiling and submitting pile load test reports. No payment will be made for rejected pile static axial compressive load tests.

1.5.6.2 Measurement
Steel pipe pile static axial compressive load tests will be measured for payment on the basis of the applicable contract unit price per load test.

1.5.6.3 Unit of Measure
Each.

1.5.7 Steel Pipe Pile Static Tensile Load Tests

1.5.7.1 Payment
Payment will be made for costs associated with steel pipe pile static tensile load tests in accordance with ASTM D3689, including material and labor for fabricating and furnishing load frames; calibrating load cells and hydraulic jacks; furnishing specified test equipment; installing strain rods; placing and removing test loads and test equipment; recording, reducing, and submitting test data; and compiling and submitting pile load test reports. No payment will be made for rejected pile static tensile load tests.

1.5.7.2 Measurement
Steel pipe pile tensile load tests will be measured for payment on the basis of the applicable contract unit price per number of tensile load test.

1.5.7.3 Unit of Measure
Each.
1.5.8 Steel Pipe Pile Lateral Load Tests

1.5.8.1 Payment

Payment will be made for costs associated with steel pipe pile lateral load tests in accordance with ASTM D3966/D3966M, including material and labor for fabricating and furnishing load frames; calibrating load cells and hydraulic jacks; furnishing specified test equipment; installing inclinometers; placing and removing test loads and test equipment; recording, reducing, and submitting test data; and compiling and submitting pile load test reports. No payment will be made for rejected pile lateral load tests.

1.5.8.2 Measurement

Steel pipe pile lateral load tests will be measured for payment on the basis of the applicable contract unit price per lateral load test.

1.5.8.3 Unit of Measure

Each.

1.5.9 Pulled Load Test Steel Pipe Piles

1.5.9.1 Payment

Payment will be made for costs associated with load test steel pipe piles pulled prior to load testing at the direction of the Contracting Officer and found to be undamaged. The cost of furnishing, delivering, driving, and pulling undamaged load test piles will be paid for at the applicable contract unit price for payment item "Steel pipe Piles for Load Tests". The cost of pulling undamaged load test piles the second time after redriving and testing will be paid for at twice the applicable contract unit price for payment item "Driving Steel pipe Piles". The cost of redriving pulled undamaged load test piles will be paid for at the applicable contract unit price for payment item "Driving Steel pipe Piles". No payment will be made for furnishing, delivering, driving, pulling, and disposing of load test piles pulled at the direction of the Contracting Officer and found to be damaged. New load test piles replacing damaged piles will be paid for at the applicable contract unit price for payment item "Steel pipe Piles for Load Tests".

1.5.9.2 Measurement

Pulled undamaged load test steel pipe piles will be measured for payment as specified in paragraph PAYMENT, subparagraph STEEL PIPE PILES FOR LOAD TESTS. Pulling undamaged load test steel pipe piles the second time after redriving and testing will be measured for payment as specified in paragraph PAYMENT, subparagraph DRIVING STEEL PIPE PILES. Redriving pulled undamaged steel pipe piles will be measured for payment as specified in paragraph PAYMENT, subparagraph DRIVING STEEL PIPE PILES. New load test steel pipe piles replacing damaged piles will be measured for payment as specified in paragraph PAYMENT, subparagraph STEEL PIPE PILES FOR LOAD TESTS.

1.5.9.3 Unit of Measure

As specified in paragraph PAYMENT, subparagraphs DRIVING STEEL PIPE PILES
and STEEL PIPE PILES FOR LOAD TESTS, respectfully.

1.5.10 Pile Driving Shoes

1.5.10.1 Payment

Payment will be made for costs associated with pile driving shoes, including furnishing, delivering, and installing.

1.5.10.2 Measurement

Pile driving shoes will be measured for payment on the basis of the number of pile driving shoes required.

1.5.10.3 Unit of Measure

Each.

1.5.11 Steel Pipe Pile Splices

1.5.11.1 Payment

Payment will be made for costs associated with steel pipe pile splices, including all plant, labor, and material required to make the splice.

1.5.11.2 Measurement

Steel pipe pile splices will be measured for payment on the basis of the applicable contract unit price per pile splice.

1.5.11.3 Unit of Measure

Each.

1.5.12 Vibration Monitoring

1.5.12.1 Payment

Payment will be made for costs associated with vibration monitoring.

1.5.12.2 Measurement

Vibration monitoring will be measured for payment on the basis of the applicable contract unit price per vibration monitoring point.

1.5.12.3 Unit of Measure

Each.

1.5.13 Sound Monitoring

1.5.13.1 Payment

Payment will be made for costs associated with sound monitoring.

1.5.13.2 Measurement

Sound monitoring will be measured for payment on the basis of the applicable contract unit price per vibration monitoring point.
1.5.13.3 Unit of Measure
Each.

1.5.14 Preconstruction Condition Survey

1.5.14.1 Payment
Payment will be made for costs associated with preconstruction condition surveys.

1.5.14.2 Measurement
Preconstruction condition survey will be measured for payment on the basis of the applicable contract unit price per structure to be surveyed.

1.5.14.3 Unit of Measure
Each.

1.5.15 Construction Instrumentation and Monitoring

1.5.15.1 Payment
Payment will be made for costs associated with construction instrumentation and monitoring.

1.5.15.2 Measurement
Construction instrumentation and monitoring will be measured as a single pay item.

1.5.15.3 Unit of Measure
One.

1.6 SUBMITTALS

******************************************************************************
NOTE: Review Submittal Description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office.
(Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy, Air Force, and NASA projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy, Air Force, and NASA projects, or choose the second bracketed item for Army projects.

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.] [for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-01 Preconstruction Submittals

Installation Procedures; G[, [_____]]

Contractor's Geotechnical Consultant Qualification; G[, [_____]]

1.7 DELIVERY, STORAGE, AND HANDLING

Conform all delivery, storage, and handling of materials to the requirements specified herein. Develop and submit plans for the delivery, storage, and handling of piles. Submit plans at least 30 calendar days prior to delivery of piles to the job site.

1.7.1 Delivery and Storage

Stack piles during delivery and storage so that each pile is maintained in a straight position and is supported every 3 meters 10 feet or less along its length (ends inclusive). Do not stack piles more than 1.5 meters 5 feet
1.7.2 Handling

Lift piles to ensure that the maximum permissible curvature is not exceeded. Holes may be burned above the cutoff length for lifting piles into the leads. If there is evidence of pile damage during driving due to the holes, Contracting Officer may forbid the burning of holes. Do not damage piles when dragging piles across the ground or barge deck.

Inspect piles for excessive curvature and for damage before transporting them from the storage area to the driving area and immediately prior to placement in the driving leads. Curvature in the pile must be measured with the pile laying on a flat surface and is the distance between the pile at the mid-length of the pile and the flat surface. Straightness of the sections of steel pipe piles must conform to AWS D1.5M/D1.5, Section 3.5.1.1. Piles having excessive curvature will be rejected.

1.7.3 Damaged Piles

Inspect each pile for straightness and structural damage before transporting them to the project site and immediately prior to placement in the driving leads. Bring any damage to the attention of the Contracting Officer. Piles which are damaged during delivery, storage, or handling to the extent they are rendered unsuitable for the work, in the opinion of the Contracting Officer, will be rejected and removed from the project site, or may be repaired, if approved, at no cost to the Government.

Any pile damaged by reason of internal defects or by improper driving must be corrected by one of the following methods approved by the Engineer for the pile in question:

a. The pile is withdrawn, if practicable, and replaced by a new and, if necessary, longer pile.

b. One or more replacement piles are driven adjacent to the defective pile.

c. A Pile Dynamic Analysis and low integrity testing must be performed by the Contractor's Geotechnical Consultant to assess the structural integrity of the driven pile(s).

A pile driven below the specified butt elevation must be corrected by one of the following methods approved by the Engineer:

a. The pile is spliced (if approved).

b. A sufficient portion of the footing is extended down to properly embed the pile.

A pile driven out of its proper location or out of plumb as approved by the Engineer, must be corrected by one of the following methods approved by the engineer:

a. One or more replacement piles are driven next to the pile in question.

b. As directed by the structural engineer.
1.8 QUALITY CONTROL

1.8.1 Piles

Prepare and submit shop drawings for piles. Indicate placement of piles. Indicate location of special embedded or attached lifting devices, employment of pick-up points, support points other than pick-up points, and any other methods of pick-up. Perform quality control testing of the concrete infill in accordance with Section 03 30 00 CAST-IN-PLACE CONCRETE and 31 62 13.13 CAST-IN-PLACE CONCRETE PILES.

1.8.2 Quality Control Procedures

Submit the pile manufacturer's quality control procedures.

1.8.3 Installation Procedures

a. Submit information on the type of equipment proposed to be used, proposed methods of operation, pile driving plan including proposed sequence of driving, and details of all pile driving equipment and accessories. Submit descriptions of pile driving equipment, including hammers, power packs, driving helmets, hammer cushions, pile cushions, leads, extractors, jetting equipment, and preboring equipment at least 30 days prior to commencement of work.

b. Provide details of pile driving equipment and a Wave Equation Analysis of pile drivability for selection of the hammer along with a statement of driving procedures. Provide instructions and procedures on how the Contractor will perform Dynamic Pile Testing, Inspection and Monitoring of piles during installation and testing. The Wave Equation Analysis is to be completed by the Contractor's Geotechnical Consultant for each test pile location where different subsurface conditions exist and is to include the following information pertaining to the proposed pile driving equipment:

(1) Complete Pile and Driving Equipment Data Form, (which can be downloaded at: https://www.wbdg.org/ffc/dod/unified-facilities-guide-specifications-ufgs/forms-graphics-tables) for each proposed pile hammer and pile type combination.

(2) Copies of computer input and output sheets and graphs showing soil resistance versus blow count as well as maximum tension and compression stresses versus blow count. Analysis must be run at the estimated tip elevation as well as other required elevations to define maximum stress levels in the pile during driving.

c. Provide detailed procedures for conducting the dynamic pile load test and equipment to be used for conducting the load test. The detailed description must explain how specific information of pile performance will be evaluated.

1.8.4 Pile Load Test Supporting Data

Submit test set-up and procedures. Submit Jack calibration records, a testing arrangement description and diagram, and the proposed loading sequence.
PART 2   PRODUCTS

2.1 PILE REQUIREMENTS

**************************************************************************
NOTE: Delete sentence in brackets when test piles are not required. Government requires the Contractor to employ a Geotechnical Consultant to determine the calculated tip elevation and provide oversight of piling installation and testing.
**************************************************************************

[Order test piles [3] [_____] meters [10] [_____] feet longer in length than production piles.[ Drive the additional test pile length only when based upon the recommendation of the Contractor's Geotechnical Consultant and approved by the Contracting Officer.] The [Contractor's Geotechnical Consultant ][Contracting Officer ]will use test pile data to determine "calculated" pile tip elevation and necessary driving resistance. This information will be given to the Contractor no later than 7 days from receipt of complete test data. Use this list as the basis for ordering the piles. Do not order piles until list is provided by the[ Contractor's Geotechnical Consultant][ Contracting Officer].][ Provide test piles [1.5] [_____] meter [5] [_____] feet longer than the bid length.]

2.2 MATERIALS

2.2.1 Steel Pipe Piles

**************************************************************************
NOTE: Base selection of material on a comprehensive study of strength, cost, and corrosion resistance requirements.
**************************************************************************

ASTM A36/A36M and ASTM A572/A572M steels have the same corrosion resistance; ASTM A572/A572M can be obtained in yield strengths of 350 MPa through 448 MPa 42 ksi through 65 ksi; however, 350 MPa 50 ksi is the most available grade. ASTM A588/A588M has twice the atmospheric resistance of ASTM A36/A36M steel with 20 percent copper added.

1. Marine environment: Evaluate steel section piles exposed to seawater on the basis of application, location, degree of exposure, type of structure, and required service life. Where additional service life in the splash zone is required over that provided by conventional steel grades, ASTM A690/A690M or ASTM A588/A588M may be considered. ASTM A690/A690M steel 350 MPa 50 ksi (yield strength) has two to three times greater resistance to seawater splash zone corrosion than ordinary ASTM A36/A36M steel.

2. Seawater protection: To obtain reasonably long life for a structure immersed in seawater, provide steel piles with coatings, cathodic protection, or concrete encasement. Choice of protection is ultimately based on economics; usually, more than one type of protection will be used on a structure.
for most economical, adequate protection. The following criteria applies:

a. The use of coating systems for protection, such as coal tar epoxy, is usually low in initial cost but may require relatively frequent maintenance; also, it is extremely difficult to renew in the tidal zone between mean tide and low tide.

b. Cathodic protection is low in initial cost and low in maintenance. It can be of value only where the piles are continually wet, as in the submerged zone.

c. Concrete encasement or metal jacketing is relatively expensive in initial cost but requires no maintenance if properly constructed. When concrete encasement is to be continuously submerged in water with low resistivity, it must (1) extend below the mudline, or (2) be coated to electrochemically insulate the concrete from the steel.

Use high-strength steel only when design analyses show that the use is the most economical solution or to increase the design life if approved by the Contractor's Geotechnical Consultant.

ASTM A27/A27M cast steel is used for some commercially available pile points.

----------------------------------------------------------------------------------

ASTM A252, [Grade 3] [____]. Provide test piles identical to those used elsewhere in the project. Provide steel pipe piles of the shape, size and sections shown in the drawings. Pipe piles must be either seamless pipe or full penetration welded with straight or spiral seams. Pipe must be welded in a manner that welding will not crack or fail when the pile is subjected to its intended use, including during installation. The weld seam of each length of pipe must be tested for acceptance by ultrasonic testing in accordance with the provisions for Nondestructive Electric Test of Weld Seam of ASTM A53/A53M.

2.2.2 Pile Splices

Submit detail drawings of shop and field pile splices prior to fabrication. Provide ASTM A148/A148M Grade 90-60 proprietary pile splicer sleeves or provide ASTM A109/A109M or ASTM A36/A36M backing rings to prevent weld blow out during weld process. Submit procedure for insufficient pile length.

2.2.3 Pile Shoes

----------------------------------------------------------------------------------

NOTE: Outside flange open end cutting shoe may be allowed based on specific project needs such as drilling inside the pipe pile or rock socketing etc. Maximum friction may not be mobilized when using outside flange cutting shoe. Closed end cutting shoe may also be used based on project needs such as pipe pile closure, breaking through
Submit details about pile shoes used, if any. ASTM A148/A148M Grade 90/60 for cast steel cutting shoe. Submit Certificates of compliance certifying that materials meet the requirements specified herein. Provide [inside flange open end] [_____] cutting shoe on all pipe piles. Perform all welding in accordance with the requirements for pile splices.

2.2.4 Pile Caps and Pile Inserts

Provide ASTM A572/A572M Grade 50 [_____] plates for pile caps and pile inserts. Pile caps must conform to details shown.

2.2.5 Fabrication

Fabrication must conform to the requirements shown and as specified herein and in Section 05 50 13 MISCELLANEOUS METAL FABRICATIONS. Submit steel plant certification.

2.2.5.1 Pile Splices

Perform all welding in accordance with the requirements for shield metal arc welding of AWS D1.1/D1.1M. Submit welding procedure for shop splices and verification of welder certification and qualifications. Make no more than [one] [_____] field splice per [_____] [25 m 80 feet] of pile, unless directed by the Contracting Officer. Fabrication drawings must show all shop splices.

Only use welders qualified by tests prescribed by AWS D1.1/D1.1M.

Splice sections of pipe with an approved full penetration butt or single bevel-groove weld. Both pipe ends must be square cut and seated to bear. Use an approved jig or alignment device during welding to maintain the required straightness of pipe. Field splices must be minimized or eliminated if possible. [No splices will be allowed in the top [7.6] [_____] meters [25] [_____] feet of pile to eliminate coating vulnerability.] For splices made during pile installation, rigid frame pile leads may be used as a jig in a manner approved by the Contracting Officer.

See paragraph FIELD QUALITY CONTROL for requirements.

2.2.5.2 Pile Caps

Ground the top of piles sufficiently smooth to provide a good welding surface for structural-shape pile caps.

2.2.5.3 Fusion-Bonded Epoxy Coating

Pipe piles [_____] must have fusion-bonded epoxy coating applied from the cutoff elevation to [4 meters 14-feet below mean low water] [_____].
Coating of steel surfaces with an electrostatically applied fusion-bonded epoxy must be in accordance with ASTM A972/A972M. Submit supporting product data and details for fusion-bonded epoxy coating.

2.2.6 Concrete Infill

Concrete infill must conform to the requirements as identified in the Sections 03 30 00 CAST-IN-PLACE CONCRETE and 31 62 13.13 CAST-IN-PLACE CONCRETE PILES. Submit a concrete mix design at least 30 calendar days before concrete is placed, for each type of concrete used for the piles. Material certifications and test data for aggregates, silica fume, admixtures, cement, fly ash and pozzolans must be provided. Submit concrete compressive strength test results.

2.3 PILE DRIVING EQUIPMENT

Select the proposed pile driving equipment, including hammers and other required items, and submit complete descriptions of the proposed equipment in accordance with paragraph SUBMITTALS. Final approval of the proposed equipment is subject to the satisfactory completion and approval of pile tests. Submit pile test plan at least 30 calendar days prior to installing any test piles. Approval of the plan will not relieve the Contractor of the responsibility for structural and operational adequacies of the testing system. Changes in the selected pile driving equipment will not be allowed after the equipment has been approved except as directed. No additional contract time will be allowed for Contractor proposed changes in the equipment.

2.3.1 Pile Driving Hammers

**************************************************************************

NOTE: When specifying the minimum driving energy, make an allowance for reduced penetration caused by shock absorption of pile helmets. Enter the appropriate minimum allowable driving energy for the project. Minimum allowable driving energy must be not less than the following:

<table>
<thead>
<tr>
<th>Design Bearing Pile Capacity for Single Pile (Kilonewton) (Kips)</th>
<th>Minimum Rated Hammer Driving Energy (Joules) (Foot-Pounds)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Up to 534 120</td>
<td>20,350 15,000</td>
</tr>
<tr>
<td>Up to 534 120</td>
<td>25,750 19,000</td>
</tr>
</tbody>
</table>

The minimum and maximum hammer energies required may be determined from experience on other jobs or by a series of wave equation analyses.

**************************************************************************

Provide impact or vibratory type pile driving hammers.

2.3.1.1 Impact Hammers

Provide air, hydraulic or diesel-powered impact pile hammers of the single-acting, double-acting, or differential-acting type. The size or capacity of hammers must be as recommended by the hammer manufacturer for
the total pile mass weight and the character of the soil formation to be penetrated.][ The rated driving energy of hammers is limited to a minimum of [20,350] [25,750] joules [15,000] [19,000] foot-pounds.][ Hammers must be capable of, and so demonstrated during the development of refusal criteria,] hard driving in excess of 20 blows per 25 mm one inch.][ Provide boiler, compressor, or engine capacity sufficient to operate hammers continuously at the full rated speed. Hammers must have a gage to monitor hammer bounce chamber pressure for diesel hammers or pressure at the hammer for air hammers. This gage must be operational during the driving of piles and be mounted in an accessible location for monitoring by the Contractor and the Contracting Officer.[ Provide two spare operational bounce chamber read out units on site.][ Provide bounce chamber pressure gage correction tables and charts for the type and length of hose to be used with the pressure gage to the Contracting Officer.][ Hydraulic hammers must be equipped with a system for measurement of ram energy. The system must be in good working order and the results must be easily and immediately available to the Engineer. Install an energy monitor on the hydraulic hammers and record readings every 250 mm 10 inches of pile installation.] Use wave equation analysis to verify that the hammer will develop stresses within acceptable limits in the piles. Position a pile cap or drive cap between the pile and hammer. Place hammer cushion or cap block between ram and the pile cap or drive cap. Hammer cushion or cap block must have consistent elastic properties, minimize energy absorption, and transmit hammer energy uniformly and consistently during the entire driving period.[ Do not use a pile cushion block.][ In accordance with paragraph SUBMITTALS, submit the following information for each impact hammer proposed:

a. Make and model.

b. Ram mass (kilograms) weight (pounds).

c. Anvil mass (kilograms) weight (pounds).

d. Rated stroke millimeters inches.

e. Rated energy range joules foot-pounds.

f. Rated speed (blows per minute).

g. Air pressure, hammer, and boiler [and] [or] compressor MPa psi.

h. Rated bounce chamber pressure curves or charts, including pressure correction chart for type and length of hose used with pressure gage bar pounds per square inch.

i. Pile driving cap, make, and mass (kilograms) weight (pounds).

j. Cushion block dimensions and material type.

k. Power pack description.

2.3.1.2 Vibratory Hammers

[The use of vibratory hammers is dependent upon satisfactory driving and load testing of piles.][ Final approval of the proposed hammer and other driving equipment is subject to the satisfactory completion and approval of the pile tests.][ The size or capacity of hammers must be as recommended by the hammer manufacturer for the total pile mass weight and the character
of the soil formation to be penetrated.) The hammer must provide for maintaining a rigid connection between the hammer and the pile. In accordance with paragraph SUBMITTALS, submit the following information for each vibratory hammer proposed:

- Make and model.
- Eccentric moment \( \text{newton-meters} \) \( \text{inch-pounds} \).
- Dynamic force \( \text{kilonewtons} \) \( \text{tons} \).
- Steady state frequency or frequency range \( \text{cycles per minute} \).
- Vibrating mass \( \text{kilonewtons} \) weight \( \text{pounds} \).
- Amplitude \( \text{millimeters} \) \( \text{inches} \).
- Maximum pull capacity \( \text{metric tons} \) \( \text{tons} \).
- Non-vibrating mass \( \text{kilonewtons} \) weight \( \text{pounds} \).
- Power pack description.

2.3.2 Pile Driving Leads

**************************************************************************
NOTE: Suspended leads should not be used on jobs where accurate pile placement and alignment are required.

Vibratory hammers are typically operated free hanging without leads unless accurate placement and alignment of the piles are required.
**************************************************************************

Support and guide hammers with fixed extended leads or fixed underhung leads. For driving battered piles, support and guide impact hammers with three-axis, fixed-extended leads capable of 1 H and 2-1/2 V before and after batter and 1 H on 6 V side batter, with 30-degree rotation each side of an axis running along the center line of rotation of the crane through the center line of the leads.] Provide two intermediate supports for the pile in the leads to reduce the unbraced length of the pile during driving and pulling.

2.3.3 Pile Extractors

Pile extractors may be vibratory or impact pile driving hammers. Impact hammers are required for pulling piles not extractable with vibratory hammers.

[2.3.4 Jetting Equipment

**************************************************************************
NOTE: Do not use jetting on piles carrying significant tension loads, lateral loads, or compression loads developed predominantly from skin friction.
**************************************************************************
Provide jetting equipment with not less than two removable or fixed jets of the water or combination air-water type. Water jets must be designed so that the discharge volume and pressure are sufficient to freely erode the material immediately under and adjacent to piles without resulting in pile drift. Submit jetting equipment including plant description, volume of water and pressure, and size and length of hoses and pipes in accordance with paragraph SUBMITTALS.

PART 3 EXECUTION

3.1 PRELIMINARY WORK

3.1.1 Wave Equation Analysis of Pile Drivability

a. Prior to driving any pile, submit a pile Wave Equation Analysis, performed by Contractor's Geotechnical Consultant, for each size pile and distinct subsurface profile condition. These analyses must take into account the proposed hammer assembly, pile cap block and cushion characteristics, the pile properties and estimated lengths and the soil properties anticipated to be encountered throughout the installed pile length based on static capacity analysis with consideration of driving gain/loss factors. Only one specific model of pile hammer may be used for each pile type and capacity.

b. Demonstrate using the Wave Equation Analysis that the piles will not be damaged during driving, indicate that the driving stresses will be maintained within the limits below and indicate the blow count necessary to achieve the required ultimate static pile capacities.

   Allowable Driving Stresses

   Steel Piles

   Compression  -  0.9 fy
   Tension      -  0.9 fy

   Where fy is yield strength of steel

c. Perform a refined Wave Equation Analysis upon completion of the dynamic and static testing programs outlined in this specification section, taking into consideration the evaluated capacities, gain/loss factors and recommended production pile lengths. Develop production pile driving criteria based on the results of the refined Wave Equation Evaluations.

d. All pile driving equipment provided by the Contractor will be subject to the approval of the Contractor's Geotechnical Consultant. Complete the attached pile and driving equipment data form, including hammer information, in full as part of the submittal of the results of the Wave Equation Analyses.

e. Pay for the cost of performing the Wave Equation Analyses and include in the base bid.

3.1.2 Order List

Submit to the Contracting Officer for approval, an itemized quantities list for piles prior to placing the order with the supplier. Indicate the pile lengths required at each location as shown on the plans and the
corresponding ordered length of each pile in the list. [Complete load testing and refined wave equation analysis and submit to Government for review and approval prior to submission of an order list.]

3.2 INSTALLATION

Inspect piles when delivered and when in the leads immediately before driving. Cut piles at cutoff grade by an approved method. Where cutoff is below existing ground or mudline elevation, complete excavation, sheeting, and dewatering before driving pile to driving criteria.

3.2.1 Lengths of Production Piles

The estimated quantities of piles are given for bidding purposes only. Drive piles to [or below "calculated"] [indicated] tip elevation [to reach a driving resistance established by the wave equation analyses (WEAP) in accordance with the schedule which the Contractor's Geotechnical Consultant will prepare from the test-pile driving data].

3.2.2 Pile Driving Records

**************************************************************************
NOTE: Omit reference to load test when not required in project. Omit reference to test piles and "calculated tip elevation" when test piles are not driven. Where special or unusual soil conditions are expected, consultation with the Contracting Officer's Technical Representative (Geotechnical Branch) regarding special engineering supervision of driving, testing, recording and analysis of data for project may be useful.

The Specifier must attach the specifications pile driving log graphic (for all pile driving projects) and the pile driving equipment data form (for projects using PDA) to the end of this specification section.
**************************************************************************

Keep a complete and accurate record of each pile driven. Indicate the pile location, deviations from pile location, cross section shape and dimensions, original length, ground elevation, tip elevation, cut-off elevations, [batter alignment,] number of blows required for each 300 mm [foot] of penetration and number of blows for the last 150 mm [6 inches] penetration or fraction thereof [as required] for the "calculated" [driving resistance]. Include in the record the beginning and ending times of each operation during driving of pile, type and size of hammer used, rate of operation, stroke or equivalent stroke for diesel hammer, type of driving helmet, and type and dimension of hammer cushion (capblock) and pile cushion used. Record retap data and unusual occurrences during pile driving such as redriving, heaving, weaving, splicing, obstructions, [jetting,] and any driving interruptions. [Install an energy monitor on the hammers and record readings during pile installation.] A preprinted pile driving log for recording pile driving data [and pile driving equipment data form], which can be downloaded at: https://www.wbdg.org/ffc/dod/unified-facilities-guide-specifications-ufgs/forms-graphics-tables.
3.2.3 Pile Placement and Tolerances in Driving

Develop and submit a pile placement plan which shows the installation sequence and the methods proposed for controlling the location and alignment of piles. Submit pile placement plans at least 30 calendar days prior to delivery of piles to the job site. Complete all foundation preparation in the area prior to the placement of piles for driving. Accurately place piles in the correct location and alignments, both laterally and longitudinally, and to the vertical or batter lines indicated. Establish a permanent base line to provide for inspection of pile placement by the Contracting Officer during pile driving operations prior to driving production piles and maintain during the installation of the production piles.

A final lateral deviation from the correct location at the cutoff elevation of not more than 76 mm 3 inches will be permitted for vertical and battered piles. Manipulation of piles will not be permitted. A variation of not more than 6 mm per 300 mm 0.25 inch per foot of pile length from the vertical for vertical piles nor more than 12 mm per 300 mm 0.50 inch per foot of pile length from the required angle for batter piles will be permitted. In addition to complying with the tolerances stated herein, the clear distance between the heads of piles and the edges of caps must be not less than 150 mm 6 inches. With prior approval of the Contracting Officer, the Contractor may provide additional concrete and reinforcement to maintain the required minimum clear distance. Redesign of pile caps or additional work required due to improper location of piles is the responsibility of the Contractor. A vertical deviation of not more than 25 mm one inch from the correct cutoff elevations shown is permitted. Inspect piles for heave. Redrive heaved piles to the required pile driving criteria. Maintain the correct relative position of all piles by the use of templates or by other approved means. Piles damaged or not located properly or exceeding the maximum limits for lateral and vertical deviation, or variation in alignment must be pulled and new piles redriven, or provide additional piles, at a location directed at no additional cost to the Government.

3.2.3.1 Survey Data

After the driving of each pile group is complete and before superimposed concrete is placed, provide the Contracting Officer with an as-driven survey showing actual location and top elevation of each pile. Submit the as-driven survey showing actual location and top elevation of each [production pile] [test pile] within 7 [_____] calendar days of completing the pile installation. Do not proceed with placing concrete until the Contracting Officer has reviewed the survey and verified the safe load for the pile group driven. Present a survey in such form that it gives deviation from plan location in two perpendicular directions and elevations of each pile to nearest 13 mm half inch. Survey must be prepared and certified by a land surveyor licensed in [______].

3.2.4 Pile Penetration Criteria

The controlling driving resistance for production piles will be determined by the Contractor's Geotechnical Consultant. The required initial driving criteria and restrike will be established subsequent to the analysis of pile tests as specified in paragraph PILE TESTS.
3.2.5 Pile Length Markings

Mark each pile prior to driving with horizontal lines at 305 mm one foot intervals. Mark the interval number on pile every 1.52 m 5 feet from pile tip.

3.2.6 Pile Driving

**************************************************************************

NOTE: Delete bracketed option for foundation excavation when not required. Delete items in brackets dealing with tip elevation and driving resistance when test piles or load tests are not used. Delete item in brackets regarding predrilling or jetting when procedure is not used. If needed, insert maximum hammer energy for no tip resistance. This can be determined by comparing tensile stresses in pile resulting from a Wave Equation Analysis with effective prestress in pile.

**************************************************************************

Notify Contracting Officer 10 days prior to driving of [test] piles [and load test]. [ Submit records for test piles] [and ] [data for load tests]. [The Contractor's Geotechnical Consultant will determine the terminal driving criteria based on results of [dynamic pile driving tests at the end of drive or restrike] [static load tests] [wave equation analysis].] [Stop foundation excavation at 300 mm one foot above foundation grade before piles are driven. Do not drive piles within 30 meter 100 feet of concrete less than 7 days old. Complete excavation to lines and grades shown when pile driving is completed.] Drive piles to [the terminal driving criteria] [or below "calculated"] [indicated tip elevation] [to reach a driving resistance established by the [dynamic pile driving tests at the end of drive or restrike] [static load tests] [wave equation analyses (WEAP)] in accordance with the schedule which the [Contractor's Geotechnical Consultant] [Contracting Officer] will prepare from the test-pile driving data. During initial driving and until pile tip has penetrated beyond layers of very soft soil [or below bottom of predrilled or prejetted holes], use a reduced driving energy of the hammer as required to prevent pile damage. Refusal criteria will be established by the Contracting Officer. If a pile fails to reach ["calculated"] [indicated] tip elevation, [or if a pile reaches ["calculated"] tip elevation without reaching required driving resistance,] notify Contracting Officer and perform corrective measures as directed. Provide hearing protection when noise levels exceed 140 dB. Do not handle or move piles or pile sections in any manner that would result in cracking or permanent damage to the concrete or to the grout surrounding the prestressing cables. Piles may be driven without pile guides or leads providing a hammer guide frame is used to keep the pile and hammer in alignment.

3.2.7 Protection of Piles

**************************************************************************

NOTE: Delete references to batter piles when not applicable to the project.

**************************************************************************

Take care to avoid damage to piles during handling, placing pile in leads, and during pile driving operations. Support piles laterally during driving, but allow rotation in leads. [Where pile or projecting
reinforcement orientation is essential, take precautionary measures to maintain the orientation during driving. Take special care in supporting battered piles to prevent excessive bending stresses in pile. Maintain axial alignment of pile hammer with that of the pile. If the Contractor elects to use a pile head with projecting strands or mild steel reinforcement, prevent direct impact forces from being transmitted through the reinforcement, by using a special driving head.

3.2.8 Rejected Piles

Withdraw piles damaged or impaired for use during handling or driving, mislocated, or driven out of alignment beyond the maximum tolerance. Replace with new piles or cut-off and abandon damaged or impaired piles and drive new piles as directed. Remove excess cut-off from piles and unacceptable piles from the work site. Perform all work in connection with withdrawing and removing rejected piles from the site at no additional cost to the Government.

3.2.8.1 Obstructions

If a pile encounters an underground obstruction within 5 feet of the ground surface of such size as to prevent driving the pile to the required driving criteria, the pile must be pulled or cut off at no cost to the Government. If such an obstruction is encountered more than 5 feet below the ground surface, the pile must be cut off and paid for as if a completed pile. In either event, a replacement pile must be installed at a location indicated by the Contracting Officer and paid for as a completed pile.

3.2.8.2 Splicing Piles

************************************************************************************************
NOTE: Splicing of piles normally should not be permitted except where extremely long or heavy piles are required. If splices are permitted, drawings should indicate splice details. (See PCI standard drawings for typical splice details).
************************************************************************************************

[Splicing of piles is not permitted.] [Make splices as indicated. Splices must be capable of developing the full strength of the member in compression, tension, shear, and bending. Submit detail drawings of splices and design calculations demonstrating the strength of the splice for approval.]

3.2.9 Jetting of Piles

************************************************************************************************
NOTE: Jetting should generally not be permitted for piles:

1. Dependent on side friction in fine-grained low permeability soils (high clay or silt content) where considerable time is required for the soil to reconsolidate around the piles.

2. Subject to uplift or lateral forces.

3. Adjacent to existing structures.

************************************************************************************************
4. In closely spaced clusters unless the load capacity is confirmed by test.

Water jets will [not] be permitted. [Use jetting to assist driving piles through strata that cannot be penetrated practicably by use of the hammer alone. [Restrict driving to a static weight while water is being injected to prevent inducing tensile stresses in the piles which damage the concrete.] Discontinue jetting and resume hammer driving after the penetration of the strata requiring jetting has been accomplished.] [Discontinue jetting when the pile tip is approximately 1.5 m 5 feet above the [calculated] [indicated] pile tip elevation. Drive pile the final 1.5 m 5 feet of penetration or more to meet the required driving criteria.] [Take adequate measures for collecting and disposing of runoff water.] [Jetting method and equipment must be approved by the Contracting Officer prior to commencing jetting operation.] Before starting final driving, firmly seat piles in place by application of a number of reduced energy hammer blows. [Employ measures, including use of a silt curtain, to contain turbid water created by jetting piles.]

3.2.10 Predrilling of Piles

NOTE: Predrilling should generally not be permitted for piles:

1. Dependent on side friction in fine-grained low permeability soils (high clay or silt content) where considerable time is required for the soil to reconsolidate around the piles.

2. Subject to uplift or lateral forces.

3. Located in cohesionless soils.

4. In closely spaced clusters unless the load capacity is confirmed by test.

Predrilling to remove soil or other material representing the bulk of the volume of the pile to be driven [will not be permitted] [will be provided]. [The diameter of the hole must not exceed two-thirds the width of the pile.] [Predrill only to a depth of [_____] meters feet below cut-off elevation prior to setting piles.] [Discontinue drilling when the pile tip is approximately 1.5 m 5 feet above the [calculated] [indicated] pile tip elevation. Drive pile the final 1.5 m 5 feet of penetration or more to meet the required driving criteria.]

3.2.10.1 Heaved Piles

When driving piles in clusters or under conditions of relatively close spacing, perform observations to detect heave of adjacent piles. Backdrive heaved piles to original to the required [depth of penetration] [tip elevation] [refusal blow count] as directed by the Contractor’s Geotechnical Consultant, after reviewing the heave data, without additional cost to the Government.
3.2.10.2 Pulled Piles

Pull and replace piles damaged or impaired for use during driving with new piles, or cut off and abandon and drive new piles as directed without additional cost to the Government. The Contracting Officer may require that any pile be pulled for inspection. Redrive piles pulled as directed and found to be in suitable condition at another location as directed. Replace piles pulled as directed and found to be damaged with new piles at the Contractor's expense.

3.2.10.3 Long Piles

Provide pile driving rig with rigid supports so that leads remain accurately aligned. Where a high degree of accuracy is required, erect templates or guide frames at or close to the ground or water surface.

3.2.10.4 Welding

AWS D1.1/D1.1M. Welding of splices must conform to the requirements of Section 05 50 14 STRUCTURAL METAL FABRICATIONS. Shop and field welding, qualification of welding procedures, welders, and welding operators must be in accordance with AWS D1.1/D1.1M.

[3.2.11 Protection of Existing Structures

**************************************************************************

NOTE: Include this paragraph only when protection of existing structures from pile driving activities is required.

The designer must indicate on the drawings all structures and facilities for which protection is required. The designer must also provide a project specific document that details design criteria, requirements for preconstruction condition surveys, post construction condition surveys, geotechnical instrumentation to measure ground movements and any other requirements.

Add any additional requirements as necessary.

**************************************************************************

Mitigate impact on existing facilities due to pile driving activities in accordance with the [project specific document] [______].

][3.2.12 Concrete Infill

**************************************************************************

NOTE: Include this paragraph only when concrete infill is required.

Add any additional requirements as necessary.

**************************************************************************

Mix and place concrete infill in accordance with Section 03 30 00 CAST-IN-PLACE CONCRETE and Section 31 62 13.13 CAST-IN-PLACE CONCRETE PILES. Concrete shall be placed to the elevations as shown on the [contract documents] [Drawings] [plans].
3.3 FIELD QUALITY CONTROL

3.3.1 Test Piles

**************************************************************************
NOTE: Select the second bracketed option when soil conditions dictate the use of a test pile longer than production piles. The ordered pile length for test piles should be 1.5 m 5 feet longer than ordered length for production piles to allow additional penetration if driving conditions dictate. Indicate location and number (if required) of test piles on plans, or list appropriate soil boring test hole numbers.
**************************************************************************

[Use test piles of type, and drive as specified for piling elsewhere in this section.][ Order test piles [_____] meters feet longer in length than production piles. Drive the additional test pile length only at the direction of the Contracting Officer.] The [Contractor's Geotechnical Consultant] [Contracting Officer] will use test pile data to determine "calculated" pile tip elevation or necessary driving criteria. Drive test piles [at the locations indicated] [in vicinity of soil boring test holes Nos. [_____,] [_____,] and [_____.]]. Drive test piles to [indicated tip elevation] [indicated bidding lengths] [required driving criteria]. Use test piles, if located properly and offering adequate driving resistance in finished work.[ Pre-drilling or jetting is permitted only when test piles clearly establish validity of its use, or as directed by the Contracting Officer.][ Provide and operate a pile driving analyzer as specified in paragraph DYNAMIC PILE ANALYSIS during the driving of each test pile. Modify driving as required based upon recommendation of [Contracting Officer] [Contractor's Geotechnical Consultant and approval of the Contracting Officer].]

3.3.1.1 Dynamic Pile Analysis

Dynamic testing provides supplemental information for evaluating pile integrity, hammer and drive system performance, assess pile installation driving stresses, and pile capacities. Perform dynamic testing on [_____] percent of the [test] piles during the full length of the pile driving and during restrike a minimum of [_____] days after initial driving. Dynamic pile testing must also be performed on [_____] production piles as chosen by the Contracting Officer. Use [test] piles of type as specified elsewhere in this section. Provide equipment to obtain dynamic measurements, record, reduce and display its data that meet the requirements of ASTM D4945. The equipment must have been calibrated within [6] [_____] months prior to the start of the testing operations and thereafter throughout the contract duration. Drive [test] piles at the locations indicated or at the locations selected by the Contracting Officer. Employ an independent inspection firm, hereinafter referred to as the "Contractor's Geotechnical Consultant", experienced in the pile driving process[, monitoring of test pile installation,] and in the use of the Pile Driving Analyzer and its related equipment. Submit a performance report summarizing dynamic test results for [test] piles within [7] [_____] calendar days of completing field work.[ For production piles, submit a performance report within one day of testing. Submit a typed report summarizing the results of dynamic testing of production piles on a monthly basis.] Perform dynamic pile analysis as follows:
3.3.1.2 Pile Analyzing

[_____] working days prior to driving the [test] piles, submit the pile and complete driving equipment data to the Contracting Officer. The Contractor's Geotechnical Consultant must use the submitted information to perform wave equation analyses and must prepare a summary report of the wave equation results. The wave equation analysis using GRLWEAP software by Pile Dynamics, Inc. or equivalent must be used to assess the ability of the proposed driving system to install the pile to the required capacity and desired penetration depth within the allowable driving stresses. Approval of the proposed driving system by the Contracting Officer must be based upon the wave equation analyses indicating that the proposed driving system can develop a pile capacity of [_____] kN kips at a driving resistance not greater than [_____] mm/blow blows per inch within allowable driving stress limits. The hammer must also be sized or adjustable such that the penetration per blow at the required ultimate capacity does not exceed 12 mm 0.5 inches.

3.3.1.3 Pile Drivability

Perform each dynamic pile analysis in two steps. The first step is to check the hammer, pile and soil performance, and to determine the suitability of the proposed hammer for the size, length and type of pile being installed for the soil types encountered as the piles are driven. This initial monitoring must determine whether pre-augering or jetting is appropriate, efficiency of the hammer relative to specified efficiency, effectiveness of cushion, level of compressive and tensile stress in pile and extent/location of any pile damage caused by the initial driving. With each blow of the pile, record the information listed below electronically and analyze the information using the Pile Driving Analyzer:

a. Blow number
b. Blow rate per minute and stroke.
c. Input and reflected values of force and velocity.
d. Value of upward and downward traveling force wave with time.
e. Maximum and final transferred energy to pile, hammer system efficiency.
f. Maximum compressive stress, velocity, acceleration and displacement.
g. Maximum tensile stress in pile.
h. Pile structural integrity, damage detection, extent and location.
i. Bearing capacity of pile by Case method.

If the pile, hammer and soil performance evaluation recommends changes to the hammer stroke, pile cushioning, augering or any other aspect for the pile driving operation, incorporate these changes into production pile driving in an effort to control excessive stresses and pile damage. Replace test piles damaged or broken during installation, incorporating driving modifications as determined by the Contractor's Geotechnical Consultant and reviewed and approved by the Contracting Officer. Repeat this procedure until allowable tensile and compressive stresses are achieved in the pile and pile damage is minimized. Subject selected initial driving records to rigorous computer analysis by the Case Pile Wave
Analysis Program (CAPWAP) for determination of resistance distribution, soil resistance and properties, and estimation of anticipated gain/loss factors.

3.3.1.4 CAPWAP

Signal matching analysis by CAPWAP software of the dynamic pile testing data must be performed on data obtained from the end of initial driving and the beginning of restrike of all control piles. CAPWAP analyses must be performed by an engineer who has achieved Advanced Level or better on the PDI / PDCA Dynamic Measurement and Analysis Proficiency Test for Providers of PDA Testing Services.

Upon completion of [test] pile driving, allow the piles to set-up for at least [72 hours] [____ days]. After evaluation of pile, hammer and soil performance by the Contractor's Geotechnical Consultant, the second step of the dynamic pile analysis may proceed. This portion of the evaluation requires striking the set-up piles a minimum of 20-50 times, or as directed by the Contractor's Geotechnical Consultant using the same hammer which was used for the [test] pile driving and which will be used for production pile driving. "Warm up" the hammer and make it optimally ready prior to restriking, in order to avoid capacity losses during evaluation of restrike data. Apply maximum hammer energy during restrike in order to fully mobilize the soil resistance. However, exercise care so as to not overstress the pile. In addition to those items listed above, selected restrike driving records (as directed by the Contractor's Geotechnical Consultant are to be subjected to rigorous computer analysis by the Case Pile Wave Analysis Program (CAPWAP) for determination of resistance distribution, soil resistance and properties, and plot of applied load vs. average pile displacement based on the calculated soil properties.

3.3.1.5 Dynamic Load Test Reporting

a. Upon satisfactory completion of each dynamic load test, submit [a minimum of three copies of] a Pile Performance Report for the Contractor by the Contractor's Geotechnical Consultant. The submittal must be prepared and sealed by a Professional Engineer registered in [____].

b. The report for the Dynamic Pile Analysis must contain the following information:

1. Capacity of pile from Case Pile Wave Analysis Program (CAPWAP). Information resulting from analysis of a selected restrike blow.

2. Maximum and final transferred energy, hammer system efficiency during pile installation.

3. Maximum compressive stress, velocity, acceleration and displacement.

5. Pile structural integrity, damage detection, extent and location.

7. Input and reflection values of force and velocity, upward and downward traveling force wave with time.
(8) Pile skin friction and toe resistance distribution.

(9) Maximum energy transferred to pile.

c. The maximum allowable pile design load must be proposed by the Contractor's Geotechnical Consultant based upon the results of a satisfactory pile load test conducted on a pile driven as specified herein and must include the effects of load transfer to the soil above the foundation stratum.

Use either a Model 8G or PAX Pile Driving Analyzer as manufactured by Pile Dynamics, Inc., of Cleveland Ohio or approved equivalent, for dynamic testing of the pile hammer and for dynamic load testing of the test pile. All equipment necessary for the dynamic monitoring such as sensors, cables or wireless transmitters, must be furnished by the Contractor's Geotechnical Consultant. The equipment must conform to the requirements of ASTM D4945.

Pay for all services of the Contractor's Geotechnical Consultant. The Contractor's Geotechnical Consultant must be available throughout the pile driving operation to consult with the Contracting Officer when required by the Contracting Officer. The cost of changes in the Contractor's procedure, as required by evaluation of the results of the Pile Driving Analysis, will be at the Contractor's expense.

3.3.2 Static Load Tests

**************************************************************************

NOTE: If pile load tests are required and approved by the Contracting Officer, specify number and location of piles. Select method of load test. In ASTM D1143/D1143M, permit anchor piles only if approved by the Contracting Officer's Technical Representative (Geotechnical Branch). Insert figure kN \text{ kips} \ corresponding to 200 percent of the design load. Select appropriate acceptance criteria. The offset method (first option) is usually recommended.

**************************************************************************

Perform compressive load tests on [_____] test piles in accordance with ASTM D1143/D1143M (standard loading procedure) as modified herein. [ Allow a minimum of [72 hours] [_____] days following final test pile driving for pile set-up prior to load testing.] [ Do not use anchor piles.] Provide apparatus for applying vertical loads as required by method, using load from weighted box or platform[ or reaction frame attached to sufficient uplift piles to safely take required load] applied to pile by hydraulic jack. Increase load in increments until rapid progressive settlement takes place or until application of total compressive load of [_____] kN \text{ kips} for compressive load tests. Consider load test satisfactory when [after one hour at full test load gross settlement of pile butt is not greater than gross elastic pile compression plus 4 mm 0.15 inch plus one percent of pile tip diameter or width in [_____] mm inches,] [slope of gross load-settlement curve under full test load does not exceed 1.5 mm per metric ton 0.05 inches per ton,] [net settlement after removal of test load does not exceed 19 mm 3/4 inch]. Perform load tests at locations [as proposed by the Contractor's Geotechnical Consultant and] as directed by the Contracting Officer. Additional load tests, at Government expense, may be required by the Contracting Officer. Perform the loading, testing, and
recording and analysis under the direct supervision of a Registered Professional Engineer, registered in the state of project location, and provided and paid for by the Contractor.

3.3.2.1 Safe Design Capacity

Determine the safe design capacity of a test pile as determined from the results of load tests according to UFC 3-220-01.

3.3.3 Tensile Load Test

Perform tensile load tests on [_____] test piles in accordance with ASTM D3689, as modified [and] in paragraph LOAD TESTS. Apply a tensile load of [_____] kN kips to each tensile load test pile. In performing the tension load test, apply the ultimate load equal to one and one-half times the safe tension capacity, and employ the Standard Loading Procedure.

Perform dynamic measurements on [_____] piles designated as dynamic test piles in accordance with ASTM D4945 during driving. During easy driving, ensure that damaging tension stresses do not develop in the pile. Signal matching must be performed by the Contractor's Geotechnical Consultant on representative data collected at the end of the initial driving and at the beginning of all restrike events. Additional signal matching analysis must be performed as determined by the Engineer.

3.3.4 Lateral Load Test

Perform lateral load tests on [_____] piles in accordance with ASTM D3966/D3966M, as modified [and] in paragraph LOAD TESTS. Lateral load tests must consist of jacking two piles apart with a hydraulic jack, with one pile serving as the reaction pile for the other. Apply a lateral load of [_____] kN kips to each pair of lateral load test piles. Record required movement readings for each pile.

3.3.5 Pile Records

******************************************************************************
NOTE: Omit reference to load test when not required in project. Omit reference to test piles and "calculated tip elevation" when test piles are not driven. Where special or unusual soil conditions are expected, consultation with the Contracting Officer's Technical Representative (Geotechnical Branch) regarding special engineering supervision of driving, testing, recording and analysis of data for project may be useful.
******************************************************************************

******************************************************************************
NOTE: The Specifier must attach the specifications pile driving log graphic (for all pile driving projects) and the pile driving equipment data form (for projects using PDA) to the end of this specification section.
******************************************************************************

Keep a complete and accurate record of each pile driven. Indicate the pile location, deviations from pile location, cross section shape and dimensions, original length, ground elevation, tip elevation, cut-off
elevations, [batter alignment,] number of blows required for each 300 mm foot of penetration and number of blows for the last 150 mm 6 inches penetration or fraction thereof [as required] for the "calculated" [driving resistance]. Include in the record the beginning and ending times of each operation during driving of pile, type and size of hammer used, rate of operation, stroke or equivalent stroke for diesel hammer, type of driving helmet, and type and dimension of hammer cushion (capblock) and pile cushion used. Record retap data and unusual occurrences during pile driving such as redriving, heaving, weaving, splicing, obstructions, [jetting,] and any driving interruptions.[ Install an energy monitor on the hammers and record readings every 250 mm 10 inches of pile installation.] Submit to the Contracting Officer complete and accurate test and production pile driving records within 15 calendar days after completion of driving. Make pile driving records available to the Contracting Officer at the job site, within 24 hours after each day of pile driving. A preprinted pile driving log for recording pile driving data[ and pile driving equipment data form], which can be downloaded at: https://www.wbdg.org/ffc/dod/unified-facilities-guide-specifications-ufgs/forms-graphics-tables.

3.3.6 Testing Agency Qualifications

Engage an independent testing agency to observe the production piles installation. The testing agency must be qualified according to ASTM E329 for testing indicated. Submit testing agency qualifications to the Contracting Officer for approval.

3.3.7 Welding Inspection

Employ a testing agency to perform the welding inspections as specified in the statement of special inspection.

3.3.8 Weld Testing

In addition to visual inspection, welds must be tested and inspected according to AWS D1.1/D1.1M and inspection procedures listed below, at testing agency's option. Correct deficiencies in Work that test reports and inspections indicate do not comply with the Contract Documents.[ Test [10] [_____] percent of pile splices, the steel pile cap splice connections and the steel pile insert connection.]

a. Liquid Penetrant Inspection: ASTM E165/E165M.

b. Magnetic Particle Inspection: ASTM E709; performed on root pass and on finished weld. Cracks or zones of incomplete fusion or penetration are not accepted.

c. Radiographic Inspection: ASTM E94/E94M, minimum quality level "2-2T."

d. Ultrasonic Inspection: ASTM E164.

3.3.9 Concrete Infill

Perform field quality control testing of the concrete infill in accordance with Sections 03 30 00 CAST-IN-PLACE CONCRETE and 31 62 13.13 CAST-IN-PLACE CONCRETE PILES.
3.4 TOUCHUP PAINTING

Clean field welds, splices, and abraded painted areas and field-apply paint according to SSPC PA 1. Use same paint and apply same number of coats as specified. Apply touchup paint before driving piles to surfaces that are immersed or inaccessible after driving.

3.5 SPECIAL INSPECTION AND TESTING FOR SEISMIC-RESISTING SYSTEMS

**************************************************************************
NOTE: Include this paragraph only when special inspection and testing for seismic-resisting systems is required by the International Building Code (IBC).

This paragraph will be applicable to both new buildings designed and to existing building seismic rehabilitation designs done according to UFC 1-200-01, "General Building Requirements" and UFC 3-301-01 "Structural Engineering" and UFC 3-301-02, "Design of Risk Category V Structures, National Strategic Military Assets".

The designer must indicate on the drawings all locations and all features for which special inspection and testing is required in accordance with Chapter 17 of the IBC. This includes indicating the locations of all structural components and connections requiring inspection.

Add any additional requirements as necessary.
**************************************************************************

Perform special inspections and testing for seismic-resisting systems and components in accordance with Section 01 45 35 SPECIAL INSPECTIONS.

3.6 VIBRATION CONTROL

Perform vibration monitoring at the locations [shown in the plan] [decided by the Contracting Officer] during the pile driving operations. Perform vibration monitoring [using] [seismographs] [and geophones] within a distance of 61 meters 200 feet from the pile driving activity.[ Engage the services of a qualified, independent vibration consultant, acceptable to the Government, to conduct the vibration monitoring. The vibration consultant must have minimum of [five] [_____] years of experience in vibration monitoring. A minimum of [28] [_____] days before the installation of vibration monitors, submit to the Government the name of the vibration consultant and a list of at least [three] [_____] previously completed projects of similar scope and purpose.]

Prior to the pile driving activities, obtain baseline readings of ambient vibrations. The vibration during the pile driving activities must be limited to [a peak particle velocity of not more than 5 cm 2.0 inches per second] [the limits mentioned in the [contract documents] ].[ Determine appropriate vibration limits as per [US Bureau of Mines] [American Association of State Highway and Transportation Officials (AASHTO)] guidelines.] During pile driving activities, monitor the vibrations to ensure the limits are not exceeded. If the limits are exceeded, cease the pile driving activity causing the vibration until [the Vibration consultant and the Contracting Officer] [_____] are on site to observe the structures.
nearest to the vibration monitor which has exceeded the limits.

The Contractor must be responsible for all damages resulting from the pile driving operations and must take whatever measures necessary to maintain peak particle velocity within the specified limit. After completion of the project, remove the vibration monitors off the site and off Government property and restore the monitoring locations back to their original condition.

][3.7 NOISE CONTROL

**************************************************************************
NOTE: Include this paragraph when noise monitoring is required. Add any additional criteria or requirements as necessary for the particular project.
**************************************************************************

Perform noise monitoring at the locations [shown in the plan] [decided by the Contracting Officer] [at noise sensitive public areas] during the pile driving operations. [Perform noise monitoring using [noise meters][, and][_____]]. [Engage the services of a qualified, independent noise consultant, acceptable to the Government, to conduct the noise monitoring. The noise consultant must have minimum of [five] [_____] years of experience in noise monitoring. A minimum of [28] [_____] days before the installation of noise monitors, submit to the Government the name of the noise consultant and a list of at least [three] [_____] previously completed projects of similar scope and purpose.]

Prior to the pile driving activities, obtain baseline readings of ambient noise levels. [The noise limits are mentioned in the [plan] [contract documents].] [Determine appropriate noise limits as per [local agency] [Occupation Safety and Health Administration] guidelines.] During pile driving activities, monitor the noise to ensure the limits are not exceeded. If the limits are exceeded, cease the pile driving activity and install noise mitigation measures.

The Contractor must be responsible for all damages resulting from the pile driving operations and must take whatever measures necessary to maintain noise within the specified limit. After completion of the project, remove the noise monitors off the site and off Government property and restore the monitoring locations back to their original condition.

][3.8 PRECONSTRUCTION CONDITION SURVEY

**************************************************************************
NOTE: Add any additional criteria or requirements as necessary for the particular project.
**************************************************************************

Perform preconstruction condition survey of [structures] [and utilities] [within 61 meters 200 feet of the pile driving activity] [specified in the plans] [decided by the Contracting Officer]. Perform outreach to the owner of the structures [28] [_____] days before performing the preconstruction condition survey. The Contractor must obtain written permission from the owner of the structure prior to accessing the structure. The preconstruction condition survey must include video and photographic documentation of the exterior and interior of above ground structures and of the interior of underground structures. Video documentation must be in high definition, and show existing conditions and highlight, where
possible, existing cracks, deteriorated concrete, exposed and corroded reinforcement, cracked or broken brick or mortar, and other signs of distress. For utilities, perform the survey when the greatest extent of the interior is exposed. Provide supplementary artificial lighting as needed. The video must include annotation with location and structure nomenclature which describes any areas of distress over the video and time code superimposed on the video. Photographs must be accompanied by sketches or descriptions that indicate the location and direction of each photograph. For each structure surveyed, provide a Pre-Construction Condition Survey Report following completion of the survey. The report must contain all documentation associated with the survey including DVD copies. In the report, include notes, sketches, photographs, and videos. Provide general information, such as location details and structure type, as well as particular information on materials, condition, existing damage, aperture and persistence of cracks, and disrepair observed during visual survey. Provide a graphical depiction of locations of damage or other features of concern. Submit the Preconstruction Condition Survey Reports no later than [28] [_____] days before the commencement of pile driving activity. Accept responsibility for damages to existing adjacent or adjoining structures created by pile driving work, and repair any damages to these structures without cost to the Government.

3.9 CONSTRUCTION INSTRUMENTATION AND MONITORING PROGRAM

**************************************************************************
NOTE: Include this section if instrumentation is to be installed due to concerns about vibration, settlement, lateral movement, etc. during pile driving activities. Instrumentation should be specified and included in the specification. This section can be deleted if there are no instrumentation requirements.

Add any additional criteria or requirements as necessary for the particular project.
**************************************************************************

Prepare a geotechnical instrumentation program to monitor settlement [and lateral movement] of temporary and permanent structures, utilities, [embankments] [and excavations] during pile driving. The design and distribution of instrumentation must demonstrate an understanding of the need, purpose and application of each proposed type.[ Perform noise and vibration monitoring in accordance with NOISE CONTROL and VIBRATION CONTROL sections.]

Monitoring must extend before, during and for a period after completion of construction activities related to pile driving when long-term performance issues are a concern. The monitoring plan must be designed to protect adjacent structures and utilities against damage due to the pile driving activities. Establish limiting values of vertical [and horizontal] movement [and angular distortion] [and vibration] for each structure and utility within the zone of influence, subject to review by the Government.

Prepare a report detailing the proposed program of instrumentation and monitoring, establishing threshold values of monitored parameters, and describing the response plans that will be implemented when threshold parameters are exceeded. The report must include details about instrumentation consultant's experience, appropriate types, quantities, locations and monitoring frequencies of the instruments.
Upon acceptance of the instrumentation and monitoring program, provide, install and monitor the instrumentation and interpret the data. Submit instrument and monitoring program reports not less than every [_____] days after the monitoring program has begun. Take corrective actions, as necessary, based on the field instrumentation data and as defined in the instrumentation and monitoring program.

NOTE: This guide specification covers the requirements for furnishing all equipment, labor, and materials (except materials specified to be furnished by the Government) and performing all operations in connection with the furnishing, installing and testing of steel H-piles in accordance with these specifications and applicable drawings.

Adhere to [UFC 1-300-02](http://www.wbdg.org/ffc/dod/unified-facilities-guide-specifications-ufgs/forms-graphics-tables) Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a [Criteria Change Request (CCR)](http://www.wbdg.org/ffc/dod/unified-facilities-guide-specifications-ufgs/forms-graphics-tables).

NOTE: The extent and location of the work to be accomplished should be indicated on the project drawings or included in the project specification.
NOTE: Show the following information on the project drawings:

1. Location, size, and cutoff elevation of project piles.

2. Location, size, cutoff elevation, and identification of test piles.

3. Subsurface soil data logs. Other subsurface data is design information and is not a part of the contract. Make data available for examination by the bidders at appropriate locations.

4. Staging area.

PART 1   GENERAL

NOTE: Structural engineer must confirm the structural capacity of piles and provide specific bending moments, lateral loads and other design requirements for pile design.

1.1 DESCRIPTION

Design, furnish, install and test piles at the locations indicated on the drawings and specified herein. [Assume test pile[s] will be directed to be placed in [a ]location[s] that can be incorporated into the work.]

1.2 REFERENCES

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

[1.3] SUBSURFACE DATA

******************************************************************************
NOTE: Section 00 31 32.13 Subsurface Drilling and Sampling Information is not a UFGS. CSI MasterFormat prescribes this section for inclusion of this data.
******************************************************************************

Subsurface soil data logs are [indicated] [appended to the special contract requirements] [provided on the project drawings]. The subsoil investigation report samples of material taken from subsurface investigations may be examined at [_____] .

[1.4] BASIS OF BID

******************************************************************************
NOTE: Select one of the following options:
******************************************************************************

******************************************************************************
NOTE: Use "Lump Sum" paragraph below for lump (principal) sum bidding of piles. Use this in all projects except those where exact pile lengths cannot be practically determined prior to the actual work. Clearly show number of piles, pile capacity, pile locations, and tip and cutoff elevations on the drawings.

Use "Unit Price" paragraph for unit price bidding of piles. Specify unit price bid items for piles only for projects where exact quantities cannot be practically determined prior to the actual work. Lengths of piles must be determined as accurately as possible, prior to bidding, since the unit price per meter foot of the piles varies as the length increases or decreases. Refer to Standard Test Method for High-Strain Dynamic Testing of Deep Foundations (ASTM D4945).
******************************************************************************

1.4.1 Production Pile Acceptance Criteria

Safe design capacity for piles is [_____] KN [_____] kips. Drive piles to [minimum tip elevation] [a minimum depth of [_____] m [_____] feet below...
cut-off elevation], and to such additional depth as required to obtain a bearing capacity of not less than \([\_] \text{ KN} \ [\_] \text{ kips}\). The Contractor's Geotechnical Consultant will determine the terminal driving criteria based on results of [dynamic pile driving tests at end of drive or restrike] [static load tests] [wave equation analysis].

The following formulas can be used in cases where allowable pile loads are less than 355 kN 80 kips (determined using a factor of safety of 3 for individual piles and 4 for pile groups) and are presented only as a guide to aid in establishing the controlling penetration per blow, which, together with the minimum depth of penetration will serve to determine the required minimum depth of penetration of each individual pile:

\[ R = \frac{2E}{S + 0.1} \quad \text{For double acting hammers} \]

\[ R = \frac{2WH}{S + 0.1} \quad \text{For single acting hammers} \]

Where \( R \) is the approximate allowable pile load in kips; \( E \) equals the energy in foot-kips per blow based on an acceptable certified statement from the manufacturer of the hammer; \( W \) equals the weight of the hammer or ram in kips; \( H \) equals the height of fall of the hammer of ram in feet; and \( S \) equals the average inches of penetration per blow for the last three blows. An allowance will be made for reduced penetration caused by shock absorption of the cushion or cap blocks.

[1.4.2 Lump Sum Payment]

**************************************************************************
NOTE: Use this paragraph for lump-sum contracts, consult with Contracting Officer's Technical Representative (Geotechnical Branch) on applicability of use prior to selection. This paragraph will be typically used when there are 1) relatively small quantity of piles, 2) allowable pile loading is less than 355 kN 80 kips (, and 3) the subsurface conditions are well defined. Fill in Table I as required selecting columns applicable to project. Generally, pile capacity, location, and minimum tip elevation are shown on plans. Test piles and load tests are not incorporated on lump sum contracts. Delete this paragraph for unit-price contracts.
**************************************************************************

Base bids upon providing the number, size, capacity, and length of piles as indicated on the [drawings.][following Table I:

<table>
<thead>
<tr>
<th>Location</th>
<th>Number</th>
<th>Size</th>
<th>Capacity</th>
<th>Length (Tip to Cut-Off)</th>
<th>Maximum Bending Moment</th>
<th>Maximum Shear Force</th>
</tr>
</thead>
</table>

Include the cost of all necessary equipment, tools, material, labor, and supervision required to: deliver, handle, install, cut-off, dispose of any cut-offs, and meet the applicable contract requirements. Include

SECTION 31 62 16.16 Page 9
mobilization, pre-drilling, and redriving heaved piles. If, in redriving, it is found that any pile is not of sufficient length to provide the capacity specified, notify the Contracting Officer, who reserves the right to increase or decrease the total length of piles to be provided and installed by changing the pile locations or elevations, requiring the installation of additional piles, or directing the omission of piles from the requirements shown and specified. If total number of piles or number of each length vary from that specified as the basis for bidding, an adjustment in the contract price or time for completion, or both, will be made in accordance with the contract documents. Payment for piles will be based on successfully installing piles to both the minimum tip elevation and satisfying the acceptance criteria identified herein. No additional payment will be made for: damaged, rejected, or misplaced piles; withdrawn piles; any portion of a pile remaining above the cut-off elevation; backdriving; cutting off piles; splicing; build-ups; any cut-off length of piles; or other excesses beyond the assumed pile length indicated for which the Contractor is responsible.[ Include payments for vibration monitoring, sound monitoring and precondition construction surveys].

[1.4.3  Unit Price

**************************************************************************
NOTE: Delete this paragraph for lump-sum contracts.

For NAVFAC PAC projects: Where there is unit pricing for piles, use this paragraph and edit applicable attachments in price schedule for inclusion in Standard Form 1442, "Solicitation, Offer and Award" and "Schedule of Bid Items."

For NAVFAC Southeast projects, where there is a need for unit pricing of piles, include this paragraph. Refer to NAVFAC SE Instruction 00010, "Instructions for Preparing Basis of Bid Statement With Unit-Priced Items," for method of specifying unit price bid items.

**************************************************************************

For unit price bid, see SF 1442, "Solicitation, Offer and Award" and "Schedule of Bid Items."

**************************************************************************

NOTE: For NAVFAC LANT projects, use the following paragraph for measurement and payment and subsequent sub-parts.

**************************************************************************

Requirements of FAR 52.211-18 Variation in Estimated Quantity do not apply to payment for piling. Each pile and test pile acceptably provided will be paid for at the bid unit price per unit length, which will include items incidental to furnishing and driving the piles including mobilization and demobilization, [jetting] [pредривелинг] [probing], redriving uplifted piles, [an additional 1.5 m 5 feet in furnished length for any test pile not driven beyond estimated pile length, ]and cutting off piles at the cut-off elevation.[ Include the cost for additional length for the test piles in the total unit price cost for the job.] Payment will be made for production [and test piles ]at the bid unit price for the length of pile, from tip to final cut-off, actually provided, excluding buildups and splices directed by the Contracting Officer to be made. If the actual

SECTION 31 62 16.16  Page 10
cumulative pile length driven (tip to cut-off) vary more than 25 percent from the total pile length specified as a basis for bidding, at the direction of the Contracting Officer, the unit price per unit length will be adjusted in accordance with provisions of FAR 52.236-2 Differing Site Conditions. [Payments will be made per each at the respective bid unit price for pile cut-offs, pile build-ups, pile loads tests and pile splices.] [Include payments for vibration monitoring, sound monitoring, construction instrumentation and monitoring, and precondition construction surveys].

][1.5 PAYMENT

******************************************************************************
NOTE: Delete this paragraph for lump-sum contracts.

If Section 01 20 00 PRICE AND PAYMENT PROCEDURES is included in the project specifications, this paragraph title (UNIT PRICES) should be deleted from this section and the remaining appropriately edited subparagraphs below should be inserted into Section 01 20 00 PRICE AND PAYMENT PROCEDURES.

******************************************************************************

1.5.1 Furnishing and Delivering Piles

1.5.1.1 Payment

Payment will be made for costs associated with furnishing and delivering the required lengths of permanent steel H piles, which includes costs of furnishing and delivering piles to the work site. No payment will be made for the driving head or lengths of piles exceeding required lengths. No payment will be made for piles damaged during delivery, storage, or handling to the extent that they are rendered unsuitable for the work, in the opinion of the Contracting Officer.

1.5.1.2 Measurement

Furnishing and delivering steel H piles will be measured for payment by the linear meter foot of piles required below the cut-off elevation as determined by the Contracting Officer and furnished to the Contractor [indicated].

1.5.1.3 Unit of Measure

Linear meter foot.

1.5.2 Driving Steel H Piles

1.5.2.1 Payment

Payment will be made for costs associated with driving steel H piles, which includes costs of handling, driving, [and splicing of piles,] [performing dynamic testing, interpreting data and submitting reports,] measuring heave, redriving heaved piles, removal of [build-ups] driving heads or cutting off piles at the cut-off elevation and removing from the work site, compiling and submitting pile driving records, backfilling voids around piles, and any other items incidental to driving piles to the required elevation.
1.5.2.2 Measurement

Steel H piles will be measured for payment for driving on the basis of lengths, to the nearest hundredth (tenth) of a linear meter foot, along the axis of each pile acceptably in place below the cut-off elevation shown.

1.5.2.3 Unit of Measure

Linear meter foot.

1.5.3 Pulled Steel H Piles

1.5.3.1 Payment

Payment will be made for costs associated with piles pulled at the direction of the Contracting Officer and found to be undamaged. The cost of furnishing and delivering pulled and undamaged piles will be paid for at the applicable contract unit price for payment item "Furnishing and Delivering Piles". The cost of driving pulled and undamaged piles will be paid for at the applicable contract unit price for payment item "Driving Steel H Piles". The cost of pulling undamaged piles will be paid for at twice the applicable contract unit price for payment item "Driving Steel H Piles", which includes backfilling any remaining void. The cost of redriving pulled and undamaged piles will be paid for at the applicable contract unit price for payment item "Driving Steel H Piles". No payment will be made for furnishing, delivering, driving, pulling, and disposing of piles, including pile driving points, pulled and found to be damaged and backfilling voids. New piles replacing damaged piles will be paid for at the applicable contract unit price for payment items "Furnishing and Delivering Steel H Piles" and "Driving Steel H Piles".

1.5.3.2 Measurement

Furnishing and delivering pulled and undamaged steel H piles will be measured for payment as specified in paragraph UNIT PRICES, subparagraph FURNISH AND DELIVER STEEL H PILES. Pulling steel H piles will be measured for payment as specified in paragraph UNIT PRICES, subparagraph DRIVING STEEL H PILES. Redriving pulled undamaged steel H piles will be measured for payment as specified in paragraph UNIT PRICES, subparagraph DRIVING STEEL H PILES. New piles replacing damaged piles will be measured for payment as specified in paragraph UNIT PRICES, subparagraphs FURNISH AND DELIVER STEEL H PILES and DRIVING STEEL H PILES.

1.5.3.3 Unit of Measure

Linear meter foot.

1.5.4 Pile Driving Tests

1.5.4.1 Payment

Payment will be made for costs associated with furnishing, delivering, driving, pulling, and disposing of driven test piles, [including [pile driving points][ and ][splices]]; ]conducting pile driving tests; backfilling voids around piles; compiling pile driving test records[; performing dynamic testing; interpreting data; and submitting reports].
1.5.4.2 Measurement

Pile driving tests will be measured for payment on the basis of the applicable contract unit price per pile driving test.

1.5.4.3 Unit of Measure

Each.

1.5.5 Piles for Load Tests

1.5.5.1 Payment

Payment will be made for costs associated with furnishing, delivering, driving, pulling, and disposing of load test piles, [including [pile driving points][ and ][splices]; ]backfilling voids around piles; compiling pile driving records[, furnishing, fabricating, and mounting of strain rods and protective assembly][; furnishing, fabricating, and mounting of inclinometer and inclinometer protective assembly][; performing dynamic testing; interpreting data; and submitting reports]. No additional payment will be made for load test piles incorporated in the permanent work other than as provided.

1.5.5.2 Measurement

Piles piles for load tests will be measured for payment on the basis of the applicable contract unit price per load test pile.

1.5.5.3 Unit of Measure

Each.

1.5.6 Pile Static Axial Compressive Load Tests

1.5.6.1 Payment

Payment will be made for costs associated with pile static axial compressive load tests in accordance with ASTM D1143/D1143M, including material and labor for fabricating and furnishing load frames; calibrating load cells and hydraulic jacks; furnishing specified test equipment; installing strain rods; placing and removing test loads and test equipment; recording, reducing, and submitting test data; and compiling and submitting pile load test reports. No payment will be made for rejected pile static axial compressive load tests.

1.5.6.2 Measurement

Pile static axial compressive load tests will be measured for payment on the basis of the applicable contract unit price per load test.

1.5.6.3 Unit of Measure

Each.

1.5.7 Pile Static Tensile Load Tests

1.5.7.1 Payment

Payment will be made for costs associated with pile static tensile load
tests in accordance with ASTM D3689, including material and labor for fabricating and furnishing load frames; calibrating load cells and hydraulic jacks; furnishing specified test equipment; installing strain rods; placing and removing test loads and test equipment; recording, reducing, and submitting test data; and compiling and submitting pile load test reports. No payment will be made for rejected pile static tensile load tests.

1.5.7.2 Measurement

Pile tensile load tests will be measured for payment on the basis of the applicable contract unit price per number of tensile load test.

1.5.7.3 Unit of Measure

Each.

1.5.8 Pile Lateral Load Tests

1.5.8.1 Payment

Payment will be made for costs associated with pile lateral load tests in accordance with ASTM D3966/D3966M, including material and labor for fabricating and furnishing load frames; calibrating load cells and hydraulic jacks; furnishing specified test equipment; installing inclinometers; placing and removing test loads and test equipment; recording, reducing, and submitting test data; and compiling and submitting pile load test reports. No payment will be made for rejected pile lateral load tests.

1.5.8.2 Measurement

Pile lateral load tests will be measured for payment on the basis of the applicable contract unit price per lateral load test.

1.5.8.3 Unit of Measure

Each.

1.5.9 Pulled Load Test Piles

1.5.9.1 Payment

Payment will be made for costs associated with load test piles pulled prior to load testing at the direction of the Contracting Officer and found to be undamaged. The cost of furnishing, delivering, driving, and pulling undamaged load test piles will be paid for at the applicable contract unit price for payment item "Piles for Load Tests". The cost of pulling undamaged load test piles the second time after redriving and testing will be paid for at twice the applicable contract unit price for payment item "Driving Steel H Piles". The cost of reDriving pulled undamaged load test piles will be paid for at the applicable contract unit price for payment item "Driving Steel H Piles". No payment will be made for furnishing, delivering, driving, pulling, and disposing of load test piles pulled at the direction of the Contracting Officer and found to be damaged. New load test piles replacing damaged piles will be paid for at the applicable contract unit price for payment item "Piles for Load Tests".
1.5.9.2 Measurement

Pulled undamaged load test piles will be measured for payment as specified in paragraph UNIT PRICES, subparagraph PILES FOR LOAD TESTS. Pulling undamaged load test piles the second time after redriving and testing will be measured for payment as specified in paragraph UNIT PRICES, subparagraph DRIVING STEEL H PILES. Redriving pulled undamaged steel H piles will be measured for payment as specified in paragraph UNIT PRICES, subparagraph DRIVING STEEL H PILES. New load test piles replacing damaged piles will be measured for payment as specified in paragraph UNIT PRICES, subparagraph PILES FOR LOAD TESTS.

1.5.9.3 Unit of Measure

As specified in paragraph UNIT PRICES, subparagraphs DRIVING STEEL H PILES and PILES FOR LOAD TESTS, respectfully.

1.5.10 Pile Driving Shoes and Points

1.5.10.1 Payment

Payment will be made for costs associated with pile driving shoes, pile driving points, including furnishing, delivering, and installing.

1.5.10.2 Measurement

Pile driving shoes will be measured for payment on the basis of the number of pile driving shoes required.

1.5.10.3 Unit of Measure

Each.

1.5.11 Pile Splices

1.5.11.1 Payment

Payment will be made for costs associated with pile splices, including all plant, labor, and material required to make the splice.

1.5.11.2 Measurement

Pile splices will be measured for payment on the basis of the applicable contract unit price per pile splice.

1.5.11.3 Unit of Measure

Each.

1.5.12 Vibration Monitoring

1.5.12.1 Payment

Payment will be made for costs associated with vibration monitoring.

1.5.12.2 Measurement

Vibration monitoring will be measured for payment on the basis of the applicable contract unit price per vibration monitoring point.
1.5.12.3 Unit of Measure
Each.

][1.5.13 Sound Monitoring

1.5.13.1 Payment
Payment will be made for costs associated with sound monitoring.

1.5.13.2 Measurement
Sound monitoring will be measured for payment on the basis of the applicable contract unit price per vibration monitoring point.

1.5.13.3 Unit of Measure
Each.

][1.5.14 Preconstruction Condition Survey

1.5.14.1 Payment
Payment will be made for costs associated with preconstruction condition surveys.

1.5.14.2 Measurement
Preconstruction condition survey will be measured for payment on the basis of the applicable contract unit price per structure to be surveyed.

1.5.14.3 Unit of Measure
Each.

][1.5.15 Construction Instrumentation and Monitoring

1.5.15.1 Payment
Payment will be made for costs associated with construction instrumentation and monitoring.

1.5.15.2 Measurement
Construction instrumentation and monitoring will be measured as a single pay item.

1.5.15.3 Unit of Measure
One.

][1.6 SUBMITTALS

**************************************************************************
NOTE: Review Submittal Description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals
required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy, Air Force, and NASA projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy, Air Force, and NASA projects, or choose the second bracketed item for Army projects.

**************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-01 Preconstruction Submittals

Installation Procedures; G[, [____]]
Contractor's Geotechnical Consultant; G[, [____]]

SECTION 31 62 16.16  Page 17
1.7 DELIVERY, STORAGE, AND HANDLING

Conform all delivery, storage, and handling of materials to the requirements specified herein. Develop and submit plans for the delivery, storage, and handling of piles. Submit delivery, storage, and handling plans for piles at least 30 calendar days prior to delivery of piles to the job site.

1.7.1 Delivery and Storage

Stack piles during delivery and storage so that each pile is maintained in a straight position and is supported every 3 m 10 feet or less along its length (ends inclusive) to prevent exceeding the maximum camber or sweep. Do not stack piles more than 1.5 m 5 feet high.
1.7.2 Handling

Lift piles using a cradle or multiple points pick-up to ensure that the maximum permissible camber or sweep is not exceeded due to insufficient support for lifting piles that are not extremely long into the driving leads. One pick up point can be used for short piles. Point pick-up devices must be of the type that clamp to both pile flanges at each pick-up point. Holes may be burned in the flanges or webs of piles above the cutoff length for lifting piles into the leads. Do not damage piles when dragging piles across the ground.

1.7.3 Excessive Camber, Sweep, and Damage

Inspect piles for excessive camber and sweep and for damage before transporting them from the storage area to the driving area and immediately prior to placement in the driving leads. Camber, curvature in the pile in the direction normal to the pile flanges, must be measured with the pile flange base laying on a flat surface and is the distance between the flange base at the mid-length of the pile and the flat surface. Sweep, curvature in the pile in the direction parallel to the pile flanges, must be measured with the pile flange tips laying on a flat surface and is the distance between the flange tips at the mid-length of the pile and the flat surface. The maximum permissible camber [and] sweep is 50 mm 2 inches over the length of the pile. Piles having excessive camber or sweep will be rejected.

1.7.4 Damaged Piles

Inspect each pile for straightness and structural damage before transporting them to the project site and immediately prior to placement in the driving leads. Bring any damage to the attention of the Contracting Officer. Piles which are damaged during delivery, storage, or handling to the extent they are rendered unsuitable for the work, in the opinion of the Contracting Officer, will be rejected and removed from the project site, or may be repaired, if approved, at no cost to the Government.

Any pile damaged by reason of internal defects or by improper driving must be corrected by one of the following methods approved by the Engineer for the pile in question:

a. The pile is withdrawn, if practicable, and replaced by a new and, if necessary, longer pile.

b. One or more replacement piles are driven adjacent to the defective pile.

c. A Pile Dynamic Analysis and low integrity testing must be performed by the Contractor's Geotechnical Consultant to assess the structural integrity of the driven pile(s).

1.7.5 Pile Butt Location and Elevation

A pile driven below the specified butt elevation must be corrected by one of the following methods approved by the Engineer:

a. One or more replacement piles are driven next to the pile in question.

b. As directed by the structural engineer.

A pile driven out of its proper location or out of plumb as approved by the
Engineer, must be corrected by one of the following methods approved by the engineer:

a. One or more replacement piles are driven next to the pile in question.
b. As directed by the structural engineer.

[1.7.6 Pile Sweep]

Limit sweep to 3 mm per 3 M 1/8 inch per 10 feet over the length of the pile. Piles having excessive sweep will be rejected.

]1.8 QUALITY CONTROL

1.8.1 Piles

Prepare and submit shop drawings. Indicate placement of piles. Indicate location of special embedded or attached lifting devices, employment of pick-up points, support points other than pick-up points, and any other methods of pick-up.

1.8.2 Contractor's Geotechnical Consultant

Hire the services of an independent, Registered Professional Geotechnical Engineer, experienced in soil mechanics and Pile Dynamic Analysis, to observe test pile installation and production pile installation as specified herein. The Contractor's Geotechnical Consultant must be independent of the Contractor and must have no employee of employer relationship which could constitute a conflict of interest. Submit Contractor's geotechnical consultant qualifications at least 30 calendar days before pile installation.

Provide instructions and procedures on how the Contractor will assist the Government in the processes of [Dynamic Pile Testing,] Inspection and Monitoring of piles during installation and testing.

1.8.3 Pile Manufacturer's Quality Control Procedures

Submit the pile manufacturer's quality control procedures.

1.8.4 Installation Procedures

a. Submit information on the type of equipment proposed to be used, proposed methods of operation, pile driving plan including proposed sequence of driving, and details of all pile driving equipment and accessories. Submit pile driving equipment information at least 30 calendar days prior to commencement of work.

b. Provide details of pile driving equipment and a Wave Equation Analysis of pile drivability for selection of the hammer along with a statement of driving procedures. [Submit wave equation analysis for each pile location.] The Wave Equation Analysis is to be completed by the Contractor's Geotechnical Consultant for each test pile location where different subsurface conditions exist and is to include the following information pertaining to the proposed pile driving equipment:

(1) Complete Pile and Driving Equipment Data Form, (which can be downloaded at: [https://www.wbdg.org/ffc/dod/unified-facilities-guide-specifications-ufgs/forms-graphics-tables](https://www.wbdg.org/ffc/dod/unified-facilities-guide-specifications-ufgs/forms-graphics-tables)) for each proposed
pile hammer and pile type combination.

(2) Copies of computer input and output sheets and graphs showing soil resistance versus blow count as well as maximum tension and compression stresses versus blow count. Analysis must be run at the estimated tip elevation as well as other required elevations to define maximum stress levels in the pile during driving.

c. Provide detailed procedures for conducting the dynamic pile load test and equipment to be used for conducting the load test. The detailed description must explain how specific information of pile performance will be evaluated.

[1.8.5 Load Test Supporting Data

Submit Jack calibration records, a testing arrangement description and diagram, and the proposed loading sequence.

]PART 2 PRODUCTS

2.1 PILE REQUIREMENTS

**************************************************************************

NOTE: Delete sentence in brackets when test piles are not required. Government requires the Contractor to employ a Geotechnical Consultant to determine the calculated tip elevation and provide oversight of piling installation and testing.

**************************************************************************

[Order test piles [3] [_____] meters [10] [_____] feet longer in length than production piles. [Drive the additional test pile length only when based upon the recommendation of the Contractor's Geotechnical Consultant and approved by the Contracting Officer.] Submit test pile and load test reports. The [Contractor's Geotechnical Consultant] [Contracting Officer] will use test pile data to determine "calculated" pile tip elevation and necessary driving resistance. This information will be given to the Contractor no later than 7 days from receipt of complete test data. Use this list as the basis for ordering the piles. Do not order piles until list is provided by the [Contractor's Geotechnical Consultant] [Contracting Officer].] [Provide test piles [1.5] [_____] meter [5] [_____] feet longer than the bid length.]

2.2 MATERIALS

**************************************************************************

NOTE: Base selection of material on a comprehensive study of strength, cost, and corrosion resistance requirements.

ASTM A36/A36M and ASTM A572/A572M steels have the same corrosion resistance; ASTM A572/A572M can be obtained in yield strengths of 350 MPa through 448 MPa 42 ksi through 65 ksi; however, 350 MPa 50 ksi is the most available grade. ASTM A588/A588M has twice the atmospheric resistance of ASTM A36/A36M steel with 20 percent copper added.

1. Marine environment: Evaluate steel section
piles exposed to seawater on the basis of application, location, degree of exposure, type of structure, and required service life. Where additional service life in the splash zone is required over that provided by conventional steel grades, ASTM A690/A690M or ASTM A588/A588M may be considered. ASTM A690/A690M steel 350 MPa 50 ksi (yield strength) has two to three times greater resistance to seawater splash zone corrosion than ordinary ASTM A36/A36M steel.

2. Seawater protection: To obtain reasonably long life for a structure immersed in seawater, provide steel piles with coatings, cathodic protection, or concrete encasement. Choice of protection is ultimately based on economics; usually, more than one type of protection will be used on a structure for most economical, adequate protection. The following criteria applies:

   a. The use of coating systems for protection, such as coal tar epoxy, is usually low in initial cost but may require relatively frequent maintenance; also, it is extremely difficult to renew in the tidal zone between mean tide and low tide.

   b. Cathodic protection is low in initial cost and low in maintenance. It can be of value only where the piles are continually wet, as in the submerged zone.

   c. Concrete encasement or metal jacketing is relatively expensive in initial cost but requires no maintenance if properly constructed. When concrete encasement is to be continuously submerged in water with low resistivity, it must (1) extend below the mudline, or (2) be coated to electrochemically insulate the concrete from the steel.

Use high-strength steel only when design analyses show that the use is the most economical solution or to increase the design life if approved by the Contractor’s Geotechnical Consultant.

ASTM A27/A27M cast steel is used for some commercially available pile points.

2.2.1 H-Piles

NOTE: Base selection of material on a comprehensive study of strength, cost, and corrosion resistance requirements.

ASTM A36/A36M and ASTM A572/A572M steels have the same corrosion resistance; ASTM A572/A572M can be obtained in yield strengths of 350 MPa through 448
MPa 42 ksi through 65 ksi; however, 350 MPa 50 ksi is the most available grade. ASTM A588/A588M has twice the atmospheric resistance of ASTM A36/A36M steel with 20 percent copper added.

1. Marine environment: Evaluate steel section piles exposed to seawater on the basis of application, location, degree of exposure, type of structure, and required service life. Where additional service life in the splash zone is required over that provided by conventional steel grades, ASTM A690/A690M or ASTM A588/A588M may be considered. ASTM A690/A690M steel 350 MPa 50 ksi (yield strength) has two to three times greater resistance to seawater splash zone corrosion than ordinary ASTM A36/A36M steel.

2. Seawater protection: To obtain reasonably long life for a structure immersed in seawater, provide steel piles with coatings, cathodic protection, or concrete encasement. Choice of protection is ultimately based on economics; usually, more than one type of protection will be used on a structure for most economical, adequate protection. The following criteria applies:

   a. The use of coating systems for protection, such as coal tar epoxy, is usually low in initial cost but may require relatively frequent maintenance; also, it is extremely difficult to renew in the tidal zone between mean tide and low tide.

   b. Cathodic protection is low in initial cost and low in maintenance. It can be of value only where the piles are continually wet, as in the submerged zone.

   c. Concrete encasement or metal jacketing is relatively expensive in initial cost but requires no maintenance if properly constructed. When concrete encasement is to be continuously submerged in water with low resistivity, it must (1) extend below the mudline, or (2) be coated to electrochemically insulate the concrete from the steel.

Use high-strength steel only when design analyses show that the use is the most economical solution.

ASTM A27/A27M cast steel is used for some commercially available pile points.

**************************************************************************

[ASTM A36/A36M][ASTM A572/A572M, Grade [_____]][ASTM A588/A588M][ASTM A690/A690M]. [Provide test piles identical to those used elsewhere in the project.][ Provide square and blunt pile tips, as received from the mill.][Provide pile tip reinforcements or cast steel points.][Coat piles in accordance with Section 09 97 13.26 COATING OF STEEL WATERFRONT STRUCTURES, ZERO VOC, (SZC) SPLASH ZONE CONTROL.][Provide piles with concrete encasements in accordance with Section 03 30 00 CAST-IN-PLACE
CONCRETE.

Provide H-piles of the shape and sections shown. Submit pile material certificates of compliance certifying that materials meet the requirements specified herein. Determine lengths of piles as specified in paragraph "Installation," subparagraph "Lengths of Production Piles" [and paragraph "Pile Tests," subparagraph "Test Piles"][. Submit pile load test plan at least 30 days prior to installing any test piles. Approval of the plan does not relieve the Contractor of the responsibility for structural and operational adequacies of the testing system.]

[2.2.2 Pile Splices

][2.2.3 Pile Points

**************************************************************************

NOTE: Pile points may be required when driving piles in dense sand strata, gravel strata and cobble-boulder zones, and when driving piles to refusal on a hard layer or bedrock.

**************************************************************************

[[ASTM A148/A148M for cast steel points.][ASTM A36/A36M][ASTM A572/A572M, Grade [____] for pile tip reinforcements.]] Pile points must [be the type] [conform to details] shown[ and be provided on all piles].

][2.2.4 Pile Caps

[ASTM A36/A36M.][ASTM A572/A572M, Grade [____].][ASTM A588/A588M.] Pile caps must conform to details shown.

][2.2.5 Pile Tension Anchors

[ASTM A36/A36M.][ASTM A572/A572M, Grade [____].][ASTM A588/A588M.] Pile tension anchors must conform to details shown.

][2.2.6 Fabrication

Fabrication must conform to the requirements shown and as specified herein and in [Section 05 50 13 MISCELLANEOUS METAL FABRICATIONS] [Section 05 51 33 METAL LADDERS] [Section 05 52 00 METAL RAILINGS] [Section 05 51 00 METAL STAIRS].

[2.2.6.1 Pile Splices

**************************************************************************

NOTE: Splices are generally not permitted where required lengths are available in one piece or the pile is designed for a moment connection. Where splices are permitted, show details of the splice.

**************************************************************************

Fabricate pile splices as shown. Submit detail drawings of splices in accordance with paragraph SUBMITTALS. Perform all welding in accordance with the requirements for shield metal arc welding of AWS D1.1/D1.1M. Submit welding procedure for shop splices and verification of welder
qualifications. Make no more than one field splice per 25 m [80] feet of pile, unless directed by the Contracting Officer. Fabrication drawings must show all shop splices.

2.2.6.2 [Pile Caps,] [Pile Points,] [Pile Tension Anchors,] [Pile Shoes]

[Attach [pile caps,] [pile points,] [piles shoes,] [and] [pile tension anchors] as shown.][ Ground the top of piles sufficiently smooth to provide a good welding surface for structural-shape pile caps.) Submit Certificates of compliance certifying that materials meet the requirements specified herein.

2.3 PILE DRIVING EQUIPMENT

Select the proposed pile driving equipment, including hammers and other required items, and submit complete descriptions of the proposed equipment in accordance with paragraph SUBMITTALS. Final approval of the proposed equipment is subject to the satisfactory completion and approval of pile tests. Changes in the selected pile driving equipment will not be allowed after the equipment has been approved except as directed. No additional contract time will be allowed for Contractor proposed changes in the equipment.

2.3.1 Pile Driving Hammers

******************************************************************************

NOTE: When specifying the minimum driving energy, make an allowance for reduced penetration caused by shock absorption of pile helmets. Enter the appropriate minimum allowable driving energy for the project. Minimum allowable driving energy must be not less than the following:

<table>
<thead>
<tr>
<th>Design Bearing Pile Capacity for Single Pile (Kilonewton) (Kips)</th>
<th>Minimum Rated Hammer Driving Energy (Joules) (Foot-Pounds)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Up to 534 120</td>
<td>20,350 15,000</td>
</tr>
<tr>
<td>Over 534 120</td>
<td>25,750 19,000</td>
</tr>
</tbody>
</table>

The minimum and maximum hammer energies required may be determined from experience on other jobs or by a series of wave equation analyses.

******************************************************************************

Provide impact or vibratory type pile driving hammers.

2.3.1.1 Impact Hammers

Provide air, hydraulic or diesel-powered impact pile hammers of the single-acting, double-acting, or differential-acting type. The size or capacity of hammers must be as recommended by the hammer manufacturer for the total pile mass (weight) and the character of the soil formation to be penetrated. The rated driving energy of hammers is limited to a minimum of 20,350 joules 15,000 foot-pounds. Hammers must
be capable of, and so demonstrated during the development of refusal criteria, hard driving in excess of 20 blows per 25 mm. Provide boiler, compressor, or engine capacity sufficient to operate hammers continuously at the full rated speed. Hammers must have a gage to monitor hammer bounce chamber pressure for diesel hammers or pressure at the hammer for air hammers. This gage must be operational during the driving of piles and be mounted in an accessible location for monitoring by the Contractor and the Contracting Officer. Provide two spare operational bounce chamber readout units on site. Provide two spare operational bounce chamber readout units on site. Provide bounce chamber pressure gage correction tables and charts for the type and length of hose to be used with the pressure gage to the Contracting Officer. Hydraulic hammers must be equipped with a system for measurement of ram energy. The system must be in good working order and the results must be easily and immediately available to the Engineer. Install an energy monitor on the hydraulic hammers and record readings every 300 mm 12 inches of pile installation. Use wave equation analysis to verify that the hammer will develop stresses within acceptable limits in the piles. Position a pile cap or drive cap between the pile and hammer. Place hammer cushion or cap block between ram and the pile cap or drive cap. Hammer cushion or cap block must have consistent elastic properties, minimize energy absorption, and transmit hammer energy uniformly and consistently during the entire driving period. Do not use a pile cushion block. In accordance with paragraph SUBMITTALS, submit the following information for each impact hammer proposed:

a. Make and model.
b. Ram mass (kilograms) weight (pounds).
c. Anvil mass (kilograms) weight (pounds).
d. Rated stroke (millimeters) (inches).
e. Rated energy range (joules) (foot-pounds).
f. Rated speed (blows per minute).
g. Air pressure, hammer, and boiler [and] [or] compressor (MPa) (psi).

h. Rated bounce chamber pressure curves or charts, including pressure correction chart for type and length of hose used with pressure gage (bar) (pounds per square inch).

i. Pile driving cap, make, and mass (kilograms) weight (pounds).

j. Cushion block dimensions and material type.
k. Power pack description.

2.3.1.2 Vibratory Hammers

The use of vibratory hammers is dependent upon satisfactory driving and load testing of piles. Final approval of the proposed hammer and other driving equipment is subject to the satisfactory completion and approval of the pile tests. The size or capacity of hammers must be as recommended by the hammer manufacturer for the total pile mass weight and the character of the soil formation to be penetrated. The hammer must provide for maintaining a rigid connection between the hammer and the pile. In accordance with paragraph SUBMITTALS, submit the following information for
each vibratory hammer proposed:

a. Make and model.

b. Eccentric moment *(newton-meters) (inch-pounds).*

c. Dynamic force *(kilonewtons) (tons).*

d. Steady state frequency or frequency range *(cycles per minute).*

e. Vibrating mass *(kilonewtons) weight (pounds).*

f. Amplitude *(millimeters) (inches).*

g. Maximum pull capacity *(metric tons) (tons).*

h. Non-vibrating mass *(kilonewtons) weight (pounds).*

i. Power pack description.

2.3.2 Pile Driving Leads

**************************************************************************

NOTE: Suspended leads should not be used on jobs where accurate pile placement and alignment are required.

Vibratory hammers are typically operated free hanging without leads unless accurate placement and alignment of the piles are required.

**************************************************************************

Support and guide hammers with fixed extended leads or fixed underhung leads.[ For driving battered piles, support and guide impact hammers with three-axis, fixed-extended leads capable of 1 H and 2-1/2 V before and after batter and 1 H on 6 V side batter, with 30 degree rotation each side of an axis running along the center line of rotation of the crane through the center line of the leads.] Provide two intermediate supports for the pile in the leads to reduce the unbraced length of the pile during driving and pulling.

2.3.3 Pile Extractors

Pile extractors may be vibratory or impact pile driving hammers. Impact hammers are required for pulling piles not extractable with vibratory hammers.

2.3.4 Jetting Equipment

**************************************************************************

NOTE: Do not use jetting on piles carrying significant tension loads, lateral loads, or compression loads developed predominantly from skin friction.

**************************************************************************

Provide jetting equipment with not less than two removable or fixed jets of the water or combination air-water type. Water jets must be designed so that the discharge volume and pressure are sufficient to freely erode the
material immediately under and adjacent to piles without resulting in pile drift. Submit jetting equipment including plant description, volume of water and pressure, and size and length of hoses and pipes in accordance with paragraph SUBMITTALS.

PART 3 EXECUTION

3.1 PRELIMINARY WORK

3.1.1 Wave Equation Analysis of Pile Drivability

a. Prior to driving any pile, submit a pile Wave Equation Analysis, performed by Contractor's Geotechnical Consultant, for each size pile and distinct subsurface profile condition. These analyses must take into account the proposed hammer assembly, pile cap block and cushion characteristics, the pile properties and estimated lengths and the soil properties anticipated to be encountered throughout the installed pile length based on static capacity analysis with consideration of driving gain/loss factors. Only one specific model of pile hammer may be used for each pile type and capacity. Provide instructions and procedures on how the Contractor will perform [Dynamic Pile Testing,] Inspection and Monitoring of piles during installation and testing.

b. Demonstrate using the Wave Equation Analysis that the piles will not be damaged during driving, indicate that the driving stresses will be maintained within the limits below and indicate the blow count necessary to achieve the required ultimate static pile capacities.

Allowable Driving Stresses

Steel Piles

Where fy is yield strength of steel

c. Perform a refined Wave Equation Analysis upon completion of the dynamic and static testing programs outlined in this specification section, taking into consideration the evaluated capacities, gain/loss factors and recommended production pile lengths. [Develop production pile driving criteria based on the results of the refined Wave Equation Evaluations.]

d. All pile driving equipment provided by the Contractor will be subject to the approval of the Contractor's Geotechnical Consultant. Complete the attached pile and driving equipment data form, including hammer information, in full as part of the submittal of the results of the Wave Equation Analyses.

e. Pay for the cost of performing the Wave Equation Analyses and include in the base bid.

3.1.2 Order List

Submit to the Contracting Officer for approval, an itemized quantities list for piles prior to placing the order with the supplier. Indicate the pile lengths required at each location as shown on the plans and the corresponding ordered length of each pile in the list. [Complete load
testing and refined wave equation analysis and submit to Government for review and approval prior to submission of an order list.]

3.2 INSTALLATION

Inspect piles when delivered and when in the leads immediately before driving. Cut piles at cutoff grade by an approved method. Where cutoff is below existing ground or mudline elevation, complete excavation, sheeting, and dewatering before driving pile to cutoff elevation.

3.2.1 Lengths of Production Piles

The estimated quantities of piles are given for bidding purposes only. Drive piles to [or below "calculated"] [indicated] tip elevation [to reach a driving resistance established by the wave equation analyses (WEAP) in accordance with the schedule which the Contractor's Geotechnical Consultant will prepare from the test-pile driving data].

3.2.2 Pile Driving Records

**************************************************************************

NOTE: Omit reference to load test when not required in project. Omit reference to test piles and "calculated tip elevation" when test piles are not driven. Where special or unusual soil conditions are expected, consultation with the Contracting Officer's Technical Representative (Geotechnical Branch) regarding special engineering supervision of driving, testing, recording and analysis of data for project may be useful.

NOTE: The Specifier must attach the specifications pile driving log graphic (for all pile driving projects) and the pile driving equipment data form (for projects using PDA) to the end of this specification section.

**************************************************************************

Submit the proposed form for compiling pile driving records 30 calendar days prior to commencement of work.

Keep a complete and accurate record of each pile driven. Indicate the pile location, deviations from pile location, cross section shape and dimensions, original length, ground elevation, tip elevation, cut-off elevations, [batter alignment,] number of blows required for each 300 mm foot of penetration and number of blows for the last 150 mm 6 inches penetration or fraction thereof [as required] for the "calculated" [driving resistance]. Include in the record the beginning and ending times of each operation during driving of pile, type and size of hammer used, rate of operation, stroke or equivalent stroke for diesel hammer, type of driving helmet, and type and dimension of hammer cushion (capblock) and pile cushion used. Record retap data and unusual occurrences during pile driving such as redriving, heaving, weaving, splicing, obstructions, [jetting,] and any driving interruptions.[ Install an energy monitor on the hammers and record readings during pile installation.] A preprinted pile driving log for recording pile driving data[ and pile driving equipment data form], which can be downloaded at: https://www.wbdg.org/ffc/dod/unified-facilities-guide-specifications-ufgs/forms-graphics-tables

SECTION 31 62 16.16  Page 29
Submit [to the Contracting Officer] complete and accurate [test and] job pile driving records as specified in paragraph RECORDS of this section, within [15] [_____] calendar days after completion of driving. Make pile driving records available to the Contracting Officer at the job site, within 24 hours after each day of pile driving.

3.2.3 **Pile Placement** and Tolerances in Driving

Develop and submit a pile placement plan which shows the installation sequence and the methods proposed for controlling the location and alignment of piles. Submit pile placement plan at least 30 calendar days prior to delivery of piles to the job site. Complete all foundation preparation in the area prior to the placement of piles for driving. Accurately place piles in the correct location and alignments, both laterally and longitudinally, and to the vertical or batter lines indicated. Establish a permanent base line to provide for inspection of pile placement by the Contracting Officer during pile driving operations prior to driving production piles and maintain during the installation of the production piles.

A final lateral deviation from the correct location at the cutoff elevation of not more than 76 mm 3 inches will be permitted for vertical and battered piles. Manipulation of piles will not be permitted. A variation of not more than 6 mm per 300 mm 0.25 inch per foot of pile length from the vertical for vertical piles nor more than 12 mm per 300 mm 0.50 inch per foot of pile length from the required angle for batter piles will be permitted. In addition to complying with the tolerances stated herein, the clear distance between the heads of piles and the edges of caps must be not less than 150 mm 6 inches. Redesign of pile caps or additional work required due to improper location of piles is the responsibility of the Contractor. A vertical deviation of not more than 25 mm one inch from the correct cutoff elevations shown is permitted. Inspect piles for heave. Redrive heaved piles to the required pile driving criteria. Maintain the correct relative position of all piles by the use of templates or by other approved means. Piles damaged or not located properly or exceeding the maximum limits for lateral and vertical deviation, or variation in alignment must be pulled and new piles redriven, or provide additional piles, at a location directed at no additional cost to the Government.

3.2.3.1 **Survey Data**

After the driving of each pile group is complete, provide the Contracting Officer with an as-driven survey showing actual location and top elevation of each pile. Do not proceed until the Contracting Officer has reviewed the survey and verified the safe load for the pile group driven. Present a survey in such form that it gives deviation from plan location in two perpendicular directions and elevations of each pile to nearest 13 mm half inch. Survey must be prepared and certified by a land surveyor licensed in [______].

3.2.4 **Pile Penetration Criteria**

The controlling driving resistance for production piles will be determined by the Contractor's Geotechnical Consultant. The required initial driving criteria and restrike will be established subsequent to the analysis of pile tests as specified in paragraph PILE TESTS.
3.2.5 Pile Length Markings

Mark each pile prior to driving with horizontal lines at 300 mm one foot intervals. Mark the interval number on pile every 1.5 m 5 feet from pile tip.

3.2.6 Pile Driving

**************************************************************************

NOTE: Delete bracketed option for foundation excavation when not required. Delete items in brackets dealing with tip elevation and driving resistance when test piles or load tests are not used. Delete item in brackets regarding predrilling or jetting when procedure is not used. If needed, insert maximum hammer energy for no tip resistance. This can be determined by comparing tensile stresses in pile resulting from a Wave Equation Analysis with effective prestress in pile.

**************************************************************************

Notify Contracting Officer 10 days prior to driving of [test] piles[ and load test].[ Stop foundation excavation at 300 mm one foot above foundation grade before piles are driven. Do not drive piles within 30 meter 100 feet of concrete less than 7 days old. Complete excavation to lines and grades shown when pile driving is completed.][ The Contractor's Geotechnical Consultant will determine the terminal driving criteria based on results of [dynamic pile driving tests at the end of drive or restrike] [static load tests] [wave equation analysis].] Drive piles to [the terminal driving criteria] [or below "calculated" [indicated tip elevation] [to reach a driving resistance established by the [dynamic pile driving tests at the end of drive or restrike] [static load tests] [wave equation analyses (WEAP)] in accordance with the schedule which the [Contractor's Geotechnical Consultant] [Contracting Officer] will prepare from the test-pile driving data]. During initial driving and until pile tip has penetrated beyond layers of very soft soil [or below bottom of predrilled or prejetted holes], use a reduced driving energy of the hammer as required to prevent pile damage. Refusal criteria will be established by the Contracting Officer. If a pile fails to reach ["calculated"] [indicated] tip elevation, [or if a pile reaches ["calculated"] tip elevation without reaching required driving resistance,] notify Contracting Officer and perform corrective measures as directed. Provide hearing protection when noise levels exceed 140 dB. Piles may be driven without pile guides or leads providing a hammer guide frame is used to keep the pile and hammer in alignment.

3.2.7 Protection of Piles

**************************************************************************

NOTE: Delete references to batter piles when not applicable to the project.

**************************************************************************

Take care to avoid damage to piles during handling, placing pile in leads, and during pile driving operations. Support piles laterally during driving, but allow rotation in leads.[ Where pile or projecting reinforcement orientation is essential, take precautionary measures to maintain the orientation during driving.][ Take special care in supporting battered piles to prevent excessive bending stresses in pile.] Maintain
axial alignment of pile hammer with that of the pile. If the Contractor elects to use a pile head with projecting strands or mild steel reinforcement, prevent direct impact forces from being transmitted through the reinforcement, by using a special driving head.

3.2.8 Rejected Piles

Withdraw piles damaged or impaired for use during handling or driving, mislocated, or driven out of alignment beyond the maximum tolerance. Replace with new piles or cut-off and abandon damaged or impaired piles and drive new piles as directed. Remove excess cut-off from piles and unacceptable piles from the work site. Perform all work in connection with withdrawing and removing rejected piles from the site at no additional cost to the Government.

3.2.8.1 Obstructions

If a pile encounters an underground obstruction within 1.5 meters 5 feet of the ground surface of such size as to prevent driving the pile to the required driving criteria, the pile must be pulled or cut off at no cost to the Government. If such an obstruction is encountered more than 5 feet below the ground surface, the pile must be cut off and paid for as if a completed pile. In either event, a replacement pile must be installed at a location indicated by the Contracting Officer and paid for as a completed pile.

3.2.8.2 Splicing Piles

NOTE: Splicing of piles normally should not be permitted except where extremely long or heavy piles are required. If splices are permitted, drawings should indicate splice details. (See PCI standard drawings for typical splice details).

[Splicing of piles is not permitted.] [Make splices as indicated. Splices must be capable of developing the full strength of the member in compression, tension, shear, and bending. Submit detail drawings of splices and design calculations demonstrating the strength of the splice for approval.] [Provide a detailed procedure for insufficient pile length where recovering of pile length is required.]

3.2.9 Jetting of Piles

NOTE: Jetting should generally not be permitted for piles:

1. Dependent on side friction in fine-grained low permeability soils (high clay or silt content) where considerable time is required for the soil to reconsolidate around the piles.

2. Subject to uplift or lateral forces.

3. Adjacent to existing structures.

4. In closely spaced clusters unless the load...
capacity is confirmed by test.

**************************************************************************

Water jets will [not] be permitted. [Use jetting to assist driving piles through strata that cannot be penetrated practicably by use of the hammer alone. [Restrict driving to a static weight while water is being injected to prevent inducing tensile stresses in the piles.] Discontinue jetting and resume hammer driving after the penetration of the strata requiring jetting has been accomplished.] [Discontinue jetting when the pile tip is approximately 1.5 m 5 feet above the [calculated] [indicated] pile tip elevation. Drive pile the final 1.5 m 5 feet of penetration or more to meet the required driving criteria.] [Take adequate measures for collecting and disposing of runoff water.] [Jetting method and equipment must be approved by the Contracting Officer prior to commencing jetting operation.] Before starting final driving, firmly seat piles in place by application of a number of reduced energy hammer blows. [Employ measures, including use of a silt curtain, to contain turbid water created by jetting piles.]

3.2.10 Predrilling of Piles

**************************************************************************

NOTE: Predrilling should generally not be permitted for piles:

1. Dependent on side friction in fine-grained low permeability soils (high clay or silt content) where considerable time is required for the soil to reconsolidate around the piles.

2. Subject to uplift or lateral forces.

3. Located in cohesionless soils.

4. In closely spaced clusters unless the load capacity is confirmed by test.

**************************************************************************

Predrilling to remove soil or other material representing the bulk of the volume of the pile to be driven [will [not] be permitted] [will be provided]. [The diameter of the hole must not exceed two-thirds the width of the pile.] [Predrill only to a depth of [_____] meters feet below cut-off elevation prior to setting piles.] [Discontinue drilling when the pile tip is approximately 1.5 m 5 feet above the [calculated] [indicated] pile tip elevation. Drive pile the final 1.5 m 5 feet of penetration or more to meet the required driving criteria.]

3.2.10.1 Heaved Piles

When driving piles in clusters or under conditions of relatively close spacing, perform observations to detect heave of adjacent piles. Backdrive heaved piles to original to the required [depth of penetration] [tip elevation] [refusal blow count] as directed by the Contractor's Geotechnical Consultant, after reviewing the heave data, without additional cost to the Government.

3.2.10.2 Pulled Piles

Pull and replace piles damaged or impaired for use during driving with new
piles, or cut off and abandon and drive new piles as directed without additional cost to the Government. The Contracting Officer may require that any pile be pulled for inspection. Redrive piles pulled as directed and found to be in suitable condition at another location as directed. Replace piles pulled as directed and found to be damaged with new piles at the Contractor's expense.

3.2.10.3 Long Piles

Provide pile driving rig with rigid supports so that leads remain accurately aligned. Where a high degree of accuracy is required, erect templates or guide frames at or close to the ground or water surface.

3.2.10.4 Welding

AWS D1.1/D1.1M. Welding of splices must conform to the requirements of Section 05 50 14 STRUCTURAL METAL FABRICATIONS. Shop and field welding, qualification of welding procedures, welders, and welding operators must be in accordance with AWS D1.1/D1.1M.

[3.2.11 Protection of Existing Structures

**************************************************************************

NOTE: Include this paragraph only when protection of existing structures from pile driving activities is required.

The designer must indicate on the drawings all structures and facilities for which protection is required. The designer must also provide a project specific document that details design criteria, requirements for preconstruction condition surveys, post construction condition surveys, geotechnical instrumentation to measure ground movements and any other requirements.

Add any additional requirements as necessary.

**************************************************************************

Mitigate impact on existing facilities due to pile driving activities in accordance with the [project specific document][____].

]3.3 FIELD QUALITY CONTROL

3.3.1 Test Piles

**************************************************************************

NOTE: Select the second bracketed option when soil conditions dictate the use of a test pile longer than production piles. The ordered pile length for test piles should be 1.5 m 5 feet longer than ordered length for production piles to allow additional penetration if driving conditions dictate. Indicate location and number (if required) of test piles on plans, or list appropriate soil boring test hole numbers.

**************************************************************************

[Use test piles of type, and drive as specified for piling elsewhere in
this section.) Order test piles [____] meters [____] feet longer in length than production piles. Drive the additional test pile length only at the direction of the Contracting Officer. The [Contractor's Geotechnical Consultant] [Contracting Officer] will use test pile data to determine "calculated" pile tip elevation or necessary driving criteria. Drive test piles [at the locations indicated] [in vicinity of soil boring test holes Nos. [____,] [____,] and [____]]. Drive test piles to [indicated tip elevation] [indicated bidding lengths] [required driving criteria]. Use test piles, if located properly and offering adequate driving resistance in finished work. [Pre-drilling or jetting is permitted only when test piles clearly establish validity of its use, or as directed by the Contracting Officer.]

Provide and operate a pile driving analyzer as specified in paragraph DYNAMIC PILE ANALYSIS during the driving of each test pile. Modify driving as required based upon recommendation of [Contractor's Geotechnical Consultant and approval of the Contracting Officer].

3.3.1.1 Dynamic Pile Analysis

Submit a performance report summarizing dynamic test results for [test] piles within [7] [_____] calendar days of completing field work. [For production piles, submit a performance report within one day of testing. Submit a typed report summarizing the results of dynamic testing of production piles on a monthly basis.]

Dynamic testing provides supplemental information for evaluating pile integrity, hammer and drive system performance, assess pile installation driving stresses, and pile capacities. Perform dynamic testing on [____] percent of the [test] piles during the full length of the pile driving and during restrike a minimum of [_____] days after initial driving. Dynamic pile testing must also be performed on [____] production piles as chosen by the Contracting Officer. Use [test] piles of type as specified elsewhere in this section. Provide equipment to obtain dynamic measurements, record, reduce and display its data that meet the requirements of ASTM D4945. The equipment must have been calibrated within [6] [_____] months prior to the start of the testing operations and thereafter throughout the contract duration. Drive [test] piles at the locations indicated or at the locations selected by the Contracting Officer. Employ an independent inspection firm, hereinafter referred to as the "Contractor's Geotechnical Consultant", experienced in the pile driving process[, monitoring of test pile installation,] and in the use of the Pile Driving Analyzer and its related equipment. Perform dynamic pile analysis as follows:

3.3.1.2 Pile Analyzing

[____] working days prior to driving the [test] piles, submit the pile and complete driving equipment data to the Contracting Officer. The Contractor's Geotechnical Consultant must use the submitted information to perform wave equation analyses and must prepare a summary report of the wave equation results. The wave equation analysis using GRLWEAP software by Pile Dynamics, Inc. or equivalent must be used to assess the ability of the proposed driving system to install the pile to the required capacity and desired penetration depth within the allowable driving stresses. Approval of the proposed driving system by the Contracting Officer must be based upon the wave equation analyses indicating that the proposed driving system can develop a pile capacity of [_____] kN kips at a driving resistance not greater than [_____] blows per mm blows per inch within allowable driving stress limits. The hammer must also be sized or
adjustable such that the penetration per blow at the required ultimate capacity does not exceed 12 mm 0.5 inches.

3.3.1.3 Pile Drivability

Perform each dynamic pile analysis in two steps. The first step is to check the hammer, pile and soil performance, and to determine the suitability of the proposed hammer for the size, length and type of pile being installed for the soil types encountered as the piles are driven. This initial monitoring must determine whether pre-augering or jetting is appropriate, efficiency of the hammer relative to specified efficiency, effectiveness of cushion, level of compressive and tensile stress in pile and extent/location of any pile damage caused by the initial driving. With each blow of the pile, record the information listed below electronically and analyze the information using the Pile Driving Analyzer:

a. Blow number.

b. Blow rate per minute and stroke.

c. Input and reflected values of force and velocity.

d. Value of upward and downward traveling force wave with time.

e. Maximum and final transferred energy to pile, hammer system efficiency.

f. Maximum compressive stress, velocity, acceleration and displacement.

g. Maximum tensile stress in pile.

h. Pile structural integrity, damage detection, extent and location.

i. Bearing capacity of pile by Case method.

If the pile, hammer and soil performance evaluation recommends changes to the hammer stroke, pile cushioning, augering or any other aspect for the pile driving operation, incorporate these changes into production pile driving in an effort to control excessive stresses and pile damage. Replace test piles damaged or broken during installation, incorporating driving modifications as determined by the Contractor’s Geotechnical Consultant and reviewed and approved by the Contracting Officer. Repeat this procedure until allowable tensile and compressive stresses are achieved in the pile and pile damage is minimized. Subject selected initial driving records to rigorous computer analysis by the Case Pile Wave Analysis Program (CAPWAP) for determination of resistance distribution, soil resistance and properties, and estimation of anticipated gain/loss factors.

3.3.1.4 CAPWAP

Signal matching analysis by CAPWAP software of the dynamic pile testing data must be performed on data obtained from the end of initial driving and the beginning of restrike of all control piles. CAPWAP analyses must be performed by an engineer who has achieved Advanced Level or better on the PDI / PDCA Dynamic Measurement and Analysis Proficiency Test for Providers of PDA Testing Services.

Upon completion of [test] pile driving, allow the piles to set-up for at least [72 hours] [____ days]. After evaluation of pile, hammer and soil
performance by the Contractor's Geotechnical Consultant, the second step of
the dynamic pile analysis may proceed. This portion of the evaluation
requires striking the set-up piles a minimum of 20-50 times, or as directed
by the Contractor's Geotechnical Consultant using the same hammer which was
used for the [test] pile driving and which will be used for production pile
driving. "Warm up" the hammer and make it optimally ready prior to
restriking, in order to avoid capacity losses during evaluation of restrike
data. Apply maximum hammer energy during restrike in order to fully
mobilize the soil resistance. However, exercise care so as to not
overstress the pile. In addition to those items listed above, selected
restrike driving records (as directed by the Contractor's Geotechnical
Consultant) are to be subjected to rigorous computer analysis by the Case
Pile Wave Analysis Program (CAPWAP) for determination of resistance
distribution, soil resistance and properties, and plot of applied load vs.
average pile displacement based on the calculated soil properties.

3.3.1.5 Dynamic Load Test Reporting

a. Upon satisfactory completion of each dynamic load test, submit [a
minimum of three copies of] a Pile Performance Report for the
Contractor by the Contractor's Geotechnical Consultant. The submittal
must be prepared and sealed by a Professional Engineer registered in
[______].

b. The report for the Dynamic Pile Analysis must contain the following
information:

(1) Capacity of pile from Case Pile Wave Analysis Program (CAPWAP).
Information resulting from analysis of a selected restrike blow.

(2) Maximum and final transferred energy, hammer system efficiency
during pile installation.

(3) Maximum compressive stress, velocity, acceleration and
displacement.

(4) Maximum tensile stress in pile.

(5) Pile structural integrity, damage detection, extent and location.

(6) Blows per minute and blow number.

(7) Input and reflection values of force and velocity, upward and
downward traveling force wave with time.

(8) Pile skin friction and toe resistance distribution.

(9) Maximum energy transferred to pile.

c. The maximum allowable pile design load must be proposed by the
Contractor's Geotechnical Consultant based upon the results of a
satisfactory pile load test conducted on a pile driven as specified
herein and must include the effects of load transfer to the soil above
the foundation stratum.

Use either a Model 8G or PAX Pile Driving Analyzer as manufactured by Pile
Dynamics, Inc., of Cleveland Ohio or approved equivalent, for dynamic
testing of the pile hammer and for dynamic load testing of the test pile.
All equipment necessary for the dynamic monitoring such as sensors, cables
or wireless transmitters, must be furnished by the Contractor's Geotechnical Consultant. The equipment must conform to the requirements of ASTM D4945.

Pay for all services of the Contractor's Geotechnical Consultant. The Contractor's Geotechnical Consultant must be available throughout the pile driving operation to consult with the Contracting Officer when required by the Contracting Officer. The cost of changes in the Contractor's procedure, as required by evaluation of the results of the Pile Driving Analysis, will be at the Contractor's expense.

3.3.2 Static Load Tests

NOTE: If pile load tests are required and approved by the Contracting Officer, specify number and location of piles. Select method of load test. In ASTM D1143/D1143M, permit anchor piles only if approved by the Contracting Officer's Technical Representative (Geotechnical Branch). Insert figure KN kips corresponding to 200 percent of the design load. Select appropriate acceptance criteria. The offset method (first option) is usually recommended.

Submit details and procedures for Pile load test frame.

Perform compressive load tests on [_____] test piles in accordance with ASTM D1143/D1143M (standard loading procedure) as modified herein. [Allow a minimum of [72 hours] [_____ days] following final test pile driving for pile set-up prior to load testing. ] [Do not use anchor piles.] Provide apparatus for applying vertical loads as required by method, using load from weighted box or platform [or reaction frame attached to sufficient uplift piles to safely take required load] applied to pile by hydraulic jack. Increase load in increments until rapid progressive settlement takes place or until application of total compressive load of [_____] KN [_____] kips for compressive load tests. Consider load test satisfactory when [after one hour at full test load gross settlement of pile butt is not greater than gross elastic pile compression plus 4 mm 0.15 inch plus one percent of pile tip diameter or width in [_____] mm [_____] inches,] [slope of gross load-settlement curve under full test load does not exceed 1.5 mm per metric ton 0.05 inches per ton,] [net settlement after removal of test load does not exceed 19 mm 3/4 inch]. Perform load tests at locations [as proposed by the Contractor's Geotechnical Consultant and] as directed by the Contracting Officer. Additional load tests, at Government expense, may be required by the Contracting Officer. Perform the loading, testing, and recording and analysis under the direct supervision of a Registered Professional Engineer, registered in the state of project location, and provided and paid for by the Contractor.

3.3.2.1 Safe Design Capacity

Determine the safe design capacity of a test pile as determined from the results of load tests according to UFC 3-220-01.

3.3.3 Tensile Load Test

Perform tensile load tests on [_____] test piles in accordance with ASTM D3689, as modified [and] in paragraph LOAD TESTS. Apply a tensile
Perform the tension load test, apply the ultimate load equal to one and one-half times the safe tension capacity, and employ the Standard Loading Procedure.

Perform dynamic measurements on [_____] piles designated as dynamic test piles in accordance with ASTM D4945 during driving. During easy driving, ensure that damaging tension stresses do not develop in the pile. Signal matching must be performed by the Contractor's Geotechnical Consultant on representative data collected at the end of the initial driving and at the beginning of all restrike events. Additional signal matching analysis must be performed as determined by the Engineer.

3.3.4 Lateral Load Test

Perform lateral load tests on [_____] piles in accordance with ASTM D3966/D3966M, as modified [and] in paragraph LOAD TESTS. Lateral load tests must consist of jacking two piles apart with a hydraulic jack, with one pile serving as the reaction pile for the other. Apply a lateral load of [_____] kN kips to each pair of lateral load test piles. Record required movement readings for each pile.

3.3.5 Pile Records

NOTE: Omit reference to load test when not required in project. Omit reference to test piles and "calculated tip elevation" when test piles are not driven. Where special or unusual soil conditions are expected, consultation with the Contracting Officer's Technical Representative (Geotechnical Branch) regarding special engineering supervision of driving, testing, recording and analysis of data for project may be useful.

NOTE: The Specifier must attach the specifications pile driving log graphic (for all pile driving projects) and the pile driving equipment data form (for projects using PDA) to the end of this specification section.

Keep a complete and accurate record of each pile driven. Indicate the pile location, deviations from pile location, cross section shape and dimensions, original length, ground elevation, tip elevation, cut-off elevations, [batter alignment,] number of blows required for each 300 mm foot of penetration and number of blows for the last 150 mm 6 inches penetration or fraction thereof [as required] for the "calculated" [driving resistance]. Include in the record the beginning and ending times of each operation during driving of pile, type and size of hammer used, rate of operation, stroke or equivalent stroke for diesel hammer, type of driving helmet, and type and dimension of hammer cushion (capblock) and pile cushion used. Record retap data and unusual occurrences during pile driving such as redriving, heaving, weaving, splicing, obstructions, [jetting,] and any driving interruptions.[ Install an energy monitor on the hammers and record readings every 300 mm 12 inches of pile installation.] A preprinted pile driving log for recording pile driving data[ and pile driving equipment data form], which can be downloaded at:
[3.3.6  Testing Agency Qualification

Engage an independent testing agency to observe the production piles installation. The testing agency must be qualified according to ASTM E329 for testing indicated. Submit testing agency qualifications to the Contracting Officer for approval.

3.3.7  Welding Inspection

Employ a testing agency to perform the welding inspections as specified in the statement of special inspection.

3.3.8  Weld Testing

In addition to visual inspection, welds must be tested and inspected according to AWS D1.1/D1.1M and inspection procedures listed below, at testing agency's option. Correct deficiencies in Work that test reports and inspections indicate do not comply with the Contract Documents.[ Test [10] [%_] percent of pile splices, the steel pile cap splice connections and the steel pile insert connection.]

a. Liquid Penetrant Inspection: ASTM E165/E165M.

b. Magnetic Particle Inspection: ASTM E709; performed on root pass and on finished weld. Cracks or zones of incomplete fusion or penetration are not accepted.

c. Radiographic Inspection: ASTM E94/E94M, minimum quality level "2-2T."

d. Ultrasonic Inspection: ASTM E164.

3.4  TOUCHUP PAINTING

Clean field welds, splices, and abraded painted areas and field-apply paint according to SSPC PA 1. Use same paint and apply same number of coats as specified. Apply touchup paint before driving piles to surfaces that are immersed or inaccessible after driving.

3.5  SPECIAL INSPECTION AND TESTING FOR SEISMIC-RESISTING SYSTEMS

**************************************************************************
NOTE: Include this paragraph only when special inspection and testing for seismic-resisting systems is required by the International Building Code (IBC).

This paragraph will be applicable to both new buildings designed and to existing building seismic rehabilitation designs done according to UFC 1-200-01, "General Building Requirements" and UFC 3-310-04, "Seismic Design for Buildings".

The designer must indicate on the drawings all locations and all features for which special inspection and testing is required in accordance with Chapter 17 of the IBC. This includes indicating the locations of all structural
components and connections requiring inspection.

Add any additional requirements as necessary.

Perform special inspections and testing for seismic-resisting systems and components in accordance with Section 01 45 35 SPECIAL INSPECTIONS.

][3.6 VIBRATION CONTROL

NOTE: Include this paragraph when vibration monitoring is required. Add any additional criteria or requirements as necessary for the particular project.

Perform vibration monitoring at the locations [shown in the plan] [decided by the Contracting Officer] during the pile driving operations. Perform vibration monitoring [using] [seismographs] and geophones within a distance of [61] [_____] meters [200] [_____] feet from the pile driving activity. Engage the services of a qualified, independent vibration consultant, acceptable to the Government, to conduct the vibration monitoring. The vibration consultant must have minimum of [five] [_____] years of experience in vibration monitoring. A minimum of [28] [_____] days before the installation of vibration monitors, submit to the Government the name of the vibration consultant and a list of at least [three] [_____] previously completed projects of similar scope and purpose.

Prior to the pile driving activities, obtain baseline readings of ambient vibrations. The vibration during the pile driving activities must be limited to [a peak particle velocity of not more than [5] [_____] cm [2.0] [_____] inches per second.] [the limits mentioned in the [contract documents] [_____] .] [Determine appropriate vibration limits as per [US Bureau of Mines] [American Association of State Highway and Transportation Officials (AASHTO)] guidelines.] During pile driving activities, monitor the vibrations to ensure the limits are not exceeded. If the limits are exceeded, cease the pile driving activity causing the vibration until [the Vibration consultant and the Contracting Officer] [_____] are on site to observe the structures nearest to the vibration monitor which has exceeded the limits.

The Contractor must be responsible for all damages resulting from the pile driving operations and must take whatever measures necessary to maintain peak particle velocity within the specified limit. After completion of the project, remove the vibration monitors off the site and off Government property and restore the monitoring locations back to their original condition.

][3.7 NOISE CONTROL

NOTE: Include this paragraph when noise monitoring is required. Add any additional criteria or requirements as necessary for the particular project.

Perform noise monitoring at the locations [shown in the plan] [decided by the Contracting Officer] [at noise sensitive public areas] during the pile
driving operations. Perform noise monitoring using [noise meters], and engage the services of a qualified, independent noise consultant, acceptable to the Government, to conduct the noise monitoring. The noise consultant must have minimum of [five] years of experience in noise monitoring. A minimum of [28] days before the installation of noise monitors, submit to the Government the name of the noise consultant and a list of at least [three] previously completed projects of similar scope and purpose.

Prior to the pile driving activities, obtain baseline readings of ambient noise levels. The noise limits are mentioned in the [plan] [contract documents]. Determine appropriate noise limits as per [local agency] [Occupation Safety and Health Administration] guidelines. During pile driving activities, monitor the noise to ensure the limits are not exceeded. If the limits are exceeded, cease the pile driving activity and install noise mitigation measures.

The Contractor must be responsible for all damages resulting from the pile driving operations and must take whatever measures necessary to maintain noise within the specified limit. After completion of the project, remove the noise monitors off the site and off Government property and restore the monitoring locations back to their original condition.

3.8 PRECONSTRUCTION CONDITION SURVEY

NOTE: Add any additional criteria or requirements as necessary for the particular project.

Perform preconstruction condition survey of [structures] [and utilities] within [61] feet of the pile driving activity [specified in the plans] [decided by the Contracting Officer]. Perform outreach to the owner of the structures [28] days before performing the preconstruction condition survey. The Contractor must obtain written permission from the owner of the structure prior to accessing the structure. The preconstruction condition survey must include video and photographic documentation of the exterior and interior of above ground structures and of the interior of underground structures. Video documentation must be in high definition, and show existing conditions and highlight, where possible, existing cracks, deteriorated concrete, exposed and corroded reinforcement, cracked or broken brick or mortar, and other signs of distress. For utilities, perform the survey when the greatest extent of the interior is exposed. Provide supplementary artificial lighting as needed. The video must include annotation with location and structure nomenclature which describes any areas of distress over the video and time code superimposed on the video. Photographs must be accompanied by sketches or descriptions that indicate the location and direction of each photograph. For each structure surveyed, provide a Pre-Construction Condition Survey Report following completion of the survey. The report must contain all documentation associated with the survey including DVD copies. In the report, include notes, sketches, photographs, and videos. Provide general information, such as location details and structure type, as well as particular information on materials, condition, existing damage, aperture and persistence of cracks, and disrepair observed during visual survey. Provide a graphical depiction of locations of damage or other features of concern. Submit the Preconstruction Condition Survey Reports no later than [28] days before the commencement of pile driving activity. Accept responsibility for damages to existing adjacent or
adjoining structures created by pile driving work, and repair any damages to these structures without cost to the Government.

[3.9 CONSTRUCTION INSTRUMENTATION AND MONITORING PROGRAM

**************************************************************************
NOTE: Include this section if instrumentation is to be installed due to concerns about vibration, settlement, lateral movement, etc. during pile driving activities. Instrumentation should be specified and included in the specification. This section can be deleted if there are no instrumentation requirements.

Add any additional criteria or requirements as necessary for the particular project.
**************************************************************************

Prepare a geotechnical instrumentation program to monitor settlement [and lateral movement] of temporary and permanent structures, utilities, [embankments] [and excavations] during pile driving. The design and distribution of instrumentation must demonstrate an understanding of the need, purpose and application of each proposed type. Perform noise and vibration monitoring in accordance with NOISE CONTROL and VIBRATION CONTROL sections.

Monitoring must extend before, during and for a period after completion of construction activities related to pile driving when long-term performance issues are a concern. The monitoring plan must be designed to protect adjacent structures and utilities against damage due to the pile driving activities. Establish limiting values of vertical [and horizontal] movement [and angular distortion] [and vibration] for each structure and utility within the zone of influence, subject to review by the Government.

Prepare a report detailing the proposed program of instrumentation and monitoring, establishing threshold values of monitored parameters, and describing the response plans that will be implemented when threshold parameters are exceeded. The report must include details about instrumentation consultant's experience, appropriate types, quantities, locations and monitoring frequencies of the instruments. Submit interim and final instrumentation and monitoring program reports.

Upon acceptance of the instrumentation and monitoring program, provide, install and monitor the instrumentation and interpret the data. Submit instrumentation data reports not less than every [_____] days after the monitoring program has begun. Take corrective actions, as necessary, based on the field instrumentation data and as defined in the instrumentation and monitoring program.

3.8 CONSTRUCTION INSTRUMENTATION AND MONITORING PROGRAM

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for procurement, installation, and testing of land and fresh water construction timber piles.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

NOTE: The extent and location of the work to be accomplished should be indicated on the project drawings or included in the project specification.

NOTE: Add requirements for materials and procedures for special or unusual design as necessary to fit specific projects. Specify marine piling for waterfront and other marine (salt water) type structures in another section of the project specification. Marine and Highway construction use of round piles requires the review of AWPA use categories 5A, 5B and 5C subject to geographical location.
NOTE: Show, as a minimum, the following information on the project drawings:

Subsurface data: Subsurface-soil-data logs.

The subsoil investigation report and samples of material taken from subsurface investigations may be examined in the office where bids are received, the office of the Resident Officer in Charge of Construction, and the Architect/Engineer's office.

Pile location plan with GPS coordinates.

Test Pile Locations

PART 1   GENERAL

NOTE: Structural engineer must confirm the structural capacity of piles and provide specific bending moments, lateral loads and other design requirements for pile design.

1.1 DESCRIPTION

Design, furnish, install and test timber piles at the locations indicated on the drawings and specified herein. (Assume test pile[s] will be directed to be placed in [a] location[s] that can be incorporated into the work.)

1.2 REFERENCES

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

The publications listed below form a part of this specification to the
extent referenced. The publications are referred to within the text by the basic designation only.

**************************************************************************

NOTE: The American Wood Protection Association (AWPA) has recently adopted many new Standards (2006 Book of Standards) as well as establishing the new USE CATEGORY SYSTEM: User Specification for Treated Wood. Specifiers are advised to familiarize themselves with the latest standards and their relationship to the specific project requirements and environmental considerations. Specifiers should refer to Section 3 of U1 and review the following use categories prior to editing this guideline specification:

"4C" for wood foundation piles used for building construction completely embedded in soil (ground contact).

"4C" for round piles used for highway construction (ground contact or fresh water).

"4B" for sawn piles supporting residential/business structures.

"4C" for sawn piles supporting residential/business structures, critical.

Specifier should also refer to Section 3 of AWPA U1.

The existence of the AWPA Standards for treated products does not imply that all other regulatory bodies recognize or permit the use of the particular combination of preservatives, processes, and wood species listed in the AWPA Standards.

**************************************************************************

AMERICAN WOOD PROTECTION ASSOCIATION (AWPA)

AWPA M1 (2021) Standard for the Purchase of Treated Wood Products

AWPA M2 (2019) Standard for the Inspection of Preservative Treated Wood Products for Industrial Use

AWPA M3 (2016) Standard for the Quality Control of Preservative Treated Products for Industrial Use

AWPA M4 (2021) Standard for the Care of
Preservative-Treated Wood Products

AWPA M6 (2013) Brands Used on Preservative Treated Materials

AWPA P1/P13 (2019) Standard for Creosote Preservative

AWPA P3 (2019) Standard for Creosote - Petroleum Oil Solution

AWPA T1 (2021) Use Category System: Processing and Treatment Standard

1.3 SUBSURFACE DATA

Subsurface soil data logs are [indicated] [appended to the special contract requirements] [provided on the project drawings]. [The subsoil
investigation report may be examined at [______].

1.4  BASIS OF BID

******************************************************************************
NOTE: Select one of the following options:
******************************************************************************
******************************************************************************
NOTE: Use "Lump Sum" paragraph below for lump (principal) sum bidding of piles. Use this in all projects except those where exact pile lengths cannot be practically determined prior to the actual work. Clearly show number of piles, pile capacity, pile locations, and tip and cutoff elevations on the drawings.

Use "Unit Price" paragraph for unit price bidding of piles. Specify unit price bid items for piles only for projects where exact quantities cannot be practically determined prior to the actual work. Lengths of piles must be determined as accurately as possible, prior to bidding, since the unit price per meter foot of the piles varies as the length increases or decreases. Refer to Standard Test Method for High-Strain Dynamic Testing of Deep Foundations (ASTM D4945).
******************************************************************************

1.4.1  Production Pile Acceptance Criteria

Base bids on the number, circumference of piles at the butt and tip, and length of piles from tip to cutoff as indicated. Safe design capacity for piles is [______] KN kips. Drive piles to [minimum tip elevation] [a minimum depth of [______] m feet below cut-off elevation], and to such additional depth as required to obtain a bearing capacity of not less than [______] KN kips. The Contractor's Geotechnical Consultant will determine the terminal driving criteria based on results of [dynamic pile driving tests at end of drive or restrike] [static load tests] [wave equation analysis]. [Test piles that meet performance requirements may be included into the permanent work.]

The following formulas can be used in cases where allowable pile loads are less than 355 kN 80 kips (determined using a factor of safety of 3 for individual piles and 4 for pile groups) and are presented only as a guide to aid in establishing the controlling penetration per blow, which, together with the minimum depth of penetration will serve to determine the required minimum depth of penetration of each individual pile:

\[ R = \frac{2E}{S + 0.1} \quad \text{For double acting hammers} \]

\[ R = \frac{2WH}{S + 0.1} \quad \text{For single acting hammers} \]

Where \( R \) is the approximate allowable pile load in kips; \( E \) equals the energy in foot-kips per blow based on an acceptable certified statement from the manufacturer of the hammer; \( W \) equals the weight of the hammer or ram in kips; \( H \) equals the height of fall of the hammer of ram in feet; and \( S \)
equals the average inches of penetration per blow for the last three
blows. An allowance will be made for reduced penetration caused by shock
absorption of the cushion or cap blocks.

[1.4.2 Lump Sum Payment

**************************************************************************
NOTE: Use this paragraph for lump-sum contracts,
consult with Contracting Officer's Technical
Representative (Geotechnical Branch) on
applicability of use prior to selection. This
paragraph will be typically used when there are 1)
relatively small quantity of piles, 2) allowable
pile loading is less than 355 kN 80 kips, and 3)
the subsurface conditions are well defined. Fill in
Table I as required selecting columns applicable to
project. Generally, pile capacity, location, and
minimum tip elevation are shown on plans. Test
piles and load tests are not incorporated on lump
sum contracts. Delete this paragraph for unit-price
contracts.
**************************************************************************

Base bids upon providing the number, size, capacity, and length of piles as
indicated on the [drawings.] [following Table I:

<table>
<thead>
<tr>
<th>Location</th>
<th>Number</th>
<th>Size</th>
<th>Capacity</th>
<th>Length (Tip to Cut-Off)</th>
<th>Maximum Bending Moment</th>
<th>Maximum Shear Force</th>
</tr>
</thead>
</table>

Include the cost of all necessary equipment, tools, material, labor, and
supervision required to: deliver, handle, install, cut-off, dispose of any
cut-offs, and meet the applicable contract requirements. Include
mobilization, pre-drilling, and redriving heaved piles. If, in redriving,
it is found that any pile is not of sufficient length to provide the
capacity specified, notify the Contracting Officer, who reserves the right
to increase or decrease the total length of piles to be provided and
installed by changing the pile locations or elevations, requiring the
installation of additional piles, or directing the omission of piles from
the requirements shown and specified. If total number of piles or number
of each length vary from that specified as the basis for bidding, an
adjustment in the contract price or time for completion, or both, will be
made in accordance with the contract documents. Payment for piles will be
based on successfully installing piles to both the minimum tip elevation
and satisfying the acceptance criteria identified herein. No additional
payment will be made for: damaged, rejected, or misplaced piles; withdrawn
piles; any portion of a pile remaining above the cut-off elevation;
backdriving; cutting off piles; splicing; build-ups; any cut-off length of
piles; or other excesses beyond the assumed pile length indicated for which
the Contractor is responsible. [ Include payments for vibration monitoring,
sound monitoring and precondition construction surveys].

][1.4.3 Unit Price

**************************************************************************
NOTE: Delete this paragraph for lump-sum contracts.
For NAVFAC PAC projects: Where there is unit pricing for piles, use this paragraph and edit applicable attachments in price schedule for inclusion in Standard Form 1442, "Solicitation, Offer and Award" and "Schedule of Bid Items."

For NAVFAC Southeast projects, where there is a need for unit pricing of piles, include this paragraph. Refer to NAVFAC SE Instruction 00010, "Instructions for Preparing Basis of Bid Statement With Unit-Priced Items," for method of specifying unit price bid items.

**************************************************************************
For unit price bid, see SF 1442, "Solicitation, Offer and Award" and "Schedule of Bid Items."
**************************************************************************

NOTE: For NAVFAC LANT projects, use the following paragraph for measurement and payment and subsequent sub-parts.

**************************************************************************
Requirements of FAR 52.211-18 Variation in Estimated Quantity do not apply to payment for piling. Each pile and test pile acceptably provided will be paid for at the bid unit price per unit length, which will include items incidental to furnishing and driving the piles including mobilization and demobilization, [jetting] [predrilling] [probing], redriving uplifted piles, [an additional 1.5 m 5 feet in furnished length for any test pile not driven beyond estimated pile length,] and cutting off piles at the cut-off elevation.[ Include the cost for additional length for the test piles in the total unit price cost for the job.] Payment will be made for production [and test piles] at the bid unit price for the length of pile, from tip to final cut-off, actually provided, excluding buildups and splices directed by the Contracting Officer to be made. If the actual cumulative pile length driven (tip to cut-off) vary more than 25 percent from the total pile length specified as a basis for bidding, at the direction of the Contracting Officer, the unit price per unit length will be adjusted in accordance with provisions of FAR 52.236-2 Differing Site Conditions.[ Payments will be made per each at the respective bid unit price for pile cut-offs, pile build-ups, pile loads tests and pile splices.][ Include payments for vibration monitoring, sound monitoring, construction instrumentation and monitoring, and precondition construction surveys].

][1.5 PAYMENT

**************************************************************************
NOTE: Delete this paragraph for lump-sum contracts.
**************************************************************************

If Section 01 20 00 PRICE AND PAYMENT PROCEDURES is included in the project specifications, this paragraph title (UNIT PRICES) should be deleted from this section and the remaining appropriately edited subparagraphs below should be inserted into Section 01 20 00 PRICE AND PAYMENT PROCEDURES.
1.5.1 Furnishing and Delivering Timber Piles

1.5.1.1 Payment

Payment will be made for costs associated with furnishing and delivering the required lengths of permanent timber piles, which includes costs of furnishing and delivering piles to the work site. No payment will be made for the driving head or lengths of piles exceeding required lengths. No payment will be made for piles damaged during delivery, storage, or handling to the extent that they are rendered unsuitable for the work, in the opinion of the Contracting Officer.

1.5.1.2 Measurement

Furnishing and delivering permanent timber piles will be measured for payment by the linear meter foot of piles required below the cut-off elevation as [determined by the Contracting Officer and furnished to the Contractor] [indicated].

1.5.1.3 Unit of Measure

Linear meter foot.

1.5.2 Driving Timber Piles

1.5.2.1 Payment

Payment will be made for costs associated with driving permanent timber piles, which includes costs of handling, driving, [and splicing of piles,] [performing dynamic testing, interpreting data and submitting reports,] measuring heave, redriving heaved piles, removal of [build-ups] driving heads or cutting off piles at the cut-off elevation and removing from the work site, compiling and submitting pile driving records, backfilling voids around piles, and any other items incidental to driving piles to the required elevation.

1.5.2.2 Measurement

Permanent timber piles will be measured for payment for driving on the basis of lengths, to the nearest hundredth (tenth) of a linear meter foot, along the axis of each pile acceptably in place below the cut-off elevation shown.

1.5.2.3 Unit of Measure

Linear meter foot.

1.5.3 Pulled Timber Piles

1.5.3.1 Payment

Payment will be made for costs associated with piles pulled at the direction of the Contracting Officer and found to be undamaged. The cost of furnishing and delivering pulled and undamaged piles will be paid for at the applicable contract unit price for payment item "Furnishing and Delivering Timber Piles". The cost of driving pulled and undamaged piles will be paid for at the applicable contract unit price for payment item "Driving Timber Piles". The cost of pulling undamaged piles will be paid for at twice the applicable contract unit price for payment item "Driving
Timber Piles", which includes backfilling any remaining void. The cost of redriving pulled and undamaged piles will be paid for at the applicable contract unit price for payment item "Driving Timber Piles". No payment will be made for furnishing, delivering, driving, pulling, and disposing of piles, including pile driving points, pulled and found to be damaged and backfilling voids. New piles replacing damaged piles will be paid for at the applicable contract unit price for payment items "Furnishing and Delivering Timber Piles" and "Driving Timber Piles".

1.5.3.2 Measurement

Furnishing and delivering pulled and undamaged permanent timber piles will be measured for payment as specified in paragraph UNIT PRICES, subparagraph FURNISH AND DELIVER TIMBER PILES. Pulling undamaged timber piles will be measured for payment as specified in paragraph UNIT PRICES, subparagraph DRIVING TIMBER PILES. Redriving pulled undamaged timber piles will be measured for payment as specified in paragraph UNIT PRICES, subparagraph DRIVING TIMBER PILES. New piles replacing damaged piles will be measured for payment as specified in paragraph UNIT PRICES, subparagraphs FURNISH AND DELIVER TIMBER PILES and DRIVING TIMBER PILES.

1.5.3.3 Unit of Measure

Linear meter foot.

1.5.4 Timber Pile Driving Tests

1.5.4.1 Payment

Payment will be made for costs associated with furnishing, delivering, driving, pulling, and disposing of driven test piles[, including [pile driving points] [and] [splices]]; conducting pile driving tests; backfilling voids around piles; compiling pile driving test records[; performing dynamic testing; interpreting data; and submitting reports].

1.5.4.2 Measurement

Timber pile driving tests will be measured for payment on the basis of the applicable contract unit price per pile driving test.

1.5.4.3 Unit of Measure

Each.

1.5.5 Timber Piles for Load Tests

1.5.5.1 Payment

Payment will be made for costs associated with furnishing, delivering, driving, pulling, and disposing of load test piles[, including [pile driving points] [and] [splices]]; backfilling voids around piles; compiling pile driving records[; furnishing, fabricating, and mounting of strain rods and protective assembly][; furnishing, fabricating, and mounting of inclinometer and inclinometer protective assembly][; performing dynamic testing; interpreting data; and submitting reports]. No additional payment will be made for load test piles incorporated in the permanent work other than as provided.
1.5.5.2 Measurement

Timber piles for load tests will be measured for payment on the basis of the applicable contract unit price per load test pile.

1.5.5.3 Unit of Measure

Each.

1.5.6 Timber Pile Static Axial Compressive Load Tests

1.5.6.1 Payment

Payment will be made for costs associated with timber pile static axial compressive load tests in accordance with ASTM D1143/D1143M, including material and labor for fabricating and furnishing load frames; calibrating load cells and hydraulic jacks; furnishing specified test equipment; installing strain rods; placing and removing test loads and test equipment; recording, reducing, and submitting test data; and compiling and submitting pile load test reports. No payment will be made for rejected pile static axial compressive load tests.

1.5.6.2 Measurement

Timber pile static axial compressive load tests will be measured for payment on the basis of the applicable contract unit price per load test.

1.5.6.3 Unit of Measure

Each.

1.5.7 Timber Pile Static Tensile Load Tests

1.5.7.1 Payment

Payment will be made for costs associated with timber pile static tensile load tests in accordance with ASTM D3689, including material and labor for fabricating and furnishing load frames; calibrating load cells and hydraulic jacks; furnishing specified test equipment; installing strain rods; placing and removing test loads and test equipment; recording, reducing, and submitting test data; and compiling and submitting pile load test reports. No payment will be made for rejected pile static tensile load tests.

1.5.7.2 Measurement

Timber pile tensile load tests will be measured for payment on the basis of the applicable contract unit price per number of tensile load test.

1.5.7.3 Unit of Measure

Each.

1.5.8 Timber Pile Lateral Load Tests

1.5.8.1 Payment

Payment will be made for costs associated with timber pile lateral load tests in accordance with ASTM D3966/D3966M, including material and labor.
for fabricating and furnishing load frames; calibrating load cells and
hydraulic jacks; furnishing specified test equipment; installing
inclinometers; placing and removing test loads and test equipment;
recording, reducing, and submitting test data; and compiling and submitting
pile load test reports. No payment will be made for rejected pile lateral
load tests.

1.5.8.2 Measurement

Timber pile lateral load tests will be measured for payment on the basis of
the applicable contract unit price per lateral load test.

1.5.8.3 Unit of Measure

Each.

1.5.9 Pulled Load Test Timber Piles

1.5.9.1 Payment

Payment will be made for costs associated with load test timber piles
pulled prior to load testing at the direction of the Contracting Officer
and found to be undamaged. The cost of furnishing, delivering, driving,
and pulling undamaged load test piles will be paid for at the applicable
contract unit price for payment item "Timber Piles for Load Tests". The
cost of pulling undamaged load test piles the second time after redriving
and testing will be paid for at twice the applicable contract unit price
for payment item "Driving Timber Piles". The cost of redriving pulled
undamaged load test piles will be paid for at the applicable contract unit
price for payment item "Driving Timber Piles". No payment will be made for
furnishing, delivering, driving, pulling, and disposing of load test piles
pulled at the direction of the Contracting Officer and found to be
damaged. New load test piles replacing damaged piles will be paid for at
the applicable contract unit price for payment item "Timber Piles for Load
Tests".

1.5.9.2 Measurement

Pulled undamaged load test timber piles will be measured for payment as
specified in paragraph UNIT PRICES, subparagraph TIMBER PILES FOR LOAD
TESTS. Pulling undamaged load test timber piles the second time after
redriving and testing will be measured for payment as specified in
paragraph UNIT PRICES, subparagraph DRIVING TIMBER PILES. Redriving pulled
undamaged timber piles will be measured for payment as specified in
paragraph UNIT PRICES, subparagraph DRIVING TIMBER PILES. New load test
piles replacing damaged piles will be measured for payment as
specified in paragraph UNIT PRICES, subparagraph TIMBER PILES FOR LOAD
TESTS.

1.5.9.3 Unit of Measure

As specified in paragraph UNIT PRICES, subparagraphs DRIVING TIMBER PILES
and TIMBER PILES FOR LOAD TESTS, respectfully.

1.5.10 Pile Driving Shoes

1.5.10.1 Payment

Payment will be made for costs associated with pile driving shoes,
including furnishing, delivering, and installing.

1.5.10.2 Measurement

Pile driving shoes will be measured for payment on the basis of the number of pile driving shoes required.

1.5.10.3 Unit of Measure

Each.

1.5.11 Timber Pile Splices

1.5.11.1 Payment

Payment will be made for costs associated with timber pile splices, including all plant, labor, and material required to make the splice.

1.5.11.2 Measurement

Timber pile splices will be measured for payment on the basis of the applicable contract unit price per pile splice.

1.5.11.3 Unit of Measure

Each.

1.5.12 Vibration Monitoring

1.5.12.1 Payment

Payment will be made for costs associated with vibration monitoring.

1.5.12.2 Measurement

Vibration monitoring will be measured for payment on the basis of the applicable contract unit price per vibration monitoring point.

1.5.12.3 Unit of Measure

Each.

1.5.13 Sound Monitoring

1.5.13.1 Payment

Payment will be made for costs associated with sound monitoring.

1.5.13.2 Measurement

Sound monitoring will be measured for payment on the basis of the applicable contract unit price per vibration monitoring point.

1.5.13.3 Unit of Measure

Each.
1.5.14 Preconstruction Condition Survey

1.5.14.1 Payment

Payment will be made for costs associated with preconstruction condition surveys.

1.5.14.2 Measurement

Preconstruction condition survey will be measured for payment on the basis of the applicable contract unit price per structure to be surveyed.

1.5.14.3 Unit of Measure

Each.

1.5.15 Construction Instrumentation and Monitoring

1.5.15.1 Payment

Payment will be made for costs associated with construction instrumentation and monitoring.

1.5.15.2 Measurement

Construction instrumentation and monitoring will be measured as a single pay item.

1.5.15.3 Unit of Measure

One.

1.6 SUBMITTALS

********************************************************************************

NOTE: Review Submittal Description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy, Air Force, and NASA projects.

********************************************************************************
The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy, Air Force, and NASA projects, or choose the second bracketed item for Army projects.

**************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.] [for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-01 Preconstruction Submittals
   Testing Agency Qualifications; G[, [____]]

SD-02 Shop Drawings
   Installation Drawings; G[, [____]]

SD-03 Product Data
   Driving Equipment; G[, [____]]
   Helmets and Cushion Blocks; G[, [____]]
   Pile Shoes; G[, [____]]

SD-04 Samples
   Test Piles; G[, [____]]

SD-06 Test Reports
   [ Pile Driving Test Data; G[, [____]]
   ][ Pile Driving Analyzer; G[, [____]]
   ][ Dynamic Testing Of Piles
   ] Test Piles; G[, [____]]
   Load Tests; G[, [____]]

SD-07 Certificates
   Timber Piles; G[, [____]]

SD-11 Closeout Submittals
   Pile Driving Records; G[, [____]]
1.7 DELIVERY, STORAGE, AND HANDLING

Stack piles during delivery and storage so that each pile is maintained in a straight position and is supported every 3 meters 10 feet or less along its length (ends inclusive). Do not stack piles more than 1.5 meters 5 feet high. Use methods for handling and storage of piles such that the piles are not subjected to excessive bending stress.

Load, unload or transfer treated wood products using procedures specified in AWPA M4. Use slings, padding, or any method to prevent or minimize damage to treated wood products. Treat any damage sustained during handling as specified above.

Untreated piles to be stored for an extended period of time must be inspected periodically, as well as shortly before driving, to detect damage due to fungus and insect attack. If treated piles are to be stored in a horizontal position for an extended period of time, they must be inspected periodically to ensure that the treatment does not seep to the lower half of the pile to the extent that the upper half does not contain a sufficient amount of treatment. Inspect piles for excessive curvature and for damage before transporting them from the storage area to the driving area and immediately prior to placement in the driving leads. Curvature in the pile must be measured with the pile laying on a flat surface and is the distance between the pile at the mid-length of the pile and the flat surface. Maximum permissible curvature is 50 mm 2 inches over the length of the pile. Piles having excessive curvature will be rejected.

1.7.1 Damaged Piles

Inspect each pile for soundness, splits, knots and holes before transporting them to the project site and immediately prior to placement in the driving leads. Bring any unusual pile conditions to the attention of the Contracting Officer. Piles which are damaged during delivery, storage, or handling to the extent they are rendered unsuitable for the work, in the opinion of the Contracting Officer, will be rejected and removed from the project site, or may be repaired, if approved, at no cost to the Government.

Any pile damaged by reason of internal defects or by improper driving must be corrected by one of the following methods approved by the Engineer for the pile in question:

a. The pile is withdrawn, if practicable, and replaced by a new and, if necessary, longer pile.

b. One or more replacement piles are driven adjacent to the defective pile.

c. A Pile Dynamic Analysis and integrity testing must be performed by the Contractor's Geotechnical Consultant to assess the structural integrity of the driven pile(s).

A pile driven below the specified butt elevation must be corrected by one of the following methods approved by the Engineer:

a. The pile is spliced (if approved).

b. A sufficient portion of the footing is extended down to properly embed the pile.

A pile driven out of its proper location or out of plumb as approved by the
Engineer, must be corrected by one of the following methods approved by the engineer:

a. One or more replacement piles are driven next to the pile in question.

b. As directed by the structural engineer.

1.7.2 Pile Sweep

**************************************************************************
NOTE: Sweep and camber typically apply to steel piles. In special cases, this paragraph may apply to precast/pre-stressed concrete piles or timber piles.
**************************************************************************

Limit sweep to 3 mm per 3 M 1/8 inch per 10 feet over the length of the pile. Piles having excessive sweep will be rejected.

1.8 QUALITY ASSURANCE

The producer must brand each treated pile, in accordance with AWPA M1, AWPA M2, AWPA M6, AWPA T1 and AWPA U1. Submit the inspection report of an independent inspection agency, approved by the Contracting Officer, stating that offered products comply with applicable AWPA Standards, and that the plant conforms to AWPA M3.

1.9 PLANT INSPECTION

The Government, at its discretion, reserves the right to inspect the treating process. Notify the Contracting Officer at least 3 weeks prior to beginning the treatment, stating where preservative treatment will be done. Allow Government inspector access to all parts of the plant. Allow inspection of all facets of the treating process.

PART 2 PRODUCTS

2.1 MATERIALS

2.1.1 Piles

**************************************************************************
NOTE: Choose one of the following options.
**************************************************************************

**************************************************************************
NOTE: The option below covers piles pressure treated with a preservative for land or fresh water. Specify or indicate on the drawings the minimum butt or tip circumference of the pile. Use butt circumference for a friction pile and tip circumference for an end-bearing pile.
**************************************************************************

**************************************************************************
NOTE: For NAVFAC LANT projects only, the following minimum circumferences normally apply:
<table>
<thead>
<tr>
<th>Capacity (metric tons)</th>
<th>Minimum Butt Circumference for Friction Piles (Use Table 1. ASTM D25) (mm)</th>
<th>Minimum Tip Circumference for End-Bearing Piles (Use Table 2. ASTM D25) (mm)</th>
</tr>
</thead>
<tbody>
<tr>
<td>(18)</td>
<td>(965 mm)</td>
<td>(483 mm)</td>
</tr>
<tr>
<td>(23)</td>
<td>(965 or 1041 mm)*</td>
<td>(559 mm)</td>
</tr>
<tr>
<td>(27)</td>
<td>(1041 mm)</td>
<td>(635 mm)</td>
</tr>
</tbody>
</table>

*Depends on specific soil conditions encountered at the site.

<table>
<thead>
<tr>
<th>Capacity (tons)</th>
<th>Minimum Butt Circumference for Friction Piles (Use Table 1. ASTM D25) (inches)</th>
<th>Minimum Tip Circumference for End-Bearing Piles (Use Table 2. ASTM D25) (inches)</th>
</tr>
</thead>
<tbody>
<tr>
<td>(200)</td>
<td>(38 inches)</td>
<td>(19 inches)</td>
</tr>
<tr>
<td>(25)</td>
<td>(38 or 41 inches)*</td>
<td>(22 inches)</td>
</tr>
<tr>
<td>(30)</td>
<td>(41 inches)</td>
<td>(25 inches)</td>
</tr>
</tbody>
</table>

*Depends on specific soil conditions encountered at the site.

[Provide pressure treated Douglas fir or southern pine clean-peeled piles conforming to ASTM D25. Minimum [butt circumference measured at 900 mm 3 feet from the butt] [tip circumference] must be [[_____] mm inches] [as indicated]. Piles must be in one piece. Splicing is [not] permitted. Submit the inspection report of an independent inspection agency, approved by the Contracting Officer, stating that offered products comply with applicable AWPA Standards. Identify treatment on each piece by the quality mark of an agency accredited by the Board of Review of the America Lumber Standard Committee.

**************************************************************************

[Provide untreated [Douglas fir or southern pine] [_____] [clean-peeled] [rough-peeled] [unpeeled] piles conforming to ASTM D25, AWPA T1, and AWPA U1. Minimum [butt circumference measured at 900 mm 3 feet from the butt] [tip circumference] must be [[_____] mm inches] [as indicated]. Piles must be in one piece. [ Splices are not permitted.][ Splices are permitted.] A straight line drawn from the center of the butt to the center of the tip.
must lie entirely within the body of the pile per ASTM D25. [Ensure a continuous taper from the point of butt measurement to the tip.]

2.1.2 Preservative Treatment

**************************************************************************
NOTE: This paragraph covers preservative and preservative treatment for land or fresh water piling. Compliance with treatment standards must be confirmed, by an inspection report from an approved independent inspection agency, on each pile. Select appropriate treatment for intended use. Do not use CCA, ACA, or ACZA treatment for round timber piles when significant bending or impact loads are expected.
**************************************************************************

Provide [round] piles[ conforming to ASTM D25 and AWPA T1] treated with [creosote per AWPA A1, AWPA P1/P13, and AWPA P2], [or] [creosote-coal tar solution conforming to AWPA A1, AWPA P1/P13, and AWPA P3] [waterborne preservative either, Ammoniacal Copper Arsenate (ACA), Ammoniacal Copper Zinc Arsenate (ACZA), or Chromated Copper Arsenate (CCA) in accordance with AWPA A2 and AWPA P5] for Land and Fresh Water Piles, confirmed by the report of an approved independent inspection agency.

[Treat cut, bored, dappled, and damaged surfaces as specified in AWPA M4[ project requirements].]

2.2 PILE DRIVING EQUIPMENT

Provide Pile Driving Equipment as mentioned in this section.

2.2.1 Pile Hammers

Provide a hammer capable of developing the indicated ultimate pile capacity at blow count less than 100 per 300 mm foot considering hammer impact velocity; ram weight; stiffness of hammer and pile cushions; cross section, length, and total weight of pile; and character of subsurface material to be encountered. [Use the same pile hammer, operating at the same rate and in the same manner, as that used for driving test piles.] Use wave equation analysis to verify that the hammer will develop stresses within acceptable limits in the piles. At final driving, operate pile hammer in accordance with manufacturer's recommendation. Provide the plant and equipment for air hammers that have sufficient capacity to maintain, under working conditions, the pressure at the hammer specified by the manufacturer. The hose connecting the compressor with the hammer must be at least the minimum size recommended by the Manufacturer. Evaluate hammer performance at the end of driving by measuring blows per minute and comparing with the manufacturer's recommendations. Measure impact velocity of open-end (single acting) diesel hammers at all times during pile driving operations with a device for this purpose. If such a device is not available, obtain the stroke by measuring the speed of operation either manually or with a device that makes the measurement automatically. Equip closed-end (double acting) diesel hammers with a bounce chamber pressure gauge in good working order, mounted near ground level so as to be easily read by the Contracting Officer. Provide a correlation chart of bounce chamber pressure and potential energy. Equip hydraulic hammers with a system for measurement of ram energy. The system must be in good working order and the results must be easily and immediately available to the
2.2.2 Driving Helmets and Cushion Blocks

2.2.2.1 Driving Helmets or Pile Cushions

Use a steel driving helmet or pile cushion between top of pile and driving helmet or cap to prevent impact damage to pile. Use a driving helmet or pile cushion combination capable of protecting pile head, minimizing energy absorption and dissipation, and transmitting hammer energy uniformly over top of pile. Provide driving helmet that fits sufficiently loose around top of pile so that pile may be free to rotate without binding within driving helmet.[ During test pile installation, demonstrate to satisfaction of Contracting Officer that equipment to be used on project performs specified function.] Use pile cushion of solid wood or of laminated construction using plywood, softwood or hardwood boards with grain parallel to end of pile. Select the pile cushion thickness placed on the pile head prior to driving by wave equation analysis so that the limiting driving stresses are not exceeded. Replace pile cushion at the start of driving of each pile and when it becomes highly compressed, charred or burned, or has become spongy or deteriorated in any manner. Show details of driving helmets, and pile cushions. Submit 2 weeks prior to [test] pile installation.

2.2.2.2 Hammer Cushion

**************************************************************************
NOTE: Select either wood or aluminum/micarta cushion. Delete inappropriate sentences. An aluminum/micarta cushion is recommended because of its consistent elastic properties and long life. If final pile penetration resistance is based on a Wave Equation analysis, the type of cushion used should be the same as that used in the analysis.
**************************************************************************

Use a hammer cushion between driving helmet or cap and hammer ram consisting of [a solid hardwood block with grain parallel to the pile axis and enclosed in a close-fitting steel housing] [aluminum and micarta (or equal) discs stacked alternately in a steel housing or a suitable polymer designed for this specific purpose as indicated by the hammer manufacturer]. Use steel plates at top and bottom of hammer cushion.[ Replace hammer cushion when it becomes highly compressed, charred or burned or becomes spongy or deteriorated in any manner].[ Replace aluminum, micarta or polymer discs that have become damaged, split or deteriorated in any manner].[ Do not replace hammer cushion during final driving of any pile.] Do not use small wood blocks, wood chips, rope or other materials that permit excessive loss of hammer energy.

If the cushion is other than that specified above, submit to the Contracting Officer at least two weeks prior to the commencement of test pile driving, detailed drawings and records of previous successful use. Generally, follow the pile hammer manufacturer's recommendations with respect to hammer cushions.
PART 3 EXECUTION

3.1 PRELIMINARY WORK

3.1.1 Installation Drawings

Submit pile installation drawings at least 28 calendar days prior to installation. Drawings must indicate individual pile numbers, sequencing, and any phasing or special installation considerations.

3.1.2 Wave Equation Analysis of Pile Drivability

a. Prior to driving any pile, submit a pile Wave Equation Analysis, performed by Contractor's Geotechnical Consultant, for each size pile and distinct subsurface profile condition. These analyses must take into account the proposed hammer assembly, pile capblock and cushion characteristics, the pile properties and estimated lengths and the soil properties anticipated to be encountered throughout the installed pile length based on static capacity analysis with consideration of driving gain/loss factors. Only one specific model of pile hammer may be used for each pile type and capacity.

b. Demonstrate using the Wave Equation Analysis that the piles will not be damaged during driving, indicate that the driving stresses will be maintained within the limits below and indicate the blow count necessary to achieve the required ultimate static pile capacities.

**Allowable Driving Stresses**

<table>
<thead>
<tr>
<th>Wood</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Compression</td>
<td>20.7 MPa 3 ksi</td>
</tr>
<tr>
<td>Tension</td>
<td>20.7 MPa 3 ksi</td>
</tr>
</tbody>
</table>

Qa Allowable static timber stress

c. Perform a refined Wave Equation Analysis upon completion of the dynamic and static testing programs outlined in this specification section, taking into consideration the evaluated capacities, gain/loss factors and recommended production pile lengths.

d. All pile driving equipment provided by the Contractor will be subject to the approval of the Contractor's Geotechnical Consultant. Complete the attached pile and driving equipment data form, including hammer information, in full as part of the submittal of the results of the Wave Equation Analyses.

e. Pay for the cost of performing the Wave Equation Analyses and include in the base bid.

3.1.3 Pile Length Markings

Mark each pile prior to driving with horizontal lines at 305 mm one foot intervals. Mark the interval number on pile every 1.52 m 5 feet from pile tip.
3.2 PILE DRIVING

3.2.1 Driving Piles

**************************************************************************
NOTE: Delete bracketed option for foundation excavation when not required. Delete items in brackets dealing with tip elevation and driving resistance when test piles or load tests are not used. Delete item in brackets regarding predrilling or jetting when procedure is not used. If needed, insert maximum hammer energy for no tip resistance. This can be determined by comparing tensile stresses in pile resulting from a Wave Equation Analysis with effective prestress in pile.
**************************************************************************

Notify Contracting Officer 10 days prior to driving of [test] piles[ and load test].[ Submit pile driving test data and reports of the dynamic testing of piles within one [day] [week] after each test is completed.]

[Stop foundation excavation at 300 mm one foot above foundation grade before piles are driven. Do not drive piles within 30 meter 100 feet of concrete less than 7 days old. Complete excavation to lines and grades shown when pile driving is completed.] Piles may be driven when the specified 28-day concrete strength has been achieved but not less than 7 days after casting.[ The Contractor's Geotechnical Consultant will determine the terminal driving criteria based on results of [dynamic pile driving tests at the end of drive or restrike] [static load tests] [wave equation analysis].] Drive piles to [the terminal driving criteria] [or below "calculated"] [indicated tip elevation] [to reach a driving resistance established by the [dynamic pile driving tests at the end of drive or restrike] [static load tests] [wave equation analyses (WEAP)] in accordance with the schedule which the [Contractor's Geotechnical Consultant] [Contracting Officer] will prepare from the test-pile driving data]. During initial driving and until pile tip has penetrated beyond layers of very soft soil [or below bottom of predrilled or prejetted holes], use a reduced driving energy of the hammer as required to prevent pile damage. Refusal criteria will be established by the Contracting Officer. If a pile fails to reach ["calculated"] [indicated] tip elevation, [or if a pile reaches ["calculated"] tip elevation without reaching required driving resistance,] notify Contracting Officer and perform corrective measures as directed. Provide hearing protection when noise levels exceed 140 dB. Do not handle or move piles or pile sections in any manner that would result in cracking or permanent damage to the concrete or to the grout surrounding the prestressing cables. Piles may be driven without pile guides or leads providing a hammer guide frame is used to keep the pile and hammer in alignment.

3.2.2 Protection of Piles

**************************************************************************
NOTE: Delete references to batter piles when not applicable to the project.
**************************************************************************

Take care to avoid damage to piles during handling, placing pile in leads, and during pile driving operations. Support piles laterally during driving, but allow rotation in leads.[ Where pile or projecting
reinforcement orientation is essential, take precautionary measures to maintain the orientation during driving. [Take special care in supporting battered piles to prevent excessive bending stresses in pile.] Square top of pile to longitudinal axis of pile. Maintain axial alignment of pile hammer with that of the pile. If the Contractor elects to use a pile head with projecting strands or mild steel reinforcement, prevent direct impact forces from being transmitted through the reinforcement, by using a special driving head.

3.2.3 Pile Placement and Tolerances in Driving

******************************************************************************
NOTE: Omit references to batter piles when not applicable to the project. Select appropriate tolerances for type of pile. Use more stringent criteria as necessary based on the application. Confirm with the structural engineer.
******************************************************************************

Drive piles with a variation of not more than 2 percent from vertical for plumb piles or more than 4 percent from required angle for batter piles. Maintain and check axial alignment of pile and leads at all times. If subsurface conditions cause pile drifting beyond allowable axial alignment tolerance, notify Contracting Officer and perform corrective measures as directed. Place butts within 100 mm 4 inches of location indicated. [Manipulation of piles within specified tolerances [will not be permitted.][will be permitted, to a maximum of 1-1/2 percent of their exposed length above ground surface or mudline.]} In addition to specified tolerances, maintain a location to provide a clear distance of at least 125 mm 5 inches from butt to edge of pile cap. If clear distance can not be maintained, then notify Contracting Officer. Piles must be monitored for heave immediately after installation and after adjacent piles are installed. If piles heave more than 13 mm 1/2 inch notify the Contracting Officer Redrive heaved piles to required point elevation. Piles damaged or driven outside the above tolerances must be replaced, or additional piles driven at locations specified by the Contracting Officer at no expense to the Government.

3.2.4 Rejected Piles

Withdraw piles damaged or impaired for use during handling or driving, mislocated, or driven out of alignment beyond the maximum tolerance. Replace with new piles or cut-off and abandon damaged or impaired piles and drive new piles as directed. Remove excess cut-off from piles and unacceptable piles from the work site. Perform all work in connection with withdrawing and removing rejected piles from the site at no additional cost to the Government.

3.2.5 Jetting of Piles

******************************************************************************
NOTE: Jetting should generally not be permitted for piles:

1. Dependent on side friction in fine-grained low permeability soils (high clay or silt content) where considerable time is required for the soil to reconsolidate around the piles.

SECTION 31 62 19 Page 25
2. Subject to uplift or lateral forces.

3. Adjacent to existing structures.

4. In closely spaced clusters unless the load capacity is confirmed by test.

**************************************************************************

Water jets will [not] be permitted. [Use jetting to assist driving piles through strata that cannot be penetrated practicably by use of the hammer alone. [Restrict driving to a static weight while water is being injected to prevent inducing tensile stresses in the piles which damage the concrete.] Discontinue jetting and resume hammer driving after the penetration of the strata requiring jetting has been accomplished.][Discontinue jetting when the pile tip is approximately 1.5 m 5 feet above the [calculated] [indicated] pile tip elevation. Drive pile the final 1.5 m 5 feet of penetration or more to meet the required driving criteria.][Take adequate measures for collecting and disposing of runoff water.][Jetting method and equipment must be approved by the Contracting Officer prior to commencing jetting operation.] Before starting final driving, firmly seat piles in place by application of a number of reduced energy hammer blows. [Employ measures, including use of a silt curtain, to contain turbid water created by jetting piles.]

3.2.6 Predrilling of Piles

**************************************************************************

NOTE: Predrilling should generally not be permitted for piles:

1. Dependent on side friction in fine-grained low permeability soils (high clay or silt content) where considerable time is required for the soil to reconsolidate around the piles.

2. Subject to uplift or lateral forces.

3. Located in cohesionless soils.

4. In closely spaced clusters unless the load capacity is confirmed by test.

**************************************************************************

Predrilling to remove soil or other material representing the bulk of the volume of the pile to be driven [will [not] be permitted] [will be provided]. [The diameter of the hole must not exceed two-thirds the width of the pile.][Predrill only to a depth of [_____] meters feet below cut-off elevation prior to setting piles.][Discontinue drilling when the pile tip is approximately 1.5 m 5 feet above the [calculated] [indicated] pile tip elevation. Drive pile the final 1.5 m 5 feet of penetration or more to meet the required driving criteria.]

3.2.7 Pile Splices

**************************************************************************

NOTE: Timber pile splices are difficult and undesirable. AASHTO(2010) LRFD Bridge Construction Specifications state that timber piles should not be spliced unless specified in the contract documents.
and approved by the engineer.

[Splicing of piles is not permitted.][ Make splices as indicated in the contract drawings.][ Splices must be capable of developing the full strength of the member in compression, tension, shear, and bending.][ Submit detail drawings of splices and design calculations demonstrating the strength of the splice for approval.]

3.2.8 Pile Cut-Off

Cut-off piles with a smooth level cut using pneumatic tools, sawing, or other suitable methods approved by Contracting Officer. Use of explosives for cutting is not permitted. Remove cut-off sections of piles from the site and off government property upon completion of the work.

3.2.9 As-Driven Survey

After the driving of each pile group is complete and before concrete is placed, provide the Contracting Officer with an as-driven survey showing actual location and top elevation of each pile. Do not proceed with placing concrete until the Contracting Officer has reviewed the survey and verified the safe load for the pile group driven. Present a survey in such form that it gives deviation from plan location in two perpendicular directions and elevations of each pile to nearest 13 mm half inch. Survey must be prepared and certified by a licensed land surveyor.

3.2.10 Protection of Existing Structures

NOTE: Include this paragraph only when protection of existing structures from pile driving activities is required.

The designer must indicate on the drawings all structures and facilities for which protection is required. The designer must also provide a project specific document that details design criteria, requirements for preconstruction condition surveys, post construction condition surveys, geotechnical instrumentation to measure ground movements and any other requirements.

Add any additional requirements as necessary.

Mitigate impact on existing facilities due to pile driving activities in accordance with the [project specific document] [____].

3.2.11 Pile Shoes

Where indicated or directed, securely attach pile shoes of an approved design to the piles in a manner described in the detail drawings.

3.3 FIELD QUALITY CONTROL

3.3.1 Test Piles
NOTE: Select the second bracketed option when soil conditions dictate the use of a test pile longer than production piles. The ordered pile length for test piles should be 1.5 m (5 feet) longer than ordered length for production piles to allow additional penetration if driving conditions dictate. Indicate location and number (if required) of test piles on plans, or list appropriate soil boring test hole numbers.

[Use test piles of type, and drive as specified for piling elsewhere in this section.][1] Order test piles [_____] meters (feet) longer in length than production piles. Drive the additional test pile length only at the direction of the Contracting Officer. The [Contractor's Geotechnical Consultant] [Contracting Officer] will use test pile data to determine "calculated" pile tip elevation or necessary driving criteria.[2] Submit pile driving analyzer data and report within one [day] [week] after each test is completed.

Drive test piles [at the locations indicated] [in vicinity of soil boring test holes Nos. [____], [____], and [____]]. Drive test piles to [indicated tip elevation] [indicated bidding lengths] [required driving criteria]. Use test piles, if located properly and offering adequate driving resistance in finished work. Pre-drilling or jetting is permitted only when test piles clearly establish validity of its use, or as directed by the Contracting Officer. [3] Provide and operate a pile driving analyzer as specified in paragraph DYNAMIC PILE ANALYSIS during the driving of each test pile. Modify driving as required based upon recommendation of [Contracting Officer] [Contractor's Geotechnical Consultant and approval of the Contracting Officer].]

3.3.1.1 Dynamic Pile Analysis

Dynamic testing provides supplemental information for evaluating pile integrity, hammer and drive system performance, assess pile installation driving stresses, and pile capacities. Perform dynamic testing on [_____] percent of the [test] piles during the full length of the pile driving and during restrike a minimum of [_____] days after initial driving. Dynamic pile testing must also be performed on [_____] production piles as chosen by the Contracting Officer. Use [test] piles of type as specified elsewhere in this section. Provide equipment to obtain dynamic measurements, record, reduce and display its data that meet the requirements of ASTM D4945. The equipment must have been calibrated within [6] [_____] months prior to the start of the testing operations and thereafter throughout the contract duration. Drive [test] piles at the locations indicated or at the locations selected by the Contracting Officer. Employ an independent inspection firm, hereinafter referred to as the "Contractor's Geotechnical Consultant", experienced in the pile driving process[, monitoring of test pile installation,] and in the use of the Pile Driving Analyzer and its related equipment. Perform dynamic pile analysis as follows:

3.3.1.2 Pile Analyzing

[_____] working days prior to driving the [test] piles, submit the pile and complete driving equipment data to the Contracting Officer. The Contractor's Geotechnical Consultant must use the submitted information to perform wave equation analyses and must prepare a summary report of the
wave equation results. The wave equation analysis using GRLWEAP software by Pile Dynamics, Inc. or equivalent must be used to assess the ability of the proposed driving system to install the pile to the required capacity and desired penetration depth within the allowable driving stresses. Approval of the proposed driving system by the Contracting Officer must be based upon the wave equation analyses indicating that the proposed driving system can develop a pile capacity of [_____] kN kips at a driving resistance not greater than [_____] blows per mm blows per inch within allowable driving stress limits. The hammer must also be sized or adjustable such that the penetration per blow at the required ultimate capacity does not exceed 12 mm 0.5 inches.

3.3.1.3 Pile Drivability

Perform each dynamic pile analysis in two steps. The first step is to check the hammer, pile and soil performance, and to determine the suitability of the proposed hammer for the size, length and type of pile being installed for the soil types encountered as the piles are driven. This initial monitoring must determine whether pre-augering or jetting is appropriate, efficiency of the hammer relative to specified efficiency, effectiveness of cushion, level of compressive and tensile stress in pile and extent/location of any pile damage caused by the initial driving. With each blow of the pile, record the information listed below electronically and analyze the information using the Pile Driving Analyzer:

a. Blow number

b. Blow rate per minute and stroke.

c. Input and reflected values of force and velocity.

d. Value of upward and downward traveling force wave with time.

e. Maximum and final transferred energy to pile, hammer system efficiency.

f. Maximum compressive stress, velocity, acceleration and displacement.

g. Maximum tensile stress in pile.

h. Pile structural integrity, damage detection, extent and location.

i. Bearing capacity of pile by Case method.

If the pile, hammer and soil performance evaluation recommends changes to the hammer stroke, pile cushioning, augering or any other aspect for the pile driving operation, incorporate these changes into production pile driving in an effort to control excessive stresses and pile damage. Replace test piles damaged or broken during installation, incorporating driving modifications as determined by the Contractor's Geotechnical Consultant and reviewed and approved by the Contracting Officer. Repeat this procedure until allowable tensile and compressive stresses are achieved in the pile and pile damage is minimized. Subject selected initial driving records to rigorous computer analysis by the Case Pile Wave Analysis Program (CAPWAP) for determination of resistance distribution, soil resistance and properties, and estimation of anticipated gain/loss factors.
Signal matching analysis by CAPWAP software of the dynamic pile testing data must be performed on data obtained from the end of initial driving and the beginning of restrike of all control piles. CAPWAP analyses must be performed by an engineer who has achieved Advanced Level or better on the PDI / PDCA Dynamic Measurement and Analysis Proficiency Test for Providers of PDA Testing Services.

Upon completion of [test] pile driving, allow the piles to set-up for at least [72 hours] [_____ days]. After evaluation of pile, hammer and soil performance by the Contractor's Geotechnical Consultant, the second step of the dynamic pile analysis may proceed. This portion of the evaluation requires striking the set-up piles a minimum of 20-50 times, or as directed by the Contractor's Geotechnical Consultant using the same hammer which was used for the [test] pile driving and which will be used for production pile driving. "Warm up" the hammer and make it optimally ready prior to restriking, in order to avoid capacity losses during evaluation of restrike data. Apply maximum hammer energy during restrike in order to fully mobilize the soil resistance. However, exercise care so as to not over stressing the pile. In addition to those items listed above, selected restrike driving records (as directed by the Contractor's Geotechnical Consultant) are to be subjected to rigorous computer analysis by the Case Pile Wave Analysis Program (CAPWAP) for determination of resistance distribution, soil resistance and properties, and plot of applied load vs. average pile displacement based on the calculated soil properties.

3.3.1.5 Dynamic Load Test Reporting

a. Upon satisfactory completion of each dynamic load test, submit[ a minimum of three copies of] a Pile Performance Report for the Contractor by the Contractor's Geotechnical Consultant. The submittal must be prepared and sealed by a Professional Engineer registered in [______].

b. The report for the Dynamic Pile Analysis must contain the following information:

1. Capacity of pile from Case Pile Wave Analysis Program (CAPWAP). Information resulting from analysis of a selected restrike blow.

2. Maximum and final transferred energy, hammer system efficiency during pile installation.

3. Maximum compressive stress, velocity, acceleration and displacement.

5. Pile structural integrity, damage detection, extent and location.

7. Input and reflection values of force and velocity, upward and downward traveling force wave with time.

8. Pile skin friction and toe resistance distribution.

9. Maximum energy transferred to pile.
c. The maximum allowable pile design load must be proposed by the Contractor's Geotechnical Consultant based upon the results of a satisfactory pile load test conducted on a pile driven as specified herein and must include the effects of load transfer to the soil above the foundation stratum.

Use either a model Model 8G or PAX Pile Driving Analyzer as manufactured by Pile Dynamics, Inc., of Cleveland Ohio or approved equivalent, for dynamic testing of the pile hammer and for dynamic load testing of the test pile. All equipment necessary for the dynamic monitoring such as sensors, cables or wireless transmitters, must be furnished by the Contractor's Geotechnical Consultant. The equipment must conform to the requirements of ASTM D4945.

Pay for all services of the Contractor's Geotechnical Consultant. The Contractor's Geotechnical Consultant must be available throughout the pile driving operation to consult with the Contracting Officer when required by the Contracting Officer. The cost of changes in the Contractor's procedure, as required by evaluation of the results of the Pile Driving Analysis, will be at the Contractor's expense.

3.3.2 Static Load Tests

Perform compressive load tests on [_____] test piles in accordance with ASTM D1143/D1143M (standard loading procedure) as modified herein. [Allow a minimum of [72 hours] [____ days] following final test pile driving for pile set-up prior to load testing.][Do not use anchor piles.] Provide apparatus for applying vertical loads as required by method, using load from weighted box or platform [or reaction frame attached to sufficient uplift piles to safely take required load] applied to pile by hydraulic jack. Increase load in increments until rapid progressive settlement takes place or until application of total compressive load of [____] KN kips for compressive load tests. Consider load test satisfactory when [after one hour at full test load gross settlement of pile butt is not greater than gross elastic pile compression plus 4 mm 0.15 inch plus one percent of pile tip diameter or width in [_____] mm inches,] [slope of gross load-settlement curve under full test load does not exceed 1.5 mm per metric ton 0.05 inches per ton,] [net settlement after removal of test load does not exceed 19 mm 3/4 inch]. Perform load tests at locations [as proposed by the Contractor's Geotechnical Consultant and] as directed by the Contracting Officer. Additional load tests, at Government expense, may be required by the Contracting Officer. Perform the loading, testing, and recording and analysis under the direct supervision of a Registered Professional Engineer, registered in the state of project location, and provided and paid for by the Contractor.

[3.3.2.1 Safe Design Capacity

Determine the safe design capacity of a test pile as determined from the results of load tests according to UFC 3-220-01.

][3.3.3 Tensile Load Test

Perform tensile load tests on [_____] test piles in accordance with ASTM D3689, as modified [and] in paragraph LOAD TESTS. Apply a tensile load of [_____] kN kips to each tensile load test pile. In performing the tension load test, apply the ultimate load equal to one and one-half times the safe tension capacity, and employ the Standard Loading Procedure.
Perform dynamic measurements on [_____] piles designated as dynamic test piles in accordance with ASTM D4945 during driving. During easy driving, ensure that damaging tension stresses do not develop in the pile. Signal matching must be performed by the Contractor's Geotechnical Consultant on representative data collected at the end of the initial driving and at the beginning of all restrike events. Additional signal matching analysis must be performed as determined by the Engineer.

3.3.4 Lateral Load Test

Perform lateral load tests on [_____] piles in accordance with ASTM D3966/D3966M, as modified [and] in paragraph LOAD TESTS. Lateral load tests must consist of jacking two piles apart with a hydraulic jack, with one pile serving as the reaction pile for the other. Apply a lateral load of [_____] kN kips to each pair of lateral load test piles. Record required movement readings for each pile.

3.3.5 Pile Driving Records

**************************************************************************
NOTE: Omit reference to load test when not required in project. Omit reference to test piles and "calculated tip elevation" when test piles are not driven. Where special or unusual soil conditions are expected, consultation with the Contracting Officer's Technical Representative (Geotechnical Branch) regarding special engineering supervision of driving, testing, recording and analysis of data for project may be useful.
**************************************************************************

NOTE: The Specifier must attach the specifications pile driving log graphic (for all pile driving projects) and the pile driving equipment data form (for projects using PDA) to the end of this specification section.

**************************************************************************

Keep a complete and accurate record of each pile driven. Indicate the pile location, deviations from pile location, cross section shape and dimensions, original length, ground elevation, tip elevation, cut-off elevations, [batter alignment,] number of blows required for each 300 mm foot of penetration and number of blows for the last 150 mm 6 inches penetration or fraction thereof [as required] for the "calculated" [driving resistance]. Include in the record the beginning and ending times of each operation during driving of pile, type and size of hammer used, rate of operation, stroke or equivalent stroke for diesel hammer, type of driving helmet, and type and dimension of hammer cushion and pile cushion used. Record retap data and unusual occurrences during pile driving such as redriving, heaving, weaving, splicing, obstructions, [jetting,] and any driving interruptions. [Install an energy monitor on the hammers and record readings every 300 mm 12 inches of pile installation.] A preprinted pile driving log for recording pile driving data [and pile driving equipment data form], which can be downloaded at: http://www.wbdg.org/ffc/ dod/unified-facilities-guide-specifications-ufgs/forms-graphics-tables

Submit complete and accurate pile driving records of installed piles to
Contracting Officer within [15] [_____] calendar days after completion of pile driving. Make pile driving records available to the Contracting Officer at the job site, within 24 hours after each day of pile driving. Preparation of the record must be by, or under the direct supervision of a registered professional engineer.

3.3.6 Testing Agency Qualifications

Engage an independent testing agency qualified according to ASTM C1077 and ASTM E329 for testing indicated and approved by the Contracting Officer.

[3.4 SPECIAL INSPECTION AND TESTING FOR SEISMIC-RESISTING SYSTEMS]

**************************************************************************

NOTE: Include this paragraph only when special inspection and testing for seismic-resisting systems is required by the International Building Code (IBC).

This paragraph will be applicable to both new buildings designed and to existing building seismic rehabilitation designs done according to UFC 1-200-01, "General Building Requirements" and UFC 3-301-01, "Structural Engineering".

The designer must indicate on the drawings all locations and all features for which special inspection and testing is required in accordance with Chapter 17 of the IBC. This includes indicating the locations of all structural components and connections requiring inspection.

Add any additional requirements as necessary.

**************************************************************************

Perform special inspections and testing for seismic-resisting systems and components in accordance with Section 01 45 35 SPECIAL INSPECTIONS.

[3.5 VIBRATION CONTROL]

**************************************************************************

NOTE: Include this paragraph when vibration monitoring is required. Add any additional criteria or requirements as necessary to the particular project.

**************************************************************************

Perform vibration monitoring at the locations [shown in the plan] [decided by the Contracting Officer] during the pile driving operations. Perform vibration monitoring [using] [seismographs] [and geophones] within a distance of 61 meters 200 feet from the pile driving activity. Engage the services of a qualified, independent vibration consultant, acceptable to the Government, to conduct the vibration monitoring. The vibration consultant must have minimum of [five] [_____] years of experience in vibration monitoring. A minimum of [28] [_____] days before the installation of vibration monitors, submit to the Government the name of the vibration consultant and a list of at least [three] [_____] previously completed projects of similar scope and purpose.

Prior to the pile driving activities, obtain baseline readings of ambient
vibrations. The vibration during the pile driving activities must be limited to [a peak particle velocity of not more than 5 cm 2 inches per second] [the limits mentioned in the [contract documents]]. [Determine appropriate vibration limits as per [US Bureau of Mines] [American Association of State Highway and Transportation Officials (AASHTO)] guidelines.] During pile driving activities, monitor the vibrations to ensure the limits are not exceeded. If the limits are exceeded, cease the pile driving activity causing the vibration until [the Vibration consultant and the Contracting Officer] [_____] are on site to observe the structures nearest to the vibration monitor which has exceeded the limits.

The Contractor must be responsible for all damages resulting from the pile driving operations and must take whatever measures necessary to maintain peak particle velocity within the specified limit. After completion of the project, remove the vibration monitors off the site and off Government property and restore the monitoring locations back to their original condition.

][3.6 NOISE CONTROL

**************************************************************************
NOTE: Include this paragraph when noise monitoring is required. Add any additional criteria, references or requirements as necessary to the particular project.
**************************************************************************

Perform noise monitoring at the locations [shown in the plan] [decided by the Contracting Officer] [at noise sensitive public areas] during the pile driving operations. [Perform noise monitoring using [noise meters][, and] [_____]]. [Engage the services of a qualified, independent noise consultant, acceptable to the Government, to conduct the noise monitoring. The noise consultant must have minimum of [five] [_____] years of experience in noise monitoring. A minimum of [28] [_____] days before the installation of noise monitors, submit to the Government the name of the noise consultant and a list of at least [three] [_____] previously completed projects of similar scope and purpose.]

Prior to the pile driving activities, obtain baseline readings of ambient noise levels. [The noise limits are mentioned in the [plan] [contract documents].] [Determine appropriate noise limits as per [local agency] [Occupation Safety and Health Administration] guidelines.] During pile driving activities, monitor the noise to ensure the limits are not exceeded. If the limits are exceeded, cease the pile driving activity and install noise mitigation measures.

The Contractor must be responsible for all damages resulting from the pile driving operations and must take whatever measures necessary to maintain noise within the specified limit. After completion of the project, remove the noise monitors off the site and off Government property and restore the monitoring locations back to their original condition.

][3.7 PRECONSTRUCTION CONDITION SURVEY

**************************************************************************
NOTE: Add any additional criteria, references or requirements as necessary to the particular project.
**************************************************************************
Perform preconstruction condition survey of [structures] [and utilities] [within 61 meters 200 feet of the pile driving activity] [specified in the plans] [decided by the Contracting Officer]. Perform outreach to the owner of the structures [28] [_____] days before performing the preconstruction condition survey. The Contractor must obtain written permission from the owner of the structure prior to accessing the structure. The preconstruction condition survey must include video and photographic documentation of the exterior and interior of above ground structures and of the interior of underground structures. Video documentation must be in high definition, and show existing conditions and highlight, where possible, existing cracks, deteriorated concrete, exposed and corroded reinforcement, cracked or broken brick or mortar, and other signs of distress. For utilities, perform the survey when the greatest extent of the interior is exposed. Provide supplementary artificial lighting as needed. The video must include annotation with location and structure nomenclature which describes any areas of distress over the video and time code superimposed on the video. Photographs must be accompanied by sketches or descriptions that indicate the location and direction of each photograph. For each structure surveyed, provide a Pre-Construction Condition Survey Report following completion of the survey. The report must contain all documentation associated with the survey including DVD copies. In the report, include notes, sketches, photographs, and videos. Provide general information, such as location details and structure type, as well as particular information on materials, condition, existing damage, aperture and persistence of cracks, and disrepair observed during visual survey. Provide a graphical depiction of locations of damage or other features of concern. Submit the Preconstruction Condition Survey Reports no later than [28] [_____] days before the commencement of pile driving activity. Accept responsibility for damages to existing adjacent or adjoining structures created by pile driving work, and repair any damages to these structures without cost to the Government.

3.8 CONSTRUCTION INSTRUMENTATION AND MONITORING PROGRAM

NOTE: Include this section if instrumentation is to be installed due to concerns about vibration, settlement, lateral movement, etc. during pile driving activities. Instrumentation should be specified and included in the specification. This section can be deleted if there are no instrumentation requirements.

Add any additional criteria or requirements as necessary for the particular project.

Prepare a geotechnical instrumentation program to monitor settlement[ and lateral movement] of temporary and permanent structures, utilities, [embankments] [and excavations] during pile driving. The design and distribution of instrumentation must demonstrate an understanding of the need, purpose and application of each proposed type.[ Perform noise and vibration monitoring in accordance with NOISE CONTROL and VIBRATION CONTROL sections.]

Monitoring must extend before, during and for a period after completion of construction activities related to pile driving when long-term performance issues are a concern. The monitoring plan must be designed to protect adjacent structures and utilities against damage due to the pile driving
activities. Establish limiting values of vertical [and horizontal] movement [and angular distortion] [and vibration] for each structure and utility within the zone of influence, subject to review by the Government.

Prepare a report detailing the proposed program of instrumentation and monitoring, establishing threshold values of monitored parameters, and describing the response plans that will be implemented when threshold parameters are exceeded. The report must include details about instrumentation consultant's experience, appropriate types, quantities, locations and monitoring frequencies of the instruments.

Upon acceptance of the instrumentation and monitoring program, provide, install and monitor the instrumentation and interpret the data. Submit instrumentation data reports not less than every [_____] days after the monitoring program has begun. Take corrective actions, as necessary, based on the field instrumentation data and as defined in the instrumentation and monitoring program.

NOTE: This guide specification covers the requirements for furnishing all plant, labor, materials, and equipment, except material and equipment specified to be furnished by the Government, and for performing all operations in connection with the installation of round (treated) (untreated) (treated and untreated) timber piles and the testing of such piles for waterfront and other marine type structures as directed in accordance with this section of the specifications and the applicable drawings.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).
PART 1   GENERAL

1.1   REFERENCES

**************************************************************************
NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.
**************************************************************************

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

AMERICAN WOOD PROTECTION ASSOCIATION (AWPA)

AWPA M2 (2019) Standard for the Inspection of Preservative Treated Wood Products for Industrial Use

AWPA M4 (2021) Standard for the Care of Preservative-Treated Wood Products

AWPA M6 (2013) Brands Used on Preservative Treated Materials

AWPA P1/P13 (2019) Standard for Creosote Preservative

AWPA T1 (2021) Use Category System: Processing and Treatment Standard

AWPA U1 (2021) Use Category System: User
1.2 SUBMITTALS

**************************************************************************

NOTE: Review Submittal Description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item if the submittal is sufficiently important or
complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy, Air Force, and NASA projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy, Air Force, and NASA projects, or choose the second bracketed item for Army projects.

**************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.] [for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

Software Document Data

SD-03 Product Data

Piles; G[, [_____]]

Pile Driving Equipment; G[, [_____]]

Submit complete descriptions of pile driving equipment, including hammers, leads, driving helmets, cushion blocks, driving blocks, collars, extractors, and other appurtenances for approval prior to commencement of work.

[ ] Pile Caps; G[, [_____]]

[ ] Pile Shoes; G[, [_____]]

[ ] Jetting Equipment and Method; G[, [_____]]

[ ] Spudding Equipment; G[, [_____]]

[ ] Predrilling Equipment; G[, [_____]]

The Contractor must provide the Contracting Officer's Representative (COR) with the predrilling method and size.

[ ] SD-04 Samples

Test Piles; G[, [_____]]
If approved after test completion, include properly located test piles in finished work.

] SD-06 Test Reports

[ Load Tests; G[, [____]]

Test data and results as specified in paragraph LOAD TESTS.

] Preservative Treatment - Timber Marine Piles; G[, [____]]

The Contractor must provide the Contracting Officer's Representative (COR) with the inspection report of an independent inspection agency, approved by the Contracting Officer, that offered products comply with applicable AWPA standards.

Delivery Inspection List; G[, [____]]

SD-07 Certificates

SDS and CIS; G[, [____]]

Pesticide Applicator Company Self-Certification; G[, [____]]

Best Management Practices (BMPs); G[, [____]]

SD-11 Closeout Submittals

Pile Driving Records; G[, [____]]

Submit pile driving records within 15 calendar days after completion of driving.

As-Driven Pile Survey; G[, [____]]

1.3 DELIVERY, STORAGE, AND HANDLING

Handle and store piles in accordance with AWPA M4. Follow precautions identified in SDS or CIS provided by the supplier of treated wood products. Special care must be taken in supporting piles to prevent the induction of excessive bending stresses in the piles. Piles must be carefully handled without dropping, breaking of outer fibers, and penetrating the surface with tools. Peaveys, cant hooks, pikes, and other pointed tools must not be used in handling treated piles.

1.4 QUALITY ASSURANCE

**************************************************************************
NOTE: Do not use untreated piling except for fender piles where an analysis of pile maintenance and replacement records clearly justifies its use or where plastic covered piling is specified. Special care in handling and frequent inspections of installed plastic-covered piles are required to ensure that no exposure of the untreated wood occurs.
**************************************************************************

**************************************************************************

SECTION 31 62 19.13 Page 7
NOTE: References listed in article REFERENCES, are intended for general references only. Consult with appropriate environmental office for possible local regulations or policies that restrict either the use of treated wood in aquatic environments or the eventual disposal of treated piles. If applicable, the specifier should add those regulatory requirements.

******************************************************************************

1.4.1 Preservative Treatment - Timber Marine Piles

The Contractor must be responsible for the quality of treated wood products. The Contractor must provide the Contracting Officer's Representative (COR) with the inspection report of an independent inspection agency, approved by the Contracting Officer, certifying that the offered products comply with applicable AWPA standards. Identify treatment on each piece by the quality mark of an agency accredited by the Board of Review of the American Lumber Standard Committee. Inspect all preservative-treated wood visually to ensure there are no excessive residual materials or preservative deposits. Material must be clean and dry or it will be rejected because of environmental concerns.

1.4.2 SDS and CIS

Provide Safety Data Sheets (SDS) and Consumer Information Sheets (CIS) associated with timber pile preservative treatment. Contractor must comply with all safety precautions indicated on the SDS and CIS.

1.4.3 Delivery Inspection List

Field inspect and submit a verification list of each treated timber pile indicating the wording and lettering of the quality control markings, the species and the condition of the wood. Do not incorporate piles damaged in transport from plant to site. Inspect all preservative-treated piles, visually to ensure there are no excessive residual materials or preservative deposits. Material must be clean and dry or it will be rejected due to environmental concerns.

******************************************************************************

NOTE: Consult with appropriate environmental office for possible local regulations or policies that restrict pile installation or the use of preservative products at the project location.

******************************************************************************

[1.4.4 Regulatory Requirements

[____].

]1.4.5 Pesticide Applicator Company Self-Certification

Provide the Contracting Officer, a statement signed by the responsible site supervisor or higher company representative, certifying that the contractor will comply with all pesticide label instructions. The certification should identify by name all individuals (applicators) who will be working with wood preserving pesticide products on site.
1.4.6 Best Management Practices (BMPs)

The producer of the treated wood products must provide certification that WWPI Mgt Practices for the use of Treated Wood in Aquatic and Wetland Environments were utilized including a written description and appropriate documentation of the BMPs utilized.

As part of the BMPs for CCA treated pier timberwork, certification must be provided that documents that the Chromotropic Acid Test (AWPA A3-Methods for Determination of the Presence of Hexavalent Chromium in Treated Wood) was performed on the timber and adequate fixation of the CCA treatment has been achieved prior to installation.

[NOTE: For NAVFAC (Navy) projects, use and edit the appropriate following paragraph(s). Do not use for Army projects.]

1.5 BASIS OF BIDS

[NOTE: Choose one of the two following Basis of Bids methods.]

[NOTE: For lump sum bidding of piles. This option should be used in all projects except those where exact quantities cannot be practically determined prior to the actual work. Numbers of piles, pile capacity, pile locations, and tip and cutoff elevations must be clearly shown on the drawings.]

[Base bids on the number, circumference, and length of piles from tip to cutoff as indicated. [Test piles must be [1.5] [_____] meter [5] [_____] feet longer than bid length piles. [Base bids on the number of load tests indicated or specified.] From the data obtained as a result of driving the test piles [and load tests] specified herein, the Government will determine and list for the Contractor the calculated minimum pile tip elevations, the driving resistance for piles, or both. The information will be given to the Contractor no later than 10 days after receipt of complete test pile data. The list must be used as the basis for ordering piles. The Contractor must not order production piles prior to receipt of the above information from the Government.] Should the total number of piles or number of each length vary from that specified as the basis for bidding, the contract price will be adjusted in accordance with Contract Clause entitled "Changes." Adjustment in contract price will not be made for cutting off piles, for any portion of a pile remaining above the cutoff elevation, disposal of piles, or for broken, damaged, or rejected piles.]

[NOTE: For unit price bidding of piles or NAVFAC LANT projects. Specify unit price bid items for piles only for projects where exact quantities cannot be practically determined prior to the actual]
work. Lengths of piles must be determined as accurately as possible prior to bidding, since the unit price per meter foot of the pile varies as the length increases or decreases.

**************************************************************************
NOTE: For NAVFAC PAC projects: Edit contract's price schedule for inclusion in Standard Form 1442, "Solicitation, Offer and Award" and "Schedule of Bid Items."
**************************************************************************

[ For unit price bid, see SF 1442, "Solicitation, Offer and Award" and "Schedule of Bid Items."

Payment will be at the contract unit price for furnishing labor, materials, tools, equipment, and incidentals required for furnishing and driving piles. Work includes furnishing and driving piles including [test piles] [load test] [jetting] [spudding] [predrilling], pile cutoff, redriving, and removal and replacement of damaged, misallocated, or otherwise rejected piles. Base bids on the number of piles with pile length from tip to cutoff, as indicated, and on total length of piling from tip to cutoff, including test piles. Include in bid a unit price per [load test[s] and] unit length of piling based on the quantity stated. From data obtained as a result of driving the test piles [and load tests] specified herein, the Government will determine and list for the Contractor the calculated minimum pile tip elevations, the driving resistance for piles, or both. The information will be given to the Contractor no later than 10 calendar days after receipt of complete test pile data. The list must be used as the basis for ordering piles. The Contractor must not order production piles prior to receipt of the above information from the Government. If the Contracting Officer requires an increase or a decrease in the unit length of piles furnished and installed, the contract price will be adjusted in accordance with FAR 52.211-18 Variation in Estimated Quantity. [ Adjustment in contract price will also be made for each increase or decrease in number of pile load tests.]

**************************************************************************
NOTE: For USACE (Army) projects, use and edit the appropriate following paragraph(s). Do not use for Navy projects.
**************************************************************************

[1.6 UNIT PRICES

**************************************************************************
NOTE: If Section 01 20 00 PRICE AND PAYMENT PROCEDURES is included in the project specifications, the paragraph UNIT PRICES should be deleted from this section and the remaining appropriately edited subparagraphs below should be inserted into Section 01 20 00 PRICE AND PAYMENT PROCEDURES.
**************************************************************************
1.6.1 Round Timber Piles, [Vertical] [Batter]

1.6.1.1 Payment

Payment for each acceptably driven pile will be made at the applicable contract unit price for each pile as determined by the length and type of pile specified or directed to be driven; this price includes all items incidental to furnishing and driving the piles, redriving uplifted piles, any required notching, the cutting off of all piles at the cutoff elevation, disposal of cutoffs [and the preservative treatment of the tops of treated piles which are headed] but exclusive of any capping of heads.

1.6.1.2 Measurement

Acceptably driven piles will be measured for payment based upon each pile.

1.6.1.3 Unit of Measure

Unit of measure: each.

1.6.2 Test Piles

1.6.2.1 Payment

Payment will be made for test piles, driven as directed and not incorporated in the permanent work. Payment will be made for test piles incorporated in the permanent work.

1.6.2.2 Measurement

Test piles, driven as directed and not incorporated in the permanent work, will be measured for payment at twice the applicable contract unit price for a permanent pile of the same type and length. Test piles, incorporated in the permanent work, will be measured for payment at the contract unit price for permanent piles.

1.6.2.3 Unit of Measure

Unit of measure: each.

1.6.3 Pile Load Tests

**************************************************************************
NOTE: The designer will specify the number of pile loading tests to be performed and the loading data.
**************************************************************************

1.6.3.1 Payment

Payment for each complete test load of a single pile will be made at the contract unit price for each pile load test. When a group of piles is required to be test loaded, payment for the load test will be made at the contract unit price for "Pile Load Test" for the first loaded pile of the group, plus 50 percent of this amount for each additional loaded pile in the group.

1.6.3.2 Measurement

Pile load test will be measured for payment based upon furnishing, placing,
and removing testing equipment and test loads.

1.6.3.3 Unit of Measure

Unit of measure: each.

][1.6.4 Pile Shoes

1.6.4.1 Payment

Payment will be made for furnishing all plant, labor, and materials for pile shoes and will be paid for at the contract unit price for each pile shoe.

1.6.4.2 Measurement

Pile shoes will be measured for payment based upon each pile shoe furnished.

1.6.4.3 Unit of Measure

Unit of measure: each.

][1.6.5 Pile Caps

1.6.5.1 Payment

Payment will be made for furnishing all plant, labor, and materials for pile caps and will be paid for at the contract unit price for each pile cap.

1.6.5.2 Measurement

Pile caps will be measured for payment based upon each pile cap furnished.

1.6.5.3 Unit of Measure

Unit of measure: each.

][1.6.6 Pulled Piles

1.6.6.1 Payment

Payment will be made for satisfactorily driven piles which are pulled at the direction of the Contracting Officer and found to be in good condition. Where piles are pulled at the direction of the Contracting Officer and found to be damaged, no payment will be made for originally furnishing and driving such piles nor for the operation of pulling, and damaged piles must be replaced by new piles for which payment will be made.

1.6.6.2 Measurement

Satisfactorily driven piles which are pulled at the direction of the Contracting Officer and found to be in good condition will be measured for payment at the applicable contract unit price for furnishing and driving the pile at its original position plus 50 percent of this amount to cover the cost of pulling. Pulled timber piles found to be sound and in a satisfactory condition by the Contracting Officer must be redriven and measured for payment at 50 percent of the applicable contract unit price for furnishing and driving the pile. Where piles are pulled at the direction of the Contracting Officer and found to be damaged, no
measurement for payment will be made for originally furnishing and driving such piles nor for the operation of pulling, and the damaged piles must be replaced by new piles which will be measured for payment at the applicable contract unit price for furnishing and driving the pile.

1.6.6.3 Unit of Measure

Unit of measure: each.

]]PART 2 PRODUCTS

2.1 MATERIALS

2.1.1 Piles

**************************************************************************
NOTE: For Bearing Piles specify the minimum butt circumference for a friction pile or specify the minimum tip circumference for an end-bearing pile. Clean-peeled piles should be specified where preservative treatment is required.
**************************************************************************

Provide Douglas fir, Southern pine, or Red pine [clean-peeled] [rough-peeled], [treated] [and] [untreated] piles in accordance with AWPA U1 Commodity Specification G and conforming to ASTM D25 and other requirements as specified. Piles must be in one piece for the length[s] [shown] [as determined from pile load tests]. Splices will not be permitted. Each treated pile must be branded by the producer, in accordance with AWPA M6. Pile circumferences must be as follows:

a. Bearing Piles: Minimum [butt circumference measured at 0.91 m 3 feet from the butt end] [tip circumference] must be [[_____] mm inches] [as indicated].

b. [Fender] [,] [and] [Cluster] [,] [and] [Dolphin] [_____] Piles: Minimum butt circumference measured at 0.91 m 3 feet from the butt end must be [[_____] mm inches] [_____] .

2.1.2 Preservative Treatment

**************************************************************************
NOTE: Select preservative treatment of marine piles as follows (consult the nearest organizational Applied Biologist for specific requirements for specific locations):

Based on AWPA's Use Criteria System (UCS) wood and wood products exposed to salt or brackish water in U.S. Coastal Waters must fall under one of three Use Categories for Marine Use.

UC5A MARINE USE Northern Waters
UC5B MARINE USE Central Waters
UC5C MARINE USE Southern Waters

Use Category requirements are based on the presence of specific marine organisms in the waters that require higher preservative loadings for control.
Refer to AWPA's U1, Commodity Specification G to determine the approximate geographical location for each Use Category.

Recommended preservative treatment type (ACZA, CCA, and Creosote), minimum preservative penetration, and retention requirements must be as specified by AWPA U1, Commodity Specification G based on wood species and Use Category.

NOTE: Consult with appropriate environmental office for possible local regulations or policies that restrict the use of creosote at the project location.

*****************************************************************************************************************************************

NOTE: In areas where limnoria, teredo or pholads are expected or known, pressure treated piles may be further protected by wrapping in plastic coatings. Load bearing piles not subject to excessive abrasion or severe impacts are particularly suited for this process.

*****************************************************************************************************************************************

NOTE: For fender piles, dolphin piles, and other piling requiring lateral load-carrying capacity, consideration should be given to increasing pile diameter because preservative pressure treatment tends to reduce lateral load-carrying capacity.

*****************************************************************************************************************************************

Treat piles based on Use Category and species in accordance with AWPA U1 and AWPA T1 to the retention and penetration for marine piling and produce in accordance with WWPI Mgt Practices. Piles preservative treatment must be [Creosote or creosote solution for marine piles in accordance with AWPA P1/P13 or AWPA P2, respectively] [Waterborne preservative for marine piles in accordance with AWPA P5 (ACZA - Ammoniacal Copper Zinc Arsenate, CCA - Chromated Copper Arsenate)] [Dual treatment of creosote or creosote solution plus waterborne preservative for marine piles in accordance with AWPA P1/P13 or AWPA P2, and AWPA P5].

2.1.3 Field Treatment

Piles must be field treated in accordance with AWPA M4. All cuts, holes and injuries such as holes from removal of spikes or nails which may penetrate the treated zone must be field treated with copper naphthenate conforming to AWPA P34 [and] [coal-tar roofing cement conforming to ASTM D5643/D5643M].

[2.1.4 Pile Shoes

*****************************************************************************************************************************************

NOTE: Pile shoes should be required only when extremely hard driving is required in upper strata for the penetration of such strata to reach the bearing stratum.

*****************************************************************************************************************************************
Pile Shoes must be a steel boot or welded-plate point shoe especially fabricated for pile driving and in accordance with ASTM A1011/A1011M. The product must be fabricated by a manufacturer regularly engaged in the manufacture of pile fittings. Welding procedures must be in accordance with a nationally recognized welding code. Provide size to fit pile tip. Fabricate boot type of 5 mm 3/16 inch carbon steel fully welded, with at least three straps, each with three 5 mm 3/16 inch nail holes. Fabricate welded-plate point type of four 5 mm 3/16 inch or 6 mm 1/4 inch steel plates, fully welded and sized to adequately cover full pointed area of pile; provide each plate with one 5 mm 3/16 inch or one 6 mm 1/4 inch nail hole. The length of the joints formed by the intersection of the sides must not be less than one half of the height of the shoe. Shoes must be cleaned and painted with at least one coat of paint. The color and paint must be the manufacturer's standard. [Shoes may be furnished without painted finish.] Provide on the point of [each pile] [each bearing pile] [each fender, cluster, and dolphin pile] [_____].

[2.1.5  Pile Caps]

Marine pile caps must consist of [a permanently fixed coating of epoxy] [fiberglass or polyethylene conical caps permanently attached to the pile] [_____].

[2.1.6  Hardware]

**************************************************************************
NOTE: Give special attention to corrosion protection of hardware used with timber preserved with water-borne salts. Specify protection ranging from simple coatings to changing of the hardware metals dependent upon the required use and critical features of the hardware. Hot-dip galvanized hardware and fasteners will usually suffice in such cases.
**************************************************************************

Pile hardware must consisting of bolts with necessary nuts and washers, timber connectors, drift pins, dowels, nails, screws, spikes, and other fastenings. Provide bolts with washers under nut and head. Bolts and nuts must conform to ASTM A307. Provide cast-iron ogee, malleable iron washers, or plate or cut washers where indicated. Provide bolts with washers under nut and head. Provide timber connectors and other metal fastenings of type and size indicated. Hot-dip galvanize all hardware in accordance with ASTM A123/A123M or ASTM A153/A153M, as applicable.

[2.1.7  Wire Rope and Fitting]

Wire ropes must be in accordance with FS RR-W-410 [Type III, Class 2][Type III, Class 3][Type I, Class 2]. All wire ropes must be zinc coated in accordance with ASTM A1023/A1023M. [ Provide staples of 10 mm 0.375 inch diameter zinc-coated steel at least 125 mm 5 inches long.][ Provide clips or clamps of zinc-coated steel.]

[2.2  TESTS, INSPECTIONS, AND VERIFICATIONS]

2.2.1  Inspection of Piles

The Contractor must provide the necessary facilities for the proper inspection of each pile. Piles to be preservative treated will be
inspected prior to treatment. Piles will be inspected at the shipping point or at the work site if so decided. Pile inspection at the shipping point will not be performed for less than 100 piles in one locality. Piles with specified variations in characteristics must be placed in separate lots for inspection. Piles must be so marked or segregated into marked lots that there will be no possibility of error in assignment after they have been inspected. Piles damaged after inspection may be subsequently rejected if damage is deemed sufficient for rejection. All rejected piles must be removed as directed.

2.2.2 Inspection of the Preservative Treatment Process

Inspection of the preservative treatment process will be in accordance with AWPA M2. The Contractor must notify the Contracting Officer where preservative treatment will be done not less than 15 days prior to the start of the treatment and must provide the necessary facilities for the proper inspection of the treatment process. Allow the Contracting Officer unlimited access to the plant and inspection privileges for each facet of the treating process.

PART 3 EXECUTION

3.1 INSTALLATION

3.1.1 Pile Driving Equipment

Pile driving equipment must meet the following requirements.

3.1.1.1 Pile Driving Hammers

**************************************************************************

NOTE: If vibratory hammers should not be used, the references to vibratory hammers should be deleted from the text.
**************************************************************************

Pile driving hammers must be steam, air or diesel, single-action, double-acting, differential-acting [or] [vibratory] [_____] type. [The use of vibratory hammers is dependent upon satisfactory driving and load testing of piles.] The size or capacity of hammers must be as recommended by the manufacturer for the pile weights and solid formation to be penetrated. The pile hammer must be of sufficient weight and energy to install the specified pile without damage into the soils [as indicated] [expected to be encountered]. The maximum driving energy of hammers must be [16,270] [20,330] joules [12,000] [15,000] foot-pounds for piles for any length. Test piles must be driven with the same size and type hammer, operating with the same effective energy and efficiency as that to be used in driving job piles. Diesel powered hammers must be operated at the rate recommended by the manufacturer throughout the entire driving period. Sufficient pressure must be maintained at the hammer so that:

a. For double-acting hammers, the number of blows per minute during and at the completion of driving of a pile is equal approximately to that at which the hammer is rated;

b. For single-acting hammers, there is a full upward stroke of the ram; and,

c. For differential-type hammers, there is a slight rise of the hammer
base during each upward stroke.

3.1.1.2 Leads

Leads are required and must be fixed at the top and adjustable at the bottom. Swinging leads [will] [will not] be permitted.

3.1.1.3 Driving Cap or Helmet and Cushion Block

Driving cap or helmet must be an approved design and must be capable of protecting pile heads, minimizing energy absorption, and transmitting hammer energy uniformly and consistently to piles. Place driving helmet or cap and cushion block combination between top of pile and the ram. Driving cap must fit snugly on the top of piles and must employ a cushion block to prevent impact damage to piles. The cushion block may be a solid or laminated softwood block with the grain parallel to the pile axis and enclosed in a close-fitting steel housing. The thickness of the block must be suitable for the length of pile to be driven and the character of subsurface material to be encountered. [Generally, thicker blocks are required for longer piles and softer subsurface material.] If block is damaged, split, highly compressed, charred or burned, or has become spongy or deteriorated, replace with new block. Under no circumstances will the use of small wood blocks, wood chips, rope, or other material permitting excessive loss of hammer energy be permitted.

3.1.1.4 Pile Collars

Collars or bands for protecting pile butts against splitting, brooming, and other damage while being driven must be of an approved design.

3.1.2 Pile Installation

Inspect piles when delivered and when in the leads immediately before driving. Cut piles at cutoff grade with pneumatic tools by sawing or other approved method. Where cutoff is below existing mudline elevation, complete excavation, sheeting and dewatering before pile is driven to cutoff elevation.

[3.1.2.1 Test Piles]

**************************************************************************
NOTE: Insert the number of test piles required. Test pile locations should be shown on the drawings. The number of test piles is normally between 5 and 10 percent of the total number of piles required, dependent upon the magnitude of the project. Test piles are furnished longer than job piles to allow additional penetration if driving conditions dictate. Delete this paragraph if test piles are not required.
**************************************************************************

Provide [_____] test piles conforming to the same requirements as specified for job piles. Drive test piles in the same manner as specified for job piles. Furnish test piles([1.5] [_____] m[5] [_____] feet) longer than length specified for job piles and drive the additional depth, if directed. Drive test piles in locations indicated or as directed. Record driving data as specified in paragraph entitled "Records." Confirmation of the assumed allowable working loads of single piles must be made by static
loading and measuring [each] [_____] test pile[s] in the manner described below. Test piles indicated or directed to be driven in permanent locations may be incorporated into the work if, after satisfactory completion of the load test, they are approved for inclusion in the work by the Contracting Officer. Every facility must be provided by the Contractor for the Contracting Officer to inspect and measure the deflection or settlement of the pile under test. Furnishing of measuring equipment and making measurements of deflection or settlement will be the responsibility of the [Contracting Officer] [Contractor] [_____].

][3.1.2.2 Load Tests

**************************************************************************
NOTE: Insert the number of test piles to be load tested. The safe design capacity of a test pile as determined from the results of load test must be the lesser of the two values computed according to the following:

1. One-half the test load which causes a settlement of 0.03 mm per kN 0.01 inch per ton of test load; and

2. One-half the test load that causes a gross settlement of 25 mm one inch provided the load-settlement curve shows no sign of failure.

**************************************************************************

ARMY NOTE: The designer will specify the method of load testing and the specific pile driving formulas used for design.

**************************************************************************

Perform load tests on [_____] test piles in accordance with ASTM D1143/D1143M loading procedures, as modified herein. Perform load tests at locations shown, or as directed. Provide testing and measuring equipment, perform loading, and provide observation facilities for a registered professional engineer employed by the Contractor to inspect and record settlement and deflection of piles under test loads. Do not mobilize load test equipment until directed. Loading frames and equipment must be ready to place in operation as soon as a test pile has been driven. The loading equipment must be of sufficient capacity to apply a maximum load of not less than [_____] kN [_____] tons. The ultimate test load must be maintained for not less than [24] [_____] hours and then unloaded in accordance with ASTM D1143/D1143M.

]3.1.2.3 Driving Piles

[Drive job piles with same hammer, cushion, or cap block, and using the same operating conditions as test piles. ]Piles must not be driven within 30 meters 100 feet of concrete which is less than 7 days old unless otherwise authorized. A complete and accurate record of the driving of piles must be compiled by the Contractor for submission to the Contracting Officer. When driving long piles of high slenderness ratio, special precautions must be taken to ensure against overstressing and leading away from a plumb or true position. During driving, pile driving hammers must be operated at all times at the rate and conditions recommended by the hammer manufacturer. Each pile must be driven continuously and without interruption [to the [calculated] [indicated] tip elevation] [until the required depth of penetration and penetration rate per blow have been
attained in accordance with the schedule that the Contracting Officer will prepare from the test pile driving [and test data]. Deviation from this procedure will be permitted only in case the driving is stopped by causes which reasonably could not have been anticipated. The controlling penetration per blow will be determined by the Contracting Officer. Piles must be driven to the full penetration required where practicable to do so without damage to the piles. If found impracticable to drive any pile to the depth required, such pile must be cut off and abandoned or pulled as directed. Driven piles which have a penetration of less than [_____] meters [_____] feet [that specified for the following areas [______]] and have not been driven to the established maximum penetration per blow are not satisfactory. Driving of piles beyond the point of refusal, as indicated by excessive bonding of the hammer or kicking of the pile, or a blow count of greater than twice the blow count required to produce the safe bearing capacity must not be attempted. Piles which have uplifted after driving must be redriven to grade after conclusion of driving in that general area. The maximum permissible penetration per blow for the last 20 blows will be established by the Contracting Officer. When the penetration per blow of any pile during the final blows exceeds that permitted or it is found that a pile is not of sufficient length to give the capacity specified, and the pile has been driven to its full depth, the Contractor must pull the pile, furnish, and drive a longer pile or take other corrective measures as directed by the Contracting Officer. The use of followers or splices must not be permitted. After driving is completed, all piles must be "headed" or cut off normal at the cutoff elevation. [Fender piles must have tops beveled outboard as indicated.] Pile heads at cutoff must be sound. Headed treated piles, including those to be capped with concrete, must be treated with copper naphthenate per AWPA M4. Piles driven in locations where they are constantly subject to water spray must be given this treatment immediately after they are cut off and before the cutoff surface has been wetted. Cutoffs must become the property of the Contractor and must be removed at his expense.

3.1.2.4 Tolerances in Driving Piles

Piles must be accurately placed in the correct location and alignments both laterally and longitudinally and to the vertical or batter lines as shown. At cutoff elevation, butts must be within([100] [_____] mm[4] [_____] inches ) laterally of the location indicated. [Manipulation of piles is prohibited.] [Manipulation to move piles into position will be permitted only within the aforementioned tolerance to return the pile to the design location. [However, piles must not be manipulated more than 1.5 percent of the exposed length above the [ground] [mudline] surface.]] [[Fender] [,] [and] [Cluster] [,] [and] [Dolphin] [_____] Piles may be manipulated a maximum of 42 mm per m 0.50 inch per foot of pile length in a direction parallel to the pier face and 21 mm per m 0.25 inch per foot of pile length in a direction perpendicular to the pier face.] A variation of not more than 21 mm per m 0.25 inch per foot of pile length from the vertical for plumb piles or more than 42 mm per m 0.50 inch per foot of pile length from the required angle for batter piles will be permitted. The correct relative position of group piles must be maintained by the use of templates or by other approved means. [In addition to complying with the tolerances stated herein or otherwise specified, clear distance between heads of piles and edges of caps must be not less than 125 mm 5 inches. With prior approval of the Contracting Officer, the Contractor may provide additional concrete and reinforcement to maintain the required minimum clear distance. Redesign of pile caps or additional work required due to improper location of piles will be the responsibility of the Contractor.] Inspect piles for heave. Piles must be driven to the depths [shown] [as
directed]. Redrive heaved piles to the required tip elevation. Remove and replace with new piles those damaged, misplaced, driven below the design cutoff, or driven out of alignment, or provide additional piles, driven as directed at no additional cost to the Government.

3.1.2.5 Pile Driving Records

Keep a complete and accurate driving record of each pile driven. Indicate pile location, deviations from design location, diameter, original length, mudline elevation, tip elevation, cutoff elevation, penetration in blows per meter foot for entire length of penetration for test piles, penetration in blows per meter foot for the last 3 m 10 feet for job piles, hammer data including rate of operation, make, and size, and unusual pile behavior or circumstances experienced during driving such as redriving, heaving, weaving, obstructions, [jetting,] [spudding,] [predrilling,] and unanticipated interruptions. Preprinted forms for recording pile driving data are attached at the end of this section. Make pile driving records available to the Contracting Officer at the job site, a minimum of 24 hours after each day of pile driving. Include in the construction records the wood species, preservative type, retention, and producer of installed treated timber.

3.1.2.6 Survey Data

After the driving of each pile group is complete and before superimposed concrete is placed, provide the Contracting Officer with an As-Driven Pile Survey showing actual location and top elevation of each pile. The Contractor must not proceed with placing concrete until the Contracting Officer has reviewed the survey and verified the safe load for the pile group driven. A survey must be presented in such form that it gives deviation from plan location in two perpendicular directions and elevations of each pile to nearest 13 mm half inch. Survey must be prepared and certified by a [licensed land surveyor] [professional engineer].

3.1.2.7 Lengths of Job Piles

*****************************************************************************************************************************************
NOTE: For USACE (Army) projects, use and edit the following paragraph. When the actual required lengths of piles can be determined without test driving and loading of piles (such as when piles are to be driven to bedrock), the actual required lengths must be indicated and listed in the unit price schedule.
*****************************************************************************************************************************************

[The estimated quantities of piles listed in the unit price schedule as to be furnished by the Contractor are given for bidding purposes only. The Contracting Officer will determine the actual lengths of piles required to be driven below cutoff elevation for the various locations in the work and will furnish the Contractor a quantities list which indicates lengths and locations of all piles to be placed. This determination will be made from the results of the test pile driving and test loading. ] [The lengths of piles must be as indicated. ] The Contracting Officer will determine the number of overlength piles, if any, to be ordered to provide for variations in subsurface conditions. Where specified bearing capacities are attainable with piles of lesser length than those specified, shorter piles may be used subject to prior approval in writing. To provide for "heading" or cutting off normal after driving, piles must be furnished in lengths at
least 300 mm one foot greater than the lengths specified to be below the
cutoff elevations.

3.1.3 Framing Treated Piles

Treated piles must not be cut to permit fitting of timbers. Piles of
uniform size must be selected for each bent. If necessary, treated filler
blocks must be used to fill out between piles and bracing. Holes for drift
bolts in the tops of piles must be drilled to a depth of 75 mm 3 inches
less than the penetration of drift bolts in the piles. Drill holes for
drift bolts 3 mm 1/8 inch smaller than bolt diameter. Drill holes for
through bolts 2 mm 1/16 inch larger than diameter of bolt shank. Drill
holes for lag screws in two parts. Make lead hole for shank the same
diameter as shank. Make lead hole for the threaded portion approximately
two-thirds of the shank diameter. Counterbore holes for bolt heads and
washers as indicated. Holes drilled into piles must be treated with copper
naphthenate and sealed with coal-tar roofing cement in accordance with
paragraph ON SITE APPLICATION OF WOOD PRESERVATIVES and when not used for
bolts must be tightly closed by a treated plug. Holes must not be drilled
or spikes must not be driven into piles to support scaffolding.

3.1.4 Fastening

Where bolts are used to fasten timber to timber, timber to concrete, or
timber to steel, bolt members together when they are installed and
retighten immediately prior to final acceptance of contract. Provide bolts
having sufficient additional threading to provide at least 10 mm per m 3/8
inch per foot thickness of timber for future retightening. Provide timber
connectors of types indicated. Install split-ring and shear-plate
connectors in pre-cut grooves of the dimensions [shown] [as recommended by
the manufacturer]. Force toothed-ring and spike-grid connectors and
clamping plates into the contact surfaces of timbers joined by means of
proper pressure tools; at joints, embed connectors of these types
simultaneously and uniformly.

3.1.5 Wrapping Pile Clusters and Dolphins

Draw piles tightly together with wire rope. Fasten each turn of the wire
rope with a staple to each pile with which it is in contact. Fasten ends
of wire rope with two clips or clamps. Number of turns must be as
indicated. Through bolts must be in place and drawn up before wrapping is
finally secured.

3.1.6 Jetting of Piles

**************************************************************************

NOTE: Jetting should not generally be permitted
when:

1. Piles are dependent on side friction in
   fine-grained, low-permeability soils (high clay or
   silt content) where considerable time is required
   for the soil to reconsolidate around the piles;

2. Piles are subject to significant uplift;

3. Piles are adjacent to existing structures; and

4. Piles are in closely spaced clusters, unless the
load capacity is confirmed by test and unless jetting is completed before final driving of any pile in the cluster.

**************************************************************************

Water jets [will be permitted to assist in driving] [may be used in driving only when specifically authorized by the Contracting Officer] [may be used to assist driving of the pile through strata which cannot be penetrated practicably by use of the hammer alone.

Jetting equipment must have not less than two removable or fixed, water or combination air-water type jets. Equipment must be designed so that the discharge volume and pressure are sufficient to freely erode the material under and adjacent to the piles.

After the penetration of the strata requiring jetting has been accomplished, the use of the jet must be discontinued and direct hammer driving must be resumed] [must not be permitted to assist in driving]. [Discontinue jetting when the pile tip is approximately 1.5 m 5 feet above the [calculated] [indicated] pile tip elevation. Drive pile the final 1.5 m 5 feet of penetration [to the maximum penetration per blow established by the Contracting Officer]. Jetting equipment and method must be approved by the Contracting Officer prior to commencing jetting operations.]

3.1.7 Spudding of Piles

**************************************************************************

NOTE: Spudding should not generally be permitted when:

1. Piles are dependent on side friction in fine-grained, low-permeability soils (high clay or silt content) where considerable time is required for the soil to reconsolidate around the piles;

2. Piles are subject to significant uplift;

3. Piles are adjacent to existing structures; and

4. Piles are in closely spaced clusters, unless the load capacity is confirmed by test and unless spudding is completed before final driving of any pile in the cluster.

**************************************************************************

Spudding [will be permitted][must not be permitted]. [Discontinue driving and withdraw the spudding mandrel [approximately 1.5 m 5 feet above the [calculated] [indicated] pile tip elevation] [immediately after passing through the resistant substrate layer].] [Drive pile the final 1.5 m 5 feet of penetration [to the maximum penetration per blow established by the Contracting Officer]. Obtain Contracting Officer's approval of spudding equipment, prior to commencing spudding operations.]

3.1.8 Predrilling of Piles

**************************************************************************

NOTE: Predrilling should not generally be permitted when:
1. Piles are dependent on side friction in fine-grained, low-permeability soils (high clay or silt content) where considerable time is required for the soil to reconsolidate around the piles;

2. Piles are subject to significant uplift;

3. Piles are adjacent to existing structures; and

4. Piles are in closely spaced clusters, unless the load capacity is confirmed by test and unless predrilling is completed before final driving of any pile in the cluster.

Predrilling [will be permitted][must not be permitted][must be provided]. [Discontinue predrilling when pile tip is approximately 1.5 m 5 feet above the [calculated][indicated] pile tip elevation. Drive pile the final 1.5 m 5 feet of penetration [to the maximum penetration per blow established by the Contracting Officer]]. [Obtain Contracting Officer's approval of predrilling equipment prior to commencing predrilling operations.]

3.2 PROTECTION

3.2.1 Protection of Piles

Square the heads and tips of piles to the driving axis. Laterally support piles during driving, but do not unduly restrain piles from rotation in the leads. Where pile orientation is essential, take precautionary measures to maintain the orientation during driving. [Driven batter piles of sufficient unsupported lengths to cause a measurable deflection must have free ends secured until piles are fixed in the structure to prevent excessive bending stresses.] Handle, protect, and field treat piles in accordance with AWPA M4.

3.2.1.1 Damaged Piles

Driving of piles must not subject them to damage. Piles which are damaged, split, broomed, or broken by reason of internal defects or by improper driving below cutoff elevation so as to impair them for the purpose intended must be removed and replaced; a second pile may be driven adjacent thereto at the Contractor's expense. Minor damaged areas of treated piles must be field treated in accordance with AWPA M4. [The Contracting Officer may require the Contractor to pull certain selected piles after driving for test and inspection to determine the conditions of the piles. Any pile so pulled and found to be damaged to such extent as to impair its usefulness in the completed structure must be removed from the work and the Contractor must furnish and drive a new pile to replace the damaged pile. Piles pulled and found to be sound and in a satisfactory condition, by the Contracting Officer, must be redriven.]

3.2.1.2 On Site Application of Wood Preservatives

All on site application of wood preservatives must be performed by the person identified in accordance with paragraph PESTICIDE APPLICATOR COMPANY SELF-CERTIFICATION. Field application of wood preservatives must be made in accordance with the pesticide label. All cuts, holes and injuries such as holes from removal of spikes or nails which may penetrate the treated zone must be field treated in accordance with AWPA M4.
3.3 FIELD QUALITY CONTROL

3.3.1 Inspections

When Government inspections result in product rejection, the Contractor must promptly segregate and remove rejected material from the premises. The Government may also charge the Contractor an additional cost of inspection or test when prior rejection makes reinspection or retest necessary.

NOTE: This guide specification covers the requirements for composite, wood and cast-in-place concrete piles.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1 GENERAL

1.1 DESCRIPTION

Design, furnish, install and test composite wood and cast in-place concrete piles at the locations indicated on the drawings and specified herein. [Assume test pile[s] will be directed to be placed in [a] location[s] that can be incorporated into the work.]

1.2 REFERENCES

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.
Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

**************************************************************************

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

1.3 SUBSURFACE DATA

Subsurface soil data logs are [indicated] [appended to the special contract requirements] [provided on the project drawings]. [The subsoil investigation report may be examined at [____].]

1.4 BASIS OF BID

**************************************************************************
NOTE: Select one of the following options:
**************************************************************************
**************************************************************************
NOTE: Use "Lump Sum" paragraph below for lump (principal) sum bidding of piles. Use this in all projects except those where exact pile lengths cannot be practically determined prior to the actual work. Clearly show number of piles, pile capacity, pile locations, and tip and cutoff elevations on the drawings.

Use "Unit Price" paragraph for unit price bidding of piles. Specify unit price bid items for piles only for projects where exact quantities cannot be practically determined prior to the actual work. Lengths of piles must be determined as accurately as possible, prior to bidding, since the unit price per meter (foot) of the piles varies as the length increases or decreases.
**************************************************************************

1.4.1 Contractor's Geotechnical Consultant

Hire the services of an independent, Registered Professional Geotechnical Engineer, experienced in soil mechanics and Pile Dynamic Analysis, to observe test pile installation and production pile installation as specified herein. The Contractor's Geotechnical Consultant must be independent of the Contractor and must have no employee of employer relationship which could constitute a conflict of interest.

1.4.2 Contractor Experience and Qualifications

The work must be performed by a Contractor with a minimum of 5 years of experience with the installation of the required foundation system in similar soil conditions of the project site. Submit past project lists indicating experience with such foundation systems.

1.4.3 Production Pile Acceptance Criteria

Safe design capacity for piles is [_____] KN kips. Drive piles to [minimum tip elevation] [a minimum depth of [____] m feet below cut-off elevation], and to such additional depth as required to obtain a bearing capacity of not less than [_____] KN kips. The Contractor's Geotechnical Consultant will determine the terminal driving criteria based on results of [static
load test] [energy formulas.]

The following formulas can be used in cases where allowable pile loads are less than 355 kN 80 kips (determined using a factor of safety of 3 for individual piles and 4 for pile groups) and are presented only as a guide to aid in establishing the controlling penetration per blow, which, together with the minimum depth of penetration will serve to determine the required minimum depth of penetration of each individual pile:

For double acting hammers

\[ R = \frac{166.7E}{S + 2.54 P/W} \]

(R = \frac{2E}{S + 0.1 P/W})

For single acting hammers

\[ R = \frac{166.7WH}{S + 2.54 P/W} \]

(R = \frac{2WH}{S + 0.1 P/W})

Where:

- **R** is the allowable static pile load in newtons pounds.
- **W** is the weight of the striking part of the hammer in newtons pounds.
- **H** is the effective height of fall in m feet.
- **E** is the actual energy delivered by the hammer per blow in newton-meters foot-pounds.
- **S** is the average net penetration in mm inches per blow for the last 5 blows after the pile has been driven to a depth where successive blows produce approximately equal net penetration (a minimum distance of 1 meter 3 feet for friction piles).
- **P** is the weight of the pile in N (pounds). (If **P** is less than **W**, **P/W** must be taken as unity.)

An allowance must be made for reduced penetration caused by shock absorption of the cushion or cap blocks.

[1.4.4 Lump Sum Payment]

**************************************************************************

NOTE: Use this paragraph for lump-sum contracts, consult with Contracting Officer's Technical Representative (Geotechnical Branch) on applicability of use prior to selection. This paragraph will be typically used when there are 1) relatively small quantity of piles, 2) allowable pile loading is less than 355 kN 80 kips, and 3) the subsurface conditions are well defined. Fill in Table I as required selecting columns applicable to project. Generally, pile capacity, location, and minimum tip elevation are shown on plans. Test piles and load tests are not incorporated on lump sum contracts. Delete this paragraph for unit-price contracts.

**************************************************************************

Base bids upon providing the number, size, capacity, and length of piles as indicated on the [drawings.] [following Table I:}
Include the cost of all necessary equipment, tools, material, labor, and supervision required to: deliver, handle, install, cut-off, dispose of any cut-offs, and meet the applicable contract requirements. Include mobilization, pre-drilling, and redriving heaved piles. If, in redriving, it is found that any pile is not of sufficient length to provide the capacity specified, notify the Contracting Officer, who reserves the right to increase or decrease the total length of piles to be provided and installed by changing the pile locations or elevations, requiring the installation of additional piles, or directing the omission of piles from the requirements shown and specified. If total number of piles or number of each length vary from that specified as the basis for bidding, an adjustment in the contract price or time for completion, or both, will be made in accordance with the contract documents. Payment for piles will be based on successfully installing piles to both the minimum tip elevation and satisfying the acceptance criteria identified herein. No additional payment will be made for: damaged, rejected, or misplaced piles; withdrawn piles; any portion of a pile remaining above the cut-off elevation; backdriving; cutting off piles; splicing; build-ups; any cut-off length of piles; or other excesses beyond the assumed pile length indicated for which the Contractor is responsible. (Include payments for vibration monitoring, sound monitoring and precondition construction surveys, construction instrumentation and monitoring plan).

<table>

<th>Number</th>
<th>Size</th>
<th>Capacity</th>
<th>Length (Tip to Cut-Off)</th>
<th>Maximum Bending Moment</th>
<th>Maximum Shear Force</th>
</tr>
</thead>
</table>

**NOTE:** Delete this paragraph for lump-sum contracts.

For NAVFAC PAC projects: Where there is unit pricing for piles, use this paragraph and edit applicable attachments in price schedule for inclusion in Standard Form 1442, "Solicitation, Offer and Award" and "Schedule of Bid Items."

For NAVFAC Southeast projects, where there is a need for unit pricing of piles, include this paragraph. Refer to NAVFAC SE Instruction 00010, "Instructions for Preparing Basis of Bid Statement With Unit-Priced Items," for method of specifying unit price bid items.

For unit price bid, see SF 1442, "Solicitation, Offer and Award" and "Schedule of Bid Items."

**NOTE:** For NAVFAC LANT projects, use the following paragraph for measurement and payment and subsequent sub-parts.

Requirements of "FAR 52.211-18, Variation in Estimated Quantity" do not
apply to payment for piling. Each pile and test pile acceptably provided will be paid for at the bid unit price per unit length, which will include items incidental to furnishing and driving the piles including mobilization and demobilization, [jetting] [predrilling] [probing], redriving uplifted piles, [an additional 1.5 m 5 feet in furnished length for any test pile not driven beyond estimated pile length,) and cutting off piles at the cut-off elevation. [Include the cost for additional length for the test piles in the total unit price cost for the job.] Payment will be made for production [and test piles] at the bid unit price for the length of pile, from tip to final cut-off, actually provided, excluding buildups and splices directed by the Contracting Officer to be made. If the actual cumulative pile length driven (tip to cut-off) vary more than 25 percent from the total pile length specified as a basis for bidding, at the direction of the Contracting Officer, the unit price per unit length will be adjusted in accordance with provisions of "FAR 52.236-2, Differing Site Conditions." [Payments will be made per each at the respective bid unit price for pile cut-offs, pile build-ups, pile loads tests and pile splices.]

1.5 PAYMENT

**************************************************************************
NOTE: Delete this paragraph for lump-sum contracts.

If Section 01 20 00 PRICE AND PAYMENT PROCEDURES is included in the project specifications, this paragraph title (UNIT PRICES) should be deleted from this section and the remaining appropriately edited subparagraphs below should be inserted into Section 01 20 00 PRICE AND PAYMENT PROCEDURES.
**************************************************************************

1.5.1 Furnishing and Delivering Piles

1.5.1.1 Payment

Payment will be made for costs associated with furnishing and delivering the required lengths of permanent piles, which includes costs of furnishing and delivering piles to the work site. No payment will be made for the driving head or lengths of piles exceeding required lengths. No payment will be made for piles damaged during delivery, storage, or handling to the extent that they are rendered unsuitable for the work, in the opinion of the Contracting Officer.

1.5.1.2 Measurement

Furnishing and delivering permanent piles will be measured for payment by the linear meter foot of piles required below the cut-off elevation as [determined by the Contracting Officer and furnished to the Contractor] [indicated].

1.5.1.3 Unit of Measure

Linear meter foot.
1.5.2 Driving Piles

1.5.2.1 Payment

Payment will be made for costs associated with driving permanent piles, which includes costs of handling, driving, concrete installation, [and splicing of piles,] measuring heave, redriving heaved piles, removal of [build-ups] driving heads or cutting off piles at the cut-off elevation and removing from the work site, compiling and submitting pile driving records, backfilling voids around piles, and any other items incidental to driving piles to the required elevation.

1.5.2.2 Measurement

Permanent piles will be measured for payment for driving on the basis of lengths including concrete section, to the nearest hundredth (tenth) of a linear meter foot, along the axis of each pile acceptably in place below the cut-off elevation shown.

1.5.2.3 Unit of Measure

Linear meter foot.

1.5.3 Pulled/Withdrawn Piles

1.5.3.1 Payment

Payment will be made for costs associated with piles pulled at the direction of the Contracting Officer and found to be undamaged. The cost of furnishing and delivering pulled and undamaged piles will be paid for at the applicable contract unit price for payment item "Furnishing and Delivering Piles". The cost of driving pulled and undamaged piles will be paid for at the applicable contract unit price for payment item "Driving Piles". The cost of pulling undamaged piles will be paid for at twice the applicable contract unit price for payment item "Driving Piles", which includes backfilling any remaining void. The cost of redriving pulled and undamaged piles will be paid for at the applicable contract unit price for payment item "Driving Piles". No payment will be made for furnishing, delivering, driving, pulling, and disposing of piles, including pile driving points, pulled and found to be damaged and backfilling voids. New piles replacing damaged piles will be paid for at the applicable contract unit price for payment items "Furnishing and Delivering Piles" and "Driving Piles".

1.5.3.2 Measurement

Furnishing and delivering pulled and undamaged permanent piles will be measured for payment as specified in paragraph UNIT PRICES, subparagraph FURNISH AND DELIVER PILES. Pulling undamaged piles will be measured for payment as specified in paragraph UNIT PRICES, subparagraph DRIVING PILES. Redriving pulled undamaged piles will be measured for payment as specified in paragraph UNIT PRICES, subparagraph DRIVING PILES. New piles replacing damaged piles will be measured for payment as specified in paragraph UNIT PRICES, subparagraphs FURNISH AND DELIVER PILES and DRIVING PILES.

1.5.3.3 Unit of Measure

Linear meter foot.
1.5.4 Pile Driving Tests

1.5.4.1 Payment

Payment will be made for costs associated with furnishing, delivering, driving, pulling, and disposing of driven test piles, concrete pile section, [including [pile driving points] [and] [splices]]; conducting pile driving tests; backfilling voids around piles; compiling pile driving test records.

1.5.4.2 Measurement

Pile driving tests will be measured for payment on the basis of the applicable contract unit price per pile driving test.

1.5.4.3 Unit of Measure

Each.

1.5.5 Piles for Load Tests

1.5.5.1 Payment

Payment will be made for costs associated with furnishing, delivering, driving, pulling, and disposing of load test piles [including [pile driving points] [and] [splices]]; backfilling voids around piles; compiling pile driving records []; furnishing, fabricating, and mounting of strain rods and protective assembly]; [furnishing, fabricating, and mounting of inclinometer and inclinometer protective assembly]. No additional payment will be made for load test piles incorporated in the permanent work other than as provided.

1.5.5.2 Measurement

Piles for load tests will be measured for payment on the basis of the applicable contract unit price per load test pile.

1.5.5.3 Unit of Measure

Each.

1.5.6 Pile Static Axial Compressive Load Tests

1.5.6.1 Payment

Payment will be made for costs associated with pile static axial compressive load tests in accordance with ASTM D1143/D1143M, including material and labor for fabricating and furnishing load frames; calibrating load cells and hydraulic jacks; furnishing specified test equipment; installing strain rods; placing and removing test loads and test equipment; recording, reducing, and submitting test data; and compiling and submitting pile load test reports. No payment will be made for rejected pile static axial compressive load tests.

1.5.6.2 Measurement

Pile static axial compressive load tests will be measured for payment on the basis of the applicable contract unit price per load test.
1.5.6.3 Unit of Measure
Each.

1.5.7 Pile Driving Shoes

1.5.7.1 Payment
Payment will be made for costs associated with pile driving shoes, including furnishing, delivering, and installing.

1.5.7.2 Measurement
Pile driving shoes will be measured for payment on the basis of the number of pile driving shoes required.

1.5.7.3 Unit of Measure
Each.

1.5.8 Pile Splices

1.5.8.1 Payment
Payment will be made for costs associated with pile splices, including all plant, labor, and material required to make the splice.

1.5.8.2 Measurement
Pile splices will be measured for payment on the basis of the applicable contract unit price per pile splice.

1.5.8.3 Unit of Measure
Each.

1.5.9 Vibration Monitoring

1.5.9.1 Payment
Payment will be made for costs associated with vibration monitoring.

1.5.9.2 Measurement
Vibration monitoring will be measured for payment on the basis of the applicable contract unit price per vibration monitoring point.

1.5.9.3 Unit of Measure
Each.

1.5.10 Sound Monitoring

1.5.10.1 Payment
Payment will be made for costs associated with sound monitoring.
1.5.10.2 Measurement

Sound monitoring will be measured for payment on the basis of the applicable contract unit price per sound monitoring point.

1.5.10.3 Unit of Measure

Each.

1.5.11 Preconstruction Condition Survey

1.5.11.1 Payment

Payment will be made for costs associated with preconstruction condition surveys.

1.5.11.2 Measurement

Preconstruction condition survey will be measured for payment on the basis of the applicable contract unit price per structure to be surveyed.

1.5.11.3 Unit of Measure

Each.

1.6 SUBMITTALS

**************************************************************************

NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy, Air Force, and NASA projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.
Choose the first bracketed item for Navy, Air Force and NASA projects, or choose the second bracketed item for Army projects.

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only.  When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-01 Preconstruction Submittals

Contractor Experience and Qualifications; G[, [_____]]
Contractor's Geotechnical Consultant; G[, [_____]]

SD-02 Shop Drawings

Installation Equipment and Testing Equipment; G[, [_____]]

SD-03 Product Data

Equipment Calibration Data; G[, [_____]]
Helmet and Cushion Block; G[, [_____]]
Pile Shoes; G[, [_____]]
Calibration Report

SD-06 Test Reports

Load Test Report
Field Test and Inspection Reports

SD-07 Certificates

Timber piles; G[, [_____]]
Aggregates; G[, [_____]]
Admixtures; G[, [_____]]
Cement; G[, [_____]]
Fly ash and pozzolan; G[, [_____]]

SD-11 Closeout Submittals

Pile records; G[, [_____]]
1.7 DELIVERY, STORAGE, AND HANDLING

Piles must be stored and handled avoiding overstress or any other condition that may cause damage to the piles. Untreated piles to be stored for an extended period of time must be inspected periodically, as well as shortly before driving, to detect damage due to fungus and insect attack. If treated piles are to be stored in a horizontal position for an extended period of time, they must be inspected periodically to ensure that the treatment does not seep to the lower half of the pile to the extent that the upper half does not contain a sufficient amount of treatment.

1.8 QUALITY CONTROL

1.8.1 Timber Piles

The producer must brand each treated pile, in accordance with AWPA M1, AWPA M2, AWPA M6, AWPA T1 and AWPA U1. Submit the inspection report of an independent inspection agency, approved by the Contracting Officer, stating that offered products comply with applicable AWPA Standards, and that the plant conforms to AWPA M3. Identify treatment on each piece by the quality mark of an agency accredited by the Board of Review of the America Lumber Standard Committee.

1.8.2 Quality Control Procedures

The Government, at its discretion, reserves the right to inspect the treating process. Notify the Contracting Officer at least 3 weeks prior to beginning the treatment, stating where preservative treatment will be done. Allow Government inspector access to all parts of the plant. Allow inspection of all facets of the treating process.

1.8.3 Installation Procedures

Submit information on the type of equipment proposed to be used, proposed methods of operation, pile driving plan including proposed sequence of driving, and details of all pile driving equipment and accessories.

1.8.4 Concrete Mix Design

Certify, using a Government-approved independent commercial testing laboratory, that proportioning of mix is in accordance with ACI 211.1 or ACI 318M ACI 318 for specified strength and is based on aggregate data which has been determined by laboratory tests during last twelve months. Submit a complete list of materials including type; brand; source and amount of cement, fly ash and pozzolan, ground slag, and admixtures; and applicable reference specifications. Submit additional data regarding concrete aggregates if the source of aggregate changes. Submittal must clearly indicate where each mix design will be used when more than one mix design is submitted.

1.8.5 Load Test Supporting Data

Submit Jack calibration records, equipment calibration data, a testing arrangement description and diagram, and the proposed loading sequence. Submit a calibration report (performed by an independent testing agency) for the drilling and load test equipment to be used. The report must include: the name, address, and phone number of testing agency; name of the project; name of the contractor; identification of the equipment; date of calibration; and calibration data. The equipment calibration must be
performed within six months from the start of the testing operation.

1.8.6 Silica Fume Manufacturer's Representative

Provide statement that the manufacturer's representative will be present at the plant to ensure proper mix, including high range water reducer (HRWR), and batching methods.

PART 2 PRODUCTS

2.1 PILES

2.1.1 Wood Sections

Pile diameters of the wooden piles must not be less than 300 mm 12 inches measured 900 mm 3 feet from the butt [note that piles 17 meters 55 feet and longer should be 330 mm at 900 mm 13 inches at 3 feet] (before forming of the tenon). Provide Douglas Fir or Southern Pine piles [clean peeled] [rough peeled] conforming to ASTM D25. Piles must [be pressure treated in accordance with AASHTO M 133, for Land and Fresh Water Piles by Pressure] [not be treated].

2.1.2 Metal Shells

Provide metal shells of steel of sufficient strength and rigidity to withstand all driving stresses, to prevent distortion caused by driving adjacent piles, to prevent collapse due to soil or hydrostatic pressure, and to maintain their shape, free from dents or deformation. Thickness of shells must be as indicated. Provide watertight shells to exclude groundwater during concrete placement. The actual or superficial perimeter of a cross section of the piles, at any point in their length, must be circular. Design the joint as specified herein, and in a manner to prevent the entrance of soil while driving, the leaking of concrete during placing, and the entrance of water at a rate that would not allow the shell to be properly dewatered before placement of concrete. The shells must be [step-tapered type with a minimum nominal diameter of [_____] mm inches at the joint between wood and shell and the diameter shall increase from the joint to the cut-off elevation at a rate of not less than 10 mm per meter 1 inch per 8 feet of length] [or] [constant-section shells with a minimum nominal diameter of 300 mm 12 inches].

2.1.3 Concrete

Materials, mixing, and placing of concrete shall conform with the requirements of Section 03 30 00 CAST-IN-PLACE CONCRETE. Concrete shall have a minimum compressive strength of [_____] MPa psi at 28 days using [_____] -mm -inch maximum-size coarse aggregate. Slump shall be [_____] to [_____] mm inches for manual compaction and [_____] to [_____] mm inches when concrete is mechanically vibrated.

2.1.4 Reinforcing Steel

Provide reinforcing steel of the dimensions and sizes indicated and complying with [ASTM A615/A615M, Grade [40] [60]] [ASTM A996/A996M, Grade [50] [60]].

2.2 EQUIPMENT

Submit detail drawings, to demonstrate compliance of driving equipment,
including [metal shoes and] cap blocks, splicing of timber and concrete sections, and the forming, reinforcing and casting of piles. Installation equipment and testing equipment must include a list and description of equipment to be used, including manufacturer's catalog data and sufficient information to show compliance with the requirements specified.

2.2.1 Pile Hammer

Provide a hammer with a delivered energy suitable for the total weight of the pile, the character of subsurface material to be encountered, and the pile capacity to be developed without damage to the pile. The driving energy of the hammer must be not less than 20.3 kN-m 15,000 foot-pounds. Operate diesel-powered hammers at the rate recommended by the manufacturer throughout the entire driving period. Maintain sufficient pressure at the air hammer so that:

2.2.1.1 Double-Action Hammer

The number of blows per minute during and at the completion of driving of a pile is equal approximately to that at which the hammer is rated.

2.2.1.2 Single-Acting Hammer

There is full upward stroke of the ram.

2.2.1.3 Differential Type Hammer

There is a slight rise of the hammer base during each upward stroke.

2.2.2 Driving Helmets or Caps

Use a driving helmet or cap, including a pile cushion, between the top of the pile and the ram to prevent impact damage to the pile. The driving helmet, or cap and pile cushion combination, must completely cover the top surface of the pile and be capable of protecting the head of the pile, minimizing energy absorption and dissipation, and transmitting hammer energy uniformly over the top of the pile. Submit helmet and cushion block information.

a. The driving helmet or cap must fit loosely around the top of the pile so that the pile is not restrained by the driving cap, if the pile tends to rotate during driving. The pile cushion may be of solid wood, of laminated construction using plywood, softwood, or hardwood boards, or of other approved cushioning material.

b. The minimum thickness of the pile cushion must be 75 mm 3 inches and the thickness must be increased so as to be suitable for the size and length of pile, character of subsurface material encountered, hammer characteristics, and required driving resistance. Use a new pile cushion at the start of driving for each pile and the pile cushion must be replaced whenever it becomes highly compressed, charred, burned, or deteriorated in any manner during driving.

2.3 PRODUCT QUALITY CONTROL

2.3.1 Piles

The producer must brand each treated pile, in accordance with AWPA M1, AWPA M2, AWPA M6, AWPA T1 and AWPA U1. Indicate employment of pick-up
points, support points other than pick-up points, and any other methods of pick-up.

[2.3.2 Silica Fume Manufacturer's Representative]

Provide statement that the manufacturer's representative will be present at plant to ensure proper mix, including high range water reducer (HRWR), and batching methods.

[2.3.3 Aggregate Tests]

Take samples of fine and coarse aggregate at concrete batch plant and test. Perform mechanical analysis (one test for each aggregate size) in accordance with ASTM C136/C136M. Tabulate results of tests in accordance with ASTM C33/C33M.

[2.3.4 Slump and Strength Tests]

Sample concrete in accordance with ASTM C172 at time concrete is deposited for each production line. Perform slump tests in accordance with ASTM C143/C143M. Mold cylinders in accordance with ASTM C31/C31M. Mold at least six cylinders per day or one for every [15] [45] cubic meter [20] [60] cubic yards of concrete placed, whichever is greater. Cure cylinders in same manner as piles and for accelerated curing, place at coolest point in casting bed. Perform strength tests in accordance with ASTM C39/C39M. Test two cylinders of each set at 7 days [and 14 days]. Test remaining cylinders of each set 28 days after molding.

[2.3.5 Changes in Proportions]

If, after evaluation of strength test results, compressive strength is less than specified compressive strength, make adjustments in proportions and water content and changes in temperature, moisture, and curing procedures as necessary to secure specified strength. Submit changes in mix design to Contracting Officer in writing.

[2.3.6 Compressive Strength Test Results]

Evaluate compressive strength test results at 28 days in accordance with ACI 214R using a coefficient of variation of 10 percent. Evaluate strength of concrete by averaging test results of each set of standard cylinders tested at 28 days. Not more than 10 percent of individual cylinders tested must have a compressive strength less than specified design strength.

[2.3.7 Chloride Ion Concentration]

Sampling and determination of water soluble chloride ion content in accordance with ASTM C1218/C1218M. Maximum water soluble chloride ion concentrations in hardened concrete at ages from 28 to 42 days contributed from the ingredients including water, aggregates, cementitious materials, and admixtures must not exceed 0.06 percent by weight of cement.

[2.3.8 Chloride Ion Penetration]

Proportion concrete to have the chloride ion penetration test in accordance with ASTM C1202 to ensure the durability of concrete in marine environment, and be below 3000 coulombs for concrete specimens tested at 56 days.
2.4 MATERIAL SUSTAINABILITY CRITERIA

For materials used, where applicable and to extent allowed by performance criteria, provide and document the following in accordance with Section 01 33 29 SUSTAINABILITY REQUIREMENTS AND REPORTING:

a. Recycled content for fly ash and pozzolan
b. Recycled content for Ground Iron Blast-Furnace Slag
c. Recycled content for Silica Fume

PART 3 EXECUTION

3.1 PRELIMINARY WORK

3.1.1 Pile Length Markings

Mark each pile prior to driving with horizontal lines at 300 mm one foot intervals. Mark the interval number on pile every 1.5 m 5 feet from pile tip.

3.2 PILE DRIVING

**************************************************************************

NOTE: Past experience with similar structures is probably the best indicator of the need for protection. If protection is to be provided, this paragraph should be expanded to cover the type and extent of protection required. The following typical references offer detailed information on different types of pile protection:

Additionally, the Construction Engineering Research Laboratory in Champaign, Illinois has done extensive research on pile protection, and may be contacted for information.

**************************************************************************

Submit complete and accurate pile records of each driven pile indicating the pile location (as driven), size, length, final elevations of tip and top, elevation of top of wood section, pile weight, number of splices and locations, blows required for each m foot of penetration throughout the entire length of the pile and for the final 150 mm 6 inches of penetration, and the total driving time. The record should also include the type and size of the hammer used, the rate of operation, and the type and dimensions of the driving helmet and cushion block used. Record any unusual conditions encountered during pile installation and immediately report them to the Contracting Officer. Perform driving with fixed leads to hold the
pile firmly in position, alignment, and in axial alignment with the hammer. Drive piles to or below the "calculated" tip elevation to reach a driving resistance in accordance with the schedule that the Contracting Officer will prepare from the load test results.

a. The pile hammer used for driving must be the same type, operated at the same rate and in the same manner, as that used for driving the test piles. If a pile fails to reach the "calculated" tip elevation or if a pile reaches the "calculated" tip elevation without reaching the required driving resistance, notify the Contracting Officer and perform corrective measures as instructed.

b. No piles will be driven until the excavation or fill in the area that piles are to occupy has been completed. No piles will be driven within 30.5 m 100 feet of concrete less than 7 days old, unless so directed. Carefully locate piles to the lines and spacing shown and drive them to either the plumb position or the batter indicated.

c. Limit dynamic driving stresses to the crushing strength of the timber. If the pile encounters a sudden high driving resistance, cease driving and immediately notify the Contracting Officer and proceed as directed. If during driving, the pile encounters a sudden decrease in penetration resistance, investigate the cause; unless a satisfactory reason is found and the pile is undamaged, reject the pile and replace it without additional cost to the Government.

d. Take care to operate the hammer at its short stroke when the tip of the pile encounters soft material of little resistance either at the start of the driving or in passing into poor subsoil. The hammer should continue at its short stroke until sufficient resistance is built up to prevent damage due to tensile wave stresses.

When driving is interrupted before final penetration is reached, the record of the penetration shall not be taken until after at least a 300 mm 12 inches penetration has been accomplished on the resumption of driving. Minimum penetration of the tops of wood piles being used in composite piles shall be 600 mm 2 feet below the low water table.

e. The length of the metal shell may vary according to requirements for proper seating of the piles, elevations of groundwater, and the required pile cut-off. Where piles longer than the specified length measured from point to cut-off elevations are required to provide specific bearing capacities, provide the longer piles by furnishing longer wood sections as directed. As an option, provide longer piles by increasing the lengths of concrete sections, but only after approval. Upon approval, where the specified bearing capacities are obtained with piles of less than the specified lengths, shorter piles may be used, but the tops of wood sections must be driven at least 600 mm 2 feet below the water table.

3.2.1 Concrete Placement

Materials, mixing, and placing of concrete must conform with the requirements of Section 03 30 00 CAST-IN-PLACE CONCRETE. Use an approved method for placing concrete in the shells. Place the concrete in a continuous flow from joint to top of piles. However, no concrete will be placed in any shell until all other piles within a radius of 6 m 20 feet [or heave range] have been driven. Shells must be free of deformations and water. Place concrete by tremie and not dropped through water.
3.2.2 Splices

Unless otherwise directed, construct field splices as indicated. Splices must maintain the true alignment and position of the pile sections and develop the full strength of the pile in both bearing and bending. Proprietary prefabricated splicer sleeves may be used upon approval.

3.2.3 Tolerances in Driving

**************************************************************************
NOTE: Foundation piles should not be more than 75 to 150 mm 3 to 6 inches from their intended plan position.
**************************************************************************

Top of any pile at elevation of cutoff must be within ____ mm inches of the planar location indicated. Manipulation of piles to force them into position will not be permitted. Check piles for heave and re-drive those found to have heaved to the required tip elevation. Piles damaged or driven outside the above tolerances must be replaced, or additional piles driven at locations specified by the Contracting Officer at no expense to the Government.

3.2.4 Cutting of Piles

Cut off piles at the elevations indicated by an approved method; remove surplus material from the job site.

3.2.5 Rejected Piles

Withdraw piles damaged, mislocated, or driven out of alignment beyond the maximum tolerances and replace them with new piles; or cut off and abandon them. Additional piles must be driven as directed; excess cut off from piles and unacceptable piles must be removed from the site of work. Perform all work, in connection with withdrawing and removing from the site rejected piles; without additional cost to the Government.

Any pile damaged by reason of internal defects or by improper driving must be corrected by one of the following methods approved by the Contracting Officer for the pile in question:

a. The pile is withdrawn, if practicable, and replaced by a new and, if necessary, longer pile.

b. Fill the shell with concrete, abandon the pile and install one or more replacement pile(s) adjacent to the defective pile.

A pile terminated below the specified cut-off elevation must be corrected by one of the following methods approved by the Engineer:

a. The pile is spliced (if approved).

b. A sufficient portion of the footing is extended down to properly embed the pile.

A pile driven out of its proper location or out of plumb as approved by the Engineer, must be corrected by one of the following methods approved by the engineer:
a. The pile is withdrawn, if practicable, and replaced by a new pile.
b. One or more replacement piles are driven next to the pile in question.
c. Fill the shell with concrete, abandon the pile and install one or more replacement pile(s) adjacent to the pile in question.
d. As directed by the structural engineer.

3.2.6 Predrilling

**************************************************************************
NOTE: Predrilling is normally terminated at a depth equal to two thirds of the total length of the pile embedment.
**************************************************************************

Predrilling will be permitted only when approved. The hole shall be [_____] mm inches less in diameter than the diagonal dimension of the pile. All predrilled piles must be seated by final driving to provide the required pile capacities.

3.2.7 Collars or Bands

Use collars or bands of an approved design where required for the protection of the top of piles against splitting, brooming, and other damage when the piles are being driven.

3.2.8 Metal Pile Shoes

Where indicated or directed, securely attach metal shoes of an approved design to the piles in a manner described in the detail drawings. Submit pile shoe material and installation details.

3.2.9 Joints

Joints between the wood and concrete sections must be as indicated in the detail drawings.

3.2.10 Welding

Conform all field welding, and preparation of materials for welding, to AWS D1.1/D1.1M or AWS D1.4/D1.4M, as appropriate, using proper materials and experienced personnel whose ability and qualifications to do acceptable work have been fully demonstrated.

3.2.11 Pile Heave

When large pile clusters or piles are driven with very close spacing, take periodic elevations on the tops of all piles to observe and determine pile heave. Such elevations must be taken on a telltale pipe 50 mm 2 inches in diameter placed inside the pile shell and bearing on the top of the wood section. When such checking indicates that pile heave has occurred, all heaved piles must be re-driven to either the original resistance or the elevation, or both, as directed. If pile heave occurs along the shell portion of the pile, resulting in separation of the joint, the Contractor may resort to predrilling to eliminate heave or may provide a joint of sufficient tension capacity, as authorized, without additional cost to the

SECTION 31 62 23 Page 23
3.2.12 Curing

[Maintain concrete in a moist condition for not less than 7 days for normal portland cement and for not less than 3 days for high-early-strength cement. For each decrease of \( 2 \text{ degrees C} \) below \( 20 \text{ degrees C} \) in the average curing temperature, these curing periods must be increased by 4 days for units of normal portland cement and by 2 days for units of high-early-strength cement.] [Curing must be in accordance with Section 03 30 00 CAST-IN-PLACE CONCRETE.]

3.2.13 Long Piles

Piles having a slenderness ratio greater than \( \left[ \frac{22}{\text{______}} \right] \) must be handled and driven with special precautions to ensure against overstress or leading from a plumb or true position. The slenderness ratio must be the pile length divided by the least radius of gyration of the pile. When a high-resistance strata lying near the surface must be penetrated, spud piles may be used only when authorized by the Contracting Officer to minimize hard driving of long piles during the early stages of driving operations.

3.2.14 Jetting of Piles

**************************************************************************

NOTE: Jetting generally should not be permitted:

a. For piles dependent on side friction in fine-grained soils (high clay or silt content) with low-permeability where considerable time is required for the soil to reconsolidate around the piles.

b. For piles subject to uplift or lateral forces.

c. For piles adjacent to existing structures.

d. For piles in closely spaced clusters unless the load capacity is confirmed by test.

**************************************************************************

[Jetting of piles will not be permitted] [Jetting must be discontinued at a depth approximately \( 1.5 \text{ m} \) \( 5 \text{ feet} \) above the "calculated" tip elevation; the remaining penetration must be achieved by driving. Before the driving of the final \( 1.5 \text{ m} \) \( 5 \text{ feet} \) is started, the pile must be firmly seated in place by the application of a number of reduced-energy hammer blows].

3.2.15 Survey Data

**************************************************************************

NOTE: NOTE: Include this paragraph only when protection of existing structures from pile driving activities is required.

The designer must indicate on the drawings all structures and facilities for which protection is required. The designer must also provide a project specific document that details design criteria, requirements for preconstruction condition surveys,
post construction condition surveys, geotechnical instrumentation to measure ground movements and any other requirements.

Add any additional requirements as necessary.

After the driving of each pile group is complete and before concrete is placed, provide the Contracting Officer with an as-driven survey showing actual location and top elevation of each pile. Do not proceed with placing concrete until the Contracting Officer has reviewed the survey and verified the safe load for the pile group driven. Present a survey in such form that it gives deviation from plan location in two perpendicular directions and elevations of each pile to nearest \(13\) mm half inch. Survey must be prepared and certified by a licensed land surveyor.

3.2.16 Protection of Existing Structures

Mitigate impact on existing facilities due to pile driving activities in accordance with the [project specific document].

3.3 FIELD TEST AND INSPECTION

Submit a complete report on the pile test, within [seven] [_____] days of completion of each pile test, including, but not limited to, a description of the pile driving equipment, driving records for both test piles and reaction piles, complete test data, analysis of test data, and recommended allowable design loads based on the pile test results. Provide final records of placement locations and depths of embedment of all piles. Prepare the report by or under the direct supervision of a registered professional engineer in the State of [_____________] and experienced in pile load testing and load test analysis.

3.3.1 Test Piles

Test piles must be of the type and must be driven in the manner specified. The Contractor's Geotechnical Engineer will use test pile and load test data to determine "calculated" pile tip elevations and the necessary driving resistance. Test piles that are located within the tolerances indicated and that provide a safe design capacity as determined by the results of a satisfactory load test may be used in the finished work. Drive test piles [at the locations indicated] [in the vicinity of the soil boring test holes No. [_____]]. [Jetting will be authorized only when pile testing clearly establishes the validity of its use.] Drive test piles to the tip elevation specified or indicated. Withdraw the specified number of test piles as indicated after reaching the "calculated" tip elevation for visual inspection of the pile.

3.3.2 Load Tests

Perform load tests in accordance with ASTM D1143/D1143M[, as modified], at locations shown or directed, on test piles placed to the tip elevation indicated except as otherwise directed. Loading, testing, and recording of data must be under the direct supervision of the Contractor's Geotechnical Consultant, as well as the analysis of the load test data. The installation of piles must not proceed in a new area with substantially different subsurface conditions until a satisfactory load test has been performed in that area and the results approved. Allow a minimum of [_____] days after submission of the test pile data for approval. Unless
otherwise directed, piles must not be tested sooner than [___] days after driving unless sufficient time has elapsed to allow the cast-in-place section of the pile to obtain the minimum strength of [___] MPa psi. Test loading must conform to ASTM D1143/D1143M, cyclic loading method. Apply the load to the pile [pile group] by [hydraulic jacks acting against an anchored reaction frame] [hydraulic jacks acting against a weighted platform or box] [direct loading of a weighted platform] using a spherical bearing to transmit the load to the pile. Maintain a data plot of load versus movement during the test procedures. Determine the safe design capacity of a test pile as determined from the results of load tests according to UFC 3-220-01. Submit load test report.

3.3.3 Safe Design Capacity

Determine the safe design capacity of a test pile as determined from the results of load tests according to UFC 3-220-01.

3.3.4 Inspection

The Contracting Officer may require that certain wood sections be withdrawn for test and inspection before the shell section is added to determine the condition of the wood sections. When so required, such wood sections must be redriven only when approved. Withdrawn piles not suitable for redriving must be treated as a rejected pile as specified in paragraph PILE DRIVING. Provide a suitable light for inspecting the interiors of pile shells.

3.3.5 Pile Capacity

The capacity, as driven, of single piles not in clusters in the structure must be not less than [___] metric tons tons. Determine the capacity by the following formula, modified according to the data obtained by the load tests.

\[
R = \frac{166.7WH}{S + 2.54 P/W} \quad R = \frac{2WH}{S + 0.1 P/W}
\]

Double-Acting Hammers
\[
R = \frac{166.7E}{S + 2.54 P/W} \quad R = \frac{2E}{S + 0.1 P/W}
\]

Where:

- \( R \) is the allowable static pile load in newtons pounds.
- \( W \) is the weight of the striking part of the hammer in newtons pounds.
- \( H \) is the effective height of fall in m feet.
- \( E \) is the actual energy delivered by the hammer per blow in newton-meters foot-pounds.
- \( S \) is the average net penetration in mm inches per blow for the last 5 blows after the pile has been driven to a depth where successive blows produce approximately equal net penetration (a minimum distance of 1 meter 3 feet for friction piles).
- \( P \) is the weight of the pile in N pounds. (If \( P \) is less than \( W \), \( P/W \) must be taken as unity.)

[3.4 SPECIAL INSPECTION AND TESTING FOR SEISMIC-RESISTING SYSTEMS

**************************************************************************

NOTE: Include this paragraph only when special inspection and testing for seismic-resisting systems

SECTION 31 62 23 Page 26
is required by the International Building Code (IBC).

This paragraph will be applicable to both new buildings designed and to existing building seismic rehabilitation designs done according to UFC 1-200-01, "General Building Requirements" and UFC 3-310-04, "Seismic Design for Buildings".

The designer must indicate on the drawings all locations and all features for which special inspection and testing is required in accordance with Chapter 17 of the IBC. This includes indicating the locations of all structural components and connections requiring inspection.

Add any additional requirements as necessary.

Perform special inspections and testing for seismic-resisting systems and components in accordance with Section 01 45 35 SPECIAL INSPECTIONS.

][3.5 VIBRATION CONTROL

NOTE: Include this paragraph when vibration monitoring is required. Add any additional criteria or requirements as necessary to the particular project.

Perform vibration monitoring at the locations [shown in the plan] [decided by the Contracting Officer] during the pile driving operations. Perform vibration monitoring [using] [seismographs] [and geophones] within a distance of 61 meters 200 feet from the pile driving activity. [Engage the services of a qualified, independent vibration consultant, acceptable to the Government, to conduct the vibration monitoring. The vibration consultant must have minimum of [five] years of experience in vibration monitoring. A minimum of [28] days before the installation of vibration monitors, submit to the Government the name of the vibration consultant and a list of at least [three] previously completed projects of similar scope and purpose.]

Prior to the pile driving activities, obtain baseline readings of ambient vibrations. The vibration during the pile driving activities must be limited to [a peak particle velocity of not more than 5 cm 2 inches per second.] [the limits mentioned in the [contract documents].] [Determine appropriate vibration limits as per [US Bureau of Mines] [American Association of State Highway and Transportation Officials (AASHTO)] guidelines. ]During pile driving activities, monitor the vibrations to ensure the limits are not exceeded. If the limits are exceeded, cease the pile driving activity causing the vibration until [the Vibration consultant and the Contracting Officer] are on site to observe the structures nearest to the vibration monitor which has exceeded the limits.

The Contractor must be responsible for all damages resulting from the pile driving operations and must take whatever measures necessary to maintain peak particle velocity within the specified limit. After completion of the project, remove the vibration monitors off the site and off Government property and restore the monitoring locations back to their original
[3.6 NOISE CONTROL]

**************************************************************************
NOTE: Include this paragraph when noise monitoring is required. Add any additional criteria, references or requirements as necessary to the particular project.
**************************************************************************

Perform noise monitoring at the locations [shown in the plan] [decided by the Contracting Officer] [at noise sensitive public areas] during the pile driving operations. [Perform noise monitoring using [noise meters][, and] [_______]]. [Engage the services of a qualified, independent noise consultant, acceptable to the Government, to conduct the noise monitoring. The noise consultant must have minimum of [five] years of experience in noise monitoring. A minimum of [28] days before the installation of noise monitors, submit to the Government the name of the noise consultant and a list of at least [three] previously completed projects of similar scope and purpose.]

Prior to the pile driving activities, obtain baseline readings of ambient noise levels. [The noise limits are mentioned in the [plan] [contract documents]]. [Determine appropriate noise limits as per [local agency] [Occupation Safety and Health Administration] guidelines]. During pile driving activities, monitor the noise to ensure the limits are not exceeded. If the limits are exceeded, cease the pile driving activity and install noise mitigation measures.

The Contractor must be responsible for all damages resulting from the pile driving operations and must take whatever measures necessary to maintain noise within the specified limit. After completion of the project, remove the noise monitors off the site and off Government property and restore the monitoring locations back to their original condition.

[3.7 PRECONSTRUCTION CONDITION SURVEY]

**************************************************************************
NOTE: Add any additional criteria, references or requirements as necessary to the particular project.
**************************************************************************

Perform preconstruction condition survey of [structures] [and utilities] [within 61 meters 200 feet of the pile driving activity] [specified in the plans] [decided by the Contracting Officer]. Perform outreach to the owner of the structures [28] days before performing the preconstruction condition survey. The Contractor must obtain written permission from the owner of the structure prior to accessing the structure. The preconstruction condition survey must include video and photographic documentation of the exterior and interior of above ground structures and of the interior of underground structures. Video documentation must be in high definition, and show existing conditions and highlight, where possible, existing cracks, deteriorated concrete, exposed and corroded reinforcement, cracked or broken brick or mortar, and other signs of distress. For utilities, perform the survey when the greatest extent of the interior is exposed. Provide supplementary artificial lighting as needed. The video must include annotation with location and structure nomenclature which describes any areas of distress over the video and time code superimposed on the
video. Photographs must be accompanied by sketches or descriptions that indicate the location and direction of each photograph. For each structure surveyed, provide a Pre-Construction Condition Survey Report following completion of the survey. The report must contain all documentation associated with the survey including DVD copies. In the report, include notes, sketches, photographs, and videos. Provide general information, such as location details and structure type, as well as particular information on materials, condition, existing damage, aperture and persistence of cracks, and disrepair observed during visual survey. Provide a graphical depiction of locations of damage or other features of concern. Submit the Preconstruction Condition Survey Reports no later than [28] days before the commencement of pile driving activity. Accept responsibility for damages to existing adjacent or adjoining structures created by pile driving work, and repair any damages to these structures without cost to the Government.

3.8 CONSTRUCTION INSTRUMENTATION AND MONITORING PROGRAM

**************************************************************************
NOTE: Include this section if instrumentation is to be installed due to concerns about vibration, settlement, lateral movement, etc. during pile driving activities. Instrumentation should be specified and included in the specification. This section can be deleted if there are no instrumentation requirements.

Add any additional criteria or requirements as necessary for the particular project.
**************************************************************************

Prepare a geotechnical instrumentation program to monitor settlement [and lateral movement] of temporary and permanent structures, utilities, [embankments] [and excavations] during pile driving. The design and distribution of instrumentation must demonstrate an understanding of the need, purpose and application of each proposed type. [Perform noise and vibration monitoring in accordance with NOISE CONTROL and VIBRATION CONTROL sections.]

Monitoring must extend before, during and for a period after completion of construction activities related to pile driving when long-term performance issues are a concern. The monitoring plan must be designed to protect adjacent structures and utilities against damage due to the pile driving activities. Establish limiting values of vertical [and horizontal] movement [and angular distortion] [and vibration] for each structure and utility within the zone of influence, subject to review by the Government.

Prepare a report detailing the proposed program of instrumentation and monitoring, establishing threshold values of monitored parameters, and describing the response plans that will be implemented when threshold parameters are exceeded. The report must include details about instrumentation consultant's experience, appropriate types, quantities, locations and monitoring frequencies of the instruments.

Upon acceptance of the instrumentation and monitoring program, provide, install and monitor the instrumentation and interpret the data. Submit instrumentation data reports not less than every [____] days after the monitoring program has begun. Take corrective actions, as necessary, based on the field instrumentation data and as defined in the instrumentation and
monitoring program.

Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1  GENERAL

1.1  MEASUREMENT AND PAYMENT PROCEDURES

Bids will be based on the number of piles as indicated, and on lengths from tip to cutoff as follows:

<table>
<thead>
<tr>
<th>Number of piles</th>
<th>Length, meters feet</th>
</tr>
</thead>
<tbody>
<tr>
<td>[_____]</td>
<td>[_____]</td>
</tr>
</tbody>
</table>

From the data obtained as a result of driving the test piles [and load tests] specified hereinafter, the Government will determine and will list the "calculated" pile tip elevations and the driving resistances for all piles. This list will be used as the basis for ordering piles. Payment
will be on the basis of length of piling from cutoff elevation to final tip elevation, established by the requirements specified elsewhere in this section. Should the total number of piles or the number of each length vary from that specified as the basis for bidding, an adjustment on the contract price and the time for completion will be made. If excavation is made adjacent to piling and below the grade indicated and if piling is driven before backfilling of over-excavation, no payment will be made for the length of piling equal to the depth of the over-excavation. No additional payment will be made for cutting off piles, for any portion of a pile remaining above cutoff elevation, or for broken, damaged, or rejected piles.

1.1.1 Unit Price

The Contracting Officer reserves the right to increase or decrease the total length of piles to be furnished and installed, by changing the foundation pile locations or elevations, requiring the installation of additional piles, or requiring omission of piles from the requirements shown and specified. Whether or not such changes are made, payment will be made at the contract unit price per linear meter foot (including control test piles), multiplied by the total linear meters feet of acceptable piles actually installed.

1.1.2 Full Compensation

Payment in accordance with the above paragraph, "Unit Price," will constitute full compensation for furnishing, delivering, handling, and/or installing (as applicable) all material, labor and equipment necessary to meet contract requirements applicable to the foundation piles. No payment will be allowed for withdrawn, broken or rejected piles, nor (except for control test piles) for a portion of any pile remaining above the cut-off point.

1.1.3 Load Tests

The contract includes [_____] pile load tests. The Contracting Officer reserves the right to increase or decrease the number of pile tests. Adjustments in the contract price will be made for such increases or decreases by the amounts bid for "Additional Pile Load Test" or "Omitted Pile Load Test."

1.2 REFERENCES

**************************************************************************

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically
**NOTE: Section 00 31 32.13 Subsurface Drilling and Sampling Information is not a UFGS. CSI MasterFormat prescribes this section for inclusion of this data.**

Subsurface soil data logs are [as indicated] [appended to the SPECIAL CONTRACT REQUIREMENTS] [found in Section 00 31 32.13 Subsurface Drilling and Sampling Information]. The subsurface investigation reports [and samples of materials as taken from subsurface investigations] are available for examination at [______].
work, prior to commencement of pile installations, including details of the pile hammer, power plant, leads, pile cushion, cap block, and helmet.

1.3.2.1 Pile Hammers

Provide a hammer having a delivered energy suitable for the total weight of the pile, the character of subsurface material to be encountered, and the pile capacity to be developed. The driving energy of the hammer shall be not less than [_____] newton-meters foot-pounds.

1.3.2.2 Driving Helmets and Pile Cushions

Use a driving helmet, cap block, and pile cushion between the top of the pile and the ram to prevent impact damage to the pile and capable of protecting the head of the pile, minimizing energy absorption and dissipation, and transmitting hammer energy uniformly over the top of the pile. The driving helmet shall fit loosely around the top of the pile so that the pile is not restrained if the pile tends to rotate during driving. The pile cushion and cap block may be of solid wood or of laminated construction using plywood, softwood, or hardwood boards or other cushion material as approved by the Contracting Officer. The pile cushion shall completely cover the top surface of the pile and shall be retained by the driving helmet. The minimum thickness of the pile cushion and of the cap block shall be 76 mm 3 inches each and the thickness shall be increased so as to be suitable for the size and length of pile, character of subsurface material encountered, hammer characteristics, and required driving resistance.

1.4 SUBMITTALS

**************************************************************************
NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy, Air Force, and NASA projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification.
and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy, Air Force and NASA projects, or choose the second bracketed item for Army projects.

******************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-02 Shop Drawings

Installation

SD-03 Product Data

Driving Pile Casings

Equipment

SD-06 Test Reports

Test Piles.

PART 2   PRODUCTS

2.1 MATERIALS

2.1.1 Concrete

******************************************************************************

NOTE: Delete or modify second sentence when the job is small or the existence of certified plants is beyond acceptable distance of small jobs. Insert the ultimate compressive strength required by design.

******************************************************************************

Conform materials, mixing, and placing of concrete to the requirements of Section 03 30 00 CAST-IN-PLACE CONCRETE. Ready-mix plant equipment and facilities shall be certified in accordance with NRMCA QC 3. Minimum compressive strength at 28 days shall be[_____] MPa psi. Maximum coarse aggregate size shall be 19 mm 3/4 inch.

2.1.2 Reinforcement

******************************************************************************

NOTE: Reinforcement should be required for the unsupported sections of piles, for uplift or tension piles, for piles exposed to high bending stresses not resisted by batter piles, and for anchoring the top of the pile to the pile cap or slab. Tension or uplift piles shall be reinforced throughout their entire length.

******************************************************************************
Conform materials, assembly, and placement of reinforcement to the requirements of Section 03 30 00 CAST-IN-PLACE CONCRETE. Assemble and place reinforcement in the casing as a unit as detailed and scheduled.

2.1.3 Casings

**************************************************************************
NOTE: Closed-end steel pipes should generally be used. Open-end steel pipes should be considered where:

a. It is important to avoid soil displacement as in piles driven adjacent to existing structures.

b. Soil conditions indicate a dense or clayey soil, or extremely coarse granular soil is present, such as gravel.

Where open-end pipes are specified, concrete should not be placed until all soil, water and foreign material are removed from inside casing.

**************************************************************************

Provide casings of steel and sufficient strength to prevent harmful distortions during driving, after completion of driving, and during driving of adjacent casings. Casings driven without the use of an internal mandrel shall have walls of a thickness sufficient to withstand the driving stresses. Casings shall be closed at the tip, except for steel pipe casings conforming to ASTM A252 that may be open-end driven. Make joints and tip connections watertight. Nominal circumference at any cross-section in length shall be circular, whether or not modified by helical corrugations or flutings. Leave casings permanently in place; provide any one of the following types or combination of types; but use only one type or combination throughout.

2.1.3.1 Uniform Taper

Diameter shall increase from tip to cutoff at a uniform rate. Minimum nominal diameter at tip and two-third points above tip shall be as indicated.

2.1.3.2 Step-Taper

Section increments shall increase in diameter uniformly. Minimum nominal diameter at tip and two-third points above tip shall be as indicated.

2.1.3.3 Constant Section

Steel pipes, conforming to ASTM A252, Grade 2, may be used in lieu of casings of constant section. Minimum nominal diameter shall be as indicated.

2.1.3.4 Combination Type

Combination type cast-in-place concrete piles, steel casing, may be any of the following or other types, depending upon design criteria. Specification requirements shall be in accordance with applicable paragraphs of this section.
a. Steel pipe lower section with metal casing taper or constant-diameter upper section.

b. Constant-diameter or tapered lower section with tapered upper section.

c. Tapered lower section with constant-diameter upper section.

PART 3 EXECUTION

3.1 INSTALLATION

Submit drawings demonstrating compliance of driving equipment and steel casing with contract documents. Include in the drawings shop and erection details, casing details, end closures, splices, driving helmets, and reinforcement.

3.1.1 Driving Pile Casings

Submit a complete and accurate record of each driven pile, within 3 days of completion of driving. Indicate in the record the pile location (as driven), driven length, embedded length, final elevations of tip and top, pile weight, butt and tip diameter, quantity and strength of concrete used in each pile, number of splices and locations, blows required for each meter foot of penetration throughout the entire length of the pile and for the final 150 mm 6 inches of penetration, and the total driving time. Also include in the record the type and size of the hammer used, the rate of operation, and the type and dimensions of driving helmet, pile cushion, and cap block used. Record any unusual conditions encountered during pile installation and immediately report to the Contracting Officer.

3.1.1.1 Driving Procedure

**************************************************************************
NOTE: The next-to-last sentence, concerning tip elevation and driving resistance, should be edited to conform to subsurface conditions and type of pile (friction or end bearing).

Insert the radius distance (3 to 6 meters 10 to 20 feet) and the time (2 to 7 days). No concrete shall be placed in any pile until all other casings within a radius of 3 to 6 meters 10 to 20 feet have been driven and inspected.
**************************************************************************

Stop excavation at 300 mm (1 foot) above foundation grade before casings are driven. When pile driving is accomplished, complete excavation to lines and grades shown. Drive permanent pile casings, without interruption, to the "calculated" tip elevation to reach a driving resistance in accordance with the schedule which the Government will prepare from the test-pile driving data. The pile hammer used for driving shall be the same type and operated at the same rate and in the same manner as that used for driving the test piles. Operate diesel powered hammers at the rate recommended by the manufacturer throughout the entire driving period. Maintain sufficient pressure at the steam hammer so that:

a. For a double-acting hammer, the number of blows per minute during and at the completion of driving of a pile is equal approximately to that at which the hammer is rated.
b. For a single-acting hammer, there is a full upward stroke of the ram.

c. For a differential-type hammer, there is a slight rise of the hammer base during each upward stroke.

Use a new pile cushion at the start of driving for each pile; replace the cushion whenever it has become highly compressed, charred, burned, or deteriorated in any manner during driving. Notify the Contracting Officer, to determine what procedure will be followed, if a pile reaches the "calculated" pile tip elevation without reaching the required driving resistance; or if the required driving resistance is reached before the "calculated" pile tip elevation. Casings will not be driven within a radius of [_____] m feet of any other casing in which the concrete and reinforcement has been placed for less than [_____] days.

3.1.1.2 Tolerance in Driving

Drive casings with a variation of not more than 20 mm per m 0.25 inch per foot of pile length from the vertical. Butts shall be within 100 mm 4 inches of the location indicated. Manipulation of casings to force them into position will not be permitted. Check casings for heave, after all piles are driven in a cluster or under any conditions of relatively close spacing; redrive those found to have heaved to the required tip elevation. The center of gravity of each group of footing piles shall be maintained by templates or other approved means to conform to locations shown. Casings damaged, mislocated, or driven out of alignment shall be replaced or additional casings driven as directed.

3.1.1.3 Jetting of Pile Casings

**************************************************************************
NOTE: Jetting should generally not be permitted for piles:
**************************************************************************

a. Dependent on side friction in fine-grained, low-permeability soils (high clay or silt content) where considerable time is required for soil to reconsolidate around the piles.

b. Subject to uplift.

c. Adjacent to existing structures.

d. In closely spaced clusters unless the load capacity is confirmed by test and unless all jetting is done before final driving of any pile in the cluster.

Jetting of pile casings [may be used when permitted by the Contracting Officer] [will be permitted by the Contracting Officer as indicated] [will not be permitted]. [Discontinue jetting when the pile tip is approximately 1.5 m 5 feet above the "calculated" pile tip elevation; make the final 1.5 m 5 feet of penetration by driving. Before commencing with the driving of the final 1.5 meters 5 feet, the pile casing shall be firmly seated in place by the application of a number of reduced energy hammer blows.]
3.1.2 Filling of Casings

Visually inspect each casing after its final installation and prior to depositing the concrete and placing the reinforcement. Notify the Contracting Officer prior to each such inspection to allow for quality assurance inspections of all casings. The inspection will verify the integrity of the casing throughout its length and the absence of distortion and reduction in area. Deposit concrete in the casing in a continuous operation by means of a funnel or hopper after all mud, water and other extraneous material has been removed from its interior.

3.1.3 Cutting of Casings

Cut casings with an acetylene torch or saw with prior approval by the Contracting Officer.

3.1.4 Welding

Perform shop and field welding, qualification of welders, and inspection of welds in accordance with AWS D1.1/D1.1M.

3.1.5 Splicing

Splices may be used after review by the Contracting Officer. No more than two splices per full length of casing will be permitted. They shall be able to transmit any vertical and lateral forces adequately, and in addition, develop no less than 50 percent of the flexural capacity of the ordinary pile casing cross section. Make lateral joints with a continuous full penetration butt weld in accordance with AWS D1.1/D1.1M or as approved by the Contracting Officer.

3.2 FIELD TESTS AND INSPECTIONS

3.2.1 Test Piles

Submit a complete report on the load test, within [seven] [_____] days of completion of load test, including, but not limited to, a description of the pile driving equipment, driving records for both test piles and reaction piles, complete test data, analysis of test data, and recommended allowable design loads based on the load test results. The report shall be prepared by or under the direct supervision of a registered professional engineer experienced in pile load testing and load test analysis.

3.2.1.1 Pile Driving

**************************************************************************
NOTE: Insert the number of test piles required. A minimum of three driving tests should be made; and possibly more, where subsurface conditions are questionable.
**************************************************************************

Drive test piles in the manner specified for all piling elsewhere in this section. Keep a record for each test pile of the number of blows required for each foot of penetration throughout the entire length of the pile, the penetration per blow at such intervals as directed, and the number of blows for the final 150 mm 6 inches of penetration. The record shall include the type and size of the hammer used, the rate of operation, and the type and dimensions of casings. Record any unusual occurrence during driving of the
pile casing and any increase and decrease of driving resistance and bring it to the attention of the Contracting Officer. The Government will use load test and test pile data to determine the “calculated” pile tip elevation and the necessary driving resistance. [_____] test piles shall be driven in the locations indicated, with surrounding earth at the elevations shown. Test piles properly driven and located and with adequate driving resistance may be used in the finished work. Jetting will be permitted by the Contracting Officer only when test pile driving clearly establishes the validity of its use.

3.2.1.2 Load Tests

**************************************************************************

NOTE: Delete this paragraph for projects for which load testing is not specified. Insert the number of piles to be load tested. The provisions of ASTM D1143/D1143M, such as pile set-up time after driving, test load, method of applying load, loading and unloading procedures, instrumentation, etc., should be carefully examined and modified as necessary to fit the specific load test being conducted. When it is desirable to show analysis for determination of pile capacities from load tests and for relating load test capacities to job capacities, include the following:

a. Test Measurements: Maintain the ultimate test load for not less than 24 hours and then release it. The safe design capacity of a test pile as determined from the results of load tests will be the lesser of the two values computed according to the following:

(1) One-half the load that causes a net settlement after rebound of not more than 0.23 mm per metric ton 0.01-inch per ton of total test load.

(2) One-half the load that causes a gross settlement of not more than 25 mm 1 inch provided that the load settlement curve shows no sign of failure.

b. Pile Capacity: The capacity, as driven, of single piles not in clusters in the structure should be not less than [_____] metric ton tons. The capacity will be determined by the following formulas, modified according to the data obtained by the load tests:

For single-acting hammers:  \( R = \frac{166.7W}{(s+2.54P/W)} \) (\( R = \frac{2W}{(s+0.1P/W)} \))

For double-acting hammers:  \( R = \frac{166.7E}{(s+0.1P/W)} \) (\( R = \frac{2E}{(s+0.1P/W)} \))

Where:  \( R \) is the allowable static pile load in newtons pounds.

\( W \) is the weight of the striking part of the hammer in
H is the effective height of fall in meters feet.

E is the actual energy delivered by the hammer per blow in newton-meters foot-pounds.

S is the average net penetration in millimeters inches per blow for the last five blows after the pile has been driven to a depth where successive blows produce approximately equal net penetration a minimum distance of 1 m 3 feet for friction piles.

P is the weight of the pile in newtons (pounds). If P is less than W, P/W will be taken as unity.

Dynamic pile stresses should not exceed the crushing strength of piles.

**************************************************************************

Perform load tests in accordance with ASTM D1143/D1143M, [___] loading method. The apparatus for applying the vertical loads shall be as given by the method, either for load supported directly by the pile, or load from weighted box or platform or reaction frame attached to sufficient uplift piles to take safely the required load applied to the pile by hydraulic jack. Perform the load tests; at locations shown or directed, on test piles driven to the tip elevation used for establishing lengths of piles for bidding, except as otherwise directed. Additional load test, at the expense of the Government, may be required. Pile shall have been in a place a minimum of 3 days before loading. Perform loading, testing, and recording of data under the direct supervision of a registered professional engineer. The analysis of the load test data shall be done by the registered professional engineer. The registered professional engineer shall be provided and paid for by the Contractor.

3.2.2 Concrete Testing

**************************************************************************

NOTE: The following table is recommended for use in determining the number of test cylinders required in relation to the size of each lot of piles to be tested.

<table>
<thead>
<tr>
<th>Pile Lot</th>
<th>Number of Test Cylinders</th>
</tr>
</thead>
<tbody>
<tr>
<td>25</td>
<td>2</td>
</tr>
<tr>
<td>100</td>
<td>4</td>
</tr>
<tr>
<td>1000</td>
<td>20</td>
</tr>
<tr>
<td>5000</td>
<td>50</td>
</tr>
<tr>
<td>10,000</td>
<td>100</td>
</tr>
</tbody>
</table>

Samples taken from random batches of concrete.

**************************************************************************
During Concrete placement, strength tests will be made by a testing service provided and paid for by the Contractor in accordance with requirements of Section 03 30 00 CAST-IN-PLACE CONCRETE. Take at least two specimens from each random batch and one test will be made for every [_____] piles with no less than two tests for any 1 day's operation.

3.3 SPECIAL INSPECTION AND TESTING FOR SEISMIC-RESISTING SYSTEMS

**************************************************************************

NOTE: Include this paragraph only when special inspection and testing for seismic-resisting systems is required by Appendix 11A of ASCE 7-16.

This paragraph will be applicable to both new buildings designed according to UFC 3-301-01 SEISMIC DESIGN FOR BUILDINGS, and to existing building seismic rehabilitation designs.

The designer must indicate on the drawings all locations and all features for which special inspection and testing is required in accordance with UFC 3-301-01 and Appendix 11A of ASCE 7-16. This includes indicating the locations of all structural components and connections requiring inspection.

Add any additional requirements as necessary.
**************************************************************************

Perform special inspections and testing for seismic-resisting systems and components in accordance with UFC 3-301-01 and Section 01 45 35 SPECIAL INSPECTIONS.

NOTE: This guide specification covers the requirements for the design and construction of densified aggregate piers.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

NOTE: The extent and location of the work to be accomplished should be indicated on the project drawings or included in the project specification.

NOTE: Show the following information on the drawings:

1. Locations and design loads of aggregate piers.
2. Size, shape, and length of aggregate piers.

3. Locations of test piers, if required.

4. Soil data, where required.

**************************************************************************

NOTE: Edit this document for project specific ground improvement requirements such as
reinforcement or densification. Add additional information and requirements or delete requirements
not required. Care should be taken to coordinate an installation surface that will accommodate the top
heavy equipment that is required for installation. Coordinate the use of working pads or special
subgrade requirements with the appropriate paragraphs of Sections 31 00 00 EARTHWORK or
31 23 00.00 20 EXCAVATION AND FILL.

**************************************************************************

NOTE: Provide the following information in the contract or supporting design documents as appropriate:

a. Soils data and a final Site Characterization and Geotechnical Engineering Report;

b. Dead and live loads for each footing location
   Bearing pressure diagrams for mat foundations, retaining wall footings, and shear wall footings,
   and actual load for supported slab locations. A loading diagram must be provided for any footings
   subject to a moment. Any net uplift loads must be highlighted so uplift anchors can be provided; and

c. Coordinated Civil Site design drawings that highlight all existing and future utilities and new
   fill that will be placed on site.

**************************************************************************

PART 1   GENERAL

1.1  DESCRIPTION

Work consists of designing, furnishing, installing, monitoring, and testing of the densified aggregate pier foundations to the lines and grades designated on the project foundation plan and as specified herein. Work will include all equipment, material, labor, and supervision to design and install aggregate pier elements, [load transfer platforms ]and to perform soil and aggregate pier testing.

Drawings and general provisions of the Contract, including General and Supplementary Conditions and other Division 00 and Division 01 Specification Sections, apply to this Section.

The number of piers, diameters and depth of piers are to be determined by
the aggregate pier designer. Design must rely on subsurface information presented in the project geotechnical report. The information on ground conditions must be assessed to determine its suitability for the specified ground improvement system. Prepare site [and predrill as necessary] for aggregate pier installation. The aggregate piers will be columns of compacted aggregate constructed in a columnar-type configuration to produce an intermediate foundation system for support of foundation loads to achieve the degree of improvement (allowable bearing capacity for maximum allowable settlements) as indicated in paragraph PERFORMANCE CRITERIA. The piers can be constructed with a down-hole vibratory probe, displacement mandrel system, or a down-hole tamper. It is the aggregate pier contractor's responsibility to determine and implement the systems and criteria to ensure that the specified performance is achieved.

The information on ground conditions must be assessed to determine its suitability for the specified ground improvement system. Prepare site [and predrill as necessary] for aggregate pier installation. For soils and groundwater conditions in which the predrilled hole remains open and stable, the aggregate can be placed by a loader into the open hole and compacted in lifts using a down-hole tamper. In unstable conditions, the hole stability must be maintained either with a down-hole vibratory probe, displacement mandrel system, or casing if the tamper method is used.

Removal of spoils from the site (which result from aggregate pier construction), removal of spoils off the working pad, footing excavation, and subgrade preparation following aggregate pier installation are not included. For removal of spoils from site due to aggregate pier installation, footing excavation and subgrade preparation, conform to Section [31 00 00 EARTHWORK][31 23 00.00 20 EXCAVATION AND FILL], paragraph DISPOSITION OF SURPLUS MATERIALS.

1.1.1 Definitions

a. Aggregate piers are columns of compacted aggregate used to reinforce the ground to increase bearing capacity and reduce settlement of embankments or structures or to increase the density of soil. They can be constructed with a down-hole vibratory probe, a down-hole tamper, or a displacement mandrel system.

b. Designer is the firm employed by the Installer to design aggregate piers.

c. Installer: The firm that installs aggregate piers, who can be the general contractor or his subcontractor.

d. Load Transfer Platform: A structural layer used to transfer loads from the foundation or embankment to a group of aggregate piers.

e. Soil reinforcement refers to the aggregate piers being installed in the ground to increase the overall strength and stiffness of the soil mass, with little or no increase in the density of the soils in between the aggregate piers. A soil modulus test is typically performed to verify settlement and bearing capacity of the aggregate piers in both cohesive and cohesionless soils.

f. Soil densification refers to the aggregate piers being installed in the ground to increase the density of the soil in between the aggregate piers as well as the density of the overall soil matrix. This is only applicable to cohesionless soils and is typically verified by in situ
testing of the soil between the aggregate piers, such as standard penetration, cone penetrometer, or flat dilatometer tests.

g. Down-Hole Vibrators: Down-Hole Vibrators are specially-designed, high-energy depth vibrators. The horizontal vibrations are created by a motor and eccentric weight located near the tip of the vibrator. Extension tubes are bolted to the vibrator to allow it to be lowered to the necessary treatment depth.

h. Displacement Mandrel System: Displacement mandrel systems are constructed by advancing a specially designed mandrel augmented by dynamic vertical ramming energy to the full design depth. The hollow-shaft mandrel, filled with aggregate, is incrementally raised, permitting the aggregate to be released into the shaft, and then lowered by vertically advancing and ramming to densify the aggregate and force it laterally into the adjacent soil. The cycle of raising and lowering the mandrel is repeated to the top of pier elevation. This equipment is most often used in soil conditions with high water tables or for soils where a pre-drilled hole will not remain open.

i. Down-Hole Tampers: Down-Hole Tampers are proprietary high-energy impact apparatus. The vertical tamping energy is provided by a hammer which is connected to a round, beveled tamper. The apparatus is lowered into a pre-drilled hole to the required treatment depth. Down hole tampers may also include minimum 4990 kg 11,000 pound circular steel tampers dropped from minimum heights of 7.6 m 25 feet to create high compactive energies.

(2017) Standard Test Methods for Particle-Size Distribution (Gradation) of Soils Using Sieve Analysis

**ASTM E329**
1.3 SUBSURFACE DATA

Subsurface soil data such as [Standard Penetration Tests (SPT)], [Flat Plate Dilatometer Tests (DMT)], [Seismic Piezocone Penetration Tests (SCPTu)], [Pressuremeter tests], and [laboratory test data] are [indicated] [appended to the special contract requirements] [provided on the project drawings]. [The project Geotechnical Report and samples of materials taken from subsurface investigations may be examined as indicated in specification SECTION 01 05 00 JOB CONDITIONS, paragraph 1.2.2 Explorations. These data represent the best subsurface information available; however, variations may exist in the subsurface between boring locations]

1.4 BASIS OF BID

******************************************************************************

NOTE: Select one of the following options:

******************************************************************************

NOTE: Use "Lump Sum" paragraph below for lump (principal) sum bidding of aggregate piers. Use this in all projects except those where exact aggregate piers lengths cannot be practically determined prior to the actual work. Clearly show number of aggregate piers, capacity, locations, and tip and cutoff elevations on the drawings.

Use "Unit Price" paragraph for unit price bidding of aggregate piers. Specify unit price bid items for aggregate piers only for projects where exact quantities cannot be practically determined prior to the actual work. Lengths of aggregate piers must be determined as accurately as possible, prior to bidding, since the unit price per meter foot of the aggregate piers varies as the length increases or decreases.

******************************************************************************

1.4.1 Aggregate Pier Design Acceptance Criteria

a. The ground improvement Installer is responsible for design of an Aggregate Pier ground improvement system that meets the global stability, allowable bearing capacity, densification, and settlement requirements stated on the contract plans. Industry recognized standards of design methods specific to the installer’s equipment and construction methods must be used. The design must demonstrate by calculation that the spacing and layout fulfills the requirements.

b. The Aggregate Pier design stiffness modulus value must be verified by the results of the modulus test. The Contractor's Geotechnical Consultant must verify the modulus test based on the modulus test results.

c. Design Aggregate Piers in accordance with generally-accepted engineering practice and the methods described in Section 1 of these Specifications. The design must meet the following criteria.

(2) Estimated Total Long-Term Settlement for Footings: Less than or equal to [25] [_____] mm [1.0] [_____] inches.

(3) Estimated Long-Term Differential Settlement of Adjacent Footings: Less than or equal to [13] [_____] mm [0.5] [_____] inches.

(4) Estimated Liquefaction Settlement for Footings: Less than or equal to [38] [_____] mm [1.5] [_____] inch.

(5) The modulus of the aggregate material within the aggregate piers must have a minimum modulus of [27.7x10^6] [_____] N/m^3 [100] [_____] pci.

(6) The minimum SPT blow count in the improved zone in between aggregate piers must be [15] [______].

d. The design submitted by the Installer must consider the bearing capacity and settlement of all footings and other structures supported by aggregate piers, and must be in accordance with acceptable engineering practice and these specifications. Total and differential settlement must be considered. The design life of the structure must be [50] [_____] years.

[1.4.2 Lump Sum Payment

******************************************************************************************************************************************
NOTE: Use this paragraph for lump-sum contracts, consult with Contracting Officer's Technical Representative (Geotechnical Branch) on applicability of use prior to selection. Fill in Table I as required selecting columns applicable to project. Generally, aggregate piers capacity, location, and minimum tip elevation are shown on plans. Test aggregate piers and load tests are not incorporated in lump sum contracts. Delete this paragraph for unit-price contracts.
******************************************************************************************************************************************

Base bids upon providing the number, size, capacity, and length of aggregate piers as indicated on the [drawings.] [following Table I:

<table>
<thead>
<tr>
<th>Location</th>
<th>Number</th>
<th>Size</th>
<th>Capacity</th>
<th>Length (Tip to Cut-Off)</th>
</tr>
</thead>
</table>

Include the cost of all necessary equipment, tools, material, labor, and supervision required to meet the applicable contract requirements. Include mobilization, pre-drilling, and installation. If total number of aggregate piers or number of each length vary from that specified as the basis for bidding, an adjustment in the contract price or time for completion, or both, will be made in accordance with the contract documents. Payment for aggregate piers will be based on successfully installing piers to both the minimum tip elevation and satisfying the acceptance criteria identified...
herein. No additional payment will be made for: rejected, or misplaced piers; withdrawn piers; any portion of a pier remaining above the planned top elevation; or other excesses beyond the assumed aggregate pier length indicated for which the Contractor is responsible.[ Include payments for vibration monitoring, sound monitoring and precondition construction surveys].

][1.4.3 Unit Price

**************************************************************************
NOTE: Delete this paragraph for lump-sum contracts.
**************************************************************************

For unit price bid, see SF 1442, "Solicitation, Offer and Award" and "Schedule of Bid Items."

**************************************************************************
NOTE: For NAVFAC LANT projects, use the following paragraph for measurement and payment and subsequent sub-parts.
**************************************************************************

Requirements of FAR 52.211-18 Variation in Estimated Quantity do not apply to payment for aggregate piers. Each aggregate pier and test aggregate pier acceptably provided will be paid for at the bid unit price per unit length, which will include items incidental to installing the piers including mobilization and demobilization, [jetting] [predrilling] [probing], and cutting off piers at the cut-off elevation. Payment will be made for production aggregate piers [and test aggregate piers] at the bid unit price for the length of piers, from tip to final cut-off, actually provided, excluding buildups directed by the Contracting Officer to be made. If the actual cumulative aggregate pier length installed (tip to cut-off) vary more than 25 percent from the total aggregate pier length specified as a basis for bidding, at the direction of the Contracting Officer, the unit price per unit length will be adjusted in accordance with provisions of FAR 52.236-2 Differing Site Conditions.[ Payments will be made per each at the respective bid unit price for pier cut-offs, pier build-ups and pier load tests.][ Include payments for vibration monitoring, sound monitoring, construction instrumentation and monitoring, and precondition construction surveys.]

][1.5 PAYMENT

1.5.1 Mobilization and Demobilization

1.5.1.1 Payment

Payment will be made for costs associated with mobilization and demobilization as a separate single lump sum item.

1.5.1.2 Measurement

Lump sum.

1.5.1.3 Unit of Measure

Lump sum.
1.5.2 Installing Aggregate Piers

1.5.2.1 Payment

Payment will be made for costs associated with installing aggregate piers, which includes costs of installing aggregate piers and removing excess waste from the work site, compiling and submitting aggregate pier records, and any other items incidental to installing aggregate piers to the required elevation.

1.5.2.2 Measurement

Aggregate piers will be measured for payment for installation on the basis of lengths, to the nearest hundredth of a linear meter tenth of a linear foot, along the axis of each pier acceptably in place below the cut-off elevation shown.

1.5.2.3 Unit of Measure

Linear meter foot.

[1.5.3 Aggregate Pier Modulus Compressive Load Tests

1.5.3.1 Payment

Payment will be made for costs associated with aggregate pier modulus compressive load tests in accordance with ASTM D1143/D1143M and ASTM D1196/D1196M, including material and labor for fabricating and furnishing load frames; calibrating load cells and hydraulic jacks; load test plates; furnishing specified test equipment; installing strain rods; placing and removing test loads and test equipment; recording, reducing, and submitting test data; and compiling and submitting load test reports. No payment will be made for rejected modulus compressive load tests.

1.5.3.2 Measurement

Aggregate pier modulus compressive load tests will be measured for payment on the basis of the applicable contract unit price per load test.

1.5.3.3 Unit of Measure

Each.

][1.5.4 Aggregate Pier Static Tensile Load Tests

1.5.4.1 Payment

Payment will be made for costs associated with aggregate pier static tensile load tests in accordance with ASTM D3689, including material and labor for fabricating and furnishing load frames; calibrating load cells and hydraulic jacks; furnishing specified test equipment; installing strain rods; placing and removing test loads and test equipment; recording, reducing, and submitting test data; and compiling and submitting load test reports. No payment will be made for rejected static tensile load tests.

1.5.4.2 Measurement

Aggregate pier tensile load tests will be measured for payment on the basis of the applicable contract unit price per number of tensile load tests.
1.5.4.3  Unit of Measure
Each.

1.5.5  Vibration Monitoring

1.5.5.1  Payment
Payment will be made for costs associated with vibration monitoring.

1.5.5.2  Measurement
Vibration monitoring will be measured for payment on the basis of the applicable contract unit price per vibration monitoring point.

1.5.5.3  Unit of Measure
Each.

1.5.6  Sound Monitoring

1.5.6.1  Payment
Payment will be made for costs associated with sound monitoring.

1.5.6.2  Measurement
Sound monitoring will be measured for payment on the basis of the applicable contract unit price per vibration monitoring point.

1.5.6.3  Unit of Measure
Each.

1.5.7  Preconstruction Condition Survey

1.5.7.1  Payment
Payment will be made for costs associated with preconstruction condition surveys.

1.5.7.2  Measurement
Preconstruction condition survey will be measured for payment on the basis of the applicable contract unit price per structure to be surveyed.

1.5.7.3  Unit of Measure
Each.

1.5.8  Construction Instrumentation and Monitoring

1.5.8.1  Payment
Payment will be made for costs associated with construction instrumentation and monitoring.
1.5.8.2 Measurement

Construction instrumentation and monitoring will be measured as a single pay item.

1.5.8.3 Unit of Measure

One.

1.6 SUBMITTALS

**************************************************************************
NOTE: Review Submittal Description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy, Air Force, and NASA projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy, Air Force, and NASA projects, or choose the second bracketed item for Army projects.

**************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

1.7 QUALITY CONTROL

1.7.1 Aggregate Pier Installation Equipment

Submit descriptions of proposed aggregate pier installation equipment
before commencing work. Include details of the rig type and size, auger
type, available torque and crowd. Include work procedures and control
criteria. All proprietary tampers must be approved by the Contracting
Officer prior to use.

[1.7.2 Modulus Load Test Apparatus

Submit equipment description lists or catalog cuts and a brief description
of the modulus load test procedure, including maximum load and
modifications in accordance with the procedure required by ASTM D1143/D1143M
and ASTM D1196/D1196M before commencing tests.

]1.7.3 Contractor's Geotechnical Consultant Documentation

Hire the services of an independent, Registered Professional Geotechnical
Engineer, experienced in soil mechanics, to observe test pier installation
and production pier installation as specified herein. The Contractor's
Geotechnical Consultant must be independent of the Contractor and must have
no employee of employer relationship which could constitute a conflict of
interest. The consultant must demonstrate that they have been engaged in
successful inspection of aggregate piers for at least 5 years and inspected similar projects in similar scope utilizing the methods being performed for the subject project.

1.7.4 Design Submittal

The installer must submit three sets of detailed design calculations for aggregate piers [and load transfer platforms] for approval at least four weeks prior to the beginning of construction. A detailed explanation of the design parameters for settlement and bearing calculations must be included in the Design Submittal. Additionally, the quality control test program for aggregate piers, confirming the design requirements, must be submitted. All calculations and drawings must be prepared and sealed by a Professional Engineer in the State in which the project is constructed.

The design must consider the bearing capacity and settlement of all footings supported by aggregate piers, and be in accordance with acceptable engineering practice and these specifications. Total and differential settlement will be considered. The design life of the structure is [50] [_____] years. Detailed calculations, including anticipated loads, design assumptions and relevant subsurface information, must be provided. Drawings prepared for construction use and must include site plans showing Aggregate Pier locations and depths, and footing details showing Aggregate Pier layout beneath footings and uplift anchor connection details when applicable. Minimum Modulus at maximum design stress must be as specified in the final design documents provided by the Aggregate Pier Designer.

1.7.5 Aggregate Pier Installation Work Plans and Construction Drawings

The installer must submit three sets of construction drawings; installation work plan with aggregate pier installation details and testing details; and shop drawings with the location, spacing, numbering, diameter, and depth of the aggregate piers for approval at least 28 calendar days prior to the beginning of construction sealed by the Designer who must be a Professional Engineer in the State in which the project will be constructed.

1.7.6 Concrete Mix Design

**************************************************************************
NOTE: Include this paragraph for cemented aggregate piers.
**************************************************************************

Certify, using a Government-approved independent commercial testing laboratory, that proportioning of mix is in accordance with ACI 211.1 or ACI 318M ACI 318 for specified strength and is based on aggregate data which has been determined by laboratory tests during last twelve months. Submit a complete list of materials including type; brand; source and amount of cement, [fly ash, pozzolan, ground slag, and admixtures;] and applicable reference specifications. Submit additional data regarding concrete aggregate if the source of aggregate changes. Submittal must clearly indicate where each mix design will be used when more than one mix design is submitted.

1.8 QUALIFICATIONS

Installation of aggregate piers must be performed by a specialty Contractor experienced and competent in the installation of aggregate piers as specified herein. Submit evidence that the contractor has worked on
similar type of projects. The projects must demonstrate proficiency of the designer as applicable to the intent of the project. The Designer must be a Professional Engineer registered in the state where the project is located.

Designers and Installers of aggregate pier foundation systems must have a minimum of 5 years of experience with the design and installation of aggregate piers in similar soil conditions and must have completed at least 20 similar projects of comparable size and type in similar soil conditions. These projects must demonstrate proficiency of the designer and the installer with either reinforcement or densification applications as applicable to the intent of the project. A list of projects, including name and description of the project, relative size, and contact person with phone number must be provided.

PART 2 PRODUCTS

2.1 MATERIALS

a. Aggregate used by the aggregate pier Installer must be pre-approved by the Contracting Officer and must demonstrate suitable performance during modulus testing. Gradation curves and physical property tests results must be submitted 28 calendar days prior to scheduled start.

Aggregate stone consisting of [Type I Grade B in accordance with ASTM D1241,] [ASTM C33/C33M No. 57 stone,] [or other graded aggregate] approved by the Contracting Officer. For piers constructed below the water table, particles passing the No. 40 sieve must be eliminated. Where material is deemed appropriate for a dynamic penetration test (ASTM STP 399), aggregate must be compacted to a densification and strength, which provides resistance to the dynamic penetration test of a minimum average of 15 blows per 45 mm 2 inches vertical movement. Test aggregate gradation in accordance with ASTM D6913/D6913M.

The Installer must provide the soil laboratory test data on the proposed aggregate material including the source, type, and gradation of the aggregate to be used. Submit aggregate material data at least 30 calendar days before installation. Provide letters of certification and material delivery tickets from the aggregate supplier.

b. Materials selected must remain stable during construction and working life in the anticipated soil and ground water conditions.

c. Potable water or other suitable source supply must be used to increase aggregate moisture content where required. Access to water on site must be provided to the Installer by the General Contractor.

d. General Contractor to coordinate adequate and suitable marshalling areas on the project site for the storage of aggregate and equipment.

[ e. Provide concrete as specified in [_____] except as specified otherwise herein, for minimum 28-day concrete compressive strength of [_____] MPa pounds per square inch, using 19 mm 3/4 inch maximum coarse aggregate. Concrete for base [and for uncased shaft] must have minimum 3-day compressive strength of [_____] MPa pounds per square inch. [ Cased shaft must have minimum 3-day compressive strength of [_____] MPa pounds per square inch.]

] [f. Provide uplift anchor hardware as specified in [the aggregate pier

SECTION 31 62 50 Page 17
design][____ ]. Provide drawings, diagrams, and schedules which detail hardware integration and installation. Letters of certification and material delivery tickets from the hardware suppliers must be submitted 28 calendar days prior to the scheduled start of the uplift test to verify that the materials are of the appropriate size, grade, and strength.

PART 3 EXECUTION

3.1 CONSTRUCTION

3.1.1 Aggregate Pier Construction

Aggregate piers must be constructed in accordance with generally-accepted construction and engineering practices and the methods described in Section 1 of these Specifications. If pre-drill holes do not remain open before or during aggregate pier construction, bottom feed down-hole equipment must be used. Aggregate piers must be installed after fill is placed to raise grades if the aggregate piers are not designed to support new grading fill. The construction of the aggregate piers must not start until the project Geotechnical Engineer has determined that any ground settlement associated with placement of the new fill has ceased.

**************************************************************************
NOTE: Performance requirements may include criteria for structural, thermal, acoustical, or other properties. Tolerances should be stated here only as they apply to the performance of the complete system. Tolerances of fabrication and installation should be included in their respective paragraphs under Part 2.
**************************************************************************

a. Section 03 30 00 CAST-IN-PLACE CONCRETE.

b. Section 31 23 00.00 20 EXCAVATIONS AND FILL.

c. Geotechnical Report and Recommendations.

3.1.2 Plan Location and Elevation of Aggregate Pier Elements

The location of each pier must be determined by the Designer to provide compliance with the design requirements of paragraph AGGREGATE PIER DESIGN ACCEPTANCE CRITERIA. The final measurement of the top of piers must be the lowest point on the aggregate in the last compacted lift. Piers not properly located and deemed not acceptable must be rebuilt at no additional expense to the Owner. The allowable construction tolerance must be within [152] [____] mm [6] [____] inches both for horizontal and vertical design locations.

3.1.3 Rejected Aggregate Pier Elements

Aggregate pier elements improperly located or installed beyond the allowable tolerance must be abandoned and replaced with new piers, unless the Designer approves other remedial measures. Aggregate must be replaced with fresh aggregate if cave-ins occur during aggregate placement where the volume of caved-in soil exceeds the volume of the aggregate being compacted by more than 10 percent. All material and labor required to replace rejected piers must be provided at no additional cost to the Owner, unless
the cause of the rejection is due to an obstruction that is not pre-identified or mislocated by the Contracting Officer.[ Obstructions include boulders, timbers, concrete, bricks, abandoned utilities.]

Aggregate piers must be monitored for heave immediately after installation and after adjacent aggregate piers are installed. If piers heave more than 13 mm 1/2 inch notify the Contracting Officer.

3.1.4 As-Driven Survey

After the installation of each aggregate pier group is complete provide the Contracting Officer with an as-built survey showing actual location and top elevation of each aggregate pier.[ Do not proceed with placing concrete until the Contracting Officer has reviewed the survey and verified the safe load for the pier group installed.] Present a survey in such form that it gives deviation from plan location in two perpendicular directions and elevations of each aggregate pier to nearest 13 mm half inch. Survey must be prepared and certified by a licensed land surveyor.

3.1.5 Protection of Existing Structures

**************************************************************************
NOTE: Include this paragraph only when protection of existing structures from aggregate pier installation is required.

The designer must indicate on the drawings all structures and facilities for which protection is required. The designer must also provide a project specific document that details design criteria, requirements for preconstruction condition surveys, post construction condition surveys, geotechnical instrumentation to measure ground movements and any other requirements.

Add any additional requirements as necessary.
**************************************************************************

Mitigate impact on existing facilities due to aggregate pier installation activities in accordance with the [project specific document] [_____].

3.1.6 Excavation Adjacent to Piers

Impacts to installed aggregate pier must be minimized. Submit a complete design and evaluation by the Aggregate Pier Designer in the event that utility excavations are required at horizontal distances of less than five [_____] feet from installed pier locations. Provide a drawing by the aggregate pier design which illustrates distances that must be maintained between aggregate piers and adjacent excavations.

3.2 Field Quality Control

3.2.1 Quality Control Representative

The Contractor's Geotechnical Consultant must verify and report all aggregate pier installation procedures. Immediately report any unusual conditions encountered during installation to the Contracting Officer. The QC procedures must include the preparation of Aggregate Pier Progress Reports completed during each day of installation and containing the following minimum information:
a. Footing and Aggregate Pier location.
b. Aggregate Pier length and installed diameter.
c. Planned and actual Aggregate Pier elevations at the top and bottom of the element.
d. Average lift thickness for each Aggregate Pier.
e. Soil types encountered at the bottom of the Aggregate Pier and along the length of the element, if the holes were pre-drilled.
f. Depth to groundwater, if encountered.
g. Documentation of any unusual conditions encountered.
h. Type and size of densification equipment used.
i. Quality of aggregate in each individual pier.
j. Any additional quality control testing performed, such as modulus tests, dynamic penetrometer tests, and standard penetration tests, as deemed appropriate by the Contracting Officer.

3.2.2 Quality Control Verification Program

 **************************************************************************
NOTE: Edit this paragraph for project specific field verification testing and geotechnical instrumentation requirements. The minimum instrumentation requirements must be specified by the Owner and be provided in separate contract documents. The contractor should retain a testing agency (Contractor's Geotechnical Consultant) to perform quality control observations and testing. Typically a modulus test is specified if aggregate piers are installed for soil reinforcement (generally in cohesive soils), while in-situ testing such as Standard Penetration Testing is specified if aggregate piers are installed for soil densification (generally in cohesionless soils).
 **************************************************************************

The Installer must be responsible for design of a verification program to assure the quality of the construction. The program must verify that the installed ground improvement system satisfies the performance requirements noted on the contract plans and the design requirements determined by the ground improvement system designer. The quality control program must include testing and observations by the Contractor’s Geotechnical Consultant. As a minimum, the verification program must include the following:

a. Program to monitor performance of the ground improvement system during and after construction of the proposed structure. This program may include installation of settlement plates, monitoring points, inclinometers, piezometers, or other instrumentation.

b. Proposed means and methods for verification that the installed
aggregate piers meet the strength and stiffness criteria required by the design. This may include, but must not be limited to modulus or load tests on individual elements and groups, soil borings, standard penetration testing (SPT), and other methods such as monitoring by instrumentation or settlement plates as approved by the Designer. Submit load test set-up and procedures utilized to confirm that the installation procedure develops the pier modulus utilized in design. Submit load test supporting data.

c. Quality control program to verify that the ground improvement system is installed in accordance with the designer's specifications and the requirements in this specification. The quality control program must include testing and observations by Contractor's Geotechnical Consultant.

3.2.3 Bottom Stabilization Verification Test

After completion of the bottom pier bulb, or at any time during the process of construction of the pier, the energy source may be turned off, and bottom stabilization verification test may be performed. These tests must be performed when a new soil formation is encountered, or at the beginning of a project to provide quantitative information on pier stabilization. Acceptable performance is indicated if the vertical movement of the shaft is less than 150 percent of the vertical movement measured for the modulus test pier.

**************************************************************************
NOTE: A modulus compressive load test is appropriate if aggregate piers are installed for soil reinforcement (generally in cohesive soils).
**************************************************************************

3.2.4 Modulus Testing of Aggregate Piers and Test Aggregate Pier Records

A modulus test must be performed by the Installer to obtain the parameter values used in design. The number of tests and locations must be determined by the Contracting Officer. The Installer must provide and install all dial indicators and other measuring devices, conduct tests, and prepare the test reports. The tests must be performed generally in accordance with ASTM D1143/D1143M and ASTM D1196/D1196M. The aggregate piers must be tested to satisfy bearing capacity at 150 percent of the design stress and to satisfy the settlement criteria in paragraph AGGREGATE PIER DESIGN ACCEPTANCE CRITERIA at 100 percent of the design stress. The Installer must submit four copies of test reports for each test no later than seven days after the test is completed. Report must include a description of the testing equipment, records, complete test data, analysis of the test data and recommended design parameter values based on the modulus test results. The report must be prepared under supervision of and sealed by a professional engineer registered in the state of project location.

3.2.5 Standard Penetration Testing (SPT)

**************************************************************************
NOTE: Standard Penetration Testing on soils between aggregate pier locations is appropriate if aggregate piers are installed for densification of soils between piers.
**************************************************************************

a. The SPT must be performed by the Installer to verify if the ground
modification criteria as measured by the SPT blow counts as specified in the Aggregate Pier Design Acceptance Criteria is met. The SPTs must be performed at midpoint locations between the aggregate piers.

b. The SPTs must be performed in accordance with ASTM D1586/D1586M.

c. The SPTs must be performed at 0.76 m 2.5 ft intervals through the entire depth of the improved soil zone.

Submit test results.

3.2.6 Dynamic Cone Penetrometer Testing of Aggregate Piers

**************************************************************************
NOTE: Dynamic Cone Penetrometer Test must only be performed on dense graded aggregate material and not on ASTM C33 No. 57 open graded aggregate.
**************************************************************************

a. The Aggregate Pier element must be tested by the Dynamic Cone Penetrometer method (ASTM STP 399) at locations within the upper one third of the pier shaft length.

b. The minimum acceptable criteria as an indicator of acceptable densification must be at least 15 blows per 50 mm 2 inches penetration.

c. Perform dynamic Cone Penetrometer in each Aggregate Pier until such time as five consecutive tests indicate that the minimum criterion is met. Thereafter, such tests need not to be performed on every pier, provided that aggregate used in the element is representative of that previously tested. If average penetration resistances measured exceed 15 blows, and less than 10 percent of tests fall below 15 blows, the testing may be reduced to spot checks. A pattern of successful tests is sufficient to reduce testing to several tests per day.

d. Observation of questionable aggregate moisture content or questionable aggregate gradation appearance may determine the need for additional dynamic penetration testing to verify that the proper densification is being achieved.

e. Use of Dynamic Cone Penetrometer is not appropriate for use on open graded aggregate such as No. 57 stone.

3.2.7 Testing Agency Qualifications

Engage an independent testing agency qualified according to ASTM C1077 and ASTM E329 for testing indicated. Submit testing agency qualifications to the Contracting Officer for approval.

3.2.8 Responsibilities of Contractor's Geotechnical Consultant

a. Review and verify that design meets the project requirements.

b. Report any discrepancies immediately.

c. Monitor the modulus compressive load tests when performed.

d. Monitor the installation of aggregate pier elements to verify that the production installation practices are similar to those used during the
installation of the modulus compressive load test elements.

[ e. Perform Dynamic Cone Penetrometer tests as described herein.

]3.2.9 Aggregate Pier Records

**************************************************************************
**NOTE: Omit reference to load test when not required in project. Where special or unusual soil conditions are expected, consultation with the Contracting Officer's Technical Representative (Geotechnical Branch) regarding special engineering supervision of installation, testing, recording and analysis of data for project may be useful.**
**************************************************************************

Keep a complete and accurate record of each aggregate pier installed. Indicate the pier location, deviations from pier location, cross section shape and dimensions, original length, ground elevation, tip elevation, cut-off elevations, volume of aggregate used or number of lifts, densification forces during installation, and final elevations or depths of the base and top of piers. The records must also indicate the type and size of the installation equipment used, and the type of aggregate used and testing and material sampling that was performed. Provide a complete and accurate progress drawing of aggregate pier installation. Provide final drawing upon completion of installation activities.

Submit test aggregate pier records. [Submit load test data and results.]

The Installer must furnish a complete and accurate record of Aggregate Pier installation to the Government and the General Contractor. The record must indicate the pier location, length, average lift thickness and final elevations of the bases and tops of piers. The installation reports must also indicate the type and size of the densification equipment used. The installer must immediately report any unusual conditions encountered during installation to the General Contractor, to the Designer and to the Government. Submit Daily Progress and Final Reports Aggregate Pier Progress and Final Reports. Provide a Final Report documenting the results of all observations and tests conducted during the complete installation process. Report will certify that the bearing pressure has been achieved within settlement tolerances.

Provide warranty document good for [1][_____] year.

3.3 RESPONSIBILITIES OF GENERAL CONTRACTOR

3.3.1 Preparation

a. Locate the underground utilities. The Installer must protect underground and aboveground utilities and other structures from damage during installation of the Aggregate Pier elements.

b. Provide the site to the Installer after earthwork in the area has been completed, if applicable.

c. Site subgrade must be established by the General Contractor within 150 mm 6 inches of final design subgrade, as approved by the Contracting Officer.
d. Perform layout of the aggregate piers and provide a work platform if necessary.

3.3.2 Utility Excavations and Excavation to Adjacent Piers

The General Contractor must coordinate all excavations made subsequent to aggregate pier installations so that at least 1.5 m (5 feet) of horizontal distance remains between the edge of any installed Aggregate Pier and the excavation[ and that the piers are outside the zone of influence of the excavation]. In the event that utility excavations are required at horizontal distances of less than 1.5 m (5 feet) from installed aggregate piers or the piers are within the zone of influence of the excavation, the General Contractor must notify the Aggregate Pier Designer to develop construction solutions to minimize impacts on the installed aggregate piers.

3.3.3 Footing Bottoms

a. Excavation and surface compaction of all footings is the responsibility of the General Contractor.

b. Foundation excavations to expose the tops of Aggregate Pier elements must be made in a workman like manner, and must be protected until concrete placement, with procedures and equipment best suited to (1) prevent softening of the matrix soil between and around the Aggregate Pier elements before pouring structural concrete, (2) achieve direct and firm contact between the dense, undisturbed Aggregate Pier elements and the concrete footing. Disturbed soil and aggregate must be recompacted per paragraph FOOTING BOTTOMS, list item c.(3) (below).

c. The following criteria must apply, and a written inspection report sealed by the Contractor's Geotechnical Consultant Agency must be furnished to the installer to confirm:

(1) That water (which may soften the unconfined matrix soil between and around the Aggregate Pier elements, and may have detrimental effects on the supporting capability of the aggregate pier reinforced subgrade) has not been allowed to pond in the footing excavation at any time.

(2) That all aggregate pier elements designed for each footing have been exposed in the footing excavation.

(3) That immediately before footing construction, the tops of all aggregate pier elements exposed in each footing excavation have been inspected and recompacted as necessary with mechanical compaction equipment, and that the tops of any aggregate pier elements which may have been disturbed by footing excavation and related activity have been recompacted to a dry density equivalent to at least 95 percent of the maximum dry density obtainable by the [Standard] [Modified] Proctor method [ASTM D698] [ASTM D1557] unless approved otherwise by the Contracting Officer.

(4) No excavations or drilled shafts must be made after installation of aggregate pier elements within a horizontal distance of five feet from the edge of any pier, without the written approval of the Contracting Officer.
### 3.4 SPECIAL Inspection AND TESTING FOR SEISMIC-RESISTING SYSTEMS

NOTE: Include this paragraph only when special inspection and testing for seismic-resisting systems is required by the International Building Code (IBC).

This paragraph will be applicable to both new buildings designed and to existing building seismic rehabilitation designs done according to UFC 1-200-01, "General Building Requirements" and UFC 3-310-04, "Seismic Design for Buildings".

The designer must indicate on the drawings all locations and all features for which special inspection and testing is required in accordance with Chapter 17 of the IBC. This includes indicating the locations of all structural components and connections requiring inspection.

Add any additional requirements as necessary.

Perform special inspections and testing for seismic-resisting systems and components in accordance with Section 01 45 35 SPECIAL INSPECTIONS.

### 3.5 VIBRATION CONTROL

NOTE: Include this paragraph when vibration monitoring is required. Add any additional criteria or requirements as necessary to the particular project.

Perform vibration monitoring at the locations [shown in the plan] decided by the Contracting Officer during the aggregate pier installation. Perform vibration monitoring [using] [seismographs] [and geophones] within a distance of 61 meters 200 feet from the aggregate pier installation. Engage the services of a qualified, independent vibration consultant, acceptable to the Government, to conduct the vibration monitoring. The vibration consultant must have minimum of [five] _____ years of experience in vibration monitoring. A minimum of [28] _____ days before the installation of vibration monitors, submit to the Government the name of the vibration consultant and a list of at least [three] _____ previously completed projects of similar scope and purpose.

Prior to the aggregate pier installation, obtain baseline readings of ambient vibrations. The vibration during the aggregate pier installation must be limited to [a peak particle velocity of not more than 5 cm 2 inches per second.] [the limits mentioned in the [contract documents] [_____].]. Determine appropriate vibration limits as per [US Bureau of Mines] [American Association of State Highway and Transportation Officials (AASHTO)] guidelines. During aggregate pier installation, monitor the vibrations to ensure the limits are not exceeded. If the limits are exceeded, cease the aggregate pier installation causing the vibration until [the Vibration consultant and the Contracting Officer] [_____] are on site to observe the structures nearest to the vibration monitor which has exceeded the limits.
The Contractor must be responsible for all damages resulting from the aggregate pier installation and must take whatever measures necessary to maintain peak particle velocity within the specified limit. After completion of the project, remove the vibration monitors off the site and off Government property and restore the monitoring locations back to their original condition.

][3.6 NOISE CONTROL

******************************************************************************

NOTE: Include this paragraph when noise monitoring is required. Add any additional criteria, references or requirements as necessary to the particular project.

******************************************************************************

Perform noise monitoring at the locations [shown in the plan] [decided by the Contracting Officer] [at noise sensitive public areas] during the aggregate pier installation.[ Perform noise monitoring using [noise meters], and] [____].[ Engage the services of a qualified, independent noise consultant, acceptable to the Government, to conduct the noise monitoring. The noise consultant must have minimum of [five] [____] years of experience in noise monitoring. A minimum of [28] [____] days before the installation of noise monitors, submit to the Government the name of the noise consultant and a list of at least [three] [____] previously completed projects of similar scope and purpose.]

Prior to the aggregate pier installation, obtain baseline readings of ambient noise levels.[ The noise limits are mentioned in the [plan] [contract documents].][ Determine appropriate noise limits as per [local agency] [Occupation Safety and Health Administration] guidelines.] During aggregate pier installation, monitor the noise to ensure the limits are not exceeded. If the limits are exceeded, cease the aggregate pier installation and install noise mitigation measures.

The Contractor must be responsible for all damages resulting from the aggregate pier installation and must take whatever measures necessary to maintain noise within the specified limit. After completion of the project, remove the noise monitors off the site and off Government property and restore the monitoring locations back to their original condition.

][3.7 PRECONSTRUCTION CONDITION SURVEY

******************************************************************************

NOTE: Add any additional criteria, references or requirements as necessary to the particular project.

******************************************************************************

Perform preconstruction condition survey of [structures] [and utilities] [within 61 meters 200 feet of the aggregate pier installation] [specified in the plans] [decided by the Contracting Officer]. Perform outreach to the owner of the structures [28] [____] days before performing the preconstruction condition survey. The Contractor must obtain written permission from the owner of the structure prior to accessing the structure. The preconstruction condition survey must include video and photographic documentation of the exterior and interior of above ground structures and of the interior of underground structures. Video documentation must be in high definition, and show existing conditions and
highlight, where possible, existing cracks, deteriorated concrete, exposed and corroded reinforcement, cracked or broken brick or mortar, and other signs of distress. For utilities, perform the survey when the greatest extent of the interior is exposed. Provide supplementary artificial lighting as needed. The video must include annotation with location and structure nomenclature which describes any areas of distress over the video and time code superimposed on the video. Photographs must be accompanied by sketches or descriptions that indicate the location and direction of each photograph. For each structure surveyed, provide a Pre-Construction Condition Survey Report following completion of the survey. The report must contain all documentation associated with the survey including DVD copies. In the report, include notes, sketches, photographs, and videos. Provide general information, such as location details and structure type, as well as particular information on materials, condition, existing damage, aperture and persistence of cracks, and disrepair observed during visual survey. Provide a graphical depiction of locations of damage or other features of concern. Submit the Preconstruction Condition Survey Reports no later than [28] [_____] days before the commencement of aggregate pier installation. Accept responsibility for damages to existing adjacent or adjoining structures created by aggregate pier installation, and repair any damages to these structures without cost to the Government.

3.8 CONSTRUCTION INSTRUMENTATION AND MONITORING PROGRAM

**************************************************************************
NOTE: Include this section if instrumentation is to be installed due to concerns about vibration, settlement, lateral movement, etc. during aggregate pier installation. Instrumentation should be specified and included in the specification. This section can be deleted if there are no instrumentation requirements.

Add any additional criteria or requirements as necessary for the particular project.
**************************************************************************

Prepare a geotechnical instrumentation program to monitor settlement and lateral movement of temporary and permanent structures, utilities, embankments and excavations during aggregate pier installation. The design and distribution of instrumentation must demonstrate an understanding of the need, purpose and application of each proposed type. Perform noise and vibration monitoring in accordance with NOISE CONTROL and VIBRATION CONTROL sections.

Monitoring must extend before, during and for a period after completion of construction activities related to aggregate pier installation when long-term performance issues are a concern. The monitoring plan must be designed to protect adjacent structures and utilities against damage due to the aggregate pier installation. Establish limiting values of vertical and horizontal movement and angular distortion and vibration for each structure and utility within the zone of influence, subject to review by the Government.

Prepare a report detailing the proposed program of instrumentation and monitoring, establishing threshold values of monitored parameters, and describing the response plans that will be implemented when threshold parameters are exceeded. The report must include details about instrumentation consultant's experience, appropriate types, quantities,
locations and monitoring frequencies of the instruments.

Upon acceptance of the instrumentation and monitoring program, provide, install and monitor the instrumentation and interpret the data. Submit instrumentation data reports not less than every [_____] days after the monitoring program has begun. Take corrective actions, as necessary, based on the field instrumentation data and as defined in the instrumentation and monitoring program.

NOTE: This guide specification covers the requirements for augered cast-in-place grout piles.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

NOTE: This guide specification covers the requirements for augered cast-in-place piles.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).
submitted as a Criteria Change Request (CCR).

NOTE: The extent and location of the work to be accomplished should be indicated on the project drawings or included in the project specification.

NOTE: Show the following information on the drawings:

1. Locations and design loads of piles. If both tension and compression piles are contained in design, identify by type.
2. Size, shape, and length of piles.
3. Details of reinforcement.
4. Locations of test piles, if required.
5. Soil data, where required.
6. Identify piles as vertical or battered

PART 1 GENERAL

NOTE: Special care should be taken when installing augered cast in-place piles in low strength soils such as peat where "necking" of piles can occur, or in soils containing layers or fields of boulders or cobbles, where there may be difficulties extending piles through the materials, or in methane gas producing soils, where gas bubbles and subsequently voids can develop in the piles.

On the drawings, show:

1. Subsurface-soil-data logs
2. Locations and size (diameter) of piles.
3. Design tip elevation for each pile indicated.
4. Reinforcing steel details.
5. Locations of test piles if required.
6. Locations of soil probes if required.
NOTE: Structural engineer must confirm the structural capacity of piles and provide specific bending moments, lateral loads and other design requirements for pile design.

1.1 DESCRIPTION

Design, furnish, install and test augered cast in place piles at the locations indicated on the drawings and specified herein. [Test piles that meet performance requirements can be incorporated into the permanent work.][Assume test pile[s] will be directed to be placed in [a] location[s] that can be incorporated into the work.]

1.2 REFERENCES

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

Subsurface soil data logs are [indicated] [appended to the special contract requirements] [provided on the project drawings]. [The subsoil investigation report may be examined at [_____].]

[1.4] SYSTEM DESCRIPTION

**************************************************************************
**************************************************************************

Submit detail drawings to demonstrate compliance of augering, mixing, and pumping equipment, installation, and installed piles with contract
documents. Include with the drawings erection details and reinforcement as specified. Augered cast-in-place piles are formed by the rotation of a continuous flight hollow-shaft auger into the ground to the tip elevation established by the requirements specified elsewhere in this section. Grout is then injected through the auger shaft as the auger is being withdrawn in such a way as to exert removing pressure on the withdrawing earth-filled auger as well as lateral pressure on the soil surrounding the grout-filled pile hole. Submit evidence to the Contracting Officer that the Contractor has been engaged in the successful installation of auger cast grout piles for at least 5 years.

1.4.1 Equipment

The minimum inside diameter of the hollow shaft of the augerflight must be 31.8 mm 1-1/4 inches. Provide grout injection equipment with a grout pressure gauge in clear view of the equipment operator. Rate of grout injection and rate of auger withdrawal from the soil must be so coordinated as to maintain at all times a positive pressure on this gauge which will, in turn, indicate the existence of a "removing pressure" on the bottom of the augerflight. Magnitude of this pressure and performance of other augering and grouting procedures, such as rate of augering, rate of grout injection, and control of grout return around the augerflight, are dependent on soil conditions and equipment capability and must be at the option of the Contractor, subject to review by the Contracting Officer. The auger hoisting equipment must be capable of withdrawing the auger smoothly and at a constant rate.

1.4.2 Grout Pump

Provide a positive displacement grout pump of an approved design capable of providing a positive displacement pressure not less than 2.4 MPa 350 psi. The pump discharge capacity must be calibrated at the beginning of the work to determine the volume of grout pumped per stroke in strokes per cubic meter foot or revolutions per cubic meter foot by a method approved by the Contracting Officer. The pump must be periodically recalibrated when deemed necessary by the Contracting Officer or the Contractor's Geotechnical Engineer during the project. Remove oil or other rust inhibitors from mixing drums and pressure grout pumps prior to mixing and pumping.

1.5 BASIS OF BID

**************************************************************************
NOTE: Select one of the following options:
**************************************************************************
**************************************************************************
NOTE: NOTE: Use "Lump Sum" paragraph below for lump (principal) sum bidding of piles. Use this in all projects except those where exact pile lengths cannot be practically determined prior to the actual work. Clearly show number of piles, pile capacity, pile locations, and tip and cutoff elevations on the drawings.

Use "Unit Price" paragraph for unit price bidding of piles. Specify unit price bid items for piles only for projects where exact quantities cannot be practically determined prior to the actual work.
Lengths of piles must be determined as accurately as possible, prior to bidding, since the unit price per meter (foot) of the piles varies as the length increases or decreases. Refer to Standard Test Method for Low Strain Impact Integrity Testing of Deep Foundations (ASTM D5882).

1.5.1 Production Pile Acceptance Criteria

Safe design capacity for piles is [____] KN kips. Install piles to [minimum tip elevation] [a minimum depth of [____] m feet below cut-off elevation], and to such additional depth as required to obtain a bearing capacity of not less than [____] KN kips. The Contractor's Geotechnical Consultant will determine the terminal installation criteria based on results of the static load tests [non-destructive testing results].

1.5.2 Lump Sum Payment

Base bids upon providing the number, size, capacity, and length of piles as indicated on the [drawings.] [following Table I:

<table>
<thead>
<tr>
<th>Location</th>
<th>Number</th>
<th>Size</th>
<th>Capacity</th>
<th>Length (Tip to Cut-Off)</th>
<th>Maximum Bending Moment</th>
<th>Maximum Shear Force</th>
</tr>
</thead>
</table>

Include the cost of all necessary equipment, tools, material, labor, and supervision required to: install, cut-off, dispose of any spoils, and meet the applicable contract requirements. Include mobilization, and redrilling damaged and heaved piles. If, in redrilling, it is found that any pile is not of sufficient length to provide the capacity specified, notify the Contracting Officer, who reserves the right to increase or decrease the total length of piles to be installed by changing the pile locations or elevations, requiring the installation of additional piles, or directing the omission of piles from the requirements shown and specified. If total number of piles or number of each length vary from that specified as the basis for bidding, an adjustment in the contract price or time for completion, or both, will be made in accordance with the contract documents. Payment for piles will be based on successfully installing piles to both the minimum tip elevation and satisfying the acceptance criteria identified herein. No additional payment will be made for: damaged, rejected, or misplaced piles; redrilled piles; any portion of a pile remaining above the cut-off elevation; build-ups; any cut-off length of piles; or other excesses beyond the assumed pile length indicated for which the Contractor is responsible. [Include payments for vibration monitoring, sound monitoring and precondition construction surveys].

1.5.3 Unit Price

NOTE: Delete this paragraph for lump-sum contracts.

For NAVFAC PAC projects: Where there is unit pricing for piles, use this paragraph and edit applicable attachments in price schedule for inclusion in Standard Form 1442, "Solicitation,
For NAVFAC Southeast projects, where there is a need for unit pricing of piles, include this paragraph. Refer to NAVFAC SE Instruction 00010, "Instructions for Preparing Basis of Bid Statement With Unit-Priced Items," for method of specifying unit price bid items.

For unit price bid, see SF 1442, "Solicitation, Offer and Award" and "Schedule of Bid Items."

Requirements of "FAR 52.211-18, Variation in Estimated Quantity" do not apply to payment for piling. Each pile and test pile acceptably provided will be paid for at the bid unit price per unit length, which will include items incidental to furnishing and installing the piles including mobilization and demobilization, [jetting] [predrilling] [probing], redrilling uplifted piles, [and cutting off piles at the cut-off elevation] and reinforcing steel. [Include the cost for additional length for the test piles in the total unit price cost for the job.] Payment will be made for production [and test piles] at the bid unit price for the length of pile, from tip to final cut-off, actually provided, excluding buildups directed by the Contracting Officer to be made. If the actual cumulative pile length installed (tip to cut-off) varies more than 25 percent from the total pile length specified as a basis for bidding, at the direction of the Contracting Officer, the unit price per unit length will be adjusted in accordance with provisions of "FAR 52.236-2, Differing Site Conditions." [Payments will be made per each at the respective bid unit price for pile cut-offs, pile build-ups and pile loads tests.] [Include payments for vibration monitoring, sound monitoring, construction instrumentation and monitoring, and precondition construction surveys].

1.6.1 Augered Cast in Place Piles Installation

1.6.1.1 Payment

Payment will be made for costs associated with installation of the required lengths of permanent augered cast in place piles, [including reinforcing steel,] [performing static load test, interpreting data and submitting
UFGS reports, compiling and submitting pile installation records, backfilling voids around piles, and any other items incidental to installing piles to the required elevation. No payment will be made for installing piles exceeding required lengths. No payment will be made for piles damaged during installation to the extent that they are rendered unsuitable for the work, in the opinion of the Contracting Officer.

1.6.1.2 Measurement

Permanent augered cast in place piles will be measured for payment for installation on the basis of lengths, to the nearest hundredth tenth of a linear meter foot, along the axis of each pile acceptably in place below the cut-off elevation shown as determined by the Contracting Officer.

1.6.1.3 Unit of Measure

Linear meter foot.

[1.6.2 Augered Cast-in-Place Test Piles

1.6.2.1 Payment

Payment will be made for costs associated with installation of augered cast-in-place test piles, backfilling voids around piles; compiling pile installation test records; performing dynamic testing; interpreting data; and submitting reports.

1.6.2.2 Measurement

Augered cast-in-place pile installation tests will be measured for payment on the basis of the applicable contract unit price per pile installation test.

1.6.2.3 Unit of Measure

Each.

[1.6.3 Augered Cast-in-Place Piles for Load Tests

1.6.3.1 Payment

Payment will be made for costs associated with installing, abandoning of load test piles [including structural steel]; backfilling voids around piles; compiling pile installation records; furnishing, fabricating, and mounting of strain rods and protective assembly; furnishing, fabricating, and mounting of inclinometer and inclinometer protective assembly; performing non-destructive testing; interpreting data; and submitting reports]. No additional payment will be made for load test piles incorporated in the permanent work other than as provided.

1.6.3.2 Measurement

Augered cast in place piles for load tests will be measured for payment on the basis of the applicable contract unit price per load test pile.

1.6.3.3 Unit of Measure

Each.
1.6.4 Augered Cast-in-Place Pile Static Axial Compressive Load Tests

1.6.4.1 Payment

Payment will be made for costs associated with augered cast in place pile static axial compressive load tests in accordance with ASTM D1143/D1143M, including material and labor for fabricating and furnishing load frames; calibrating load cells and hydraulic jacks; furnishing specified test equipment; installing strain rods; placing and removing test loads and test equipment; recording, reducing, and submitting test data; and compiling and submitting pile load test reports. No payment will be made for rejected pile static axial compressive load tests.

1.6.4.2 Measurement

Augered cast in place pile static axial compressive load tests will be measured for payment on the basis of the applicable contract unit price per load test.

1.6.4.3 Unit of Measure

Each.

1.6.5 Augered Cast-in-Place Pile Static Tensile Load Tests

1.6.5.1 Payment

Payment will be made for costs associated with augered cast-in-place pile static tensile load tests in accordance with ASTM D3689, including material and labor for fabricating and furnishing load frames; calibrating load cells and hydraulic jacks; furnishing specified test equipment; installing strain rods; placing and removing test loads and test equipment; recording, reducing, and submitting test data; and compiling and submitting pile load test reports. No payment will be made for rejected pile static tensile load tests.

1.6.5.2 Measurement

Augered cast in place pile tensile load tests will be measured for payment on the basis of the applicable contract unit price per number of tensile load test.

1.6.5.3 Unit of Measure

Each.

1.6.6 Augered Cast-in-Place Pile Lateral Load Tests

1.6.6.1 Payment

Payment will be made for costs associated with augered cast-in-place pile lateral load tests in accordance with ASTM D3966/D3966M, including material and labor for fabricating and furnishing load frames; calibrating load cells and hydraulic jacks; furnishing specified test equipment; installing inclinometers; placing and removing test loads and test equipment; recording, reducing, and submitting test data; and compiling and submitting pile load test reports. No payment will be made for rejected pile lateral load tests.
1.6.6.2 Measurement

Augered cast in place pile lateral load tests will be measured for payment on the basis of the applicable contract unit price per lateral load test.

1.6.6.3 Unit of Measure

Each.

1.6.7 Low Integrity Impact Test

1.6.7.1 Payment

Payment will be made for costs associated with Low Integrity Impact Testing.

1.6.7.2 Measurement

Low Integrity Impact Test will be measured for payment on the basis of the applicable contract unit price per test cost.

1.6.7.3 Unit of Measure

Each.

1.6.8 Sonic Logging

1.6.8.1 Payment

Payment will be made for costs associated with Sonic Logging Testing.

1.6.8.2 Measurement

Sonic Logging testing will be measured for payment on the basis of the applicable contract unit price per test cost.

1.6.8.3 Unit of Measure

Each.

1.6.9 Vibration Monitoring

1.6.9.1 Payment

Payment will be made for costs associated with vibration monitoring.

1.6.9.2 Measurement

Vibration monitoring will be measured for payment on the basis of the applicable contract unit price per vibration monitoring point.

1.6.9.3 Unit of Measure

Each.

1.6.10 Sound Monitoring

1.6.10.1 Payment

Payment will be made for costs associated with sound monitoring.
1.6.10.2 Measurement

Sound monitoring will be measured for payment on the basis of the applicable contract unit price per sound monitoring point.

1.6.10.3 Unit of Measure

Each.

1.6.11 Preconstruction Condition Survey

1.6.11.1 Payment

Payment will be made for costs associated with preconstruction condition surveys.

1.6.11.2 Measurement

Preconstruction condition survey will be measured for payment on the basis of the applicable contract unit price per structure to be surveyed.

1.6.11.3 Unit of Measure

Each.

1.6.12 Construction Instrumentation and Monitoring

1.6.12.1 Payment

Payment will be made for costs associated with construction instrumentation and monitoring.

1.6.12.2 Measurement

Construction instrumentation and monitoring will be measured as a single pay item.

1.6.12.3 Unit of Measure

One.

1.7 SUBMITTALS

**************************************************************************

NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets
following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy, Air Force, and NASA projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy, Air Force and NASA projects, or choose the second bracketed item for Army projects.

Under SD-07, from 3 to 5 years experience in installation of auger cast grout piles should be required.

**************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-01 Preconstruction Submittals

Installation Procedures; G[, [______]]

Contractor's Geotechnical Consultant Documentation; G[, [______]]

Load Tests Procedures; G[, [______]]

Grout Mix Design; G[, [______]]

Field Quality Control Procedures; G[, [______]]

Augered Cast-in-Place Piles; G[, [______]]

Load Tests; G

SD-03 Product Data

Test Piles; G[, [______]]

Grout Pump

Materials
DAMAGED PILES

Piles which are damaged during installation to the extent they are rendered unsuitable for the work, in the opinion of the Contracting Officer, will be rejected, or may be re-drilled, if approved, at no cost to the Government.

Any pile damaged by reason of improper installation must be corrected by one of the following methods approved by the Contracting Officer for the pile in question:

a. The pile is re-drilled and re-grouted, if practicable, and, if necessary, drilled deeper.

b. One or more replacement piles are installed adjacent to the defective pile.

c. Low strain integrity non-destructive testing must be performed by the Contractor's Geotechnical Consultant to assess the structural integrity of the pile(s) in question.

A pile installed below the specified butt elevation must be corrected by one of the following methods approved by the Engineer:

a. A sufficient portion of the footing is extended down to properly embed the pile.

b. Build up the pile butt by the use of casings.

A pile installed out of its proper location or out of plumb as approved by the Engineer, must be corrected by one of the following methods approved by the engineer:

a. One or more replacement piles are installed next to the pile in question.

b. As directed by the structural engineer.
1.9 QUALITY CONTROL

1.9.1 Field Quality Control Procedures

Submit the field quality control procedures. Provide instructions and procedures on how the Contractor will assist the Government in the processes of Pile Load Testing, Inspection and Monitoring of piles during installation and testing.

1.9.2 Installation Procedures

Submit information on the type of equipment proposed to be used, proposed methods of operation, pile installation plan including proposed sequence of installation, and details of all pile installation equipment and accessories.

1.9.3 Contractor's Geotechnical Consultant Documentation

Hire the services of an independent, Registered Professional Geotechnical Engineer, experienced in soil mechanics and augered cast in place pile installation, to observe test pile installation and production pile installation as specified herein. The Contractor's Geotechnical Consultant must be independent of the Contractor and must have no employee or employer relationship which could constitute a conflict of interest.

1.9.4 Grout Mix Design

Certify, using a Government-approved independent commercial testing laboratory, that proportioning of mix is in accordance with ACI 211.1 or ACI 318M ACI 318 for specified strength and is based on aggregate data which has been determined by laboratory tests during last twelve months. Submit a complete list of materials including type; brand; source and amount of cement, fly ash, pozzolan, ground slag, and admixtures; and applicable reference specifications. Submit additional data regarding fine aggregates if the source of aggregate changes. Submittal must clearly indicate where each mix design will be used when more than one mix design is submitted.

1.9.5 Load Test Supporting Data

Submit Jack calibration records, a testing arrangement description and diagram, and the proposed loading sequence.

1.9.6 Silica Fume Manufacturer's Representative

Provide statement that the manufacturer's representative will be present at plant to ensure proper mix, including high range water reducer (HRWR), and batching methods.

PART 2 PRODUCTS

2.1 MATERIALS

2.1.1 Grout

******************************************************************************

NOTE: Insert the ultimate compressive strength required by the design (20.7 MPa 3,000 psi minimum). Select a minimum flow rate of 11 seconds.
Provide grout consisting of a mixture of portland cement, a pozzolanic material when approved, fluidifier, sand, and water proportioned and mixed to produce a grout capable of being pumped with an ultimate compressive strength of \[_____] MPa psi at 28 days. Consistency must not be less than \[11\] \[_____] seconds when tested in accordance with paragraph FLOW CONE TEST. Other admixtures must not be used.

2.1.1.1 Portland Cement

Portland cement must conform to ASTM C150/C150M.

2.1.1.2 Pozzolan

Pozzolan must be a fly ash or other approved pozzolanic material conforming to ASTM C618, Class C or F.

2.1.1.3 Grout Fluidifier

Grout fluidifier must conform to ASTM C937, except that expansion must not exceed 4 percent. The fluidifier must be a compound possessing characteristics which will increase the flowability of the mixture, assist in the dispersal of cement grains, and neutralize the setting shrinkage of the high-strength cement mortar.

2.1.1.4 Chemical Admixtures

Chemical Admixtures must conform to ASTM C494/C494M and must consist of, but not be limited to, water reducers and/or set retarders.

2.1.1.5 Water

Water must be fresh, clean, and free from sewage, oil, acid, alkali, salts, organic matter, or other substances deleterious to grout or steel.

2.1.1.6 Fine Aggregate

NOTE: To be used as alternate requirement.

Fine aggregate must meet the requirements of ASTM C33/C33M. The sand must consist of hard, dense, durable, uncoated rock particles and be free from injurious amounts of silt, loam, lumps, soft or flaky particles, shale, alkali, organic matter, mica, and other deleterious substances. If washed, a washing method must be used that will not remove desirable fines, and the sand must subsequently be permitted to drain until the residual-free moisture is reasonably uniform and stable. The sand must be well-graded from fine to coarse, with fineness modulus between 1.30 and 3.40. The fineness modulus is defined as the total divided by 100 of the cumulative percentages retained on U.S. Standard Sieve 1.18, 0.600, 0.300 and 0.150 mm Numbers 16, 30, 50, and 100.

2.1.1.7 Aggregate
For exposed piles in areas where reactive aggregates are likely to be supplied, provide for additional tests and certification to insure that reactive aggregates will not be used. While not wholly conclusive, petrographic examination (ASTM C295/C295M), chemical test (ASTM C289/C289M), and mortar bar method (ASTM C227) are valuable indicators.

While more reliable, the concrete prism test (ASTM C1293) takes 1 to 2 years to complete and is not practical. The accelerated mortar bar method (ASTM C1260) is similarly reliable and takes only 16 days to yield results. In areas where reactive aggregates can not be avoided, specify use of low alkali cement, and/or cements modified to mitigate alkali-silica reactivity. Service records of concrete made with these materials along with tests should be used in evaluating these materials.

Aggregate must meet the requirements of ASTM C33/C33M, for fine aggregate, except as to grading. The sand must consist of hard, dense, durable, uncoated rock fragments and must be free from injurious amounts of silt, lumps, loam, soft, or flaky particles, shale, alkali, organic matter, mica, and other deleterious substances. If washed, the method must not remove other desirable fines, and the sand must be permitted to drain until the residual free moisture is reasonably uniform and stable. Sand grading must be reasonably consistent and must conform to the following requirements as delivered to the grout mixer:

<table>
<thead>
<tr>
<th>U.S. Standard Sieve Number</th>
<th>Cumulative Percent by Weight Passing</th>
<th>Cumulative Percent by Weight Retained</th>
</tr>
</thead>
<tbody>
<tr>
<td>2.36 mm8</td>
<td>100</td>
<td>0</td>
</tr>
<tr>
<td>1.18 mm16</td>
<td>95-100</td>
<td>0-5</td>
</tr>
<tr>
<td>0.600 mm30</td>
<td>55-80</td>
<td>20-45</td>
</tr>
<tr>
<td>0.300 mm50</td>
<td>30-55</td>
<td>45-70</td>
</tr>
<tr>
<td>0.150 mm100</td>
<td>10-30</td>
<td>70-90</td>
</tr>
<tr>

<td>0-10</td>
<td>90-100</td>
</tr>
</tbody>
</table>

The sand must have a fineness modulus of not less than 1.30 nor more than 2.10. Sand grading shown above may be modified with the approval of the Contracting Officer. Mortar test specimens made with the modified sand must exhibit compressive strength equal to or greater than that exhibited by similar specimens made with sand meeting grading and other requirements.
shown above.

2.1.2 Reinforcement

Materials, assembly, and placement of reinforcement must conform to the requirements of Section [03 30 00 CAST-IN-PLACE CONCRETE] [______].

2.1.3 Reinforcement

All Steel must conform to ASTM A1064/A1064M for spirals and ASTM A615/A615M [ASTM A706/A706M] for ties. Reinforcing bars must conform to the requirements of ASTM A615/A615M, Grade 60. Reinforcing steel assemblies must be detailed and fabricated in accordance with the latest manual of Standard Practice for Detailing Reinforced Concrete Structures ACI 315. Splicing details must be determined by the Designer and detailed on the plans. Single bars and cages should be equipped with a centralizer of acceptable size. More than one centering device must be used on long bars/cages. Centralizers must be spaced not greater than about 6 m 20 feet for vertical bars/cages, and about 3 m 10 feet for bars/cages installed in battered piles; actual spacing must be modified as necessary depending on the ground conditions or as directed by the Contracting Officer.

2.1.4 Casings

Submit a description of the materials to be used and the proposed methods of operations. Casings must be approved [steel] [_____] as soil warrants. Cylinder casings must be of sufficient strength and rigidity to withstand all installation stresses, to prevent distortion caused by placing adjacent piles, and to prevent collapse due to soil or hydrostatic pressure.

2.2 MATERIAL SUSTAINABILITY CRITERIA

For materials used, where applicable and to the extent allowed by performance criteria, provide and document the following in accordance with Section 01 33 29 SUSTAINABILITY REQUIREMENTS AND REPORTING:

a. Recycled content for fly ash and pozzolan
b. Recycled content for Ground Iron Blast-Furnace Slag
c. Recycled content for Silica Fume
d. Minimum [75 percent] recycled content for steel used for stressed tendon reinforcing

PART 3 EXECUTION

3.1 GROUT VOLUME

The volume of grout per linear meter foot of pile must be not less than the theoretical volume of grout per meter foot of test piles. Volume of placed grout must at least [120] [____] percent of theoretical volume for every 1.5 m 5 foot interval. If less than required volume is placed for any given 1.5 m 5 foot interval, lower auger a minimum of 1.5 m 5 foot, or to bottom of pile if less than 1.5 m 5 foot. Monitor pumped grout volumes using stroke counter or other means of accurately measuring the quantity of the grout placed. All volume measurements must be made and recorded by the Contractor's Geotechnical representative.
3.2 INSTALLATION

Install piles after rough grading at pile locations have been completed. The ground surface at each pile location at the time of augering and grouting must be at least 300 mm (12 inches) higher than the required pile cutoff elevation, unless a steel casing will be used, and the augered hole must be completely filled with grout.

The grout must consist of Portland cement, fine aggregate, and water, and may also contain a mineral admixture and approved fluidifier. All materials must be fed to the mixer accurately measured by weight, except water that may be measured by volume. The order of placing the materials must be in accordance with the ASTM standards. Mineral admixtures, if used, must be flyash or natural pozzolan and must conform to ASTM C618, Class C or Class F. Chemical Admixtures supplied by the ready-mix producer must conform to ASTM C494/C494M and might consist of, but not be limited to, water reducers and/or set retarders. Grout fluidifier, when utilized, must conform to ASTM C937.

Time of mixing must not be less than 1 minute. [Do not proceed with the installation of contract piles within any area of substantially different subsoil conditions until a satisfactory load test has been performed in that area.]

3.2.1 Casings Placement

Casings "can" must be approved by the Contracting Officer and must be left in place and filled with grout. The casings must be rotated by the auger drive unit or weighted or jetted to the required depth. Casings should be of proper diameter and at least 450 mm (18 inches) in length to establish the pile cut-off level and to keep surface spoil from entering the grout column before it sets. After the casing is in place, the casing and hole must be cleared of water, sediment, and debris prior to pouring the grout. [When the cut-off level is above the drilling grade, extend the pile by using a sheet metal or fiber cylindrical "can" or sleeve placed part in and part out of the pile.]

3.2.2 Drilling Refusal

**********NOTE: Delete the sentence in brackets when test piles, load tests, and soil probes are not used.**********

Except where auger withdrawal is required or directed by the Contracting Officer, each pile hole must be drilled and filled with grout in an uninterrupted operation. Drill each pile hole to the required tip elevation [or until the specified refusal criteria is satisfied]. [Should the required tip elevation shown on the drawings differ from the calculated tip elevation, an adjustment in the contract requirements will be made.] Advance the auger at a continuous rate which prevents removal of excess soil. Stop rotation of auger after reaching the required pile tip elevation or refusal. Auger refusal is defined as a rate of auger penetration of less than 76 [___] mm per 5 [___] minute of drilling 3 [___] inches per 5 [___] minutes of drilling.

3.2.3 Grouting and Auger Removal

At the start of pumping grout, raise the auger from 152 to 300 mm (6 to 12
inches and after grout pressure builds up, indicating discharge of grout, redrill auger to the required tip elevation, and fill pile hole with grout without interruption. When the auger is withdrawn to check the soil profile, it must be reinserted in the pile hole to the required tip elevation and the pile hole then filled with grout without interruption. Coordinate rate of grout injection and rate of auger removal from the soil in such a manner as to maintain a positive pressure on the grout pressure gauge. The gauge indicates the existence of a removing pressure on the bottom of the auger flight. If the auger jumps upward during withdrawal, or if the grouting process is interrupted, or if there is decreased grouting pressure, reinsert it to the original tip elevation and decrease the rate of withdrawal to prevent further jumping. The auger may rotate very slowly during withdrawal. However, counterclockwise rotation is not permitted.

3.2.4 Pile Butts

Unless a permanent steel casing is provided as specified in paragraph entitled "Casings," place a steel sleeve at top of pile to form the pile butt. For pile cutoff above ground surface, the steel sleeve must extend from the pile cutoff elevation to a point not less than 300 mm one foot below the ground surface. For pile cutoff at or below ground surface, the steel sleeve must extend from the ground surface to a point not less than 300 mm one foot below the pile cutoff elevation. Pump excess grout to displace as much potential laitance as possible. Lower pile butt to required cutoff elevation or to sound grout, whichever is lower.

3.2.5 Placement Tolerances

**************************************************************************
NOTE: Refer to the DFI, Augered Cast in Place Manual for maximum permissible placement variation.
**************************************************************************

Locate piles where indicated. The maximum permissible variation of the center of each pile from the required location is [___] mm inches at the ground surface. No pile must be out of required axial alignment by more than 2 percent. Periodically check the required axial alignment of each pile during the drilling operation and after reaching required tip elevation with not less than 1.5 m 5 feet of the auger flight extending above ground surface. Abandon piles which are damaged, mislocated, or out of alignment beyond the maximum tolerance and provide additional piles where directed.

As-installed pile surveys must be performed after 35 percent, 65 percent, and 100 percent of the piles have been installed. The as-installed surveys must measure the actual location and top elevation of each acceptably installed pile. Measurements must be performed in such a manner as to provide the horizontal deviation from plan location in two perpendicular directions and the top of pile elevation to the nearest 13 mm 1/2 inch. Provide each interim as-installed survey to the Contracting Officer within 3 days following the surveying work for each increment. The as-installed surveys must be submitted and approved prior to performing any pile cut-off work or beginning any pile cap/grade beam installation work.

3.2.6 Cutoff

Removal of pile butts above the indicated cutoff elevation may be accomplished by dipping the grout from the pile, while grout is fluid, but
not less than one hour after installation. At the option of the Contractor, and as approved prior to pile installation, grout may be allowed to harden at its initial top elevation and then carefully trimmed off to the indicated cutoff elevation with hand operated chipping guns.

3.2.7 Disposal of Excavated Material

Do not leave any piles partially completed overnight. Completely grout and protect piles at the termination of each day's operation. Dispose of excavated material, resulting from augering, [within the area indicated] [off Government property] [_____].

3.3 Flow Cone Test

The quantity of water used must produce a grout having a consistency of not less than 21 seconds when tested with a flow cone in accordance with ASTM C939/C939M. [For specified flow cone rates in the range of 10 to 25 seconds, the flow cone must be modified by removal of the 13 mm 1/2 inch orifice allowing grout to pass through the 19 mm 3/4 inch hole in bottom of cone.] Water retentive grouts that demonstrate cohesive or thixotropic properties may be more accurately tested for workability with a standard slump cone using Slump Flow (commonly referred to as a "spread" test) as described in ASTM C1611/C1611M. The Slump Flow or "Spread" test employs the use of the standard concrete slump cone.

Conduct tests at the beginning of grout injection and at subsequent intervals to ensure specification requirements are met.

3.4 Grout Specimens

Conduct grout tests in accordance with ASTM C31/C31M, ASTM C39/C39M and ASTM D942. Prepare test specimens of grout by pouring grout into 50 mm 2 inch cubes. Cure and test in accordance with ASTM C109/C109M. Cube specimens must be restrained from expansion as described in ASTM C942/C942M. Prepare test specimens of grout by pouring grout [150 mm by 305 mm 6 inch by 12 inch cylinders], [76 mm by 150 mm 3 inch by 6 inch], [50 mm by 100 mm 2 inch by 4 inch] cylinders. Provide molds with a top cover plate so designed as to restrain grout expansion and to permit escape of air and water.

Not less than one set of cylinders must be collected for each 38 m3 50 cy of grout placed, or at least one set for each day during which piles are placed. Test 2 [___] cubes at 7 [___] days, 2 [___] cubes tested at 28 [___] days, and 2 [___] cubes held in reserve. One set must consist of six [___] cubes [cylinders]. Any set of cubes [cylinders] of which one or more cylinders test at 10 percent or more below the required strength must be cause for rejection of the pile group.

3.5 Depth

**************************************************************************
NOTE: The requirement of this paragraph may be waived by those agencies that so desire. Insert the total number of pile holes requiring withdrawal of auger before inserting the mortar. Withdrawal and examination of the auger to verify soil profile should be required at all test pile locations and at 10 percent of the remaining pile locations to supplement the soil boring information.
For all test piles, the auger must be withdrawn after reaching the "calculated" tip elevation and before grout is pumped. The Contracting Officer will be present to check the soil conditions and will have the right to increase the test pile length if soil conditions warrant. In such cases, the Contracting Officer may require additional auger withdrawals after drilling to the lower tip elevation. Such additional auger withdrawals must be included in the total number of auger withdrawals made. The pile hole must not be filled with grout until the Contracting Officer has approved the final tip elevation.

3.5.1 Rejected Piles

Replace or redrill damaged piles during installation, piles with low grout volume, piles that heave or drop, mislocated, or installed out of alignment beyond the maximum tolerance. Replace rejected piles with new piles installed as directed. Perform all work in connection with rejected piles at no additional cost to the Government.

3.6 SOIL PROFILE

NOTE: The requirement of this paragraph may be waived by those agencies other than NAVFAC that wish to do so. Indicate on the drawings pile holes requiring soil probes. Soil probes should be required at all test pile locations, and at 10 percent of the remaining pile locations.

At [_____] pile holes, in addition to the test piles, the auger must be withdrawn from the ground before the grout is pumped to check the soil profiles. Drill soil probes within a radius of 6 m 20 feet of their associated test pile. The Contracting Officer will be present to verify the soil condition at the "calculated" pile tip elevation and has the right to increase the soil probe length or require additional soil probes, if soil conditions warrant. After soil conditions have been inspected and approved by the Contracting Officer, install test pile[s]. Soil probes that are located within the tolerances indicated for piles must be filled with grout and may be used in the finished work, if approved by the Contracting Officer and if satisfactorily load tested.

3.7 PROTECTION OF PILES

The sequence of pile installation must be such that adjacent piles show no evidence of disturbance. This evidence would actually appear as a drop in the grout surface. The load applied to the soil by the drilling equipment must be far enough away from the pile being drilled to avoid compressing or shearing of the soil which may in turn displace or squeeze-off the grout column. No piles must be placed within [1.5 m 5 feet] of adjacent piles until the grout in the piles has set for [24] hours, unless otherwise directed by the Contracting Officer.

When large pile clusters or piles are installed with very close spacing, take periodic elevations on the tops of all piles to observe and determine pile heave or drop. Pile heave or drop must not exceed 13 mm 1/2 inch.
3.8 PILE RECORDS

Keep complete and accurate records of all augered cast in place piles. Indicate the pile location, diameter, length, elevation of tip and top of pile, quantity of grout material actually pumped in each pile hole, and the rated load capacity of the pile. Determine grout quantity by recording grout pump displacement [and by automated monitoring equipment equipped with a display and recording unit, depth sensor, magnetic flow meter, rotary head pressure sensor, rotation sensor and pressure sensor.] [The automated monitoring equipment must not replace recording of the grout pump displacement manually.] Record and report immediately any unusual conditions encountered during pile installation. Submit specified records upon completion of work.

3.8.1 Protection of Existing Structures

**************************************************************************
NOTE: Include this paragraph only when protection of existing structures from pile installation driving activities is required.

The designer must indicate on the drawings all structures and facilities for which protection is required. The designer must also provide a project specific document that details design criteria, requirements for preconstruction condition surveys, post construction condition surveys, geotechnical instrumentation to measure ground movements and any other requirements.

Add any additional requirements as necessary.
**************************************************************************

Mitigate impact on existing facilities due to pile installation activities in accordance with the [project specific document].

3.9 FIELD QUALITY CONTROL

3.9.1 Test Piles

Submit a complete and accurate record of all auger cast grout piles (both test piles and production piles), indicating the pile location, diameter, length, elevation of tip and top of pile, and the quantity and strength of grout material actually pumped in each pile hole.

3.9.2 Test Piles Placement

**************************************************************************
NOTE: Specify load tests when needed to confirm design capacities. The requirement for performing load tests would depend on the degree of variations in subsoil conditions. A minimum of one test pile should be load tested in each area of substantially different subsoil conditions. The requirement of performing the load tests under the direct supervision of a registered Professional Engineer may be waived at the discretion of the design agency.

Insert the grout strength required at the time the
test load is applied which could be the specified 28-day strength if Type III (high-early strength) cement is used or 75 percent of the specified 28-day strength if regular cement is used.

Provide test piles of the required type placed in the manner specified elsewhere in this section for all piling. Install test piles [at the locations indicated] [in vicinity of soil boring test holes Nos. [_____,] [_____,] and [_____]]. Install test piles to [indicated tip elevation] [indicated bidding lengths]. The Government will use test pile and load test data in addition to test reports on soil samples to determine "calculated" pile tip elevations. Piles immediately adjacent to the test pile must be placed after placing test pile and prior to load testing. Test piles that are located within the tolerances indicated for all piles and provide a safe design capacity as determined by the results of a satisfactory load test may be used in the finished work. Test loads must not be applied to the piles until the grout has obtained the design strength. Report immediately any unusual conditions encountered during pile installation to the Contracting Officer. Modify installation procedures as required based upon recommendation of [Contracting Officer] [Contractor's Geotechnical Consultant and approval of the Contracting Officer].

3.9.3 Static Load Tests

NOTE: If pile load tests are required and approved by the Contracting Officer, specify number and location of piles. Select method of load test. In ASTM D1143/D1143M, permit anchor piles only if approved by the Contracting Officer's Technical Representative (Geotechnical Branch). Insert figure KN(kips) corresponding to 200 percent of the design load. Select appropriate acceptance criteria according to UFC 3-220-01.

Perform compressive load tests on [_____] test piles in accordance with ASTM D1143/D1143M (standard loading procedure) as modified herein. Allow a minimum of [7] [___] days following final test pile installation until the grout has obtained the maximum design strength to load testing. Provide apparatus for applying vertical loads as required by method, using load from weighted box or platform [or reaction frame attached to sufficient uplift piles to safely take required load] applied to pile by hydraulic jack. Increase load in increments until rapid progressive settlement takes place or until application of total compressive load of [_____] KN kips [200 percent of the designed pile capacity] for compressive load tests. Consider load test satisfactory when [after one hour at full test load gross settlement of pile butt is not greater than gross elastic pile compression plus 4 mm 0.15 inch plus one percent of pile tip diameter or width in [_____] mm inches] [slope of gross load-settlement curve under full test load does not exceed 1.5 mm per metric ton 0.05 inches per ton] [net settlement after removal of test load does not exceed 19 mm 3/4 inch]. Perform load tests at locations [as proposed by the Contractor's Geotechnical Consultant and] as directed by the Contracting Officer. Additional load tests, at Government expense, may be required by the Contracting Officer. Perform the loading, testing, and recording and analysis under the direct supervision of a Registered Professional.
Engineer, registered in the state of project location, and provided and paid for by the Contractor. Submit test set-up.

3.9.3.1 Safe Design Capacity

Determine the safe design capacity of a test pile as determined from the results of load tests according to UFC 3-220-01.

3.9.4 Tensile Load Test

Perform tensile load tests on [_____] test piles in accordance with ASTM D3689, as modified [and] in paragraph LOAD TESTS. Apply a tensile load of [_____] kN kips to each tensile load test pile. In performing the tension load test, apply the ultimate load equal to one and one-half times the safe tension capacity, and employ the Standard Loading Procedure.

3.9.5 Lateral Load Test

Perform lateral load tests on [_____] piles in accordance with ASTM D3966/D3966M, as modified [and] in paragraph LOAD TESTS. Lateral load tests must consist of jacking two piles apart with a hydraulic jack, with one pile serving as the reaction pile for the other. Apply a lateral load of [_____] kN kips to each pair of lateral load test piles. Record required movement readings for each pile.

3.9.6 Pile Records

**************************************************************************
NOTE: Omit reference to load test when not required in project. Omit reference to test piles and "calculated tip elevation" when test piles are not installed. Where special or unusual soil conditions are expected, consultation with the Contracting Officer's Technical Representative (Geotechnical Branch) regarding special engineering supervision of installing, testing, recording and analysis of data for project may be useful.
**************************************************************************

**************************************************************************
NOTE: The Specifier must attach the specifications pile installation log graphic (for all pile installation projects) and the pile testing equipment data form to the end of this specification section.
**************************************************************************

Keep a complete and accurate record of each pile installed. Indicate the pile location, deviations from pile location, cross section shape and dimensions, length, ground elevation, tip elevation, cut-off elevations, [batter alignment,] theoretical and actual grout volume for every 1524 mm 5 feet interval, and reinforcement details. Include in the record the beginning and ending times of each operation during installation of pile, installation equipment, grout pump type, and pump calibration. Record unusual occurrences during pile installation such as heaving, obstructions, and any installation interruptions. A preprinted pile log for recording pile installation data[ and pile installation equipment data form], which can be downloaded at: [http://www.wbdg.org/ccb/NAVGRAPH/graphtoc.pdf].
3.9.7 Low-Strain Integrity Testing

[Test [_____] piles for post-construction non-destructive low strain integrity testing to verify the pile integrity.] [Specific piles must be selected based on a review of the manual or automated monitoring equipment installation records for that pile.] Perform test(s) in accordance with ASTM D5882 standard. Low-Strain Integrity Testing should be limited to piles with length to diameter (L/D) ratios of approximately 30 or less. This test is typically limited to detecting defects/discontinuities that are equal to or greater than about 0.3 m 1 foot. The equipment must have been calibrated within [6] [____] months prior to the start of the testing operations and thereafter throughout the contract duration. Employ an independent inspection firm, hereinafter referred to as the "Contractor's Geotechnical Consultant", experienced in the pile Low-Strain Integrity Testing[, monitoring of test pile installation,].

3.9.8 Sonic Logging

[Test [_____] piles for post-construction non-destructive sonic logging testing to verify the pile integrity.] [Specific piles must be selected based on a review of the manual or automated monitoring equipment installation records for that pile.] Perform test(s) in accordance with ASTM D6760 standard. Perform sonic logging [3] [____] days after the pile has been installed to both allow for the grout to initially cure and to reduce the potential for de-bonding between access pipe and pile grout. The equipment must have been calibrated within [6] [____] months prior to the start of the testing operations and thereafter throughout the contract duration. Employ an independent inspection firm, hereinafter referred to as the "Contractor's Geotechnical Consultant", experienced in the pile Low-Strain Integrity Testing[, monitoring of test pile installation].

3.9.9 Testing Agency Qualifications

Engage an independent testing agency qualified according to ASTM C1077 and ASTM E329 for testing indicated, as documented according to ASTM E548, and approved by the Contracting Officer.

3.10 SPECIAL INSPECTION AND TESTING FOR SEISMIC-RESISTING SYSTEMS

**************************************************************************
NOTE: Include this paragraph only when special inspection and testing for seismic-resisting systems is required by the International Building Code (IBC).

This paragraph will be applicable to both new buildings designed and to existing building seismic rehabilitation designs done according to UFC 1-200-01, "General Building Requirements", UFC 3-301-01, "Structural Engineering", and 3-301-02, "Design of Risk Category V Structures, National Strategic Military Assets".

The designer must indicate on the drawings all locations and all features for which special inspection and testing is required in accordance with Chapter 17 of the IBC. This includes indicating the locations of all structural components and connections requiring inspection.
Add any additional requirements as necessary.

Perform special inspections and testing for seismic-resisting systems and components in accordance with and Section 01 45 35 SPECIAL INSPECTIONS.

]3.11 VIBRATION CONTROL

NOTE: Include this paragraph when vibration monitoring is required. Add any additional criteria or requirements as necessary to the particular project. This section can normally be deleted for most augered cast in place pile projects.

Perform vibration monitoring at the locations [shown in the plan] [decided by the Contracting Officer] during the pile installation operations. Perform vibration monitoring [using] [seismographs] [and geophones] within a distance of 61 meters 200 feet from the pile installation activity. [Engage the services of a qualified, independent vibration consultant, acceptable to the Government, to conduct the vibration monitoring. The vibration consultant must have minimum of [five] years of experience in vibration monitoring. A minimum of [28] days before the installation of vibration monitors, submit to the Government the name of the vibration consultant and a list of at least [three] previously completed projects of similar scope and purpose.]

Prior to the pile installation activities, obtain baseline readings of ambient vibrations. The vibration during the pile installation activities must be limited to [a peak particle velocity of not more than 5 cm 2 inches per second.] [the limits mentioned in the [contract documents]]. [Determine appropriate vibration limits as per [US Bureau of Mines] [American Association of State Highway and Transportation Officials (AASHTO)] guidelines. ]During pile installation activities, monitor the vibrations to ensure the limits are not exceeded. If the limits are exceeded, cease the pile installation activity causing the vibration until [the Vibration consultant and the Contracting Officer] are on site to observe the structures nearest to the vibration monitor which has exceeded the limits.

The Contractor must be responsible for all damages resulting from the pile installation operations and must take whatever measures necessary to maintain peak particle velocity within the specified limit. After completion of the project, remove the vibration monitors off the site and off Government property and restore the monitoring locations back to their original condition.

]3.12 NOISE CONTROL

NOTE: Include this paragraph when noise monitoring is required. Add any additional criteria, references or requirements as necessary to the particular project. This section can normally be deleted for most augered cast in place pile projects.

Perform noise monitoring at the locations [shown in the plan] [decided by
Prior to the pile installation activities, obtain baseline readings of ambient noise levels. [The noise limits are mentioned in the [plan] [contract documents]]. [Determine appropriate noise limits as per [local agency] [Occupation Safety and Health Administration] guidelines]. During pile installation activities, monitor the noise to ensure the limits are not exceeded. If the limits are exceeded, cease the pile installation activity and install noise mitigation measures.

The Contractor must be responsible for all damages resulting from the pile installation operations and must take whatever measures necessary to maintain noise within the specified limit. After completion of the project, remove the noise monitors off the site and off Government property and restore the monitoring locations back to their original condition.

[3.13 PRECONSTRUCTION CONDITION SURVEY]

**************************************************************************
NOTE: Add any additional criteria, references or requirements as necessary to the particular project.
**************************************************************************

Perform preconstruction condition survey of [structures] [and utilities] [within 61 meters 200 feet of the pile installation activity] [specified in the plans] [decided by the Contracting Officer]. Perform outreach to the owner of the structures [28] days before performing the preconstruction condition survey. The Contractor must obtain written permission from the owner of the structure prior to accessing the structure. The preconstruction condition survey must include video and photographic documentation of the exterior and interior of above ground structures and of the interior of underground structures. Video documentation must be in high definition, and show existing conditions and highlight, where possible, existing cracks, deteriorated concrete, exposed and corroded reinforcement, cracked or broken brick or mortar, and other signs of distress. For utilities, perform the survey when the greatest extent of the interior is exposed. Provide supplementary artificial lighting as needed. The video must include annotation with location and structure nomenclature which describes any areas of distress over the video and time code superimposed on the video. Photographs must be accompanied by sketches or descriptions that indicate the location and direction of each photograph. For each structure surveyed, provide a Pre-Construction Condition Survey Report following completion of the survey. The report must contain all documentation associated with the survey including DVD copies. In the report, include notes, sketches, photographs, and videos. Provide general information, such as location details and structure type, as well as particular information on materials, condition, existing damage, aperture and persistence of cracks, and disrepair observed during visual survey. Provide a graphical depiction of locations of damage or other features of concern. Submit the Preconstruction Condition Survey Reports no later than [28] days before the commencement of pile installation.
activity. Accept responsibility for damages to existing adjacent or adjoining structures created by pile installation work, and repair any damages to these structures without cost to the Government.

3.14 CONSTRUCTION INSTRUMENTATION AND MONITORING PROGRAM

**************************************************************************
NOTE: Include this section if instrumentation is to be installed due to concerns about vibration, settlement, lateral movement, etc. during pile installation activities. Instrumentation should be specified and included in the specification. This section can be deleted if there are no instrumentation requirements.

Add any additional criteria or requirements as necessary for the particular project.
**************************************************************************

Prepare a geotechnical instrumentation program to monitor settlement [and lateral movement] of temporary and permanent structures, utilities, [embankments] [and excavations] during pile installation. The design and distribution of instrumentation must demonstrate an understanding of the need, purpose and application of each proposed type. Perform noise and vibration monitoring in accordance with NOISE CONTROL and VIBRATION CONTROL sections.

Monitoring must extend before, during and for a period after completion of construction activities related to pile installation when long-term performance issues are a concern. The monitoring plan must be designed to protect adjacent structures and utilities against damage due to the pile installation activities. Establish limiting values of vertical [and horizontal] movement [and angular distortion] [and vibration] for each structure and utility within the zone of influence, subject to review by the Government.

Prepare a report detailing the proposed program of instrumentation and monitoring, establishing threshold values of monitored parameters, and describing the response plans that will be implemented when threshold parameters are exceeded. The report must include details about instrumentation consultant’s experience, appropriate types, quantities, locations and monitoring frequencies of the instruments.

Upon acceptance of the instrumentation and monitoring program, provide, install and monitor the instrumentation and interpret the data. Submit instrumentation data reports not less than every [____] days after the monitoring program has begun. Take corrective actions, as necessary, based on the field instrumentation data and as defined in the instrumentation and monitoring program.

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for the procurement, installation, and testing of drilled foundation caissons including reinforcing and cast-in-place concrete.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1 GENERAL

NOTE: Use the following specifications in conjunction with this section:

SECTION 01 35 26 GOVERNMENTAL SAFETY REQUIREMENTS

On the drawings, show:

2. Top and bottom elevation of each caisson.
3. Size (diameter in mm inches, bearing capacity,
and total number of each size of caissons.

4. Dimensions of the bell, if required.

5. Dimensions of the casing.

6. Reinforcing steel details, if required.

7. Location of caissons to be penetration tested, if required.

8. Location of caisson to be proof tested, if required.

9. Locations, size, bell dimensions, and installation sequence of load testing caisson, if required.

**************************************************************************
[1.1 UNIT PRICES

**************************************************************************
NOTE: Delete this subpart for NASA projects.
**************************************************************************

a. Requirements for price breakdown of Drilled Caisson work are specified in Section 01 20 00 PRICE AND PAYMENT PROCEDURES. Requirements for construction scheduling related to Drilled Caisson work are specified in Section 01 32 17.00 20 COST-LOADED NETWORK ANALYSIS SCHEDULES.

**************************************************************************
NOTE: If requirements for price breakdown of drilled caissons work are specified in Section 01 20 00 PRICE AND PAYMENT PROCEDURES, use the following paragraph and delete subparts 1.1.1 through 1.1.4.
**************************************************************************

b. Requirements for price breakdown of Drilled Caisson work are specified in Section 01 20 00 PRICE AND PAYMENT PROCEDURES.

**************************************************************************
NOTE: This paragraph anticipates bids on a lump sum price for an entire project including caisson work with directed changes being in accordance with the CONTRACT CLAUSES or in accordance with unit prices as defined in paragraph "Separate Unit Prices."

Delete "in accordance with the CONTRACT CLAUSES" or paragraphs "Tests" and "Separate Unit Prices" for lump sum projects.
**************************************************************************

[1.1.1 Basis of Bids

Base the bid on the number and total length of caissons, established by top and bottom elevations and diameters, as indicated and specified. Adjustment of the contract will be made [in accordance with the CONTRACT
CLAUSES], should the total length of caissons installed and approved be greater or less than the total length shown. The Contractor will not receive payment for rejected caissons or for those not conforming to specifications.

1.1.2 Tests

1.1.2.1 Load Test

The Contract includes [_____] load tests rated at [_____] metric ton per caisson. The Contracting Officer reserves the right to increase or decrease the number of load tests. Adjustments in the contract price will be made for each such increase or decrease by the amount bid for "Additional Caisson Load Test" or "Omitted Caisson Load Test".

1.1.2.2 Penetration Test

The Contract includes [_____] penetration tests. The Contracting Officer reserves the right to increase or decrease the number of penetration tests. Adjustments in the contract price will be made for each such increase or decrease by the amount bid for "Additional Penetration Test" or "Omitted Penetration Test".

1.1.2.3 Proof Test Hole

The Contract includes [_____] proof test holes. The Contracting Officer reserves the right to increase or decrease the number of proof test holes. Adjustments in the contract price will be made for each such increase or decrease by the amount bid for "Additional Proof Test Hole" or "Omitted Proof Test Hole".

1.1.3 Separate Unit Prices

1.1.3.1 Additional Caisson Lengths

Additional caisson lengths will be paid for at the contract unit price for "Additional Caisson Length" for each diameter of caisson installed as approved.

1.1.3.2 Omitted Caisson Lengths

The contract price will be reduced by the amount bid for "Omitted Caisson Length" for each diameter of caisson omitted as directed.

1.1.3.3 Casings Permanently Left in Place

Steel casings permanently left in place due to contract conditions:

a. Total pounds of steel beyond casings indicated will be paid for at the contract unit price per pound for "Additional Steel Casing."

b. Omitted Casing Steel: The contract price will be reduced by the amount bid for "Omitted Casing Steel" omitted as directed.

1.1.3.4 Reinforcing Steel for Additional Caisson

Reinforcing steel for additional caisson lengths will be paid for at the contract unit price for "Additional Caisson Reinforcing Steel" installed as approved.
1.1.3.5 Reinforcing Steel for Caissons Omitted

The contract price will be reduced by the amount bid for "Omitted Caisson Reinforcing Steel" omitted as directed.

1.1.3.6 Removal of Rock

Removal of rock within the limit of caissons will be paid for at the contract unit price for "Removal of Rock" per linear meter foot, for each diameter of caisson installed. Rock excavation is defined as any hard dense material that cannot be removed with caisson drilling equipment having the specified capacity and could only be removed by hand, air tools, blasting, or other specialized methods.

1.1.3.7 Removal of Obstructions Other Than Rock

Removal of obstructions other than rock within the limits of the caissons which cannot be removed using standard caisson drilling equipment with the specified capacity will be paid for at the contract unit price per linear meter foot for "Removal of Obstructions" for each diameter of caisson installed.

1.1.4 Basis of Payment

**************************************************************************

NOTE: Where the basis for bidding is based entirely on unit price, subpart 1.1.1 through 1.1.3 should be deleted and the subparts 1.1.4.1 through 1.1.4.5 substituted.

**************************************************************************

1.1.4.1 Unit Price

The Contracting Officer has the right to increase or decrease the total length linear footage of drilled foundation caissons to be furnished and installed by changing the foundation caisson elevations, by requiring the installation of additional caissons, or omission of caissons from the requirements shown and specified. Whether or not such changes are made, the Contractor will be paid at the contract unit price per linear meter foot (including test caissons) multiplied by the total linear meters feet of acceptable caissons actually installed provided, however, that in the event the Contracting Officer requires an increase or decrease in the total length linear footage of caissons furnished and installed, the contract unit price will be adjusted in accordance with the CONTRACT CLAUSES.

1.1.4.2 Full Compensation

Payment in accordance with the above paragraph Unit Price constitutes full compensation for furnishing, delivering, handling, and/or installing (as applicable) all material, labor and equipment necessary to meet contract requirements applicable to the foundation caissons. The Contractor will not be allowed payment for rejected caissons.

1.1.4.3 Load Tests

The Contract includes [_____] [_____] -ton caisson load tests. The Contracting Officer reserves the right to increase or decrease the number of load tests. Adjustments in the contract price will be made for such
increases or decreases by the amounts bid for "Additional Caisson Load Test" or "Omitted Caisson Load Test." Submit results of all tests performed.

1.1.4.4 Penetration Tests

The Contract includes [_____] penetration tests. The Contracting Officer reserves the right to increase or decrease the number of penetration tests. Adjustments in the contract price will be made for such increases or decreases by the amounts bid for "Additional Penetration Test" or "Omitted Penetration Test."

1.1.4.5 Proof Test Holes

The Contract includes [_____] proof test holes. The Contracting Officer reserves the right to increase or decrease the number of proof test holes. Adjustments in the contract price will be made for such increases or decreases by the amounts bid for "Additional Proof Test Hole" or "Omitted Proof Test Hole."

1.2 REFERENCES

**************************************************************************
NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.
**************************************************************************

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

AMERICAN WELDING SOCIETY (AWS)

AWS D1.1/D1.1M (2020; Errata 1 2021) Structural Welding Code - Steel

AWS D1.4/D1.4M (2011) Structural Welding Code - Reinforcing Steel

ASTM INTERNATIONAL (ASTM)

1.3 SUBMITTALS

**************************************************************************
NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy, Air Force, and NASA projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.
Choose the first bracketed item for Navy, Air Force and NASA projects, or choose the second bracketed item for Army projects.

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only.  When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-02 Shop Drawings
   Caissons; G[, [_____]]
   Survey of Caisson Locations; G[, [_____]]

SD-04 Samples
   Test Caissons; G[, [_____]]

SD-06 Test Reports
   Load Tests; G[, [_____]]
   Penetration Tests; G[, [_____]]
   Proof Test Holes Report; G[, [_____]]

SD-07 Certificates
   Caissons
   Qualifications; G[, [_____]]
   Records for Each Qualified Welding Operator; G[, [_____]]

SD-11 Closeout Submittals
   Records

1.4 QUALITY ASSURANCE

1.4.1 Survey of Caisson Locations
   Submit a certified survey meeting the requirements specified herein.

1.4.2 Specialty Subcontractor Qualifications

NOTE: Select applicable paragraph for agency requirements. 3 to 5 years should be required for qualifying experience.

Submit Contractor Qualifications for foundation systems, proving its engagement in the successful installation of similar drilled foundation caissons for at least [_____] years.
1.4.3  Welding

Perform all detail and field welding in accordance with AWS D1.1/D1.1M. Qualification of welding procedures, welders, and welding operators must be in accordance with AWS D1.1/D1.1M, Section 4. Keep and make available, for examination by the Contracting Officer, all records of test results of welding procedures not prequalified, copies of records for each qualified welding operator, and records on positions of welding and types of electrode qualifications. Submit records for each qualified welding operator.

1.4.4  Pre-installation Conference

[Within [30][15] calendar days of notice to proceed] At the Pre-installation conference provide, for approval, the following schedule of submittals: Preliminary detailed drawings in an approved form, for each caisson, showing shaft and bell diameters, depths of test holes, top and bottom elevations, bearing strata description, casing description, water conditions, concrete strength, concrete volume, rock elevations, dates of excavation and concrete placement, and other pertinent information.

1.4.5  Contractor Supervision

Provide for the supervision of all phases of drilled pier construction. Supervision is the Contractor's responsibility as outlined in Quality Control provisions of the Specialty Subcontractor Requirements. Check each drilled pier excavation for its depth, water removal, cleanup, workmanship, and for all tolerance requirements before any concrete is placed.

1.4.6  Government Inspection

The Contracting Officer will inspect each drilled pier excavation. Do not place concrete until the excavation has been approved by the Contracting Officer. Furnish the Contracting Officer all necessary equipment required for proper inspection of drilled pier excavations.

1.4.7  Safety Precautions for Workmen and Inspectors

1.4.7.1  Life Line

Provide each person, entering a drilled pier excavation, with a life line suitable for instant rescue, securely fastened to a shoulder harness, separated from any line used to remove excavated materials, and rigged so that the person can be immediately hoisted out of the excavation in an emergency. Do not lower any person into a drilled pier excavation prior to casing the shaft through the overburden.

1.4.7.2  Ventilation

Provide each drilled pier excavation with a ventilating device of sufficient capacity to ensure a safe and healthy atmosphere before workmen and inspectors are permitted to enter the drilled pier excavation and during all work periods.

1.5  DELIVERY, STORAGE, and HANDLING

**************************************************************************************************

NOTE: Insert the appropriate Section number and
Deliver casings and appurtenant equipment to the job site in an undamaged and ready to place condition. Deliver concrete in accordance with requirements of [_____].

1.6 PROJECT/SITE CONDITIONS

1.6.1 Subsurface Data

**************************************************************************

NOTE: Include location of available samples.

Section 00 31 32.13 Subsurface Drilling and Sampling Information is not a UFGS. CSI MasterFormat prescribes this section for inclusion of this data.

**************************************************************************

Subsurface soil data logs are [included in the drawings] [appended to the SPECIAL CONTRACT REQUIREMENTS] [found in Section 00 31 32.13 Subsurface Drilling and Sampling Information]. The subsurface investigation report and samples of materials, as taken from subsurface investigations, are available for examination at [_____].

1.6.2 Caisson Drilling Equipment

**************************************************************************

NOTE: Caisson drilling equipment criteria should be evaluated and specified for contract site conditions. Reference: Drilled Pier Foundations - Woodward, Gardner, Greer - McGraw-Hill Book Co. Requirements should be included for determination of minimum equipment standards.

**************************************************************************

Provide caisson drilling equipment having a minimum torque capacity and downward force capacity for the contract site conditions.

1.7 SEQUENCING

**************************************************************************

NOTE: Sequence of work criteria should be modified for agency requirements.

**************************************************************************

1.7.1 Caisson Excavation

Perform excavation of caissons or groups of caissons so that reinforcing steel and concrete placement is a continuous operation performed the same day that the excavation is completed. Do not leave excavations open overnight.

1.7.2 Acceptance

Place concrete within 3 hours after approval of the completed excavation.
PART 2   PRODUCTS

2.1   MATERIALS

2.1.1 Concrete Work

**************************************************************************
NOTE: Insert the correlated section number and
title or include concrete specification in this
section, in the blank below using the proper format
per UFC 1-300-02.
**************************************************************************

**************************************************************************
NOTE: Include information for concrete work.
Correlate with Section 03 30 00 CAST-IN-PLACE
CONCRETE for pertinent information or include
concrete specifications in this section.
**************************************************************************

Perform all concrete work in accordance with requirements of Section [_____] 03 30 00 CAST-IN-PLACE CONCRETE, as modified herein:

2.1.1.1 Strength

**************************************************************************
NOTE: Compressive strength (28 day strength or f'c)
of concrete should be 25 MPa 3000 psi or higher.
When loads are high and drilling conditions
difficult, it may be more economical to use 30 MPa
4000 psi or 35 MPa 5000 psi concrete and larger
shafts rather than a smaller shaft with reinforcing
or permanent casing. If there is a reinforcing
cage, or if there is a large bell, the ability of
the concrete to flow between reinforcing bars, or to
completely fill the bell, is a matter of prime
importance. For these piers, the concrete should
have a slump of about 150 mm 6 inches. Slump may
vary, depending on the mix, between 100 mm 4 inches
and 150 mm 6 inches. A maximum size of 19 mm 3/4
inches appropriate under these circumstances.
**************************************************************************

Provide [_____] MPa [_____] psi strength concrete at 28 days, with slump
from [_____] to [_____] mm [_____] to [_____] inches.

2.1.1.2 Coarse Aggregate

**************************************************************************
NOTE: Select 25 mm 1 inch maximum size coarse
aggregate. Coarse aggregate may be smaller where
reinforcement spacing is close or where dimension of
caisson elements is dimensionally thin.
**************************************************************************

Provide [_____] mm [_____] inch maximum size coarse aggregate.
2.1.1.3 Reinforcing Steel

***********
NOTE: Reinforcing steel grades should conform to one of the following:

ASTM A615/A615M for deformed billet - steel bars must be 400 or 500 MPa Grades 60 or 75

ASTM A966/A966M for rail-steel deformed bars must be 400 MPa Grade 60

ASTM A966/A966M for axle-steel deformed bars must be 400 MPa Grade 60

***********

Provide reinforcing steel conforming to [ASTM A615/A615M] [ASTM A996/A996M] Grade [____], welded into cages in accordance with AWS D1.4/D1.4M and inserted securely in the caissons, in position and alignment, as shown, prior to [concrete placement] [the concrete reaching an elevation of [_____] meters feet below the bottom elevation of the reinforcement].

2.1.2 Welding

Perform shop and field welding in accordance with AWS D1.1/D1.1M. Provide certification of qualification of welding procedures, welders, and welding operators in accordance with AWS D1.1/D1.1M. Keep records of test results of welding procedures not prequalified and copies of records for each qualified welding operator, containing records on positions of welding and types of electrode qualifications, and make available for examination by the Contracting Officer.

2.1.3 Casing Steel

***********
NOTE: Determine minimum wall thickness based on the structural loading conditions.

***********

ASTM A36/A36M. Provide zinc coating of casing steel conforming to ASTM A123/A123M. Provide casings with an outside diameters not less than indicated shaft sizes and a minimum of [6 mm] [1/4 inch] [_____] thick.

2.2 CAISSON DRILLING EQUIPMENT

***********
NOTE: Caisson drilling equipment criteria should be evaluated and specified for contract site conditions. Reference: Drilled Pier Foundations - Woodward, Gardener, Greer - McGraw-Hill Book Co. Requirements should be included for determination of minimum equipment standards.

***********

Provide caisson drilling equipment with minimum torque capacity and downward force capacity suitable for the site conditions.
PART 3 EXECUTION

3.1 PREPARATION

******************************************************************************
NOTE: Base selection of caissons for contract on analysis of subsurface investigation and design requirements. Provide complete installation information to the Contracting Officer.

Specify load tests when needed to confirm design capacities. At least one caisson location should be load tested in each area of substantially different subsoil conditions. Indicate number, size, and location of test caisson and sequence.
******************************************************************************

Excavate caissons to established depths and dimensions shown; clean bottoms of caissons free of loose or soft material; level caissons; and dispose of excavated material in accordance with Section 31 00 00 EARTHWORK. Submit a certified copy of the survey. Establish lines, levels, and caisson centerline locations, staked and maintained by a registered surveyor or engineer.

a. When drilling caissons, protect the surrounding soil and the earth walls against cave-ins, displacement of the surrounding earth, and retention of ground water, by means of temporary steel casings. Provide casings with outside diameters not less than indicated shaft sizes, and a minimum of 6.4 mm 1/4 inch thick. Do not remove if the structural integrity of the caisson will be impaired, as determined by the Contracting Officer. Withdraw temporary steel casings as the concrete is being placed, maintaining sufficient head of concrete within the casing to prevent extraneous material from falling in from the sides and mixing with the concrete. Casings may be jerked upward a maximum of 100 mm 4 inches to break the bottom seal, but remove thereafter with a smooth, continuous motion.

b. Thoroughly clean and oil the inside of steel casings before reuse.

c. Leave the temporary casing in place from the caisson top to the ground surface until the concrete has set if the elevation of the top of the caisson is below the adjacent ground surface.

d. Provide permanent casing with outside diameter the same as the nominal shaft diameter. Provide a minimum wall thickness of permanent casings of [_____] mm inches.

e. Continuously remove all water that flows into the excavations and from the excavation bottom, to the extent possible, prior to concrete placement. The maximum permissible depth of water is 50 mm 2 inches. In the event of a severe water condition that makes it impossible or impractical to dewater the excavation, place concrete using an underwater tremie after water movement has stabilized.

f. Enlarge the bottoms of excavations indicated to be "belled" to diameters and shapes shown. Excavate or drill bells in a similar manner to that used for shafts.

g. Prepare the excavations for caissons indicated to be ["ribbed"] [_____]
with the dimensions and shapes indicated.

h. Each caisson excavation will be inspected and approved by the Contracting Officer prior to placing concrete. Keep a record of all inspections, with related construction changes. Provide support personnel for inspection and testing procedures.

3.2 INSTALLATION

a. Continuously place concrete by methods that ensure against segregation and dislodging of excavation sidewalls, and completely fill the shaft. Place concrete by pumping or drop chutes in dry holes and by tremie or pumping in wet holes. Keep the discharge a minimum of 1 m 3 feet below the fresh concrete surface during placement. Drilling of caissons or driving of casings must not be within 6 m 20 feet of concrete placed within the last 3 days.

b. Bring concrete to a true level surface inside the shaft and a full width cross key formed, or dowels installed, if it becomes necessary to interrupt placing concrete in any caisson. Prior to placing additional concrete, clean surfaces of laitance and slush with one-to-one portland cement grout, having a water-cement ratio not exceeding that of the concrete.

c. Place concrete in dry batter caissons with a drop chute extending within 1 m 3 feet of the concrete surface in the excavation.

d. Vibrate concrete for [full height of caisson] [upper [_____] meters feet of caisson]. Vibrate belled caissons full height.

3.3 TOLERANCES

**************************************************************************
NOTE: Correlate tolerances with design criteria and types of caisson.
**************************************************************************

a. Correct any caisson out of center or plumb beyond the tolerance specified as necessary to comply with the tolerances. Any corrective cost is the responsibility of the Contractor.

b. Make cross sections of shafts and bells not less than design dimensions.

c. Install caissons with top location deviating a maximum of [75] [_____] mm [3] [_____] inches from centerline locations.

d. Install vertical caissons plumb within a maximum of 38 mm 1-1/2 inches for the first 3 m 10 feet and within 13 mm 1/2 inch for each 3 m 10 feet of additional depth.

e. Install batter caissons a maximum of [2] [_____] percent of length from specified inclination.

3.4 PENETRATION TESTS

**************************************************************************
NOTE: Include penetration tests when bearing investigations are determined to be a contract requirement.
**************************************************************************
Perform Penetration Tests conforming to the following:

a. After excavation, make penetration tests in the bottoms of the caissons, in [locations indicated] [[_____] caissons], to determine bearing conditions, in accordance with ASTM D1586/D1586M.

b. Make the tests after caisson bottoms have been cleaned out. Minimum blow count is [_____] per meter foot. [Take penetration tests to a depth of [_____] meters feet below the bearing elevation. Obtain and retain jar samples, as directed by the Contracting Officer.]

c. If the minimum blow count is not obtained, drill the shaft an additional [_____] meters feet and rerun the penetration test.

d. Submit reports to the Contracting Officer in accordance with ASTM D1586/D1586M.

The Contracting Officer will approve tests and authorize subsequent concrete placement or initiate redesign procedures.

3.5 PROOF TEST HOLE REQUIREMENTS

Perform Rock Soundness test conforming to the following:

a. After excavation, proof test the rock below each caisson bearing level for soundness by percussion or rotary core drilling one hole in each caisson in locations indicated.

b. Make holes 50 mm 2 inch diameter and drilled with a uniform downward pressure to a depth below the bearing level equal to the design caisson shaft diameter but to a minimum of 1.2 m 4 feet.

c. Record penetration time for successive 150 mm 6 inch increments, noting conditions encountered.

Submit Proof Test Holes Report to the Contracting Officer. The Contracting Officer will approve test holes and authorize subsequent concrete placement or initiate redesign procedures.

3.6 LOAD TESTS

NOTE: Specify load tests to confirm caisson design. Indicate number, size, and location of test caissons and sequence.

3.6.1 General Requirements

a. Perform caisson load tests in locations indicated.
b. Perform tests under supervision of a registered engineer provided by
the Contractor and in the presence of the Contracting Officer. Secure
Contracting Officer approval of the test prior to commencement of work.

c. Apply load in concentric manner with magnitude of load accurately
determined and controlled.

d. Laterally support the top of caisson during entire load test.

e. [Load caisson to [150] [200] percent of design load, but do not exceed
ultimate concrete strength at time of loading. Apply the load in
increments of [____]. Maintain full test load for a period of [24]
[____] hours and take settlement readings at not less than [1/2]
[____] -hour intervals.] [Perform load test in accordance with
ASTM D1143/D1143M, except the maximum load must not exceed [_____]
[200] percent of the design load.]

f. Submit [_____] copies of the test report directly to the Contracting
Officer.

**************************************************************************
NOTE: Residual settlement is not to exceed 12 mm
1/2 inch for medium sized piers. Equally, the
settlement caused by twice the design load is not to
exceed 12 mm 1/2 inch.
**************************************************************************

g. Tested installations will be considered of adequate design and
construction if:

(1) No apparent distress occurs in caisson construction.

(2) Residual settlement, after test load is removed, does not exceed
[_____] mm inches.

(3) Twice the design load does not cause a gross settlement of more
than [_____] mm inches.

3.6.2 Replacements
Replace and retest test caissons found inadequate because of improper
instrumentation, testing, or construction procedures, at no additional
cost to the Government.

3.7 PROTECTION
Provide protection around top of the excavation to prevent debris from
being dislodged into the excavation and concrete.

3.8 SPECIAL INSPECTION AND TESTING FOR SEISMIC-RESISTING SYSTEMS

**************************************************************************
NOTE: Include this paragraph only when special
inspection and testing for seismic-resisting systems
is required by Appendix 11A of ASCE 7-16.

This paragraph is applicable to both new buildings
designed according to UFC 3-301-01 SEISMIC DESIGN
FOR BUILDINGS, and to existing building seismic
rehabilitation designs.

The designer must indicate on the drawings all locations and all features for which special inspection and testing is required in accordance with UFC 3-301-01 and Appendix 11A of ASCE 7-16. This includes indicating the locations of all structural components and connections requiring inspection.

Add any additional requirements as necessary.

Perform special inspections and testing for seismic-resisting systems and components in accordance with UFC 3-301-01 and Section 01 45 35 SPECIAL INSPECTIONS.

3.9 RECORDS

Keep and submit complete, detailed and accurate records for each caisson installation. Include locations, shaft diameters, [bell dimensions,] top and bottom elevations, depths of test holes, casing dimensions, concrete strength, concrete volume, quantity of rock excavation, excavation condition, dates of excavation and concrete placement, bearing strata description, and subsurface water conditions. Base location on the survey of the registered surveys or engineer provided by the Contractor. Tabulate all records, including corrective measures. Upon completion of caisson work, provide a record of centerline locations based on the survey of the registered surveyor or engineer provided by the Contractor. In addition, also record corrective measures. Deliver a complete tabulation of all records pertaining to approved caissons to the Contracting Officer.

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for [grouted] helical piles.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

NOTE: The extent and location of the work to be accomplished should be indicated on the project drawings or included in the project specification.

NOTE: Show the following information on the drawings:

1. Locations and design loads of piles. If both tension and compression piles are contained in
Design, identify by type.

2. Size, shape, and length of piles.

3. Locations of test piles, if required.

4. Soil data, where required.

5. Identify piles as vertical or battered.

PART 1 GENERAL

NOTE: Structural engineer must confirm the structural capacity of piles and provide specific bending moments, lateral loads and other design requirements for pile design.

1.1 DESCRIPTION

Design, furnish, install and test [grouted] helical piles at the locations indicated on the drawings and specified herein. [Test piles that meet performance requirements can be incorporated into the permanent work.]

1.1.1 Definitions

a. Helical Pile (helical pier or screw pile): Consists of 1) one or more helix plates attached to a central shaft and 2) load transfer device for attachment to a structure. May also include surface coating or other corrosion protection means.

b. Torque: The measure of the rotational force times the moment arm needed to overcome the shear strength of the soil N·m ft·lb. Torque is used in an empirical approach for predicting the ultimate capacity of a helical pile.

c. Minimum Installation Torque: Minimum torque necessary to attain the required pile capacity.

d. Maximum Torque Rating: Torque which if exceeded may cause damage to the pile or equipment.

1.2 REFERENCES

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature...
References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

[1.3 SUBSURFACE DATA

Subsurface soil data logs are indicated appended to the special contract requirements provided on the project drawings. The subsoil investigation report may be examined at [____].]

]1.4 BASIS OF BID

**************************************************************************
NOTE: Select one of the following options:
**************************************************************************

**************************************************************************
NOTE: Use "Lump Sum" paragraph below for lump (principal) sum bidding of piles. Use this in all projects except those where exact pile lengths cannot be practically determined prior to the actual work. Clearly show number of piles, pile capacity, pile locations, and tip and cutoff elevations on the drawings.

Use "Unit Price" paragraph for unit price bidding of
Specify unit price bid items for piles only for projects where exact quantities cannot be practically determined prior to the actual work. Lengths of piles must be determined as accurately as possible, prior to bidding, since the unit price per meter foot of the piles varies as the length increases or decreases. Refer to Standard Test Method for High-Strain Dynamic Testing of Deep Foundations (ASTM D4945).

1.4.1 Production Pile Acceptance Criteria

Safe design capacity for piles is [_____] KN kips. Install piles to [minimum tip elevation] [a minimum depth of [_____] m feet below cut-off elevation], and to such additional depth as required to obtain a bearing capacity of not less than [_____] KN kips. The Contractor's Geotechnical Consultant will determine the terminal installation criteria based on results of [dynamic pile installation tests] [static load tests].

For cases where allowable pile loads are less than 355 kN 80 kips (determined using a factor of safety of 3 for individual piles and 4 for pile groups, the end bearing geotechnical capacity of [grouted] helical piers may be estimated during installation by monitoring and recording the final installation torque and {[ applying torque correlation factors provided by the designer]} {[ applying default torque correlation factors for the central steel shaft per well-document correlations].} [Verify with the manufacturer that the correlation factors apply to their products.] The allowable end bearing capacity may be estimated as:

\[
Q_{all} = K_t \times T
\]

Where \( Q_{all} \) is the approximate allowable end bearing pile load in KN kips; \( T \) equals the final installation torque defined as the last torque reading taken during helical pile installation which must not exceed the maximum installation torque rating of the helical pile; and \( K_t \) is the torque correlation factor. Allowable skin friction resistance must be provided by the designer determined through a generally accepted method of analysis in accordance with UFC 3-220-01.

1.4.2 Lump Sum Payment

NOTE: Use this paragraph for lump-sum contracts, consult with Contracting Officer's Technical Representative (Geotechnical Branch) on applicability of use prior to selection. This paragraph will be typically used when there are 1) relatively small quantity of piles, 2) allowable pile loading is less than 355 kN 80 kips (and 3) the subsurface conditions are well defined. Fill in Table I as required selecting columns applicable to project. Generally, pile capacity, location, and minimum tip elevation are shown on plans. Test piles and load tests are not incorporated on lump sum contracts. Delete this paragraph for unit-price contracts.
Base bids upon providing the number, size, capacity, and length of piles as indicated on the drawings. [following Table 1:

<table>
<thead>
<tr>
<th>Location</th>
<th>Number</th>
<th>Size</th>
<th>Capacity</th>
<th>(Tip to Cut-Off)</th>
<th>Maximum Bending Moment</th>
<th>Maximum Shear Force</th>
</tr>
</thead>
</table>

Include the cost of all necessary equipment, tools, material, labor, and supervision required to: design, deliver, handle, install, cut-off, dispose of any cut-offs, and meet the applicable contract requirements. Include mobilization, pre-drilling, and reinstallation of heaved piles. If, in reinstallation, it is found that any pile is not of sufficient length to provide the capacity specified, notify the Contracting Officer, who reserves the right to increase or decrease the total length of piles to be provided and installed by changing the pile locations or elevations, requiring the installation of additional piles, or directing the omission of piles from the requirements shown and specified. If total number of piles or number of each length vary from that specified as the basis for bidding, an adjustment in the contract price or time for completion, or both, will be made in accordance with the contract documents. Payment for piles will be based on successfully installing piles to both the minimum tip elevation and satisfying the acceptance criteria identified herein. No additional payment will be made for: damaged, rejected, or misplaced piles; withdrawn piles; any portion of a pile remaining above the cut-off elevation; back installation; cutting off piles; splicing; build-ups; any cut-off length of piles; or other excesses beyond the assumed pile length indicated for which the Contractor is responsible. [Include payments for vibration monitoring, sound monitoring and precondition construction surveys].

1.4.3 Unit Price

**************************************************************************
NOTE: Delete this paragraph for lump-sum contracts.

For NAVFAC PAC projects: Where there is unit pricing for piles, use this paragraph and edit applicable attachments in price schedule for inclusion in Standard Form 1442, "Solicitation, Offer and Award" and "Schedule of Bid Items."

For NAVFAC Southeast projects, where there is a need for unit pricing of piles, include this paragraph. Refer to NAVFAC SE Instruction 00010, "Instructions for Preparing Basis of Bid Statement With Unit-Priced Items," for method of specifying unit price bid items.

**************************************************************************

For unit price bid, see SF 1442, "Solicitation, Offer and Award" and "Schedule of Bid Items."

**************************************************************************

NOTE: For NAVFAC LANT projects, use the following paragraph for measurement and payment and subsequent sub-parts.
Requirements of FAR 52.211-18 Variation in Estimated Quantity do not apply to payment for piling. Each pile and test pile acceptably provided will be paid for at the bid unit price per unit length, which will include items incidental to furnishing and installation of the piles including mobilization and demobilization, [jetting] [predrilling] [probing], reinstallation of uplifted piles, [an additional 1.5 m 5 feet in furnished length for any test pile not installed beyond estimated pile length,] and cutting off piles at the cut-off elevation.[ Include the cost for additional length for the test piles in the total unit price cost for the job.] Payment will be made for production [and test piles] at the bid unit price for the length of pile, from tip to final cut-off, actually provided, excluding buildups and splices directed by the Contracting Officer to be made. If the actual cumulative pile length installed (tip to cut-off) varies more than 25 percent from the total pile length specified as a basis for bidding, at the direction of the Contracting Officer, the unit price per unit length will be adjusted in accordance with provisions of FAR 52.236-2 Differing Site Conditions. [ Payments will be made per each at the respective bid unit price for pile cut-offs, pile build-ups, pile load tests and pile splices.][ Include payments for vibration monitoring, sound monitoring, construction instrumentation and monitoring, and precondition construction surveys].

NOTE: Delete this paragraph for lump-sum contracts.

If Section 01 20 00 PRICE AND PAYMENT PROCEDURES is included in the project specifications, this paragraph title (UNIT PRICES) should be deleted from this section and the remaining appropriately edited subparagraphs below should be inserted into Section 01 20 00 PRICE AND PAYMENT PROCEDURES.

1.5.1 Furnishing and Delivering [Grouted] Helical Piles

1.5.1.1 Payment

Payment will be made for costs associated with furnishing and delivering the required lengths of permanent [grouted] helical piles, [including H-pile extensions, ]which includes costs of furnishing and delivering piles to the work site. No payment will be made for the installation head or lengths of piles exceeding required lengths. No payment will be made for piles damaged during delivery, storage, or handling to the extent that they are rendered unsuitable for the work, in the opinion of the Contracting Officer.

1.5.1.2 Measurement

Furnishing and delivering permanent [grouted] helical piles will be measured for payment by the linear meter foot of piles required below the cut-off elevation as [determined by the Contracting Officer and furnished to the Contractor][indicated].
1.5.1.3 Unit of Measure

Linear \text{meter foot}.

1.5.2 Installation of [Grouted] Helical Piles

1.5.2.1 Payment

Payment will be made for costs associated with installation of permanent [grouted] helical piles, which includes costs of handling, installation, [and splicing of piles,] [performing dynamic testing, interpreting data and submitting reports,] measuring heave, reinstallation of heaved piles, removal of [build-ups] installation of heads or cutting off piles at the cut-off elevation and removing from the work site, compiling and submitting pile installation records, backfilling voids around piles, and any other items incidental to installation of piles to the required elevation.

1.5.2.2 Measurement

Permanent [grouted] helical piles will be measured for payment for installation on the basis of lengths, to the nearest \text{hundredth tenth} of a linear \text{meter foot}, along the axis of each pile acceptably in place below the cut-off elevation shown.

1.5.3 Pulled [Grouted] Helical Piles

1.5.3.1 Payment

Payment will be made for costs associated with piles pulled at the direction of the Contracting Officer and found to be undamaged. The cost of furnishing and delivering pulled and undamaged piles will be paid for at the applicable contract unit price for payment item "Furnishing and Delivering [Grouted] helical Piles". The cost of installation pulled and undamaged piles will be paid for at the applicable contract unit price for payment item "Installation of [Grouted] Helical Piles". The cost of pulling undamaged piles will be paid for at twice the applicable contract unit price for payment item "Installation of [Grouted] Helical Piles", which includes backfilling any remaining void. The cost of reinstallation of pulled and undamaged piles will be paid for at the applicable contract unit price for payment item "Installation of [Grouted] Helical Piles". No payment will be made for furnishing, delivering, installation, pulling, and disposing of piles, including piles pulled and found to be damaged and backfilling voids. New piles replacing damaged piles will be paid for at the applicable contract unit price for payment items "Furnishing and Delivering [Grouted] Helical Piles" and "Installation of [Grouted] Helical Piles".

1.5.3.2 Measurement

Furnishing and delivering pulled and undamaged permanent [grouted] helical piles will be measured for payment as specified in paragraph UNIT PRICES, subparagraph FURNISH AND DELIVER [GROUTED] HELICAL PILES. Pulling undamaged [grouted] helical piles will be measured for payment as specified in paragraph UNIT PRICES, subparagraph INSTALLATION OF [GROUTED] HELICAL PILES. Reinstallation pulled undamaged [grouted] helical piles will be
measured for payment as specified in paragraph UNIT PRICES, subparagraph
INSTALLATION OF [GROUTED] HELICAL PILES. New piles replacing damaged piles
will be measured for payment as specified in paragraph UNIT PRICES,
subparagraphs FURNISH AND DELIVER [GROUTED] HELICAL PILES and INSTALLATION
OF [GROUTED] HELICAL PILES.

1.5.3.3 Unit of Measure

Linear meter foot.

1.5.4 [Grouted] Helical Pile Installation Tests

1.5.4.1 Payment

Payment will be made for costs associated with furnishing, delivering,
installation, pulling, and disposing of installed test piles, [including
[pile installation points][ and ][splices];] conducting pile installation
tests; backfilling voids around piles; compiling pile installation test
records[; performing dynamic testing; interpreting data; and submitting
reports].

1.5.4.2 Measurement

[Grouted] helical pile installation tests will be measured for payment on
the basis of the applicable contract unit price per pile installation test.

1.5.4.3 Unit of Measure

Each.

1.5.5 [Grouted] Helical Piles for Load Tests

1.5.5.1 Payment

Payment will be made for costs associated with furnishing, delivering,
installation, pulling, and disposing of load test piles [and] [splices];
backfilling voids around piles; compiling pile installation records[;
furnishing, fabricating, and mounting of strain rods and protective
assembly][; furnishing, fabricating, and mounting of inclinometer and
inclinometer protective assembly][; performing dynamic testing;
interpreting data; and submitting reports]. No additional payment will be
made for load test piles incorporated in the permanent work other than as
provided.

1.5.5.2 Measurement

[Grouted] helical piles for load tests will be measured for payment on the
basis of the applicable contract unit price per load test pile.

1.5.5.3 Unit of Measure

Each.

1.5.6 [Grouted] Helical Pile Static Axial Compressive Load Tests

1.5.6.1 Payment

Payment will be made for costs associated with [grouted] helical pile
static axial compressive load tests in accordance with ASTM D1143/D1143M,
including material and labor for fabricating and furnishing load frames; calibrating load cells and hydraulic jacks; furnishing specified test equipment; installing strain rods; placing and removing test loads and test equipment; recording, reducing, and submitting test data; and compiling and submitting pile load test reports. No payment will be made for rejected pile static axial compressive load tests.

1.5.6.2 Measurement

[Grouted] helical pile static axial compressive load tests will be measured for payment on the basis of the applicable contract unit price per load test.

1.5.6.3 Unit of Measure

Each.

][1.5.7  [Grouted] Helical Pile Static Tensile Load Tests

1.5.7.1 Payment

Payment will be made for costs associated with [grouted] helical pile static tensile load tests in accordance with ASTM D3689, including material and labor for fabricating and furnishing load frames; calibrating load cells and hydraulic jacks; furnishing specified test equipment; installing strain rods; placing and removing test loads and test equipment; recording, reducing, and submitting test data; and compiling and submitting pile load test reports. No payment will be made for rejected pile static tensile load tests.

1.5.7.2 Measurement

[Grouted] helical pile tensile load tests will be measured for payment on the basis of the applicable contract unit price per number of tensile load test.

1.5.7.3 Unit of Measure

Each.

][1.5.8  [Grouted] Helical Pile Lateral Load Tests

1.5.8.1 Payment

Payment will be made for costs associated with [grouted] helical pile lateral load tests in accordance with ASTM D3966/D3966M, including material and labor for fabricating and furnishing load frames; calibrating load cells and hydraulic jacks; furnishing specified test equipment; installing inclinometers; placing and removing test loads and test equipment; recording, reducing, and submitting test data; and compiling and submitting pile load test reports. No payment will be made for rejected pile lateral load tests.

1.5.8.2 Measurement

[Grouted] helical pile lateral load tests will be measured for payment on the basis of the applicable contract unit price per lateral load test.
1.5.8.3 Unit of Measure

Each.

1.5.9 Pulled Load Test [Grouted] Helical Piles

1.5.9.1 Payment

Payment will be made for costs associated with load test [grouted] helical piles pulled prior to load testing at the direction of the Contracting Officer and found to be undamaged. The cost of furnishing, delivering, installation, and pulling undamaged load test piles will be paid for at the applicable contract unit price for payment item "[Grouted] Helical Piles for Load Tests". The cost of pulling undamaged load test piles the second time after reinstallation and testing will be paid for at twice the applicable contract unit price for payment item "Installation of [Grouted] Helical Piles". The cost of reinstallation pulled undamaged load test piles will be paid for at the applicable contract unit price for payment item "Installation of [Grouted] Helical Piles". No payment will be made for furnishing, delivering, installation, pulling, and disposing of load test piles pulled at the direction of the Contracting Officer and found to be damaged. New load test piles replacing damaged piles will be paid for at the applicable contract unit price for payment item "[Grouted] Helical Piles for Load Tests".

1.5.9.2 Measurement

Pulled undamaged load test [grouted] helical piles will be measured for payment as specified in paragraph UNIT PRICES, subparagraph [GROUTED] HELICAL PILES FOR LOAD TESTS. Pulling undamaged load test [grouted] helical piles the second time after reinstallation and testing will be measured for payment as specified in paragraph UNIT PRICES, subparagraph INSTALLATION OF [GROUTED] HELICAL PILES. Reinstallation of pulled undamaged [grouted] helical piles will be measured for payment as specified in paragraph UNIT PRICES, subparagraph INSTALLATION OF [GROUTED] HELICAL PILES. New load test [grouted] helical piles replacing damaged piles will be measured for payment as specified in paragraph UNIT PRICES, subparagraph [GROUTED] HELICAL PILES FOR LOAD TESTS.

1.5.9.3 Unit of Measure

as specified in paragraph UNIT PRICES, subparagraphs INSTALLATION OF [GROUTED] HELICAL PILES and [GROUTED] HELICAL PILES FOR LOAD TESTS, respectfully.

1.5.10 [Grouted] Helical Pile Splices

1.5.10.1 Payment

Payment will be made for costs associated with [grouted] helical pile splices, including all plant, labor, and material required to make the splice.

1.5.10.2 Measurement

[Grouted] helical pile splices will be measured for payment on the basis of the applicable contract unit price per pile splice.
1.5.10.3  Unit of Measure
   Each.

][1.5.11  Vibration Monitoring
1.5.11.1  Payment
   Payment will be made for costs associated with vibration monitoring.
1.5.11.2  Measurement
   Vibration monitoring will be measured for payment on the basis of the applicable contract unit price per vibration monitoring point.
1.5.11.3  Unit of Measure
   Each.

][1.5.12  Sound Monitoring
1.5.12.1  Payment
   Payment will be made for costs associated with sound monitoring.
1.5.12.2  Measurement
   Sound monitoring will be measured for payment on the basis of the applicable contract unit price per vibration monitoring point.
1.5.12.3  Unit of Measure
   Each.

][1.5.13  Preconstruction Condition Survey
1.5.13.1  Payment
   Payment will be made for costs associated with preconstruction condition surveys.
1.5.13.2  Measurement
   Preconstruction condition survey will be measured for payment on the basis of the applicable contract unit price per structure to be surveyed.
1.5.13.3  Unit of Measure
   Each.

][1.5.14  Construction Instrumentation and Monitoring
1.5.14.1  Payment
   Payment will be made for costs associated with construction instrumentation and monitoring.
1.5.14.2 Measurement

Construction instrumentation and monitoring will be measured as a single pay item.

1.5.14.3 Unit of Measure

One.

1.6 SUBMITTALS

**************************************************************************

NOTE: Review Submittal Description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy, Air Force, and NASA projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy, Air Force, and NASA projects, or choose the second bracketed item for Army projects.

**************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-01 Preconstruction Submittals

Installation Procedures; G[, [____]]
1.7 DELIVERY, STORAGE, AND HANDLING

Use methods for handling, transporting and storage of piles such that the piles are not subjected to excessive bending stress, cracking, spalling, or other damage. Follow the handling instructions of the manufacturer.

1.7.1 Damaged Piles

Inspect each pile for structural damage before transporting them to the project site and immediately prior to installation. Bring any damage to
the attention of the Contracting Officer. Piles which are damaged during delivery, storage, or handling to the extent they are rendered unsuitable for the work, in the opinion of the Contracting Officer, will be rejected and removed from the project site, or may be repaired, if approved, at no cost to the Government.

Any pile damaged by reason of internal defects or by improper installation must be corrected by one of the following methods approved by the Structural Engineer of Record for the pile in question:

a. The pile is withdrawn, if practicable, and replaced by a new and, if necessary, longer pile.

b. One or more replacement piles are installed adjacent to the defective pile.

c. A Pile Dynamic Analysis and low integrity testing must be performed by the Contractor's Geotechnical Consultant to assess the structural integrity of the installed pile(s).

A pile installed below the specified butt elevation must be corrected by one of the following methods approved by the Engineer:

a. The pile is spliced (if approved).

b. A sufficient portion of the footing is extended down to properly embed the pile.

A pile installed out of its proper location or out of plumb as approved by the Engineer, must be corrected by one of the following methods approved by the engineer:

a. One or more replacement piles are installed next to the pile in question.

b. As directed by the structural engineer.

1.8 QUALITY CONTROL

1.8.1 Piles

Prepare and submit shop drawings. Indicate placement of piles. Indicate location of special embedded or attached lifting devices, employment of pick-up points, support points other than pick-up points, and any other methods of pick-up. Submit product designations for pile sections and connections.

1.8.2 [Grouted] Helical Pile Design

Submit data including: type material, and size of grout and helical system; maximum torque rating of system, calculations determining minimum installing torque, minimum and maximum pile depth requirements[, location and inclination tolerance requirements] and pile capacity. Design must be stamped by a Professional Engineer registered in the state of [_____] who is experienced with [grouted] helical pile foundations.

1.8.3 Pile Grout Mix Design

Submit copies of laboratory test reports showing that the pile grout mix
has been successfully tested to produce grout with the properties specified and that the mix must be suitable for the job conditions. Include mill tests and all other tests for cement, aggregates, and admixtures in the laboratory test reports. Provide maximum nominal aggregate size, gradation analysis, percentage retained and passing sieve, and a graph of percentage retained verses sieve size. Submit test reports along with the grout mix design. Obtain approval before grout placement.

]1.8.4 Manufacturer's Quality Control Procedures

Submit the pile manufacturer's quality control procedures.

1.8.5 Installation Procedures

a. Submit information on the type of equipment proposed to be used, proposed methods of operation, pile installation plan including proposed sequence of installation, and details of all pile installation equipment and accessories. Submit pile placement plans at least 30 calendar days prior to delivery of piles to the job site.

b. Provide detailed procedures for conducting the dynamic pile load test and equipment to be used for conducting the load test. The detailed description must explain how specific information of pile performance will be evaluated.

]1.8.6 Contractor Certification for Helical Pile Installation

[Grouted] helical piles must be installed by a contractor with a minimum of 5 years of experience with the installation of [grouted] helical pile foundations in similar soil conditions of the project site. Contractor must submit past project lists indicating their experience with such foundation systems. The Contractor must be trained and certified by a helical pile manufacturer in the proper methods of design and installation of [grouted] helical pile foundations. The Contractor must submit a copy of their current certification for helical pile foundation Installation. Data must include a list and description of equipment to be used, including manufacturer's catalog data and sufficient information to show compliance with the requirements specified.

]1.8.7 Contractor's Geotechnical Consultant

Hire the services of an independent, Registered Professional Geotechnical Engineer, experienced in [grouted] helical pile foundation system, soil mechanics and Pile Dynamic Analysis, to observe test pile installation and production pile installation as specified herein. The Contractor's Geotechnical Consultant must be independent of the Contractor and must have no employee of employer relationship which could constitute a conflict of interest. Submit consultant qualifications and documentation at least 28 calendar days prior to pile installation.

]1.8.8 Load Test Supporting Data

Submit Jack calibration records, a testing arrangement description and diagram, and the proposed loading sequence.

]1.8.9 Silica Fume Manufacturer's Representative

Provide statement that the manufacturer's representative will be present at plant to ensure proper mix, including high range water reducer (HRWR), and
batching methods.

PART 2 PRODUCTS

2.1 [GRouted] HELICAL PILE SYSTEM

The shaft of the [grouted] helical pile system must consist of a solid, steel square bar with one to four steel helical plates welded to the shaft, as required. The helical extension shafts, if required, must consist of steel square bar shafts with one or two steel helical formed plates. A coupling method is to be provided for the helical extensions by the contractor. The same square section bar material is to be used for helical pile extensions as is used for the lead extensions. Each extension is to be provided with a means of coupling to a lead section or to another extension. Each coupling may be forged integral to the extension or a separate sleeve type. Each coupling is to be supplied with proper bolts(s) and nut(s) to develop the rated strength. Termination must consist of the bar material being cut off to the proper elevation and a steel termination plate field welded or bolted to the end of the bar material. All steel components of the [grouted] helical pile system must be steel with an ASTM A153/A153M or ASTM A123/A123M hot dipped galvanizing. Displacement plates (lead or extension plates) must be fabricated from steel or other material that will not affect the structural integrity of the central steel shaft[ or grout column]. Displacement plates must not be made out of timber.[ All grout components of [grouted] helical piles must have a 28 day compressive strength of 28,000 kPa 4,000 psi or greater. For purposes of bidding, pile capacity must be as indicated on the drawings.]

Submit details and material data for pile connections and splices.

2.2 GROUT

2.2.1 Cement

ASTM C1157/C1157M, [Type G].

2.2.2 Water

Provide fresh, clean, potable water free from injurious amounts of sewage, oil, acid, alkali, salts, or organic matter.

2.2.3 Aggregates

Fine aggregate for sand-cement grout must conform to ACI 301M ACI 301 and [ ASTM C33/C33M for grout for backfilling holes] [or ASTM C144 for grout for pregrouting]. Aggregates must not contain substances which may be deleteriously reactive with alkalis in the cement.

2.2.4 Admixtures

******************************************************************************
NOTE: Accelerators are not permitted because of concern that they may cause corrosion of the steel. Only plasticizers or retarders should be permitted when necessary for hot conditions or long pumping distances.
******************************************************************************

Admixtures which control bleed, improve flowability, reduce water content
and retard set may be used in the grout subject to the approval of the Contracting Officer. Any admixtures used must be compatible with the prestressing steel and must be mixed in accordance with the manufacturer's recommendations.

2.3 EQUIPMENT

2.3.1 Installation Equipment

Equipment must be capable of providing continuous measurement of applied torque throughout the installation process. Equipment must be capable of applying sufficient down pressure to install the pile and must include appropriate gauges to indicate the down pressure applied. Equipment must have sufficient capacity to reverse rotation and uplift to withdraw pile. Percussion drilling equipment is not permitted. Install head must be capable of multiple positioning to accommodate adjustments in pile alignment.

2.3.2 Installation Tooling

Sufficient wrench extensions must be provided to advance the lead section a distance not less than 50 percent greater than the pile length indicated on the drawings. All installation tooling must be capable of transmitting the maximum torque of the installation machinery.

2.3.3 Torque Monitoring Equipment

Submit a calibration report (performed by an independent testing agency) for each torque indicator to be used. The report must include: the name, address, and phone number of testing agency; name of the project; name of the contractor; identification of torque indicator; date of calibration; and calibration data. The equipment calibration must be performed within six months from the start of the installation.

Device must be capable of providing continuous measurement of applied torque throughout the installation process in increments of 680 Newton meter or 500 foot pounds or less. Torque indicators which are internal with respect to installation equipment must be calibrated on-site. Torque indicators which measure torque as a function of the hydraulic pressure of the installation equipment must be calibrated at normal operation temperatures. Devices must be protected from shock, impact, or other adversities that may affect their operation. A torque indicator must be recalibrated if, in the opinion of the Contracting Officer, it has been exposed to conditions which may adversely influence the accuracy of the torque measurements.

**************************************************************************
NOTE: Suggestions for improvement of this specification are welcomed and should be submitted as a Criteria Change Request (CCR). To submit a Criteria Change Request, click on the CCR link next to the specific document located at: https://www.wbdg.org/ffc/dod/unified-facilities-guide-specifications-ufgs
**************************************************************************
PART 3 EXECUTION

3.1 PRELIMINARY WORK

3.1.1 Order List

Submit to the Contracting Officer for approval, an itemized list for piles prior to placing the order with the supplier. Indicate the pile lengths required at each location as shown on the plans and the corresponding ordered length of each pile in the list.[ Complete load testing and refined wave equation analysis and submit to Government for review and approval prior to submission of an order list.]

3.2 INSTALLATION PROCEDURES

It is the responsibility of the contractor to determine the location of any buried utilities before starting construction. If underground obstructions are encountered during installation, the contractor must stop work immediately and contact the Contracting Officer who will decide whether the obstruction is to be removed or the [grouted] helical pile relocated. The contractor must resume work only upon receipt of the Contracting Officer's decision.

3.2.1 Pre-Drilling

Pre-drilled starter holes will be required for penetrating through hard natural strata or fills. Omitting drilling or augering will be permitted only with the approval of the Contracting Officer. The hole must be no greater than two-thirds of the average helices diameter. The drilling or augering must not be deeper than required to bypass the obstructing layer. Drilling deeper than 3 meters 10 feet above the estimated pile tip elevation is not permitted. Field modification of pre-drilling operations will be permitted based on the recommendations of the Owner's Geotechnical Consultant and with the approval of the Contracting Officer.

3.2.2 Positioning, Alignment, and Advancing the Helical Lead Section

The pile must be positioned at the location indicated. Advance the helical lead section in a smooth and continuous manner. Avoid abrupt starts after interruptions. Apply sufficient down pressure to advance the lead section approximately 75 mm 3 inches per revolution. Maintain the penetration rate by adjusting the rate of rotation and magnitude of down pressure for different soil condition and depths.

A lead displacement plate of appropriate diameter must be positioned on the central steel shaft at the location necessary to install the grout column as shown on the drawings. The lead displacement plate must not be located closer than 300 mm 12 inches above the top helical plate. Extension displacement plates must be positioned on the central steel shaft at a minimum of every coupling joint. Displacement plates must not be spaced more than 2 meters 7 feet apart. Displacement plates must permit the free flow of grout without misalignment of the central steel shaft.

[ Grout must be mixed with equipment capable of providing a steady supply at the required level of production. The grout must be placed via a gravity fed reservoir located at the surface. The reservoir must consist of a temporary casing or form, which is capable of containing liquid grout. The reservoir must be appropriately sized (diameter and length) to accommodate the soil conditions and grout column diameter. The grout must be placed in
the reservoir immediately prior to the advancement of the first lead displacement plate into the soil. The volume of grout contained in the reservoir must be maintained at a level sufficient to maintain positive hydrostatic pressure on the grout column.

Grout placement must continue until the minimum grout column length has been achieved as shown on the working drawings. Volume measurements must be taken throughout the installation in order to determine the actual grout column diameter. Grout must be allowed to attain the minimum design strength prior to being loaded.

3.2.3 Rejected Piles

Withdraw piles damaged or impaired for use during handling or installation, mislocated, or installed out of alignment beyond the maximum tolerance. Replace with new piles or cut-off and abandon damaged or impaired piles and install new piles as directed. Remove excess cut-off from piles and unacceptable piles from the work site. Perform all work in connection with withdrawing and removing rejected piles from the site at no additional cost to the Government.

3.2.4 As-Installed Survey

After the installation of each pile group is complete and before concrete is placed, provide the Contracting Officer with an as-installed survey showing actual location and top elevation of each pile. Submit survey within [7] [_____] calendar days of completing the test and production pile installation. Do not proceed with placing concrete until the Contracting Officer has reviewed the survey and verified the safe load for the pile group installed. Present a survey in such form that it gives deviation from plan location in two perpendicular directions and elevations of each pile to nearest 13 mm half inch. Survey must be prepared and certified by a licensed land surveyor.

3.2.5 Termination Criteria

If the required minimum installation torque is reached before the minimum length is achieved, the installation must continue until the minimum length is attained. However, the installation torque must not exceed the maximum torque rating (refer paragraph DEFINITIONS in PART 1) of the pile or equipment. If the maximum torque rating is reached before the minimum length is achieved, the Contractor must stop torquing operations and contact the Contracting Officer. The average torque for the last 3 feet of penetration must be used as a basis of comparison with the minimum installation torque.

3.2.6 [Grouted] Helical Pile Installation Records

For each pile installed, provide a formal record including the following:

a. Name of project, contractor and contractors superintendent.

b. Date and time of installation.

c. Name and model of installation equipment and operator name.

d. Type of torque indicator.

e. Location of pile.
f. Time and duration of pile installation.
g. Elevation of lead pile.
h. Total length of installed pile.
i. Identification of lead section (manufacturer's description and catalog number).
j. Identification of extensions (manufacturer, diameter, minimum ultimate strength).
k. Number of displacement plates/centralizers and their location.
l. Down pressure applied.
m. Installation torque [and grout flow] at one-foot intervals.
n. Effective torsional resistance and calculated geotechnical capacity based on the effective torsional resistance and as derived from the pre-production test program.
o. Comments pertaining to interruptions, obstructions or other pertinent information.

3.2.7 Protection of Existing Structures

**************************************************************************
NOTE: Include this paragraph only when protection of existing structures from pile installation activities is required.

The designer must indicate on the drawings all structures and facilities for which protection is required. The designer must also provide a project specific document that details design criteria, requirements for preconstruction condition surveys, post construction condition surveys, geotechnical instrumentation to measure ground movements and any other requirements.

Add any additional requirements as necessary.
**************************************************************************

Mitigate impact on existing facilities due to pile installation activities in accordance with the [project specific document] [____].

3.2.8 Disposal of Excavated Material

Do not leave any piles partially completed overnight. Completely [grout and] protect piles at the termination of each day's operation. Dispose of excavated material, resulting from augering, [within the area indicated] [off Government property] [____].
3.3 FIELD TESTS

3.3.1 Test Piles

**************************************************************************
NOTE: Select the second bracketed option when soil conditions dictate the use of a test pile longer than production piles. The ordered pile length for test piles should be 1.5 m 5 feet longer than ordered length for production piles to allow additional penetration if installation conditions dictate. Indicate location and number (if required) of test piles on plans, or list appropriate soil boring test hole numbers.
**************************************************************************

[Use test piles of specified type, and install as specified for piling elsewhere in this section.][ Order test piles [_____] meters [feet] longer in length than production piles. Install the additional test pile length only at the direction of the Contracting Officer.]  The [Contractor's Geotechnical Consultant] [Contracting Officer] will use test pile data to determine "calculated" pile tip elevation or necessary installation criteria. Install test piles [at the locations indicated] [in vicinity of soil boring test holes Nos. [____], [____], and [____]]. Install test piles to [indicated tip elevation] [indicated bidding lengths] [required installation criteria]. Use test piles, if located properly and offering adequate installation resistance in finished work.[ Pre-drilling or jetting is permitted only when test piles clearly establish validity of its use, or as directed by the Contracting Officer.]  Provide and operate a pile driving analyzer as specified in paragraph DYNAMIC PILE ANALYSIS during the installation of each test pile. Modify installation as required based upon recommendation of [Contracting Officer] [Contractor's Geotechnical Consultant and approval of the Contracting Officer]. Submit test set-up and procedures.

3.3.1.1 Dynamic Pile Analysis

Dynamic testing provides supplemental information for evaluating pile integrity, hammer and install system performance, assess pile installation stresses, and pile capacities. Perform dynamic testing on [_____] percent of the [test] piles during the full length of the pile installation and during restrike a minimum of [_____] days after initial installation. Dynamic pile testing must also be performed on [_____] production piles as chosen by the Contracting Officer. Use [test] piles of type as specified elsewhere in this section. Provide equipment to obtain dynamic measurements, record, reduce and display its data that meet the requirements of ASTM D4945. The equipment must have been calibrated within [6] [_____] months prior to the start of the testing operations and thereafter throughout the contract duration. Install [test] piles at the locations indicated or at the locations selected by the Contracting Officer. Employ an independent inspection firm, hereinafter referred to as the "Contractor's Geotechnical Consultant", experienced in the pile installation process[, monitoring of test pile installation,] and in the use of the Pile Driving Analyzer and its related equipment. Perform dynamic pile analysis as follows:

][3.3.1.2 Pile Analyzing

[_____] working days prior to installation the [test] piles, submit the
pile and complete installation equipment data to the Contracting Officer. The Contractor's Geotechnical Consultant must use the submitted information to perform wave equation analyses and must prepare a summary report of the wave equation results. The wave equation analysis using GRLWEAP software by Pile Dynamics, Inc. or equivalent must be used to assess the ability of the proposed installation system to install the pile to the required capacity and desired penetration depth within the allowable installation stresses. Approval of the proposed installation system by the Contracting Officer must be based upon the wave equation analyses indicating that the proposed installation system can develop a pile capacity of [_____] kN kips.

][3.3.1.3 CAPWAP

Signal matching analysis by CAPWAP software of the dynamic pile testing data must be performed on data obtained from the end of initial installation and the beginning of restrike of all control piles. CAPWAP analyses must be performed by an engineer who has achieved Advanced Level or better on the PDI / PDCA Dynamic Measurement and Analysis Proficiency Test for Providers of PDA Testing Services.

Upon completion of [test] pile installation, allow the piles to set-up for at least [72 hours] [_____ days]. After evaluation of pile, hammer and soil performance by the Contractor's Geotechnical Consultant, the second step of the dynamic pile analysis may proceed. This portion of the evaluation requires striking the set-up piles a minimum of 20-50 times, or as directed by the Contractor's Geotechnical Consultant "Warm up" the hammer and make it optimally ready prior to restriking, in order to avoid capacity losses during evaluation of restrike data. Apply maximum hammer energy during restrike in order to fully mobilize the soil resistance. However, exercise care so as to not overstress the pile. In addition to those items listed above, selected restrike installation records (as directed by the Contractor's Geotechnical Consultant are to be subjected to rigorous computer analysis by the Case Pile Wave Analysis Program (CAPWAP) for determination of resistance distribution, soil resistance and properties, and plot of applied load vs. average pile displacement based on the calculated soil properties.

][3.3.1.4 Dynamic Load Test Reporting

a. Upon satisfactory completion of each dynamic load test, submit[ a minimum of three copies of] a Pile Performance Report for the Contractor by the Contractor's Geotechnical Consultant. The submittal must be prepared and sealed by a Professional Engineer registered in [______].

b. The report for the Dynamic Pile Analysis must contain the following information:

(1) Capacity of pile from Case Pile Wave Analysis Program (CAPWAP). Information resulting from analysis of a selected restrike blow.

(2) Maximum and final transferred energy, hammer system efficiency during pile installation.

(3) Maximum compressive stress, velocity, acceleration and displacement.

(4) Maximum tensile stress in pile.
(5) Pile structural integrity, damage detection, extent and location.

(6) Blows per minute and blow number.

(7) Input and reflection values of force and velocity, upward and downward traveling force wave with time.

(8) Pile skin friction and toe resistance distribution.

(9) Maximum energy transferred to pile.

c. The maximum allowable pile design load must be proposed by the Contractor's Geotechnical Consultant based upon the results of a satisfactory pile load test conducted on a pile installed as specified herein and must include the effects of load transfer to the soil above the foundation stratum.

Use either a model Model 8G as manufactured by Pile Dynamics, Inc., of Cleveland Ohio or approved equivalent, for dynamic load testing of the test pile. All equipment necessary for the dynamic monitoring such as sensors, cables or wireless transmitters, etc., must be furnished by the Contractor's Geotechnical Consultant. The equipment must conform to the requirements of ASTM D4945.

Pay for all services of the Contractor's Geotechnical Consultant. The Contractor's Geotechnical Consultant must be available throughout the pile installation operation to consult with the Contracting Officer when required by the Contracting Officer. The cost of changes in the Contractor's procedure, as required by evaluation of the results of the Pile Installation Analysis, will be at the Contractor's expense.

3.3.2 Compression Tests

Perform load tests at the test pile locations indicated on the drawings. Perform "quick test" in accordance with ASTM D1143/D1143M. Provide apparatus for applying vertical loads as required by method, using load from weighted box or platform or reaction frame attached to sufficient uplift piles to safely take the required load applied to pile hydraulic jack. Increase load in increments until rapid progressive settlement takes place or until application of total load equals 200 percent of the design load, whichever occurs first. Equipment utilized to measure pile movements must be as outlined in ASTM D1143/D1143M Section 7. Maintain a data plot of load versus movement during the test procedures. [Determine the safe design capacity of a test pile as determined from the results of load tests according to UFC 3-220-01.][Safe design capacity will be based on the maximum axial deflection of [25 mm one inch] [5 percent of helix diameter] [the deflection criteria as stated on the plans or drawings].]

3.3.3 Tensile Load Test

Perform tensile load tests on [_____] test piles in accordance with ASTM D3689, as modified [and] in paragraph LOAD TESTS. Apply a tensile load of [_____] kN kips to each tensile load test pile. In performing the tension load test, apply the ultimate load equal to one and one-half times the safe tension capacity, and employ the Standard Loading Procedure.

Perform dynamic measurements on [_____] piles designated as dynamic test piles in accordance with ASTM D4945 during installation. During easy installation, ensure that damaging tension stresses do not develop in the
pile. Signal matching must be performed by the Contractor's Geotechnical Consultant on representative data collected at the end of the initial installation and at the beginning of all restrike events. Additional signal matching analysis must be performed as determined by the Engineer.

][3.3.4 Lateral Load Test

Perform lateral load tests on [___] piles in accordance with ASTM D3966/D3966M, as modified [and] in paragraph LOAD TESTS. Lateral load tests must consist of jacking two piles apart with a hydraulic jack, with one pile serving as the reaction pile for the other. Apply a lateral load of [___] kN kips to each pair of lateral load test piles. Record required movement readings for each pile.

]3.3.5 Field Test Report

A Load Test Report must be submitted by the Contractor's Geotechnical Consultant upon satisfactory completion of each load test. The submittal must be prepared and stamped by a Professional Engineer registered in the State of [___] and must be made within three working days of the completion of the load test. The Load Test Report must contain the following information at a minimum:

a. Name or project, contractor and contractor's superintendent.

b. Name of the third party testing agency.

c. Date, time, and duration of test.

d. Type of test.

e. Name of test equipment and description of test set-up.

f. Equipment calibration data.

g. Location of pile and identification number.

h. Pile installation record, reaction piles and test pile.

i. Load increments and duration of each increment.

j. Time and amount of each interval reading.

k. Cumulative pile movement after each increment.

l. Maximum applied load.

m. Data plot of load versus movement.

n. Comments pertaining to interruptions, equipment adjustments or other pertinent information.

3.3.6 Pile Records

*************************************************************************
NOTE: Omit reference to load test when not required in project. Omit reference to test piles and "calculated tip elevation" when test piles are not installed. Where special or unusual soil conditions
are expected, consultation with the Contracting Officer's Technical Representative (Geotechnical Branch) regarding special engineering supervision of installation, testing, recording and analysis of data for project may be useful.

**********************************************************************************************

NOTE: The Specifier must attach the specifications pile installation log graphic (for all pile installation projects) and the pile installation equipment data form (for projects using PDA) to the end of this specification section.

**********************************************************************************************

Keep a complete and accurate record of each pile installed. Indicate the pile location, deviations from pile location, cross section shape and dimensions, original length, ground elevation, tip elevation, cut-off elevations[, batter alignment]. Include in the record the beginning and ending times of each operation during installation of pile. Record retap data and unusual occurrences during pile installation such as reinstallation, heaving, weaving, splicing, obstructions, [jetting,] and any installation interruptions.[ Install an energy monitor on the hammers and record readings every 300 mm 12 inches of pile installation.] A preprinted pile installation log for recording pile installation data[ and pile installation equipment data form], which can be downloaded at: http://www.wbdg.org/ffc/dod/unified-facilities-guide-specifications-ufgs/forms-graphics-tables.

3.3.7 Testing Agency Qualifications

Engage an independent testing agency qualified according to ASTM C1077 and ASTM E329 for testing indicated. Submit testing agency qualifications to the Contracting Officer for approval.

3.3.8 Flow Cone Test

The quantity of water used shall produce a grout having a consistency of not less than 21 seconds when tested with a flow cone in accordance with ASTM C939/C939M.[ For specified flow cone rates in the range of 10 to 25 seconds, the flow cone shall be modified by removal of the 13 mm 1/2 inch orifice allowing grout to pass through the 19 mm 3/4 inch hole in bottom of cone.][ Water retentive grouts that demonstrate cohesive or thixotropic properties may be more accurately tested for workability with a standard slump cone using Slump Flow (commonly referred to as a "spread" test) as described in ASTM C1611/C1611M. The Slump Flow or "Spread" test employs the use of the standard concrete slump cone.]

Conduct tests at the beginning of grout injection and at subsequent intervals to ensure specification requirements are met.

3.3.9 Grout Specimens

Conduct grout tests in accordance with ASTM C31/C31M, ASTM C39/C39M and ASTM D942. Prepare test specimens of grout by pouring grout into 50 mm 2 inch cubes. Cure and test in accordance with ASTM C109/C109M. Cube specimens must be restrained from expansion as described in ASTM C942/C942M.[ Prepare test specimens of grout by pouring grout [150 mm by 300 mm 6 inch by 12 inch cylinders], [76 mm x 150 mm 3 inch by 6 inch], [50 mm by 100 mm
2 inch by 4 inch) cylinders. Provide molds with a top cover plate so designed as to restrain grout expansion and to permit escape of air and water.

Not less than one set of cylinders shall be collected for each 38 m³ 50 cy of grout placed, or at least one set for each day during which piles are placed. Test 2 [_____] cubes at 7 [_____] days, 2 [_____] cubes tested at 28 [_____] days, and 2 [_____] cubes held in reserve. One set shall consist of six [_____] cubes [cylinders]. Any set of cubes [cylinders] of which one or more cylinders test at 10 percent or more below the required strength shall be cause for rejection of the pile group.

[3.4] SPECIAL INSPECTION AND TESTING FOR SEISMIC-RESISTING SYSTEMS

**************************************************************************
NOTE: Include this paragraph only when special inspection and testing for seismic-resisting systems is required by the International Building Code (IBC).

This paragraph will be applicable to both new buildings designed and to existing building seismic rehabilitation designs done according to UFC 1-200-01, "General Building Requirements" and UFC 3-301-01 "Structural Engineering" and UFC 3-301-02, "Design of Risk Category V Structures, National Strategic Military Assets".

The designer must indicate on the drawings all locations and all features for which special inspection and testing is required in accordance with Chapter 17 of the IBC. This includes indicating the locations of all structural components and connections requiring inspection.

Add any additional requirements as necessary.
**************************************************************************

Perform special inspections and testing for seismic-resisting systems and components in accordance with Section 01 45 35 SPECIAL INSPECTIONS.

[3.5] VIBRATION CONTROL

**************************************************************************
NOTE: Include this paragraph when vibration monitoring is required. Add any additional criteria or requirements as necessary to the particular project. This section can normally be deleted for most [grouted] helical pile projects.
**************************************************************************

Perform vibration monitoring at the locations [shown in the plan] [decided by the Contracting Officer] during the pile installation operations. Perform vibration monitoring [using] [seismographs] [and geophones] within a distance of 61 meters 200 feet from the pile installation activity. Engage the services of a qualified, independent vibration consultant, acceptable to the Government, to conduct the vibration monitoring. The vibration consultant must have minimum of [five] [_____] years of experience in vibration monitoring. A minimum of [28] [_____] days before the installation of vibration monitors, submit to the Government the name
of the vibration consultant and a list of at least [three] [_____] previously completed projects of similar scope and purpose.

Prior to the pile installation activities, obtain baseline readings of ambient vibrations. The vibration during the pile installation activities must be limited to [a peak particle velocity of not more than 5 cm 2 inches per second] [the limits mentioned in the [contract documents]]. [Determine appropriate vibration limits as per [US Bureau of Mines] [American Association of State Highway and Transportation Officials (AASHTO)] guidelines.] During pile installation activities, monitor the vibrations to ensure the limits are not exceeded. If the limits are exceeded, cease the pile installation activity causing the vibration until [the Vibration consultant and the Contracting Officer] [_____] are on site to observe the structures nearest to the vibration monitor which has exceeded the limits.

The Contractor must be responsible for all damages resulting from the pile installation operations and must take whatever measures necessary to maintain peak particle velocity within the specified limit. After completion of the project, remove the vibration monitors off the site and off Government property and restore the monitoring locations back to their original condition.

[3.6 NOISE CONTROL]

**************************************************************************
NOTE: Include this paragraph when noise monitoring is required. Add any additional criteria, references or requirements as necessary to the particular project. This section can normally be deleted for most [grouted] helical pile projects.
**************************************************************************

Perform noise monitoring at the locations [shown in the plan] [decided by the Contracting Officer] [at noise sensitive public areas] during the pile installation operations. [Perform noise monitoring using [noise meters], and] [_____] [Engage the services of a qualified, independent noise consultant, acceptable to the Government, to conduct the noise monitoring. The noise consultant must have minimum of [five] [_____] years of experience in noise monitoring. A minimum of [28] [_____] days before the installation of noise monitors, submit to the Government the name of the noise consultant and a list of at least [three] [_____] previously completed projects of similar scope and purpose.]

Prior to the pile installation activities, obtain baseline readings of ambient noise levels. [The noise limits are mentioned in the [plan] [contract documents].] [Determine appropriate noise limits as per [local agency] [Occupation Safety and Health Administration] guidelines.] During pile installation activities, monitor the noise to ensure the limits are not exceeded. If the limits are exceeded, cease the pile installation activity and install noise mitigation measures.

The Contractor must be responsible for all damages resulting from the pile installation operations and must take whatever measures necessary to maintain noise within the specified limit. After completion of the project, remove the noise monitors off the site and off Government property and restore the monitoring locations back to their original condition.
3.7 PRECONSTRUCTION CONDITION SURVEY

**************************************************************************
NOTE: Add any additional criteria, references or requirements as necessary to the particular project.
**************************************************************************

Perform preconstruction condition survey of structures[ and utilities] [within 61 meters 200 feet of the pile installation activity] [specified in the plans] [decided by the Contracting Officer]. Perform outreach to the owner of the structures [28] [_____] days before performing the preconstruction condition survey. The Contractor must obtain written permission from the owner of the structure prior to accessing the structure. The preconstruction condition survey must include video and photographic documentation of the exterior and interior of above ground structures and of the interior of underground structures. Video documentation must be in high definition, and show existing conditions and highlight, where possible, existing cracks, deteriorated concrete, exposed and corroded reinforcement, cracked or broken brick or mortar, and other signs of distress. For utilities, perform the survey when the greatest extent of the interior is exposed. Provide supplementary artificial lighting as needed. The video must include annotation with location and structure nomenclature which describes any areas of distress over the video and time code superimposed on the video. Photographs must be accompanied by sketches or descriptions that indicate the location and direction of each photograph. For each structure surveyed, provide a Pre-Construction Condition Survey Report following completion of the survey. The report must contain all documentation associated with the survey including DVD copies. In the report, include notes, sketches, photographs, and videos. Provide general information, such as location details and structure type, as well as particular information on materials, condition, existing damage, aperture and persistence of cracks, and disrepair observed during visual survey. Provide a graphical depiction of locations of damage or other features of concern. Submit the Preconstruction Condition Survey Reports no later than [28] [_____] days before the commencement of pile installation activity. Accept responsibility for damages to existing adjacent or adjoining structures created by pile installation work, and repair any damages to these structures without cost to the Government.

3.8 CONSTRUCTION INSTRUMENTATION AND MONITORING PROGRAM

**************************************************************************
NOTE: Include this section if instrumentation is to be installed due to concerns about vibration, settlement, lateral movement, etc. during pile installation activities. Instrumentation should be specified and included in the specification. This section can be deleted if there are no instrumentation requirements.
**************************************************************************

Prepare a geotechnical instrumentation program to monitor settlement[ and lateral movement] of temporary and permanent structures, utilities, [embankments][and excavations] during pile installation. The design and distribution of instrumentation must demonstrate an understanding of the need, purpose and application of each proposed type.[ Perform noise and
vibration monitoring in accordance with NOISE CONTROL and VIBRATION CONTROL sections.

Monitoring must extend before, during and for a period after completion of construction activities related to pile installation when long-term performance issues are a concern. The monitoring plan must be designed to protect adjacent structures and utilities against damage due to the pile installation activities. Establish limiting values of vertical [and horizontal] movement [and angular distortion] [and vibration] for each structure and utility within the zone of influence, subject to review by the Government.

Prepare a report detailing the proposed program of instrumentation and monitoring, establishing threshold values of monitored parameters, and describing the response plans that will be implemented when threshold parameters are exceeded. The report must include details about instrumentation consultant's experience, appropriate types, quantities, locations and monitoring frequencies of the instruments.

Upon acceptance of the instrumentation and monitoring program, provide, install and monitor the instrumentation and interpret the data. Submit instrumentation data reports not less than every [_____] days after the monitoring program has begun. Take corrective actions, as necessary, based on the field instrumentation data and as defined in the instrumentation and monitoring program.

NOTE: This guide specification covers the requirements for the procurement, installation, and testing of drilled concrete piers and shafts.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1  GENERAL

NOTE: Use the following specifications in conjunction with this section:

Section 01 35 26 GOVERNMENTAL SAFETY REQUIREMENTS

On the drawings, show:

2. Top and bottom elevation of each drilled pier and/or shaft.

3. Size (diameter in mm inches), bearing capacity, and total number of each size of drilled pier and/or shaft.
4. Dimensions of the bell, if required.

5. Dimensions of the casing.

6. Reinforcing steel details, if required.

7. Location of drilled piers and/or shafts to be penetration tested, if required.

8. Location of drilled piers and/or shafts to be proof tested, if required.

9. Locations, size, and installation sequence of load testing drilled pier and/or shaft, if required.

**************************************************************************

[1.1 UNIT PRICES

a. Requirements for price breakdown of drilled concrete piers or shafts are specified in Section 01 20 00 PRICE AND PAYMENT PROCEDURES.
Requirements for construction scheduling related to drilled concrete piers or shaft work are specified in Section 01 32 17.00 20 NETWORK ANALYSIS SCHEDULES (NAS).

b. Requirements for price breakdown of drilled concrete piers or shaft work are specified in Section 01 20 00 PRICE AND PAYMENT PROCEDURES.

**************************************************************************

NOTE: This paragraph anticipates bids on a lump sum price for an entire project including drilled concrete piers or shaft work with directed changes being in accordance with the CONTRACT CLAUSES or in accordance with unit prices as defined in paragraph SEPARATE UNIT PRICES.

Delete "in accordance with the CONTRACT CLAUSES" or paragraphs "TESTS" and "SEPARATE UNIT PRICES" for lump sum projects.

**************************************************************************

[1.1.1 Basis of Bids

Base the bid on the number and total length of drilled concrete [piers] and [shafts], established by top and bottom elevations and diameters, as indicated and specified. Adjustment of the contract will be made [in accordance with the CONTRACT CLAUSES], if the total length of drilled concrete [piers] or [shafts] installed and approved is greater or less than the total length shown. The Contractor will not receive payment for rejected concrete [piers] or [shafts] or for those not conforming to specifications.

] [1.1.2 Tests

1.1.2.1 Load Test

The Contract includes [_____] load tests rated at [_____] metric tons kips per drilled concrete [pier] or [shaft]. The Contracting Officer reserves the right to increase or decrease the number of load tests. Adjustments in
the contract price will be made for each such increase or decrease by the amount bid for "Additional Drilled Concrete [Pier] [or] [Shaft] Test" or "Omitted Drilled Concrete [Pier] [or] [Shaft] Load Test".

1.1.2.2 Penetration Test

The Contract includes [_____] penetration tests. The Contracting Officer reserves the right to increase or decrease the number of penetration tests. Adjustments in the contract price will be made for each such increase or decrease by the amount bid for "Additional Penetration Test" or "Omitted Penetration Test".

1.1.2.3 Proof Test Hole

The Contract includes [_____] proof test holes. The Contracting Officer reserves the right to increase or decrease the number of proof test holes. Adjustments in the contract price will be made for each such increase or decrease by the amount bid for "Additional Proof Test Hole" or "Omitted Proof Test Hole".

1.1.3 Separate Unit Prices

1.1.3.1 Additional Concrete [Pier] [or] [Shaft] Lengths

Additional [pier] [shaft] lengths will be paid for at the contract unit price for "Additional [Pier] [Shaft] Length" for each diameter of [pier] [shaft] installed as approved.

1.1.3.2 Omitted [Pier] [and] [Shaft] Lengths

The contract price will be reduced by the amount bid for "Omitted [Pier] [Shaft] Length" for each diameter of [pier] [shaft] omitted as directed.

1.1.3.3 Casings Permanently Left in Place

Steel casings permanently left in place due to contract conditions:

a. Total pounds of steel beyond casings indicated will be paid for at the contract unit price per pound for "Additional Steel Casing."

b. Omitted Casing Steel: The contract price will be reduced by the amount bid for "Omitted Casing Steel" omitted as directed.

1.1.3.4 Reinforcing Steel for Additional [Piers] [Shafts]

Reinforcing steel for additional [pier] [shaft] lengths will be paid for at the contract unit price for "Additional [Pier] [Shaft] Reinforcing Steel" installed as approved.

1.1.3.5 Reinforcing Steel for [Piers] [Shafts] Omitted

The contract price will be reduced by the amount bid for "Omitted [Pier] [Shaft] Reinforcing Steel" omitted as directed.

1.1.3.6 Removal of Rock

Removal of rock within the limit of [piers] [shafts] will be paid for at the contract unit price for "Removal of Rock" per linear meter foot, for each diameter of [pier] [shaft] installed. Rock excavation is defined as
any hard dense material that cannot be removed with [pier] [shaft] drilling equipment having the specified capacity and could only be removed by hand, air tools, blasting, or other specialized methods.

1.1.3.7 Removal of Obstructions Other Than Rock

Removal of obstructions other than rock within the limits of the [piers] [shafts] which cannot be removed using standard drilling equipment with the specified capacity will be paid for at the contract unit price per linear meter foot for "Removal of Obstructions" for each diameter of [pier] [shaft] installed.

1.1.4 Basis of Payment

1.1.4.1 Unit Price

The Contracting Officer has the right to increase or decrease the total length linear footage of drilled [piers] [shafts] to be furnished and installed by changing the [pier] [shaft] elevations, by requiring the installation of additional [piers] [shafts], or omission of [piers] [shafts] from the requirements shown and specified. Whether or not such changes are made, the Contractor will be paid at the contract unit price per linear meter foot (including drilled pier and/or shaft) multiplied by the total linear meters feet of acceptable [piers] [shafts] actually installed provided, however, that in the event the Contracting Officer requires an increase or decrease in the total length linear footage of [piers] [shafts] furnished and installed, the contract unit price will be adjusted in accordance with the CONTRACT CLAUSES.

1.1.4.2 Full Compensation

Payment in accordance with the above paragraph Unit Price constitutes full compensation for furnishing, delivering, handling, and/or installing (as applicable) all material, labor and equipment necessary to meet contract requirements applicable to the [piers] [shafts]. The Contractor will not be allowed payment for rejected [piers] [shafts].

1.1.4.3 Load Tests

The Contract includes [____] [____] -metric tonskips [pier] [shaft] load tests. The Contracting Officer reserves the right to increase or decrease the number of load tests. Adjustments in the contract price will be made for such increases or decreases by the amounts bid for "Additional [Pier] [Shaft] Load Test" or "Omitted [Pier] [Shaft] Load Test."

1.1.4.4 Penetration Tests

The Contract includes [_____] penetration tests. The Contracting Officer reserves the right to increase or decrease the number of penetration tests. Adjustments in the contract price will be made for such increases or decreases by the amounts bid for "Additional Penetration Test" or "Omitted Penetration Test."

1.1.4.5 Proof Test Holes

The Contract includes [_____] proof test holes. The Contracting Officer reserves the right to increase or decrease the number of proof test holes. Adjustments in the contract price will be made for such increases or decreases by the amounts bid for "Additional Proof Test Hole" or "Omitted

1.3 SUBMITTALS

**************************************************************************
NOTE: Review Submittal Description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a “G” to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy, Air Force, and NASA projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy, Air Force and NASA projects, or choose the second bracketed item for Army projects.

**************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

Bill of Lading for Ready-Mix Concrete Deliveries

Steel Reinforcement; G[, [___]]
Welding Certificates; G[, [___]]

Excavation and Drilling Equipment

Qualifications of Excavator; G[, [___]]
Qualifications of Engineer; G[, [___]]

1.4 QUALITY CONTROL

1.4.1 General

Install drilled shaft foundations in accordance with applicable requirements as described by ACI 336.1, and FHWA NHI-10-016.
1.4.2 Sequencing and Scheduling

Submit a detailed installation plan describing the schedule for drilling and/or excavation, installation of steel reinforcement and concrete placement with anticipated site conditions so that each excavated shaft is poured the same day that the drilling is performed.

1.4.3 Inspection Criteria

Design inspection activities to minimize delays while insuring the intent of the Industry Standard Specifications.

1.4.4 Qualification of Excavation Contractor

An experienced excavator with five (5) years experience and licensed in the State of [____], specialized in excavating and installing work similar in material, design, and extent to that indicated for this Project. Submit certificates substantiating the Qualifications of Excavator.

1.4.5 Qualification of Professional Engineer

Provide engineering services by an authorized engineer currently licensed in the State of [____]; having a minimum of four (4) years experience as an engineer knowledgeable in drilled shaft foundation design analysis, protocols and procedures for the ACI 336.1, FHWA NHI-10-016, ASCE 7-16, and the [____] Building Code. Submit certificates substantiating the Qualifications of Engineer.

1.4.6 Welding Qualifications

Provide and maintain qualified procedures and personnel according to AWS D1.1/D1.1M, AWS D1.4/D1.4M, and AWS A5.1/A5.1M. Submit Welding Certificates to the Contracting Officer.

1.4.7 Pre-Construction Conference

After submittals are received and approved but before drilled shaft excavation and foundation work, including associated work, is performed, the Contracting Officer will hold a pre-construction conference to review the following:

a. The drawings, specifications and the geotechnical report.

b. Finalize construction schedule and verify availability of materials, Excavator's personnel, equipment, and facilities needed to make progress and avoid delays.

c. Methods and procedures related to drilled shaft foundation installation, including engineer's written instructions.

d. Support conditions for compliance with requirements, including alignment between foundation system and erection of structural members.

e. Governing regulations and requirements for, certificates, insurance, tests and inspections if applicable.

f. Temporary protection requirements for foundation assembly during and after installation.
1.5 PROJECT CONDITIONS

**************************************************************************
NOTE: Require proof testing if the soundness of rock below the pier or shaft bearing level is unknown. Indicate location of each pier or shaft to be proof tested.
**************************************************************************

1.5.1 Existing Conditions

Locate existing underground utilities before excavating drilled shaft foundations. If existing utilities are to remain in place, provide protection during drilled shaft operations.

1.5.2 Interruption of Existing Utilities

Do not interrupt any utility to occupied facilities unless directed in writing by the Contracting Officer.

1.5.3 Weather Limitations

Proceed with installation preparation only when existing and forecasted weather conditions permit work to proceed without water entering into the area of excavation.

PART 2 PRODUCTS

2.1 DESIGN REQUIREMENTS

Submit design data for the following:

a. Drilled shaft foundation design analysis to include, but not limited to the following:
   (1) Applicable Building code criteria for the excavation's geographic area
   (2) Dead and Live Loads
   (3) Compressive and Lateral Loads
   (4) Collateral Loads
   (5) Foundation Loads
   (6) Bearing strata
   (7) Casing description

b. Mix design data in accordance with paragraph READY-MIX CONCRETE accompanied by the Bill of Lading for Ready Mix Concrete deliveries.

2.1.1 Assembly

Installation drawings are to include, but not limited to, the following items indicating a completely dimensioned layout and location of drilled shafts and concrete placement for foundation system. Submit detailed shop drawings for the following:
a. Drilled shaft diameters
b. Depth of test holes
c. Top and bottom of shaft elevations
d. Steel reinforcement
e. Anchor bolt locations
f. Accessories

2.2 EQUIPMENT

2.2.1 Drilling and Excavation Equipment

Provide drilling and excavation equipment having adequate capacity, including but not limited to, power, torque and down thrust to excavate a hole of diameter and depth indicated. Also provide excavation and over-reaming tools of adequate design, size and strength to perform the work indicated.

Provide special drilling equipment including, but not limited to, rock core barrels, rock tools, air tools and other equipment as necessary to construct the shaft excavation to the size and depth indicated when materials encountered can not be drilled using earth augers and/or over-reaming tools.

Submit certificates substantiating appropriate selection of excavation and drilling equipment.

2.3 MATERIALS

2.3.1 Steel Reinforcement

2.3.1.1 Deformed Steel Bars

Steel bars conforming to ASTM A615/A615M, Grade 60 ksi and ACI 318.

2.3.1.2 Plain Steel Wire

Steel wire conforming to ASTM A1064/A1064M.

2.3.2 Ready-Mix Concrete

Ready-Mix concrete and mix design conforming to ACI 117, ACI 301, and ACI 304R, minimum compressive strength 5,500 psi at 28 days. Slump results between 5 to 6 inches, according to ASTM C143/C143M.

Portland cements conforming to ASTM C150/C150M, Type II. Provide one brand and type of cement for formed concrete having exposed-to-view finished surfaces.

Potable water conforming to ASTM C94/C94M.

Measure, batch, mix and deliver concrete according to ASTM C94/C94M and furnish batch ticket information.
PART 3  EXECUTION

3.1  PREPARATION

Protect existing structures, utilities, sidewalks, pavements, and other facilities from damage caused by settlement, lateral movement, vibration, and other hazards created by drilled shaft foundation operations.

Provide Fall Protection as required by Section 01 35 26 GOVERNMENTAL SAFETY REQUIREMENTS and 29 CFR 1926.651.

3.2  INSTALLATION

3.2.1  Construction Criteria

Provide equipment for checking the dimensions and alignment of each shaft excavation. Determine dimensions and alignment jointly with the contractor and engineer. Measure final shaft depths with appropriate weighted tape measure or other approved method after cleaning.

Provide and install monolithically cast-in-place concrete drilled shaft foundation to the sizes indicated.

Provide and install straight cylindrical shaft foundation of the type indicated.

Tolerances:

a. Maximum variation of the center of any shaft foundation from the required location: 7.62 cm 3 inches, measured at the ground surface.

b. Bottom Diameter: Minus zero, plus 15.24 cm 6 inches, measured in any direction.

c. Maximum variation from plumb: 1:40.

d. Maximum bottom level: Plus or minus 5.08 cm 2 inches.

3.2.2  Excavation

Accomplish excavation of shaft foundations by standard excavation methods including, but not limited to, conventional augers fitted with soil and/or rock teeth, or under-reaming tools attached to drilling equipment of adequate size, power, torque and down thrust necessary for the work.

Perform excavation through whatever materials that are encountered to the dimensions, depths and applicable ACI 336.1 tolerances.

Protect excavated walls with temporary watertight steel casings of sufficient length to prevent water intrusion, cave-ins, displacement of surrounding earth, and injury to personnel and damage to construction operations.

Excavate shafts for drilled foundations to indicated elevations. Remove loose debris, materials and/or muck to make bottom surfaces level within ACI 336.1 tolerances.

Remove water from excavated shaft prior to concrete placement.
3.2.3 Steel Reinforcement

Comply with recommendations in the CRSI "Manual of Standard Practice" CRSI 10MSP for fabricating, placing and supporting reinforcement. Shop fabricate steel reinforcement in accordance with ACI SP-66.

When practicable, deliver the reinforcement cage assembly to the jobsite as a complete unit ready for installation. Should it be necessary to make any additional connections and/or splices, provide as indicated on the approved shop drawings, at-grade level prior to lowering the complete assembly into the hole.

Clean reinforcement of loose rust, mill scale, earth and other foreign materials. Do not tack weld crossing reinforcing bars. Set wire ties with ends directed into concrete, not toward exposed concrete surfaces.

Lower reinforcement steel into the hole in such a manner as to prevent damage to the walls of the excavation. Place, tie and/or clip cage symmetrically about the axis of the shaft. Use centering devices securely attached to the cage to clear the shaft walls and maintain the cage in place throughout the concrete placement operations.

Cooperate with other trades in setting of anchor bolts, inserts, and other embedded items. Where conflicts occur between reinforcing and embedded items, notify the Contracting Officer in order to reconcile conflicts before concrete placement. Position and support anchors and embedded items with appropriate accessories.

Use templates to set anchor bolts, leveling plates and other accessories required for structure erection. Provide blocking and/or holding devices to maintain required anchoring positions during final concrete placement.

3.2.4 Concrete Placement

Keep all equipment, including but not limited to, mixers, pumps, hoses, tools and screeds clean and free of set concrete throughout the placement operation.

Convey concrete from the mixer to place of deposit by best industry methods that prevents segregation and loss of material. Size and design the equipment for conveying concrete to ensure uniform, continuous placement of concrete.

Place concrete in accordance with ACI 318.

Place concrete in a continuous operation and without segregation into dry excavations whenever possible after inspection and written approval by the Contracting Officer. Use all practicable means to obtain a dry excavation before and during concrete placement.

Protect freshly placed concrete from premature drying and excessive cold or hot temperatures. When hot weather conditions exist that would impair quality and strength of placed concrete, comply with ACI 305R. Comply with ACI 306.1 for cold-weather protection.

A minimum of 50 percent of the base for each shaft is to be less than 1.27 cm 1/2 inch of sediment at the time of concrete placement. Maximum depth of sediment or debris at any place on the base of the shaft is not to exceed 3.81 cm 1-1/2 inches. Shaft cleanliness is to be determined by the
engineer by visual inspection.

3.3 FIELD QUALITY CONTROL

3.3.1 Test Reports

As a minimum, submit the following test reports and data.

a. Soils Report
b. Ground Water conditions
c. Load Test
d. Penetration Test
e. Slump
f. Concrete
g. Compressive Strength

Sample and test concrete for quality control during placement. [Quality control testing is provided by the contract.]

Sample freshly placed concrete for testing in accordance with ASTM C172.

Make concrete test specimens for compressive strength at 7 and 28 days for each design mix conforming to ASTM C31/C31M. Compression test concrete in accordance with ASTM C39/C39M.

Test Slump at plant for each design mix in accordance with ASTM C143/C143M.

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for embankments and concrete structures placed on rock foundations, including all operations on the rock surface to make that surface acceptable for the placement of embankment or concrete. This section was originally developed for USACE Civil Works projects.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1 GENERAL

NOTE: This section is not complete, but should normally be incorporated into the sections dealing with 31 00 00 EARTHWORK, and/or CONCRETE, or a separate section on FOUNDATION PREPARATION may be included in the project specifications.

1.1 UNIT PRICES
NOTE: If Section 01 20 00 PRICE AND PAYMENT PROCEDURES is included in the project specifications, this paragraph title (UNIT PRICES) should be deleted from this section and the remaining appropriately edited subparagraphs below should be inserted into Section 01 20 00.

1.1.1 Preliminary Cleanup

1.1.1.1 Payment

Payment will be made for costs for each preliminary cleanup satisfactorily performed at the direction of the Contracting Officer. Payment will be made for each cleanup of the same area if more than one cleanup has been directed and satisfactorily performed.

1.1.1.2 Measurement

Preliminary cleanup will be measured for payment by determining the area cleaned to the nearest square meter yard.

1.1.1.3 Unit of Measure

Unit of measure: square meter yard.

1.1.2 Final Cleanup

1.1.2.1 Payment

Payment will be made for costs associated with final cleanup of the area [for each type of foundation preparation] that has been satisfactorily prepared. Where preliminary cleanup has been directed and performed and the Contractor subsequently performs final cleanup, payment will be made for preliminary cleanup. Payment will not be made for any cleanup subsequent to final cleanup.

1.1.2.2 Measurement

Final cleanup will be measured for payment by determining the area cleaned to the nearest square meter yard.

1.1.2.3 Unit of measure

Square meter yard.

1.1.3 Foundation Preparation

1.1.3.1 Payment

Payment will be made for costs associated with foundation preparation of the area [for each type of foundation preparation] that has been satisfactorily prepared. Where preliminary cleanup has been directed and performed and the Contractor subsequently performs foundation preparation, payment will be made for foundation preparation. Payment will not be made for more than one foundation preparation of the same area.
1.1.3.2 Measurement

Foundation preparation will be measured for payment by determining the area prepared to the nearest square meter yard.

1.1.3.3 Unit of measure

Square meter yard.

1.1.4 Dental Concrete

1.1.4.1 Payment

Payment will be made for costs associated with dental concrete placed.

1.1.4.2 Measurement

Dental concrete will be measured for payment by determining the volume to the nearest one-tenth cubic meter yard.

1.1.4.3 Unit of measure

Cubic meter yard.

1.1.5 Dental Mortar

1.1.5.1 Payment

Payment will be made for costs associated with dental mortar placed.

1.1.5.2 Measurement

Dental mortar will be measured for payment by determining the volume to the nearest one-tenth cubic meter yard.

1.1.5.3 Unit of measure

Cubic meter yard.

1.1.6 Shotcrete

1.1.6.1 Payment

Payment will be made for costs associated with shotcrete satisfactorily placed.

1.1.6.2 Measurement

Shotcrete will be measured for payment by determining the area satisfactorily covered to the nearest square meter yard.

1.1.6.3 Unit of measure

Square meter yard.
1.1.7  Protective Coating

1.1.7.1  Payment

Payment will be made for costs associated with protective coating satisfactorily applied. Separate payment will not be made for reapplication necessary due to damage by construction activities, fault or negligence of the Contractor, or failure of the Contractor to prosecute the work in a timely manner. Otherwise, separate payment shall be made for each reapplication directed and satisfactorily performed.

1.1.7.2  Measurement

Protective coating will be measured for payment by determining the area satisfactorily covered to the nearest square meter yard.

1.1.7.3  Unit of measure

Square meter yard.

1.2  REFERENCES

**************************************************************************

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

**************************************************************************

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

AMERICAN CONCRETE INSTITUTE (ACI)

ASTM INTERNATIONAL (ASTM)

1.3 DEFINITIONS

1.3.1 Foundations

The rock foundation is comprised of the rock surfaces upon which [embankment] [and] [concrete] structures are placed. Vertical surfaces, where permitted or required by these specifications, are included.

1.3.2 Rock Joints

Rock joints are all planar and/or curvilinear fractures, including cracks, crevices, and seams which separate a rock mass into individual rock blocks of various sizes. They may be open or closed and may be filled with material other than rock material.

1.4 SUBMITTALS

**************************************************************************

NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy, Air Force, and NASA projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy, Air Force and NASA projects, or choose the second bracketed
item for Army projects.

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-03 Product Data

Tools; G[, [_____]}

PART 2 PRODUCTS

2.1 MATERIALS

2.1.1 Dental Concrete

Dental concrete shall conform to the requirements of ASTM C387/C387M, normal weight and strength.

2.1.2 Dental Mortar

Dental mortar shall conform with ASTM C270 or ASTM C387/C387M, Type N.

2.1.3 Shotcrete

NOTE: Select appropriate alternative.

Shotcrete shall conform to the requirements of [Section 03 37 13 SHOTCRETE] [ACI 506.2. The compressive strength of the concrete shall be 27.6 MPa 4000 psi].

2.1.4 Welded Wire Fabric

Welded wire fabric used shall be 150 by 150 mm 6 by 6 inches - W3 x W3, conforming to ASTM A1064/A1064M.

2.1.5 Filter Material

The Specifier should use the first paragraph if there is a concrete section, an embankment for earth dams, or a stone protection section in the specifications and if the gradation therein is satisfactory for filter materials. If there is no concrete section, or if the gradation therein is unsatisfactory for filter materials, the Specifier should use the second paragraph.
Filter material shall consist of [sand and gravel] [and crushed stone].

[Sand and gravel] [and crushed stone] for filter materials shall meet the applicable requirements of [Section 03 70 00 MASS CONCRETE, paragraph MATERIALS] [Section 35 31 19 STONE, CHANNEL, SHORELINE/COASTAL PROTECTION FOR STRUCTURES, paragraph MATERIALS] [Section 35 73 13 EMBANKMENT FOR EARTH DAMS, paragraph MATERIALS].

Filter material shall consist of [Sand,] [Gravel,] [Crushed Stone]. The [filter material] shall be composed of tough, durable particles, reasonably free from thin, flat and elongated pieces, and shall contain no organic matter nor soft, friable particles in quantities considered objectionable by the Contracting Officer. Grading shall conform to the following requirements:

<table>
<thead>
<tr>
<th>U.S. STANDARD SIEVE</th>
<th>PERMISSIBLE LIMITS PERCENT BY WEIGHT, PASSING</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
<tr>

</tbody>
</table>

The [filter materials] shall be well-graded between the limits shown. [Gravel shall not be crushed stone.] At least one test shall be performed on each 1000 tons (metric) 2,000,000 lb to be delivered to the project site for each gradation band. All points on individual grading curves obtained from representative samples of [filter material] shall lie between the boundary limits as defined by smooth curves drawn through the tabulated grading limits plotted on a mechanical analysis diagram. The individual grading curves within these limits shall not exhibit abrupt changes in slope denoting either skip grading or scalping of certain sizes or other irregularities which would be detrimental to the proper functioning of the filter.]
3.1 EXAMINATION

The limits of the proposed foundations for the various parts of the work are approximately as indicated. The Contracting Officer reserves the right to change the depth to, or the width of, the foundations if, conditions exposed in the foundation excavations, or as determined by exploratory drilling, warrant such modifications.

3.2 PREPARATION

3.2.1 Equipment

3.2.1.1 Tools

Submit for approval tabular list of light power tools, to be used in lieu of hand tools, prior to their use on the job site. Hand tools, where required or permitted by these specifications include, but are not limited to [shovels,] [bars,] [picks,] [wedges,] [and] [brooms]. Light power tools may be used in lieu of hand tools only when such use is approved.

3.2.1.2 Air Jet

An air jet shall consist of a [40] [_____] mm [1-1/2] [_____] inch nozzle with a supply hose connected to a suitable source of compressed air. The compressed air shall have a pressure between [620] [_____] and [760] [_____] kPa [90[_____] and [110] [_____] psi. The compressed air shall be controllable at the nozzle.

3.2.1.3 Air/Water Jet

An air/water jet shall consist of a [40] [_____] mm [1-1/2] [_____] inch nozzle with associated controls and supply hoses connected to suitable sources of compressed air and water. Compressed air shall have a pressure between [620] [_____] and [760] [_____] kPa [90[_____] and [110] [_____] psi. Water shall be introduced into the airstream at the nozzle when needed, at a rate of up to [2] [_____] L/s [30] [_____] gpm. The air and water shall be separately controllable at the nozzle.

3.2.1.4 Water Jet

A water jet shall consist of a [25] [_____] mm [1] [_____] inch nozzle with a supply hose connected to a suitable source of water. The system shall be capable of delivering up to [13] [_____] L/s [200] [_____] gpm. The flow rate shall be controllable at the nozzle.

3.3 PRELIMINARY CLEANUP

When the excavation has reached the approximate limits shown or when the Contracting Officer determines that a satisfactory foundation may have been reached, the Contracting Officer may direct that a preliminary cleanup be performed on all or any part of the rock foundation surface. This cleanup shall consist of removing all debris, loose rock, sand, silt, and other objectionable material by hand tools followed by [air] [water] [air/water] jets or any combination of additional methods approved or directed. The Contracting Officer may require that the excavation be continued and the preliminary cleanup procedure repeated until a satisfactory foundation surface is reached.
3.4 FINAL CLEANUP AND FOUNDATION PREPARATION

**************************************************************************
NOTE: Insert a description of the areas to receive (this type) foundation preparation.

Where more than one type of final cleanup and foundation preparation is needed, this paragraph may be repeated with appropriate variations. See EM 1110-2-2300 for guidance on where foundation preparation should be required under embankment dams. Compacted filter material should be used under overhangs only when granular fill is being placed against the foundation.
**************************************************************************

Unless otherwise directed, Final Cleanup and Foundation Preparation [, Structural] [, Embankment] [, Type [_____] ] shall be performed [______]. This work shall consist of removing loose and/or weather rock and pockets of fines, sand, rock rubble or gravel and other objectionable material from the in place rock surface including areas of depression, large crevices, and open rock joints. [The loose material need not be removed where the width of the opening is less than [_____] mm inches.] [Mechanical equipment may be used but such equipment will be rubber tired only.] Picking, barring, and hand excavation may be necessary to obtain a foundation surface free from loose, drummy, or shattered materials. [Irregularities in the rock surfaces shall be trimmed to form a reasonable uniform slope on the abutments.] [Slopes shall not be steeper than [_____] vertical on [_____] horizontal.] [Overhangs shall not be permitted at any location.] [Overhangs shall be excavated and backfilled with compacted [filter] [granular] materials. Placement of such filter materials shall be in accordance with the provisions contained in Section [35 73 13 EMBANKMENT FOR EARTH DAMS] [______].] [Vertical surfaces shall not be [permitted.] [higher than [_____] m feet] and benches between vertical surfaces shall be of such width so as to provide a stepped slope comparable to the adjacent uniform slope.] The final rock surface shall be thoroughly cleaned by use of [air jets] [water jets] [air/water jets] or other approved method and shall be maintained in a clean condition until the placement of [embankment] [or] [concrete] thereon.

3.5 DENTAL TREATMENT

**************************************************************************
NOTE: If a schedule is not provided, a description of the areas to receive dental treatment, and the minimum width joint to be treated should be included. For embankment dams, the minimum width joint to be treated depends on the gradation of the embankment material that will be placed against the joint (see EM 1110-2-2300).
**************************************************************************

Dental treatment shall consist of excavation, if necessary, of the material in joints, cavities, depressions, and overhangs and the placement of [concrete] [or] [mortar] such that the final surface is satisfactory for the subsequent placement of [embankment] [or] [concrete]. [Unless otherwise directed, Dental Treatment shall be performed in accordance with the following schedule:
Joints and cavities shall be excavated to a depth \[3\] \(____\) times the width (measured at the base of the excavation) of the joint or cavity.

### 3.5.1 Dental Concrete

**************************************************************************

NOTE: Normally the concrete specification will be included in Division 03, Concrete. When Division 03 would not otherwise be included, and only small quantities will be needed, the ASTM alternate may be used. The maximum aggregate size in dental concrete should not be more than one third the minimum widths of joints in which it is to be used.

**************************************************************************

Concrete shall be used to fill joints, cavities, depressions, and overhangs except where the use of mortar is required or permitted. Prior to placement, the surfaces of the joint, cavity, depression, or overhang will be thoroughly cleaned using \[air\] \[or\] \[air/water\] \[or\] \[water\] jets. The maximum aggregate size shall be \([____] \text{mm}\) \[inch\] [as directed]. The concrete shall conform with paragraph MATERIALS.

### 3.5.2 Dental Mortar

Mortar shall be used to fill joints, cavities, depressions, and overhangs when the width of the opening is less than \([____] \text{mm}\) \[inches\] and at other areas as directed or approved. Placement of the sand-cement mortar will be accomplished by \[troweling\] \[brooming\] the mortar \[with stiff bristled brooms\] into the cleaned joints, cracks, and crevices so as to provide a thorough seal. The surface moisture of the rock shall be such that absorption of water from the mortar mix will be minimized. However, no standing water will be allowed. All mortar which cannot be worked into the joints, shall be removed from the rock surface. \[The mortar shall be moist cured for a period of at least \([____]\).\] The mortar shall conform with paragraph MATERIALS.

### 3.6 PROTECTIVE TREATMENT

**************************************************************************

NOTE: Insert here a description of the areas to be protected, and the type(s) of protection to be used. If more than one type of protection is specified, it should be clear which method(s) is (are) required for each area. If the choice of methods is optional with the Contractor that should be stated. Care should be used when selecting protective measures. Not all methods are suitable in all situations or with all types of rock. Of the following paragraphs, only those methods specified should be included.

**************************************************************************
Protective treatment shall be [____].

3.6.1 Wetting

Keep the area wet by [continuous spraying] [flooding] or by other approved method. [Provide positive measures to control the runoff.]

3.6.2 Shotcrete

**************************************************************************
NOTE: See ACI 506.2 for additional options that may be specified and for guidance on their use. The first alternate should be used if shotcrete is being used for other purposes on the job, or if a different shotcrete specification is appropriate.
**************************************************************************

Alternate 1: [Shotcrete shall conform to the requirements of paragraph MATERIALS.]

Alternate 2: [The area to be protected shall be covered by welded wire fabric in accordance with paragraph MATERIALS.] The fabric shall be securely anchored in place as shown on the contract drawings. The shotcrete shall conform to paragraph MATERIALS. The Contractor is responsible for construction and preconstruction testing. [Gradation [____] will be used.] [Gradations [____] or [____] will be used.] The minimum cover [over reinforcement,] shall be [____] mm inches.

3.6.3 Protective Coating

**************************************************************************
NOTE: Celtite 42-51 HI-SEAL, (42-52C (Clear)), and (45-51W (White)) epoxy resin and emulsion, manufactured by Celtite, Inc., telephone 1-800-626-2948 and Aero-Spray, manufactured by American Cyanamid/CYTEC, telephone 1-800-835-9844, (Mining Products Division) have been successfully used and were available at time of publication. However, the availability of these and similar products should be investigated before their use is specified. Asphaltic emulsions have been used, with limited success, in some applications.
**************************************************************************

Apply an approved protective coating within [____] hours of exposure of the rock surface in accordance with the manufacturer's recommendations or as otherwise approved. Reapply the coating as necessary to repair damage caused by construction activities or when needed to provide adequate protection. [The protective coating shall be [____], or equal.]

3.6.4 Protective Backfill

The final [600] [____] mm [2] [____] feet of excavation, final cleanup and foundation preparation, inspection, [dental treatment,] and placement of the first [300] [____] mm [12] [____] inches of backfill shall all be accomplished within a period of [16] [____] hours. Within [48] [____] hours after the start of the final excavation, the backfill shall have a minimum thickness of [1000] [____] mm [3] [____] feet. The backfill shall be placed in accordance with the requirements of Section [31 00 00]
3.6.5 Protective Concrete

The final [600] [_____] mm [2] [_____] feet of excavation, [cleanup,]
inspection, preparation, [dental treatment,] and placement of at least
[_____] mm inches of protective concrete, shall all be accomplished within
a period of [_____] hours. The concrete shall conform to the requirements
of Section [03 30 00 CAST-IN-PLACE CONCRETE] [03 30 53 MISCELLANEOUS
CAST-IN-PLACE CONCRETE] [_____]..

3.6.6 Temporary Earth Cover

**************************************************************************
NOTE: Insert the requirements of the material to be used.
**************************************************************************

[Within [_____] hours of excavation,] [Before freezing weather is
expected,] [Before other construction activities are permitted,] the area
will be protected by a temporary earth cover [_____] mm feet thick. The
material shall [______]. The material shall be removed and the area
[cleaned,] [inspected,] [and prepared] prior to placement of [embankment]
[or] [concrete] thereon.

3.7 TESTS

3.7.1 General

Establish and maintain quality control for foundation preparation
operations to assure compliance with contract specifications and maintain
records of the quality control for all operations including but not limited
to the following:

3.7.1.1 Equipment

Quantity and type.

3.7.1.2 Foundation Excavation

Strict adherence to foundation excavation limits and depths.

3.7.1.3 Inspection, Mapping, and Cleanup

Orderly prosecution of inspections, mapping, and cleanup of foundation
excavation areas.

3.7.1.4 Specialized operations

Protective treatment [and Dental treatment].

3.7.2 Reports

Submit three copies of these records of inspection as well as corrective
action taken daily.

3.8 FOUNDATION INSPECTION AND GEOLOGIC MAPPING

Inspections to determine adequacy of the foundations will be performed by
the Contracting Officer in all foundation areas between completion of excavation and placement of [embankment,] [or] [concrete,] [or protective treatment]. The Contractor will cooperate to the extent necessary to assist in inspection and mapping activities which may require additional survey control points and access. Coordinate the schedule for foundation excavation and preliminary cleanup with the Contracting Officer to ensure that the cleanup, inspection, and mapping proceed in an orderly manner.

3.5.2 Replacement of Rejected Anchors

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for soil and rock anchors. This section was originally developed for USACE Civil Works projects.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1 GENERAL

NOTE: This specification is based on, and references, the POST-TENSION INSTITUTE (PTI) recommendations for prestressed rock and soil anchors. The PTI manual is available from:

POST-TENSIONING INSTITUTE.
1717 W. NORTHERN AVE., SUITE 114
PHOENIX, AZ 85021 U.S.A
PHONE: (602) 870-7540  FAX: (602) 870-7541

The designer should carefully investigate the PTI document to ensure that the design conforms to PTI requirements and that conflicts do not occur between the referenced document and this specification. In
the event deviations from the PTI recommendations are necessary, the specification must be edited to clearly identify such deviations. For unusual conditions, the designer should also consult specialty contractors during the design process.

Rock and soil anchors may be used for temporary support or for permanent support. This specification must be carefully edited to reflect the design parameters applicable for the intended durability.

For projects requiring specialized methods or experience, particularly those which are primarily for installation of soil or rock anchors, consideration should be given to using a REQUEST FOR PROPOSAL (RFP) Method of procurement instead of an INVITATION FOR BIDS (IFB) Method. Use of RFP permits evaluation of offers on technical criteria in addition to price.

This guide specification is written for new construction where the anchor is installed after the structure is completed or for installing anchors in existing structures. Where the anchors must be installed and/or stressed prior to completion of the structure additional requirements will be necessary. Where pre-installation is required, means must be taken to protect the anchor components during the subsequent construction of the structure. If the anchors are to be stressed prior to completion of the structure, it may be necessary to stress the anchors against casings or other structures and transfer the load to the structure upon completion of construction.

Where the design of the structure to be anchored requires that the anchors be installed and stressed prior to construction of the new structure (i.e. where a new anchored wall is to be constructed to protect or support an existing wall which is not capable of resisting stressing loads), the anchors may be stressed against casings or a waler or thrust blocks may be used to distribute the load. In this case, the casing and rock socket must be designed to prevent deflection or excessive pulling of the casing into the rock during stressing. The design of the casing and rock socket must be included in the design computations. The casing must be seated into the rock socket and remain in place after grouting of the anchors.

Monitoring of stressing should include monitoring of movement of the casing.

Where anchors must be installed prior to construction of the new structure, the Contractor must adequately protect the anchor components during subsequent construction.
The following sentence should be included in paragraph FIELD QUALITY CONTROL, subparagraph GENERAL when the conditions apply or when stressing and testing the anchor is expected to cause significant movement of the structure such as:

a. Highly loaded anchors within the top 1.5 m 5 feet of the structure

b. High test loads on passive anchors

c. Anchors designed to support future loads which are much higher than current loads

"Stressing for [performance] [and] proof [and extended creep] tests must be by a method which does not induce excessive movement or damage on the existing structure"

1.1 SYSTEM DESCRIPTION

NOTE: This guide specification may be used as a performance specification or a prescriptive specification by use of tailoring options. For the performance specification tailoring option, the Government provides the design loads, locations, minimum unbonded length, minimum bond lengths, soil- or rock-grout bond strength, corrosion protection requirements, and limitations on anchor inclination. The Contractor is then responsible for selecting the type of anchor and designing the anchor system to conform with the prescribed design criteria. In order to use the performance specification, sufficient foundation information must be given to permit the Contractor to accurately estimate the design and installation costs. For the prescriptive specification tailoring option, the design of the anchors must be completely shown on the drawings and must include location, design load, unbonded and bonded length, drilling and grouting method, drill hole size, corrosion protection, and anchor inclination.

Prior to commencing any work on the anchors, the Contractor, including all field personnel to be involved in drilling and installation of the anchors, must meet with the Contracting Officer to review the drawings and specifications, work plans, and submittals. Drilling may commence upon approval of the anchor installation plan and procedures described in paragraph SUBMITTALS and after the conduct of the Preparatory Meeting.

1.1.1 General Requirements

Submit drawings and detailed installation procedures and sequences showing complete details of the installation procedure and equipment; anchor fabrication; grouting methods; grout mix designs; anchor [and casing]
placement and installation; corrosion protection for bond length, stressing length and anchorage; anchorage and trumpet; stressing and testing procedures with lengths, forces, deformations, and elongations for the approval by the Contracting Officer. Shop drawings for anchors must include locations and details of the spacers, centralizers, and banding. If different types of anchors are to be installed, each anchor type must be readily identifiable. Once reviewed by the Contracting Officer, no changes or deviation from shop drawings will be permitted without further review by the Contracting Officer. The work includes design, fabrication and installation of the [soil] [rock] anchor system. Install and fabricate the anchors as shown on the drawings. Prepare fabrication and installation drawings and an installation plan for approval. [Soil] [Rock] anchors must be [threaded bar] [or] [strand] type.

1.1.2 Scope of Work

Provide the design of the [soil] [rock] anchor system that will be completely the Contractor's responsibility. General design criteria are [shown on the drawings] [given in paragraph Design Requirements]. The materials, design, stressing, load testing, and acceptance must be in accordance with PTI DC35.1 and these specifications.

a. [Soil] [Rock] anchors may be threaded bar or strand type. The Contractor is responsible for the design of the anchor and bearing plate, [determining top of rock], determining drilling methods, and determining hole diameter and bond length. Submit design computations and data for the [soil] [rock] anchors, bearing plates, and bond zones.

b. Include computations with drawings, design assumptions, calculations, and other information in sufficient detail to verify the design proposed. The design must be certified by a registered Professional Engineer with proven experience in design of [soil] [rock] anchor components as stated in paragraph Qualifications. Include calculations for the stressing frames.

c. The Contracting Officer will approve the design calculations. Approval of the design calculations will not relieve the Contractor of responsibility for unsatisfactory performance of the installed [soil] [rock] anchors. Furnish all design computations at least [30] calendar days prior to the proposed commencement of drilling. The complete design, including design computations, fabrication and installation drawings and installation plan, must be certified by a registered Professional Engineer and must be submitted for approval.

d. Submit a plan for installing the [soil] [rock] anchors for review and comment. The proposal must describe the sequence for installation and other restrictions as outlined on the drawings or specified. Determine the anchor [and casing] installation procedures as part of the anchor design. Include the installation plan with descriptions of methods and equipment to be used for alignment checking of anchor holes [and casings]. [Payment for [soil and] rock anchors, as specified in Section 01 20 00 PRICE AND PAYMENT PROCEDURES, must include all costs in connection with designing, fabricating, and installing the anchors.]
The anchor location, Design Load (capacity) and angle of inclination will be determined by the design of the structure being anchored. If the design load cannot be determined by the Designer, this determination may be assigned to the Contractor, in which case, the specification must be appropriately modified. The Contractor will also be required to redesign the anchored structure to the extent required to accommodate the anchor design loads. Assumed soil or rock to grout bond strength will be determined from testing of the soil or rock in which the anchors are to be installed. Minimum required bond length will be determined in accordance with PTI DC35.1, Section 6.7. Type of grouting material will be determined by site conditions and the structure being anchored. Type of corrosion protection required will be determined in accordance with PTI DC35.1, Section 5.4

Design the individual [soil] [rock] anchors to meet the following criteria:

<table>
<thead>
<tr>
<th>Anchor Location</th>
<th>As indicated</th>
</tr>
</thead>
<tbody>
<tr>
<td>Horizontal [and] [Vertical] Spacing</td>
<td>[<em><strong><strong>] m feet minimum, [</strong></strong></em>] m feet maximum</td>
</tr>
<tr>
<td>Hole Diameter</td>
<td>[<em><strong><strong>] mm inches minimum, [</strong></strong></em>] mm inches maximum</td>
</tr>
<tr>
<td>Design Load</td>
<td>[_____] N kips</td>
</tr>
<tr>
<td>Assumed [Soil-] [Rock-] Grout Bond Strength</td>
<td>[_____] MPa psi</td>
</tr>
</tbody>
</table>
| Maximum Bond Length | [[Rock:] [10.7] [_____] m [35] [_____] feet]  
[[Soil Type 1:] [10.7] [_____] m [35] [_____] feet]  
[[Soil Type 2:] [10.7] [_____] m [35] [_____] feet]  
[[Soil Type 3:] [10.7] [_____] m [35] [_____] feet] |
| Corrosion Protection | Class [I, Encapsulated Tendon] [II, Grout Protected Tendons] |
| Angle of Anchor Inclination | [_____] rad degrees from vertical [with a tolerance of + [0.05] [_____] rad [3] [_____] degrees] |

1.1.3.1 Design Load

The Design Load must not exceed 60 percent of the ultimate strength of the prestressing steel. The Lock-off Load must not exceed 70 percent of the ultimate strength of the prestressing steel. The maximum Test Load must
not exceed 80 percent of the ultimate strength of the prestressing steel. The designer should include consideration of group effect of closely spaced anchors when determining design load and minimum spacing. Design the bearing plates so that the bending stresses in the plate do not exceed the yield strength of the steel when a load equal to 95 percent of the minimum specified ultimate tensile strength of the prestressing steel is applied and so that the average bearing stress on the structure does not exceed [24.1] [____] MPa [3500] [____] psi. Design the anchorage assembly connection to the structure in accordance with [AISC 325] [ACI 318M ACI 318].

1.1.3.2 Design Schedule

Submit a design schedule for the anchors which includes the following:

a. Anchor number.
b. Anchor design load.
c. Type and size of tendon.
d. Minimum total anchor length.
e. Minimum bond length.
f. Minimum tendon bond length.
g. Minimum unbonded length.
h. Details of corrosion protection, including details of anchorage and installation.
i. Submit the design schedule at least 30 days prior to commencement of work on the anchors covered by the schedule.

1.2 REFERENCES

**************************************************************************
NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

1.3 SITE CONDITIONS

NOTE: Where unique site conditions are anticipated, as evidenced by drilling performance such as loss of drill water, the information should be clearly presented on the drilling logs or otherwise made known to the Contractor. Generally, the plans and specifications should provide sufficient information to clearly identify anticipated foundation conditions. If, based on available information and site conditions, it is anticipated that additional foundation exploration will be required by the Contractor, this work should be added to the specifications.

A foundation investigation has been conducted at the site by the government and data is presented on the foundation exploration drawings. [Logs of core borings] [subsurface soil data logs] are shown on the drawings. While the foundation information is representative of subsurface conditions at the respective locations, local variations in the characteristics of the subsurface materials may be anticipated. Local variations which may be encountered include, but are not limited to, classification and thickness of rock strata, fractures, and other discontinuities in the rock structure, and variation in the soil classifications. Such variations will not be considered as differing materially within the purview of the contract clauses, paragraph differing site conditions. [Core from the borings indicated] [additional foundation data] are available for inspection as specified in the special contract requirements, paragraph physical data. The contractor is responsible for verifying the location of all utilities that may be affected by construction or the installation of the anchors.

1.4 BASIS OF BID

NOTE: Select one of the following options:

NOTE: Use "Lump Sum" paragraph below for lump (principal) sum bidding of anchors. Clearly show number of anchors, anchor capacity, anchor locations, and elevations on the drawings.

Use "Unit Price" paragraph for unit price bidding of anchors. Specify unit price bid items for anchors only for projects where exact quantities cannot be practically determined prior to the actual work. Lengths of anchors must be determined as accurately as possible, prior to bidding, since the unit price per meter foot of the anchors varies as the length.
increases or decreases.

**************************************************************************

[1.4.1 Lump Sum Payment

**************************************************************************

NOTE: Use this paragraph for lump-sum contracts, consult with Contracting Officer's Technical Representative (Geotechnical Branch) on applicability of use prior to selection. This paragraph will be typically used when there are relatively small quantity of anchors. Delete this paragraph for unit-price contracts.

**************************************************************************

Base bids upon providing the number, size, capacity, and length of anchors as indicated on the [drawings]. Include the cost of all necessary equipment, tools, material, labor, and supervision required to: deliver, handle, install, grout, test, cut-off, dispose of any cut-offs, and meet the applicable contract requirements. Include mobilization, pre-drilling, and redrilling anchors. If it is found that any anchor is not of sufficient length to provide the capacity specified, notify the Contracting Officer, who reserves the right to increase or decrease the total length of anchors to be provided and installed by changing the anchor locations, requiring the installation of additional anchors, or directing the omission of anchors from the requirements shown and specified. If total number of anchors or number of each length vary from that specified as the basis for bidding, an adjustment in the contract price or time for completion, or both, will be made in accordance with the contract documents. Payment for anchors will be based on successfully installing anchors to satisfy the acceptance criteria. No additional payment will be made for: damaged, rejected, or misplaced anchors; withdrawn anchors; or other excesses beyond the assumed anchor length indicated for which the Contractor is responsible. [Include payments for vibration monitoring, sound monitoring and precondition construction surveys].

]1.5 UNIT PRICES

**************************************************************************

NOTE: If Section 01 20 00 PRICE AND PAYMENT PROCEDURES is included in the project specifications, this paragraph title (UNIT PRICES) should be deleted from this section and the remaining appropriately edited subparagraphs below should be inserted into Section 01 20 00.

**************************************************************************

1.5.1 Drilling Holes in Soil

**************************************************************************

NOTE: This payment item will be used only when a prescriptive specification is desired. It will be deleted when a performance specification is desired.

**************************************************************************

1.5.1.1 Payment

Payment will be made for costs associated with Drilling Holes in Soil.
1.5.1.2 Measurement

Drilling Holes in soil will be measured for payment to the nearest 300 mm foot, based upon the meters linear feet of hole actually drilled in soil in accordance with the specifications.

1.5.1.3 Unit of Measure

Meter Linear foot.

1.5.2 Drilling Holes in Rock

**************************************************************************
NOTE: This payment item will be used only when a prescriptive specification is desired. It will be deleted when a performance specification is desired.
**************************************************************************

1.5.2.1 Payment

Payment will be made for costs associated with Drilling Holes in Rock.

1.5.2.2 Measurement

Drilling Holes in Rock will be measured for payment to the nearest 300 mm foot, based upon the meters linear feet of hole actually drilled in rock in accordance with the specifications.

1.5.2.3 Unit of Measure

Meter Linear foot.

1.5.3 [Soil] [Rock] Anchors

**************************************************************************
NOTE: This payment item will be used only when a prescriptive specification is desired. It will be deleted when a performance specification is desired.
**************************************************************************

1.5.3.1 Payment

Payment will be made for costs associated with furnishing and installing [Soil] [Rock] Anchors. No payment will be made for anchors which do not meet the acceptance criteria.

1.5.3.2 Measurement

[Soil] [Rock] Anchors will be measured for payment to the nearest 300 mm foot, based upon the meters linear feet of anchor actually installed below the bearing plate in accordance with the specifications.

1.5.3.3 Unit of Measure

Meter Linear foot.
1.5.4 Performance Tests

1.5.4.1 Payment

Payment will be made for costs associated with performing Performance Tests on anchors which are accepted.

1.5.4.2 Measurement

Performance Tests will be measured based upon the number of tests performed.

1.5.4.3 Unit of Measure

Each.

1.5.5 Proof Tests

1.5.5.1 Payment

Payment will be made for costs associated with performing Proof Tests on anchors which are accepted.

1.5.5.2 Measurement

Proof Tests will be measured based upon the number of tests performed on anchors which are accepted in accordance with the specifications.

1.5.5.3 Unit of Measure

Each.

1.5.6 Creep Tests

1.5.6.1 Payment

Payment will be made for costs associated with performing Creep Tests on anchors which are accepted. No payment will be made for creep tests on anchors which do not meet the acceptance criteria.

1.5.6.2 Measurement

Performance Tests will be measured based upon the number of tests performed on anchors which are accepted in accordance with the specifications.

1.5.6.3 Unit of Measure

Each.

1.5.7 [Soil] [Rock] Anchors, Complete

**************************************************************************
NOTE: This payment item will be used only when a performance specification is desired. It will be deleted when a prescriptive specification is desired.

If significant variation in length and/or type of anchors is anticipated, separate payment items should be considered for different ranges in anchor length.
1.5.7.1 Payment

Payment will be made for costs associated with furnishing and installing [Soil] [Rock] Anchors, Complete which are accepted. The price must include installation of anchors and proof testing as specified. No payment will be made for anchors which do not meet the acceptance criteria, except when failure is due to lower than assumed [soil-][rock-]grout bond strength or other information furnished by the Government.

1.5.7.2 Measurement

[Soil] [Rock] Anchors, Complete will be measured based upon the number of anchors installed and accepted in accordance with the specifications.

1.5.7.3 Unit of Measure

Each.

1.5.8 Watertightness Testing

**************************************************************************

NOTE: This payment item will be deleted when watertightness testing is not required.
**************************************************************************

1.5.8.1 Payment

Payment will be made for costs associated with Watertightness Testing.

1.5.8.2 Measurement

Watertightness Testing will be measured for payment based upon the number of watertightness tests actually performed at the direction of the Contracting Officer and in accordance with the specifications or as otherwise required.

1.5.8.3 Unit of Measure

Each.

1.5.9 Pregrouting Holes

**************************************************************************

NOTE: This payment item will be deleted when hole pregrouting is not required.
**************************************************************************

1.5.9.1 Payment

Payment will be made for costs associated with Pregrouting Holes [which fail] [prior to] watertightness testing.

1.5.9.2 Measurement

Pregrouting Holes will be measured for payment based upon the number of 94-pound bags of cement grout or neat cement grout that were actually injected into the anchor hole as specified.
1.5.9.3 Unit of Measure

Bags of cement (42 kg 94 lbs).

1.5.10 Redrilling Grouted Holes

******************************************************************************
NOTE: This payment item will be deleted when grouted hole redrilling is not required.
******************************************************************************

1.5.10.1 Payment

Payment will be made for costs associated with Redrilling Grouted Holes.

1.5.10.2 Measurement

Redrilling Grouted Holes will be measured for payment to the nearest 300 mm foot, based upon the meters linear feet of hole actually drilled in grout in accordance with the specifications.

1.5.10.3 Unit of Measure

Meter Linear foot.

1.6 DEFINITIONS

The following definitions are in addition to those given in PTI DC35.1, Section 2.0:

1.6.1 Anchored Structure

The wall, foundation or other structure to which the anchor is to transfer force.

1.6.2 Demonstration Test Anchor

An anchor which is performance tested to verify design assumptions and installation practices.

1.7 SUBMITTALS

******************************************************************************
NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up
to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy, Air Force, and NASA projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy, Air Force and NASA projects, or choose the second bracketed item for Army projects.

**************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-01 Preconstruction Submittals

   Fabricator Qualifications; G[, [____]]
   Installer Qualifications; G[, [____]]

SD-02 Shop Drawings

   Fabrication and Installation Drawings; G[, [____]]

SD-03 Product Data

   Equipment
   Designer Qualifications; G[, [____]]
   Core Logging and Soil Sampling; G[, [____]]
   Installation Plan; G[, [____]]

   Design Computations; G[, [____]]
   Anchor Design; G[, [____]]
   Design Schedule

SD-06 Test Reports

   Prestressing Steel

SECTION 31 68 13  Page 19
1.8 QUALITY ASSURANCE

Submit anchor designer, fabricator and installer qualifications for approval in accordance with paragraph SUBMITTALS. The submittals must, where applicable, identify individuals who will be working on this contract and their relevant experience. No changes must be made in approved personnel without prior approval of the Contracting Officer.

1.8.1 Designer Qualifications

The anchors must be designed by Professional Engineers who have designed a minimum [three] [ten] anchors projects similar in size and scope to this project within the past ten years. The drawings and calculations must be signed by the Professional Engineer.

1.8.2 Fabricator Qualifications

The anchors must be fabricated by a manufacturer that has been in the practice of designing and fabricating anchors similar in size and scope to this project for at least [ten] years.

1.8.3 Installer Qualifications

Submit the qualifications and experience records for approval. In the experience record, identify all the individuals responsible for the anchors and must include a listing of projects of similar scope performed within the specified period along with points of contact. Qualifications prior to the installation of any anchors specified in this section. The anchors must be installed by a firm which is regularly engaged in the installation of anchors and has at least [ten] years experience in
the installation of similar anchors. The superintendent must have installed anchors on at least [five projects of similar scope and size] [___ years of experience installing ground anchors].

1.8.4 Core Logging and Soil Sampling

**************************************************************************
NOTE: Core logging and soil sampling should only be required when necessary to verify design assumptions or to provide additional foundation information.
**************************************************************************

Logging of core and preparation of drilling logs and records must be performed by a [Registered] Geologist or Geotechnical Engineer who has at least [five] [_____] years experience in identifying and logging rock core and soil samples.

1.9 DELIVERY, STORAGE, AND HANDLING

Materials must be suitably wrapped, packaged or covered at the factory or shop to prevent being affected by dirt, water, oil, grease, and rust. Protect materials against abrasion or damage during shipment and handling. Place materials stored at the site above ground on a well-supported platform and covered with plastic or other approved material. protect materials from adjacent construction operations. Grounding of welding leads to prestressing steel will not be permitted. Reject and remove from the site prestressing steel which is damaged by abrasion, cuts, nicks, heavy corrosions, pitting, excessive heat, welds or weld spatter. Inspect tendons prior to insertion into anchor holes for damage to corrosion protection. Repair any such damage in a manner recommended by the tendon manufacturer and approved by the Contracting Officer. Lifting of pre-grouted tendons must be to manufacturers' recommendations and not cause excessive bending, which can debond the prestressing steel from the surrounding grout.

PART 2 PRODUCTS

2.1 MATERIALS

2.1.1 Prestressing Steel

Submit certified test reports for each heat or lot of prestressing steel with materials delivered to the site. [Strands must conform to PTI DC35.1 -14 Section 4.2.1.] Submit [5] [_____] copies of mill reports and [5] [_____] copies of a certificate from the manufacturer stating chemical properties, ultimate strengths, yield strengths, modulus of elasticity, and any other physical properties needed for the required computations, for the type of steel furnished.

2.1.1.1 High-Strength Steel Bars

ASTM A722/A722M, Type [I] [or] [II], meeting all supplementary requirements.

2.1.1.2 Epoxy-Coated Steel Bars

Submit written certification for coating material and coated bars with the delivery of the bars. Epoxy coated steel bars must conform to PTI DC35.1 -14 Section 4.2.4. Coating at the anchorage end may be omitted over the length provided for threading the nut against the bearing plate.
2.1.1.3 Steel Bar

[ASTM A615/A615M] [ASTM A108, Grade [___]].

2.1.1.4 Strand

ASTM A416/A416M, Grade [1725] [1860] [250] [270], low relaxation strand. Do not weld strand.

2.1.1.5 Compact Strand

ASTM A779/A779M, Type [1790] [1860] [260] [270], low relaxation strand. Strand must not be welded.

2.1.1.6 Epoxy Coated Strand

ASTM A882/A882M, Grade [1725] [1860] [250] [270], including Supplementary Requirements S1.

2.1.2 Structural Steel

ASTM A36/A36M [ASTM A572/A572M, Grade 345 50] [ASTM A588/A588M] [ASTM A709/A709M, Grade 248 [345] [36] [50]].

2.1.3 Steel Pipe

ASTM A53/A53M, Type E or S, Grade B.

2.1.4 Steel Tube

[ASTM A500/A500M] or [API Spec 5CT, Grade N-80, Oil Field Seconds / Mill Secondary Tubing].

2.1.5 Ductile Iron Castings

ASTM A536.

2.1.6 Polyethylene Tubing

2.1.6.1 Smooth Polyethylene Tubing

[ASTM D3350] [ASTM D1248, Type III].

2.1.6.2 Corrugated Polyethylene Tubing

PTI DC35.1-14 Section 4.7, with average minimum wall thickness of 1.5 mm 0.06 inch.

2.1.7 Smooth Polypropylene Tubing

ASTM D4101, designation PP 210 B5542-11.

2.1.8 Polyvinyl Chloride (PVC) Pipe

ASTM D1785[, Schedule 40].
2.1.9 Polyvinyl Chloride (PVC) Tubing

2.1.9.1 Smooth Polyvinyl Chloride (PVC) Tubing

ASTM D1784. [Class 12454 or 13464.]

2.1.9.2 Corrugated Polyvinyl Chloride (PVC) Tubing

Manufactured from rigid PVC compounds conforming to ASTM D1784, Class 13464-8 with average minimum wall thickness of 1.0 mm 0.04 inch.

2.1.10 Heat Shrinkable Sleeve

Radiation crosslinked polyolefin tube internally coated with an adhesive sealant and conforming to PTI DC35.1-14 Section 4.8.1.

2.1.11 Corrosion Inhibiting Compound

The corrosion inhibiting compound must conform to the requirements of Section 4.6 of PTI DC35.1-14.

2.2 MANUFACTURED UNITS

2.2.1 Anchor Head

Anchor head must consist of [steel bearing plate with wedge plate and wedges for strand anchors] [or] [steel bearing plate with nut for bar anchors], trumpet and corrosion protection. Submit bearing plate material and details.

Anchorage devices must be capable of developing 95 percent of the guaranteed ultimate strength of prestressing steel. The anchorage devices must conform to the static strength requirements of Section 3.1.6 (1) and Section 3.1.8 (1) and (2) of PTI TAB.1. [Wedges must be designed to not cause premature failure of the prestressing steel due to notching or pinching. Provide special wedges as required for epoxy coated strand. Removal of epoxy coating to permit use of standard wedges will not be permitted.] [Design threaded anchorage items for epoxy coated bars to fit over the epoxy coating and maintain the capacity of the prestressing steel.] Fabricate the trumpet used to provide a transition from the anchorage to the unbonded length corrosion protection from steel pipe or steel tube. The minimum wall thickness must be 3.0 mm for diameters up to 100 mm and 5.0 mm for larger diameters 0.125 inch for diameters up to 4 inches and 0.20 inch for larger diameters. Weld the trumpet to the bearing plate.

2.2.2 Prestressing Steel Couplers

[Prestressing steel couplers for bars must be capable of developing 100 percent of the minimum specified ultimate tensile strength of the prestressing steel.] [Splicing of strand will not be permitted.]

2.2.3 Centralizers and Spacers

Fabricate centralizers [and spacers] from plastic, steel or other approved material which is nondetrimental to the prestressing steel. Do not use wood. The centralizer must be able to support the tendon in the drill hole and position the tendon so a minimum of 13 mm 0.5 inch of grout cover is provided. Centralizers and spacers must permit grout to freely flow up the
2.2.4 Casing

Casing must be [steel pipe] [or] [steel tube] [selected and sized by the Contractor where required. Casing must be the necessary type and size to permit proper drilling of anchor holes and placing of anchors as specified herein and shown on the drawings. Straightening of casings and machining of joints may be necessary in order to meet specified alignment tolerances.]

2.2.5 Anchorage Covers

**************************************************************************
NOTE: When the anchorage recess is to remain open, delete the last sentence. If anchor head has 75 mm 3 inches or more of concrete or non-shrink grout cover, the anchorage cover may be eliminated and the anchorage coated to prevent corrosion.
**************************************************************************

Fabricate anchorage covers from steel or plastic. The material used must not be subject to attack by cement, corrosion-inhibiting greases or the environment. If plastic is used, it must not be susceptible to ultraviolet light degradation. Securely attach the cover to the bearing plate. If the cover is to be grease filled, the cover must form a permanent watertight enclosure for the anchorage device.

2.3 EQUIPMENT

The Contractor's Quality Control manager must verify that the equipment used on site is the same as the equipment submitted for approval. Submit catalog cuts, brochures, or other descriptive literature describing the equipment to be used for drilling, grouting, handling, and installing the [soil] [rock] anchors. Submit sketches, drawings or details showing the access and temporary supports where required for the drilling equipment and stressing frames. Provide descriptions of stressing jacks, gages, dynamometers, load cells, or other devices for measuring stressing load, certified calibration records for each set of jacking equipment, and current testing curves for stress measurement gages which show that gages have been calibrated for the jacks for which they are used [30] [_____] days prior to the start of the testing operations.

2.3.1 Drilling Equipment

Provide drilling equipment suitable for advancing the drill tools to the depths and at the alignment [specified][required].

2.3.2 Grouting Equipment

2.3.2.1 Grout Mixer

Grout mixer must conform to PTI DC35.1-14 Section 7.8.1.

2.3.2.2 Grout Pump

The grout pump must be of the positive displacement type, and must be capable of pumping at all flow rates below [75] [_____] L/minute [20] [_____] gpm, must be capable of pumping at the pressure of at least 345 [_____] kPa [50] [_____] psi at zero flow rate. For neat cement grout, the
pump must have a screen with \( [3] \) [\_] mm \( [0.125] \) [\_] inch maximum clearance to sieve the grout before being introduced into the pump. Screens are not required for shear type mixers. Make available a pump which is capable of pumping both neat cement grout mixes and sanded grout mixes. The pumping equipment must have a pressure gage capable of measuring pressures of at least 1.0 MPa 150 psi or twice the required grout pressure, whichever is greater.

2.3.3 Stressing Equipment

Stressing equipment must be hydraulically operated and must have a capacity sufficient to stress the anchors to the [specified][required] Test Loads within the rated capacity in one stroke. Pumps must be capable of applying each load increment in less than 60 seconds and must be capable of maintaining the hydraulic pressure within 345 kPa 50 psi. The equipment must permit stressing of the tendon in increments and raising or lowering the load in the tendon. [Stressing equipment for strands must be capable of stressing all elements equally and simultaneously.] Calibrate the equipment with an accuracy of \( +2 \) percent and ensure that the calibration certificate and graphs must be available at the site. The production gage must have graduations of 500 kPa 100 psi or less. Maintain a second certified gage for periodic verification of the production gage. Provide a dial gage or approved device to measure total tendon elongation at each load increment to the nearest 0.03 mm 0.001 inch. The dial gage must be capable of measuring the entire anchor movement without being reset. Verify the calibration of gages no more than 30 calendar days prior to commencing work under this contract and at six-month intervals throughout the period of use.

2.3.4 Testing Equipment

Provide testing equipment consisting of a hydraulic jack with calibrated pressure gage for applying the load and a dial gage or vernier scale to measure anchor movement. The ram travel of the stressing equipment must be not less than the theoretical elastic elongation of the total anchor length at the maximum Test Load. Graduate the pressure gage in [500] [\_] kPa [100] [\_] psi increments. Calibrate the stressing equipment and pressure gage as a unit no more than 30 calendar days prior to commencing work under this contract and at six-month intervals throughout the period of use. The movement measuring device must have a minimum travel equal to the theoretical elastic elongation of the total anchor length at the maximum Test Load without resetting the device. Provide an approved dial gage or vernier scale and stand to measure movement of the [wall] [structure].

2.4 GROUT

2.4.1 Cement

**************************************************************************
NOTE: When the ambient rock temperature is below 10 degrees C 50 degrees F, Type III cement may be necessary.
**************************************************************************

ASTM C150/C150M, Type I, II, III or V.
2.4.2 Water

Provide fresh, clean, potable water free from injurious amounts of sewage, oil, acid, alkali, salts, or organic matter.

2.4.3 Aggregates

Fine aggregate for sand-cement grout must conform to ACI 301M and [ASTM C33/C33M for grout for backfilling holes] [or ASTM C144 for grout for pregrouting]. Aggregates must not contain substances which may be deleteriously reactive with alkalis in the cement.

2.4.4 Admixtures.

******************************************************************************
NOTE: Accelerators are not permitted because of concern that they may cause corrosion of the prestressing steel. Only plasticizers or retarders should be permitted when necessary for hot conditions or long pumping distances.
******************************************************************************

Admixtures which control bleed, improve flowability, reduce water content and retard set may be used in the grout subject to the approval of the Contracting Officer. Any admixtures used must be compatible with the prestressing steel and must be mixed in accordance with the manufacturer's recommendations.

2.4.5 Grout for Anchors

******************************************************************************
NOTE: Ground and rock ambient temperatures may only have an effect on the grout when they are below 10 degrees C 50 degrees F or when polyester resin grout is used. If unusual ground or rock temperatures are known to exist, this information should be provided to the Contractor.
******************************************************************************

2.4.5.1 Cement Grout

Cement grout must conform to PTI DC35.1-14 Section 6.11 and Section 7.8.2.3. Submit cement grout mixture proportions.

2.4.5.2 Polyester Resin Grout

******************************************************************************
NOTE: Polyester resin grout should not be used for anchors installed in wet holes. Single stage grouting can be accomplished with polyester resin grout by using fast setting resin grout in the bond zone and slower setting resin grout in the free stressing zone. The cure times of the resin grout will be affected by ground or rock ambient temperatures.
******************************************************************************

Polyester resin grout must consist of high strength, unsaturated polyester resin filled with nonreactive, inorganic aggregate and a separated catalyst.
contained in a tube of polyester film or glass. Gel time and cure time must be appropriate for the installation procedures. The polyester resin grout must have the following minimum properties:

<table>
<thead>
<tr>
<th>Property</th>
<th>Minimum Properties</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compressive Strength</td>
<td>83 MPa 12000 psi</td>
</tr>
<tr>
<td>Tensile Strength</td>
<td>27.6 MPa 4000 psi</td>
</tr>
<tr>
<td>Shear Strength</td>
<td>20.7 MPa 3000 psi</td>
</tr>
</tbody>
</table>

Resin cartridges with expired shelf life are not allowed.

2.4.6 Sand-Cement Grout

**************************************************************************

NOTE: Where an excessive volume of neat cement grout is required for pregrouting holes or grouting holes which fail watertightness tests, sand-cement grout may be used. The section below provides two options for sand-cement grout mix. The first option for grout mix is suitable for normal applications. When a specific strength grout is required, the second option should be used.

**************************************************************************

Grout for waterproofing holes, grouting holes which fail the watertightness test, and for backfilling holes which are abandoned must consist of a mixture of portland cement, [fine aggregate] [masonry sand] and water. [The grout must consist of one-part portland cement and two parts fine aggregate by volume, mixed with sufficient water to provide a uniform consistency.] [The grout mix proportions are the responsibility of the Contractor. Submit the proposed mix design to the Contracting Officer for approval. The water content must be the minimum necessary for proper placement. Base the final proportions of materials on results of tests made on sample mixtures of grout. The minimum compressive strength of two-inch cubes, molded, cured, and tested in accordance with ASTM C109/C109M, must be [27.6] [_____] MPa [4,000] [_____] psi.] The Contractor is responsible for taking, curing, and breaking of grout test cubes for determining mix design, and all testing must be done by an independent laboratory approved by the Contracting Officer. [Replicate [soil] [rock] conditions and temperatures in the curing process.]

2.4.7 Grout for Anchor Pads

Use nonshrink grout conforming to ASTM C1107/C1107M for leveling bearing plates.

2.5 TENDON FABRICATION

**************************************************************************

NOTE: The tendon consists of the prestressing steel, anchorage, corrosion protection, centralizers and spacers, and sheathing where required. For fully bonded anchors, the free stressing length is grouted after stressing. For unbonded anchors, the free stressing length is provided with bond breaker to prevent bonding with the grout or two-stage grouting is performed.
2.5.1 General

Fabrication of the anchors must be as recommended by the suppliers. Completely assemble anchors with all [centralizers], [spacers], grout and vent tubes and corrosion protection prior to insertion into the hole. Protect, transport and store fabricated anchors in a manner to prevent contamination or damage to any components.

2.5.2 Tendon

Locate all spacers for multiple element tendons as indicated on the approved shop drawings. Furnish strands full length with no splicing or coupling permitted. Tendon material must be unblemished and free of pitting, nicks, grease, or injurious defects. When required to maintain the tendon location within the hole, provide centralizers at a maximum of [3] [_____] meter [10] [_____] foot intervals center-to-center throughout the bond length. [Provide spacers at a maximum [3] [_____] meter [10] [_____] foot intervals center-to-center throughout the bond length.] The entire bond length of the tendon must be free of dirt, lubricants, loose rust, corrosion-inhibiting coatings or other contaminants.

2.5.3 Bond Breaker

Bond breaker for free stressing length of unbonded anchors must consist of smooth polyethylene tubing, minimum wall thickness 1 mm 0.04 inch, or smooth PVC tubing, minimum wall thickness 1.0 mm 0.04 inch.

2.5.4 Vent Tubes

Vent tubes used during grouting operations, if necessary, must be any appropriate type for the job, as recommended by the supplier of the anchors.

2.5.5 Grout Tubes

Grout tubes must be polyethylene tubing or as recommended by the anchor manufacturer and approved by the Contracting Officer. Inside diameter of grout tubes must be adequate to fully grout the entire hole.

2.5.6 Corrosion Protection

*********************************************************

NOTE: Type of corrosion protection required will be determined in accordance with PTI DC35.1, Paragraph 5.3. Fusion bonded epoxy coatings may contain holidays and may be damaged during fabrication and installation, therefore epoxy coating should not be relied on to provide adequate corrosion protection. The grout or encapsulation must be included in the corrosion protection design. The paragraphs on encapsulation will be included for Class I (Encapsulated Tendon) corrosion protection. Additional corrosion protection may not be required for temporary anchors.

*********************************************************

Corrosion protection must be as indicated. Provide corrosion protection for the entire anchor and include anchorages covers and trumpets filled
with corrosion inhibiting compound or grout and encapsulation of the free stressing length and bond length.

2.5.6.1 Anchorage Protection

**************************************************************************
NOTE: Compound filled trumpets should only be used for restressable anchors or anchors with permanent load cells.
**************************************************************************

The trumpet must be sealed to the bearing plate and must overlap the free stressing length encapsulation by at least \textbf{100 mm 4 inches}. The trumpet and anchorage cover must be completely filled with corrosion inhibiting compound or grout. Compound filled trumpets must have a permanent seal between the trumpet and the free length corrosion protection.

2.5.6.2 Free Stressing Length Encapsulation

**************************************************************************
NOTE: Encapsulation of the free stressing length is intended to provide corrosion protection in the free stressing length. If corrugated tubing or heat shrinkable sleeve is used for encapsulation for unbonded anchors, a separate bond breaker must be used.
**************************************************************************

Encapsulation for free stressing length must consist of a sheath of smooth polyethylene tubing, minimum wall thickness \textbf{1.5 mm 0.06 inch}; smooth polypropylene tubing, minimum wall thickness \textbf{1.5 mm 0.06 inch}; smooth PVC tubing, minimum wall thickness \textbf{1.0 mm 0.04 inch}; steel pipe or tube with minimum wall thickness \textbf{5.0 mm 0.20 inch} or corrugated tubing conforming to paragraph Bond Length Encapsulation. Sheath for bars and strands may be heat shrinkable sleeve with a minimum thickness of \textbf{0.6 mm 0.024 inch}. Free stressing length encapsulation must extend at least \textbf{100 mm 4 inches} into the trumpet, but must not contact the bearing plate during testing and stressing of the tendon. [Where corrugated tubing is used for sheath for unbonded anchors, a separate bond breaker must be provided.]

2.5.6.3 Bond Length Encapsulation

**************************************************************************
NOTE: Encapsulation of the bond length for Class I (Encapsulated Tendon) corrosion protection is intended to provide corrosion protection in the bond zone and transfer stresses from the prestressing steel through the grout. For Class II (Grout Protected Tendons) corrosion protection, the grout provides the only corrosion protection in the bond zone, and separate encapsulation will not be specified.
**************************************************************************

Bond length encapsulation must consist of corrugated polyethylene tubing, minimum wall thickness \textbf{1.5 mm 0.060 inch} or corrugated PVC tubing, minimum wall thickness \textbf{1.0 mm 0.040 inch}. 
2.6 TESTS, INSPECTIONS, AND VERIFICATIONS

Perform required material tests, on prestressing steel and accessories, by an approved laboratory to demonstrate that the materials are in conformance with the specifications. Test grout in accordance with ASTM C109/C109M. These tests will be at the Contractor's expense. Furnish to the Contracting Officer prestressing steel test results prior to beginning fabrication of any anchors and within 24 hours of testing.

PART 3 EXECUTION

3.1 DRILLING HOLES

3.1.1 General

**************************************************************************
NOTE: If redesign of anchored structures due to relocation of anchors is to be performed by the Contractor, the appropriate design criteria must be furnished by the Government.

Limitations on distance between grout holes and holes being drilled is based on prevention of washout of fresh grout by drill water. The actual distance, if required, should be determined on the basis of integrity of the rock and whether or not the hole was pregrouted.

When environmental considerations require containment and disposal of waste water, the last two sentences should be included and the work should be coordinated with Section 01 57 19 TEMPORARY ENVIRONMENTAL CONTROLS.

**************************************************************************

The [top of bond zone elevations] [and other] physical conditions indicated on the drawings are the result of [soil sampling] [and] [core borings]. (See also paragraph "PROJECT SITE CONDITIONS"). Drill holes at the locations and inclinations shown and to the depths and diameters determined by the Contractor to provide the design bond length and capacity indicated on the drawings. The locations of the holes may be changed only as approved by the Contracting Officer. Any redesign of the [anchored structure] [_____] due to relocation of anchor holes [must be performed by the Government] [must be performed by the Contractor]. Unless otherwise specified, the Contractor must determine the drilling method to be used. Do not drill holes within [[15] [_____] meters [50] [_____] feet of] a grouted hole until the grout has set at least 24 hours. [Do not preform pressure grouting and drilling simultaneously within a distance of [15] [_____] meters [50] [_____] feet.] Take care while drilling to avoid damage of any kind to the existing structures. Damages of any nature will be evaluated by the Contracting Officer and repairs or replacements must be made as required. Drill holes a maximum of [1] [_____] meter [3] [_____] feet beyond the required anchor bond length. Provide a temporary plug for all holes drilled more than 10 days prior to installation of the anchor. [Collect, recycle, or treat waste water from drilling operations; do not discharged directly into the [river] [water] or on the ground. See also Section 01 57 19 TEMPORARY ENVIRONMENTAL CONTROLS].

SECTION 31 68 13 Page 30
3.1.2 Drilling Through Existing Structures

**NOTE:** Core drilling through existing structures should only be required where close tolerances are required or where vibrations from other drilling methods might be objectionable.

Drill holes through existing structure by [core drilling equipment to prevent] [any method which does not cause] damage to the surrounding structure. The Contractor is advised that foreign material, including metals and other materials remaining from original construction of the existing structure, may be encountered during drilling through existing structures.

3.1.3 Drilling in Soil

**NOTE:** Where loss of surrounding material could endanger nearby structures, the casing should be advanced by methods which preclude removal of material surrounding the casing, such as use of duplex method with annular flow of drill water or fluid between the inner drill string and the casing.

Holes in soil may be drilled by rotary drilling, rotary percussive, or vibratory driven casing. Holes in soil must be provided with steel casing where required for support of the surrounding material. [Remove casing [prior to] [during] anchor grouting.] [Remove hollow-stem augers which are used for installation of the tendon during anchor grouting.] Where soil is susceptible to caving, holes through soil must be drilled by the duplex method using an inner and outer casing with return water flow between the casings.

3.1.4 Casing

**NOTE:** Casing may also be required to span voids when drilling through existing structures.

Utilize casing for drilling through unstable soil formations [and] [____]. Advance the casing by [rotary drilling] [or] [driving].

3.1.5 Drilling in Rock

**NOTE:** Core drilling is more expensive and slower than other drilling methods and should be specified only where excessive vibration could endanger existing structures or would otherwise be objectionable, where it is expected that embedded items will be encountered in an existing structure, or as otherwise determined by the designer to be necessary. Anchor holes which are core drilled may require overdrilling with a roller bit or other approved means to roughen the circumference of the
hole to promote bond with the grout. Where existing foundation information is not complete, e.g. when anchoring existing structures, it may be advisable to require core drilling for initial (demonstration test) anchor holes in each area to determine the nature of the rock material and permit determination of actual hole depths. If sufficient foundation information cannot be provided to permit the Contractor to estimate design and installation of the anchors prior to bidding, the prescriptive tailoring option should be used.

**************************************************************************

Unless otherwise specified, holes in rock may be drilled by core drilling, rotary drilling, percussion drilling or down-the-hole hammer using equipment suitable for the intended purpose. [The drilling method must not cause structural damage to existing structures. Modify drilling method if damage is observed.] [Perform core drilling with rotary drilling equipment using diamond-matrix coring bits.] [Core from holes must be furnished to the Contracting Officer in core boxes at the site for information. Additional drilling may be required based on the quality of the rock encountered. Rock core from demonstration test anchor holes only must be retained by the Contractor for the duration of the contract as specified in paragraph "Retention of Core". Retention of core from other holes, after evaluation and release by the Contracting Officer, is not required.] Overdrilling of holes by a maximum of one meter three feet beyond the required elevation will be permitted if complete removal of cuttings and other material cannot be accomplished. If the hole is overdrilled, the tendon must be supported so that the free length corrosion protection extends the required length into the trumpet and so that the anchor can be stressed.

3.1.6 Records

**************************************************************************

NOTE: If core recovery and logging is required to verify design assumptions or to provide additional foundation information, Section 02 32 13 SUBSURFACE DRILLING AND SAMPLING should be included in the project, or applicable portions should be inserted into this specification.

**************************************************************************

Submit driller logs and records as specified in paragraph Driller Logs. The presence of a Government inspector or the keeping of separate drilling records by the Contracting Officer must not relieve the Contractor of the responsibility for the work specified in this paragraph. Payment will not be made for any work for which the required records have not been furnished by the Contractor.

3.1.7 Alignment

**************************************************************************

NOTE: The specifier should consult PTI DC35.1, paragraph 7.3.5. Tolerances are governed by project-specific requirements. The practical lower bound is 0.01 rad 0.5 degree.
3.1.7.1 Tolerances

The anchor hole must be located within \([300] \text{[_____] mm} \ [12] \text{[_____] inches}\) of the plan location. The entry angle must be within \([0.05] \text{[_____] rad} \ [3] \text{[_____] degrees}\) of the specified inclination. The alignment of the drilled hole must be within \([0.05] \text{[_____] rad} \ [3] \text{[_____] degrees}\) of the theoretical alignment. Check tolerance for each anchor hole. If the hole alignment is not within these tolerances, [the hole must be backfilled with cement or sand-cement grout and a new hole drilled adjacent to the rejected hole] [notify Contracting Officer and perform corrective measures as directed]. If tolerances cannot be maintained, then notify Contracting Officer.

3.1.7.2 Alignment Check

**************************************************************************
NOTE: Alignment checks are rarely performed for soil anchors. Alignment check should only be required when the actual alignment of the anchor is critical to the design of the structure. Situations where alignment is critical include: anchors through structures with voids or embedded items, where there is a possibility that anchors could intersect each other, and where the purpose of the anchors is overturning resistance.
**************************************************************************

Check each drilled hole for alignment as specified herein upon completion of drilling and before commencement of any other work. Check direction and inclination of all anchor holes for each \([3-meter \ 10-foot] \text{[_____] intervals throughout the hole. Checking the alignment of each anchor hole must be done by measuring the inclination of the actual drilled anchor hole center line in place with respect to the specified anchor center line. The specified anchor center line must consist of a single, straight, continuous line extending from the top of the hole to the required bottom elevation of the hole. Specified anchor centerlines must slope at the inclinations shown on the drawings. The Contracting Officer must have access to holes for alignment surveys that may include, but not be limited to, slope indicators or other down-the-hole equipment. Drill rods may be required to be removed from the hole or left in place as directed by the Contracting Officer. Holes, or portions of holes, which are out of alignment must be corrected or filled with cement grout having a water-cement ratio of 0.40 or sand-cement grout, and a new hole drilled as directed by the Contracting Officer. Slight adjustments to inclinations indicated on the drawings may be required, as directed by the Contracting Officer. The Contractor is responsible for all drilled holes until accepted by the Contracting Officer. Holes to replace incorrectly drilled holes must be drilled at no additional cost to the Government. All equipment for checking alignment of anchor holes must be operated by personnel experienced in the operation of such equipment.

3.1.7.3 Alignment Checking Equipment

**************************************************************************
NOTE: Because of the expense involved, the down-hole gyrocompass should only be used when there is a reasonable anticipation that embedded metal will be encountered within the structure in sufficient mass to affect the magnetic compass. In
such case, an appropriate payment item for a cost per day should be included.

Check alignment of holes by means of a magnetic single shot survey instrument, or equal equipment, and selected based on the maximum expected range of angle deviation to be measured. [If embedded metal within the structure is reasonably believed to have affected the standard magnetic compass, then a down-hole gyrocompass may be required. Payment for use of the gyrocompass will be made at the contract unit price per day.]

3.1.8 Watertightness Testing

NOTE: Anchor holes should be watertight to prevent loss of grout from the rock zone, prevent dilution of grout prior to setting, and prevent corrosion of the tendon. Watertightness testing should be performed where any of the following conditions are known to occur or where sufficient data is not available to adequately determine the integrity of the rock:

a. the rock formation has open fractures which would permit loss of grout from around the prestressing steel after initial placement.

b. artesian water flow or seepage exists in the strata where the rock anchor is located.

c. interconnection exists between drilled holes.

Watertightness testing may be performed after drilling the hole or after pregrouting the hole. Where the rock is known to be highly fractured, pregrouting and redrilling should be considered prior to watertightness testing.

The rock portion of all drilled holes must be watertightness tested in accordance with the procedures of PTI DC35.1, Section 7.5. A packer must be used where necessary to facilitate pressure testing of the bond zone. Holes which have a water loss in excess of [9.5] [_____] liters [2.5] [_____] gallons in ten minutes must be grouted as specified in paragraph Waterproofing Anchor Holes, and redrilled.

3.1.9 Waterproofing Anchor Holes

NOTE: Where the rock is known to be fractured or have interconnections, pregrouting of the hole prior to watertightness testing may be required. Where the rock in the free stressing zone is fractured and where the anchor is installed through unconsolidated material, a packer will be required to properly grout the rock. Waterproof grouting of anchor holes should only be done with a Government representative present to avoid overruns in the amount of grout used. When cement grout take is excessive, a sand-cement grout should be used.
The rock portion of anchor holes which fail the watertightness test must be [tremie] [pressure] grouted with cement grout as specified in paragraph Grout for Waterproofing or Backfilling Holes. [A packer must be installed at the top of rock.] Grouted holes must be redrilled while the grout strength is considerably less than that of the surrounding rock, but not less than [24] [_____] hours after grouting. [If the grout take for the hole exceeds [_____] bags of cement, grouting with cement will be stopped and the hole will be grouted with a sand-cement grout.]

3.2 INSTALLATION OF ANCHORS

3.2.1 General

**************************************************************************
NOTE: Demonstration test anchors should be designated to verify the Contractor's installation methods and design assumptions. Demonstration test anchors should be installed and approved prior to drilling for other anchors represented by the anchor to facilitate changes which may be required in anchor depth or drilling techniques. Demonstration test anchors must be performance tested to verify capacity. The last sentence should only be included when verification of anchor bond length is needed prior to installation of production anchors.
**************************************************************************

The Contractor is responsible for each drilled hole until the anchor has been installed, grouted, stressed and accepted. Holes in rock and casings must be cleaned by pressurized air and/or water to remove drill cuttings and mud. [The anchors designated as demonstration test anchors must be installed and tested prior to drilling the bond zone for other anchors within the area represented by the demonstration test anchor.]

3.2.2 Placing

All the equipment used in handling and placing the anchors must be such that it does not damage or deteriorate the prestressing steel, corrosion protection, or the anchorages. Each anchor must be inspected prior to insertion into the hole. Any damage to corrosion protection must be repaired prior to insertion or, if determined by the Contracting Officer to be not repairable, the anchor must be replaced. Insertion of anchors must be in accordance with PTI DC35.1.

3.2.3 Resin Grouted Anchors

Insertion of resin-grouted anchors must be in accordance with the resin manufacturer's written recommendations and recommendations for hole diameter, cartridge selection, and tendon installation and rotation prior to installing the anchors. Tendons must be inserted until contact is made with the first cartridge. The tendon must then be rotated and advanced at the rate recommended by the resin grout manufacturer. After reaching its final position, the tendon must be rotated as recommended by the resin grout manufacturer to ensure complete mixing of the resin.

3.2.4 Cement Grouted Rock Anchors

**************************************************************************
NOTE: Single stage grouting requires the use of a bond breaker on the tendon in the free stressing zone to prevent bonding of the grout to prestressing steel in the stressing zone. When two-stage grouting is required, the specification must be modified to reflect the additional grouting step. [Second stage grouting must be performed after the anchor is stressed, tested, and locked off.]

Rock anchors are normally gravity grouted, however, in weak or weathered rock pressure grouting may be used to increase rock-grout bond, to consolidate the foundation or to provide a grout curtain to restrict flow of water through the rock. When pressure grouting is required, the specification must include the required grouting pressure. This grouting would normally take place during the waterproofing of the holes.

When the ambient rock temperature is known to be below 10 degrees C 50 degrees F, the provisions of ACI 306R should be added.

Grouting equipment must be of type and capacity required for successful installation of the rock anchors. All anchors must use single stage grouting to encase the anchor. Grouting must be performed by a method in accordance with PTI DC35.1, paragraph 7.6. Grouting must commence at the bottom of the grout zone and proceed to the top of the zone. Grouting must be gravity flow. [The casing must be withdrawn as the grouting proceeds.]

3.2.5 Grouting of Soil Anchors

NOTE: Soil anchors in cohesive soils will have somewhat higher bond strengths when pressure grouted. Soil anchors in cohesionless soils may have significantly higher bond strengths depending on the type of soil. Since the installation and grouting procedures for soil anchors are highly dependent on the specific soil conditions, the procedure should be left to the discretion of the Contractor to meet the performance criteria. When a specific grouting procedure is required to develop the design capacity, the procedure should be included in this paragraph.

Within the bond length, grout placement must proceed such that the hole is filled in a manner to prevent air voids. The soil anchor hole must be progressively filled with grout and maintained completely full from bottom to top of the zone until the grout has set. Grouting of a soil anchor hole must be performed within 48 hours of the time the hole is drilled. Grouting may be accomplished through the casing pipe, grout tubes, hollow-stem augers or hollow drill rods. The grouting procedure used must provide soil anchors which meet the specified design capacity. Post-grouting will normally result in higher bond values.
3.2.5.1 Gravity Grouting

Gravity grouting must proceed from the bottom of the hole to the top of the [bond zone] [hole].

3.2.5.2 Pressure Grouting

The method of pressure grouting must be determined by the Contractor and proven in the demonstration anchor. Production anchors must be grouted using the methods and target pressures that were used on the acceptable demonstration anchor. Grouting pressures and pumping rates must be controlled to prevent ground surface heave or fracturing. Grouting pressures must be incrementally increased until a refusal is reached or an acceptable amount of grout is pumped.

3.2.5.3 Post-Grouting

**************************************************************************
NOTE: Post-grouting is performed using grout tubes with special check valves in the grouting zone which are installed with the tendon. Post-grouting may be utilized as additional pressure grouting after initial grout has set to increase the bond values for anchors. It may also be used, when post-grouting tubes have been installed, for increasing the bond values of anchors which fail load tests. The maximum grouting pressure is determined by the pressure-volume characteristics of the soil. Three phases of post-grouting is considered to be the practical limit.
**************************************************************************

The number of phases of post-grouting must be determined by the Contractor and proven in the demonstration anchor. Production anchors must be grouted using the methods and target pressures that were used on the acceptable demonstration anchor. Grouting pressures and pumping rates must be controlled to prevent ground surface heave or fracturing. Grouting pressures must be incrementally increased until a refusal is reached or an acceptable amount of grout is pumped.

3.2.6 Anchorage Installation

The bearing plate and [anchor head] [nut] must be installed perpendicular to the tendon, within [0.05] [_____] rad [3] [_____] degrees, and centered on the tendon without bending of the stressing steel. [Wedges, wedge holes and tendons must be free of dirt, grout or other contaminants.] [Corrosion protection must be maintained intact at the anchorage and any damage must be repaired prior to stressing.]

3.3 STRESSING

**************************************************************************
NOTE: The lock-off loads should be a function of the structure being anchored and tolerable or anticipated movements for loading changes on the structure that will cause load changes on the anchor. Typically, lock-off loads are equal to or slightly higher than design loads. The last sentence should only be included when verification
of anchor length is needed prior to installation of production anchors.

3.3.1 General Requirements

After the anchor grout [in the bond zone] has reached sufficient strength in accordance with the Contractor's design the specified strength, as verified by grout cube break, the anchors must be stressed. Prior to stressing, surfaces upon which the stressing equipment is resting must be clean and the stressing equipment must be aligned as nearly with the center of the hole as possible. An Alignment Load of [10] [_____] percent of the Design Load must be applied to the anchor prior to setting dial gauges. Stress the anchor in accordance with the anchor manufacturer's recommendation, subject to the approval of the Contracting Officer. Design and Lock-off loads are given on the drawings. Determine the lock-off procedure so that the lift-off results meet the acceptance criteria specified in paragraph Acceptance. The maximum stress must never exceed 80 percent of the guaranteed ultimate strength of anchor steel. The process of stressing the anchors must be so conducted that accurate elongation of the anchor steel can at all times be recorded and compared with the computations submitted to, and accepted by the Contracting Officer. Stressing elements of strand anchors must be stressed simultaneously. Safety precautions must be taken to prevent workers from being [behind] [or in front of] the stressing equipment during stressing. Stressing of the anchors must be performed in a sequence submitted by the Contractor for review by the Contracting Officer. All stressing must be done in the presence of a representative of the Contracting Officer. At no time during the stressing and testing of an anchor will the stressing equipment be disconnected from the temporary stressing head or anchor. [Each anchor to be performance tested must be declared acceptable before proceeding with drilling for other anchors within the section [type] represented by that anchor.]

3.3.2 Lock-off

After completion of all required tests, the load must be returned to the Alignment Load and the specified Lock-off Load must be applied to the anchor. A lift-off test must be made to verify the load in the anchor tendon before the tendon is locked-off and the stressing equipment is removed. The lift-off reading must be within five percent of the specified lock-off load. If the lift-off reading is not within five percent of the specified lock-off load, the anchorage will be reset and another lift-off reading must be made. This procedure must be repeated until a satisfactory lift-off reading is obtained. After lock-off, the trumpet must be filled with [grout] [corrosion inhibiting compound] and [the anchor head protective cap must be installed] [the anchorage recess must be fully grouted flush with the adjacent surfaces].

3.4 FIELD QUALITY CONTROL

The first three anchors and a minimum of 2 percent of the remaining anchors must be designated as demonstration test anchors. Designated demonstration test anchors must be used to verify [top of rock elevation,] [rock] [soil] quality and the adequacy of the Contractor's anchor design and installation procedures. Demonstration test anchors must pass the performance test prior to placing other anchors within the section represented by the respective demonstration test anchor. All other anchors must be proof tested. During the stressing of each anchor, a record must be kept of gage

SECTION 31 68 13 Page 38
pressure and of anchor elongation at each stage of stressing to the
specified test or Lock-off Load, as applicable. The Test Load must not be
exceeded. Provide a qualified engineer to evaluate the anchor test results
and determine the acceptability of the anchors in accordance with the
criteria indicated hereunder. Final acceptance of each anchor will be made
by the Contracting Officer. All tests must be run in the presence of the
Contracting Officer or his representative.

3.4.1 Performance Test

**************************************************************************
NOTE: Performance tests cannot be performed on
fully-grouted resin-grouted anchors. The slow
setting resin cartridges cannot be installed for
resin-grouted anchors which are to be performance
tested and provision must be made for grouting the
free stressing length if the anchors are to be used
as production anchors.
**************************************************************************

Performance test must consist of cyclically and incrementally loading and
unloading the anchor, and must be conducted in accordance with PTI DC35.1,
Paragraph 8.3.2. During the testing of each anchor, a record must be kept
of gage pressure and of anchor elongation at each stage of stressing to
each Test Load required by PTI DC35.1. Measurements of the elongation of
prestressing steel must be made in accordance with PTI DC35.1. If the
total movement at the end of 10 minutes at the Test Load exceeds 1 mm 0.040
inch, the Test Load will be held an additional 50 minutes and the movement
readings will be taken at the interval specified in PTI DC35.1, Paragraph
8.3.2. Test records, including plots and graphical analysis of test data,
must be furnished upon acceptance of each performance tested anchor in
accordance with paragraph SUBMITTALS.

3.4.2 Proof Test

Proof test must consist of incrementally loading the anchor and will be
conducted in accordance with PTI DC35.1, Paragraph 8.3.3. During the
testing of each anchor, a record must be kept of gage pressure and of
anchor elongation at each stage of stressing to the Test Load required by
PTI DC35.1. Measurements of the elongation of prestressing steel must be
made in accordance with PTI DC35.1. If the total movement at the end of 10
minutes at the Test Load exceeds 1 mm 0.040 inch, the Test Load must be
held an additional 50 minutes and the movement readings will be taken at
the interval specified in PTI DC35.1, Paragraph 8.3.3. Test records,
including plots and graphical analysis of test data, must be furnished upon
acceptance of each proof tested anchor in accordance with paragraph
SUBMITTALS. The proof test results will be compared with similar anchors
in which performance tests have been performed. If any significant
variation from the proof tests occurs, the Contracting Officer may require
additional performance tests.

3.4.3 Supplementary Extended Creep Test

**************************************************************************
NOTE: Rock anchors installed in competent rock
normally do not exhibit time-dependent movement and
do not require extended creep test. However,
decomposed or weak argillaceous rock may exhibit
creep, and extended creep test should be
considered. At least 2 extended creep tests should be performed on permanent anchors in soils with a Plasticity Index greater than 20.

Where specified, anchors must have an extended creep test performed. Creep test must consist of cyclically and incrementally loading and unloading the anchor, and will be conducted in accordance with PTI DC35.1, Paragraph 8.3.4. Each maximum load must be held in accordance with PTI TAB.1, Table 8.3.4. A plot of each family of creep curves must be submitted along with the recorded readings taken at time of the test.

3.4.4 Driller Logs

NOTE: This paragraph should be used when a record of the drilling is desired for verification of design assumptions or to document the actual conditions encountered. The list of information must be edited to reflect the work involved (rock or soil anchor, core drilling, drilling methods, etc.

This paragraph includes a reference to DRILLING LOG, ENG FORM 1836 and 1836A. The forms, or appropriate local equivalent, must be added by the specifier.

Submit the original handwritten log and three (3) copies in typed format within two days of the completion of each hole. Keep accurate driller logs and records of all work accomplished under this contract and deliver complete, legible copies of these logs and records to the Contracting Officer upon completion of the work or at such other time or times as he may be directed. All such records must be preserved in good condition and order by the Contractor until they are delivered and accepted, and the Contracting Officer will have the right to examine such records at any time prior to their delivery. Separate logs must be made for each hole. Use DRILLING LOG, ENG FORM 1836 and 1836A [or other approved form which provides the required information] for his logs. The following information must be included on the logs or in the records for each hole:

a. Hole number or designation and elevation of top of hole.
b. Inclination of the hole.
c. Make and manufacturer's model designation of drilling equipment.
d. Dates and time when drilling operations were performed.
e. Time required for drilling each run.
f. Elevation of top of rock.
g. Steel casing seat elevation.
h. Depths and elevations at which core was recovered or attempts made to core including top and bottom depth of each run.
i. Geologic classification or description by depths of each stratigraphic unit cored. This classification or description must be made
immediately following the taking of the core.

j. Percentage of core recovered and rock quality designation per run.

k. Depth and elevation of rod drops and other unusual occurrences.

l. Depth and elevation at which groundwater is encountered.

m. Depths and elevations at which drill water is lost and regained and amounts.

n. Depth and elevation of bottom of hole, determined by measuring the drill steel length.

3.4.5 Anchor Records

Upon completion of installation of each anchor, the anchor records must be furnished to the Contracting Officer with [watertightness test results and report of remedial action taken,] [top of bond zone elevation,] bond length, free stressing length of anchor, grout mix, grouting pressure, [bags of cement injected] [grout volume], [and] a report of performance test or proof test [and extended creep test] results, [and hole alignment surveys].  The performance test, proof test [and extended creep test] results must include measured lengths of drill holes and anchors, the loads and elongations recorded during testing, monitoring and stressing of the anchors, and graphs of test results as specified in paragraph SUBMITTALS.  In addition as-built drawings showing the completed installation of the anchors must be furnished upon completion of installation of all anchors.

3.5 ACCEPTANCE

3.5.1 General

Acceptance of anchors must be determined by the Contracting Officer. The following criteria will be used in determination of the acceptability of each anchor:

3.5.1.1 Creep

Creep movement must not exceed 1 mm 0.040 inch at maximum Test Load during the first 10 minutes of the performance or proof test. If the creep movement exceeds this limit, it must not exceed 2 mm 0.080 inch at the maximum Test Load at the end of 60 minutes. If the creep movement exceeds 2 mm 0.080 inch at the maximum Test Load at the end of 60 minutes, the anchor will be rejected.

3.5.1.2 Movement

Apparent free length must be calculated from the observed elastic movement in accordance with PTI DC35.1, Section 8.6.2.

3.5.1.2.1 Minimum Apparent Free Length

**************************************************************************
NOTE: If the anchor is not returned to the Alignment Load after testing, only total movement data will be available. In this case, only the minimum apparent free length criteria will apply.
**************************************************************************
The calculated free length must be not less than [80] percent of the designed free tendon length plus the jack length. If the anchor does not meet this criteria, the anchor must be restressed from the Alignment Load to the Test Load and the apparent free length must be recalculated. If the anchor does not meet this criteria after 3 attempts (original plus 2 restresses), the anchor will be rejected.

3.5.1.2.2 Maximum Apparent Free Length

The calculated free length must be not more than 100 percent of the designed free tendon length plus 50 percent of the bond length plus the jack length. If the anchor does not meet this criteria, and the cause of the behavior is not investigated and explained to the satisfaction of the Contracting Officer, the anchor will be rejected.

3.5.1.3 Initial Lift-Off Reading

The initial lift-off reading must be within 5 percent of the specified Lock-off Load. If the anchor does not meet this criteria, the anchor must be adjusted as necessary and the lift-off reading must be repeated.

3.5.2 Replacement of Rejected Anchors

*********************************************************************************************************************************************
NOTE: For redesign of anchored structure due to relocation of anchor, see note at paragraph DRILLING HOLES, General.
*********************************************************************************************************************************************

Any anchor that fails the performance or proof test or is rejected by the Contracting Officer must be replaced. A replacement anchor, including a new anchor hole, must be provided by the Contractor at no expense to the Government. The location of the replacement anchor will be as directed by the Contracting Officer in accordance with the redesign of the anchored structure. Provide all materials, supplies, equipment, and labor necessary to provide a new anchor assembly to the satisfaction of the Contracting Officer. No drilling will be performed for a replacement anchor until the grouting of all rock anchors within [15] meters [50] feet of the replacement anchor location has been allowed to set for at least 24 hours. Payment will not be made for rejected or failed anchors. Either remove failed anchors and thoroughly ream and clear the anchor hole or remove the load and cut the anchor and casing flush.

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for tunnel and shaft grouting applicable to constructing new and repairing existing underground structures. This section was originally developed for USACE Civil Works projects.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1  GENERAL

1.1  SUMMARY

NOTE: The work will be under the direction of the Contracting Officer or his authorized representative, i.e., Government Representative who will be an engineering geologist or geotechnical engineer experienced in the design and grouting of tunnels and shafts.

This section describes the equipment, materials, and procedures to perform drilling and grouting work. It covers the equipment and materials to use;
drilling grout, drain and exploratory holes; installing grouting pipe and fittings; connections to grout holes; furnishing, handling, transporting, storing, mixing, and injecting grout; handling, controlling, and disposing of drill cuttings, waste water, and waste grout; patching finished grout and exploratory holes; final cleanup upon completion of work and all other operations incidental to drilling and grouting. The work consists of drilling exploratory and drain holes as directed or shown and performing [contact] and [tunnel and shaft] and [steel liner] and [ring curtain] grouting as shown. Exploratory drilling may be required to define problem areas or verify results ahead of the working face or through the lining during construction. The total amount of drilling and grouting required is not known and will be determined by conditions encountered as the work progresses. Grouting mixes, pressures, pumping rates, and the sequence in which holes are drilled and/or grouted will be determined in the field and shall be as directed. Work under this section shall be in accordance with EM 1110-1-3500, EM 1110-2-2901, and EM 1110-2-3506

1.2 UNIT PRICES

**************************************************************************
NOTE: If Section 01 20 00 PRICE AND PAYMENT PROCEDURES is included in the project specifications, this paragraph title (UNIT PRICES) should be deleted from this section and the remaining appropriately edited subparagraphs below should be inserted into Section 01 20 00.
**************************************************************************

1.2.1 Mobilization and Demobilization

1.2.1.1 Payment

Payment will be made for costs of assembling all plant and equipment at the site preparatory to initiating the work and for removing it when the drilling and grouting has been completed. Sixty (60) percent of the contract lump sum price for mobilization and demobilization will be paid following completion of moving onto the site, including complete assembly, in working order, of all equipment necessary to perform the required drilling and grouting operations. The remaining forty (40) percent of the contract lump sum price will be paid when all equipment has been removed from the site.

1.2.1.2 Unit of Measure

Unit of measure: lump sum.

1.2.2 Drilling Grout Holes

1.2.2.1 Payment

Payment will be made for costs associated with drilling and redrilling grout holes; washing and pressure testing of grout holes; containing and disposing of waste water and waste grout; clean-up of the site; furnishing, handling, transporting and storing of grout materials; and for furnishing all labor and supplies incidental to the work. [Unless otherwise specified, no] separate payment will be made for any material constituent of the grout, including cement and/or chemical grout materials placed in the performance of contract grouting. No payment will be made for grout, or the material constituents thereof, wasted due to improper
anchorage of grout pipe or connections, or which is wasted due to negligence on the part of the Contractor, nor for grout which is rejected by the Contracting Officer because of improper mixing. Payment will be made at the applicable contract unit prices for materials contained in grout which are wasted, where the wasting is not due to negligence on the part of the Contractor.

1.2.2.2 Measurement

Drilling of grout holes will be measured for payment on the basis of the linear meters feet of holes actually drilled in concrete, rock or soil, as shown or as directed, including all intermediate holes at locations where pipe was not installed.

1.2.2.3 Unit of Measure

Unit of measure: linear meter foot.

1.2.3 Drilling Drain Holes

1.2.3.1 Payment

Payment will be made for costs associated with drilling of drain holes actually drilled in concrete, rock, or soil, as shown or as directed.

1.2.3.2 Measurement

Drilling of drain holes will be measured for payment on the basis of the linear meters feet of holes actually drilled in concrete, rock, or soil, as shown or as directed.

1.2.3.3 Unit of Measure

Unit of measure: linear meter foot.

1.2.4 Drilling Exploratory Holes

1.2.4.1 Payment

Payment will be made for costs associated with drilling of exploratory holes. [Core boxes shall be provided at no additional cost to the Government.]

1.2.4.2 Measurement

Drilling of exploratory holes will be measured for payment on the basis of the linear meters feet of holes actually drilled in concrete, rock, or soil, as directed by the Contracting Officer.

1.2.4.3 Unit of Measure

Unit of measure: linear meter foot.

1.2.5 Placing Grout

**********************************************************************************************************************************************

NOTE: Select appropriate alternatives.

Under certain conditions it may be desirable to
include a pay item for standby time for Government directed suspension of drilling or grouting operations.

1.2.5.1 Payment

[Payment will be made for costs associated with satisfactorily placing grout in contact grout holes and behind steel liner, which includes full compensation for furnishing all materials, proportioning the mix as directed, drilling grout holes if necessary, and mixing and injecting the grout as specified or as directed.][Payment will be made for costs associated with satisfactorily placing grout in grout holes, which includes full compensation for proportioning the mix, mixing, and injecting the grout as specified or as directed. Separate payment will be made for all materials used in [contact ]grout as provided in unit price pay item(s) "Portland Cement in Grout" "Mineral Filler in Grout", "Sand in Grout", "Fluidifier in Grout", and "Chemicals in Chemical Grout".]

1.2.5.2 Measurement

The operation of placing grout will be measured for payment on the basis of the number of cubic meters cubic feet of the component materials (bulk materials), satisfactorily placed, exclusive of water and fluidifier and regardless of the proportions of the mixes, measured individually as specified in unit price pay items "Portland Cement in Grout", "Mineral Filler in Grout", and "Sand in Grout".][hours of satisfactory placing regardless of the proportions of the mixes. Measurement will begin with the initiation of grout injection at the proper elevation or stage and continue until grout injection ceases, for a given hole, exclusive downtime. Downtime is defined as any failure to inject grout continuously, except for intermittent grouting as directed by the Contacting Officer. Time will be measured cumulatively to the next whole hour of operation. Payment for placing grout in holes will be based on the total amount of time required for satisfactorily placing grout, determined by reducing the total number of minutes of operation to the nearest whole hour.]

1.2.6 Connections to Grout Holes

1.2.6.1 Payment

**************************************************************************
NOTE: The price to be inserted in this paragraph should be determined on the basis of the estimated cost to the Contractor for the operation of moving the grout supply line onto the hole. This price should not include any allowance for pipe or other materials used in making the connections. This unit price pay item may be optional for grout payment on an hourly basis.
**************************************************************************

[Payment will be made for costs associated with connections to grout holes at a rate of [_____] dollars per connection.] [Payment for only one connection will be made for each hole regardless of the number of settings.]
1.2.6.2 Measurement

Connections to grout holes will be measured for payment per connection for each time the grout supply line is connected to the ring grout hole or an exploratory hole for the purpose of injecting grout, regardless of the number of times such connections are made per hole or the amount of grout actually injected.

1.2.6.3 Unit of Measure

Unit of measure: each.

1.2.7 Portland Cement in Grout

1.2.7.1 Payment

Payment will be made for costs associated with Portland cement in grout.

1.2.7.2 Measurement

Portland cement in grout will be measured for payment on the basis of the number of cubic meters (42.6 kg) cubic feet (94 pounds) of cement used in the grout satisfactorily placed in ring grout holes and in filling exploratory holes, or wasted when such wasting is not due to the Contractor's negligence.

1.2.7.3 Unit of Measure

Unit of measure: meter (42.6 kg) cubic foot (94 pounds).

1.2.8 Mineral Filler in Grout

1.2.8.1 Payment

Payment will be made for costs associated with mineral filler in grout.

1.2.8.2 Measurement

Mineral filler in grout will be measured for payment on the basis of the number of cubic meters (36.3 kg) cubic feet (80 pounds) of filler used in the grout and satisfactorily placed in grout holes.

1.2.8.3 Unit of Measure

Unit of measure: cubic meter (36.3 kg) cubic foot (80 pounds).

1.2.9 Sand in Grout

1.2.9.1 Payment

Payment will be made for costs associated with sand in grout.

1.2.9.2 Measurement

Sand in grout will be measured for payment on the basis of the number of cubic meters cubic feet of sand [6] dry rodded measurement, used in the grout satisfactorily placed in ring grout holes or in filling exploratory holes.
1.2.9.3 Unit of Measure

Unit of measure: cubic foot.

1.2.10 Fluidifier in Grout

1.2.10.1 Payment

Payment will be made for costs associated with fluidifier in grout [including full allowance for the payment by the Contractor of all required royalties].

1.2.10.2 Measurement

Fluidifier in grout will be measured for payment on the basis of the number of pounds of fluidifier used in the grout satisfactorily placed in ring grout holes.

1.2.10.3 Unit of Measure

Unit of measure: kilogram pound.

1.2.11 Chemicals in Chemical Grout

1.2.11.1 Payment

Payment will be made for costs associated with chemicals in chemical grout.

1.2.11.2 Measurement

Chemicals in chemical grout will be measured for payment on the basis of the number of gallons of chemicals actually used in grout mixtures satisfactorily placed in ring grout holes.

1.2.11.3 Unit of Measure

Unit of measure: kilogram pound.

1.2.12 Steel Pipe and Fittings

1.2.12.1 Payment

Payment will be made for costs associated with embedded grout and drain hole pipe and fittings remaining in the permanent work, which includes costs for removal of pipe and fittings, and patching and cleanup pursuant to Section 31 73 19 TUNNEL AND SHAFT GROUTING, paragraph PATCHING AND CLEANUP. All pipe and fittings removed shall become the property of the Contractor.

1.2.12.2 Measurement

Embedded pipe and fittings through which holes will be drilled and grouted, as shown and as directed or approved, will be measured for payment on the basis of the actual kilograms [linear meters] pounds [linear feet], as differentiated by pipe size and schedule number, of satisfactorily installed pipe and fittings left in place. No additional allowance will be made for overweight [differences] caused by installation of oversized pipe (diameter or length) and pipes that are not specified or approved. Upon
completion of the grouting, no additional allowance will be made for costs of cutting off and removing from the project site all grout pipe connections protruding from the inside face of the concrete liner.

1.2.12.3 Unit of Measure

Unit of measure: kilogram pound.

1.2.13 Pressure Washing and Pressure Testing

1.2.13.1 Payment

Payment will be made for pressure washing, and pressure testing of grout holes and pressure testing of exploratory holes, which includes the cost of preliminary washing, materials for washing and testing, and making and breaking connections incidental to the work. Payment will be based upon the total amount of time required for pressure washing and pressure testing, determined by reducing the total number of minutes of operation to the nearest whole hour. No payment will be made for time lost due to fault or negligence of the Contractor, or due to defective equipment furnished by the Contractor.

1.2.13.2 Measurement

Pressure washing and pressure testing will be measured for payment on the basis of the actual time water pumps are operating. Pressure washing and pressure testing will be measured from the time pumping is begun on a hole or section of a hole until the time pumping is completed on the hole or section of the hole as determined by the Contracting Officer. Time will be measured cumulatively to the next whole minute of operations.

1.2.13.3 Unit of Measure

Unit of measure: nearest whole hour.

1.3 REFERENCES

**************************************************************************

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

**************************************************************************

The publications listed below form a part of this specification to the
extent referenced. The publications are referred to within the text by the basic designation only.

**AMERICAN SOCIETY OF MECHANICAL ENGINEERS (ASME)**

| ASME B16.3 | (2021) Malleable Iron Threaded Fittings, Classes 150 and 300 |

**ASTM INTERNATIONAL (ASTM)**

| ASTM C618 | (2019) Standard Specification for Coal Fly Ash and Raw or Calcined Natural Pozzolan for Use in Concrete |
| ASTM C937 | (2016) Grout Fluidifier for Preplaced-Aggregate Concrete |

**U.S. ARMY CORPS OF ENGINEERS (USACE)**

| COE CRD-C 400 | (1963) Requirements for Water for Use in Mixing or Curing Concrete |
1.4 SEQUENCING

Perform grouting in the work sequence as shown and as specified. [[Contact grouting][ and/or ][grouting behind steel liner] shall be done at a reasonable time following installation of the permanent liner and prior to any application of internal or external water pressure, air shock, or vibration.][ Tunnel and shaft grouting or ring grouting shall be done at the appropriate time during the excavation/muck/support mining cycle to achieve the desired water flow reduction or stabilization prior to the passage of any water within the tunnel or shaft.] Grouting, once started, shall normally proceed to completion without significant interruption.

1.5 SUBMITTALS

**************************************************************************
NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy, Air Force, and NASA projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy, Air Force
and NASA projects, or choose the second bracketed item for Army projects.

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-02 Shop Drawings
- Drilling Operations
- Pressure Washing and Pressure Testing Operations
- Cement and Chemical Grouting Operations

SD-03 Product Data
- Qualifications
  - Grouting Equipment; G[, [____]]
  - Grout Application; G[, [____]]

SD-04 Samples
- Grouting Material Samples; G[, [____]]

1.6 QUALIFICATIONS

Grouting shall be performed by a specialty Contractor or subcontractor experienced and competent in [cement grouting] [chemical grouting] [both cement and chemical grouting]. Submit evidence that the grouting specialist or grouting foreman has had at least 3 years experience within the past 5 years on similar grouting type projects.

Perform all grouting work under the direct field supervision of a qualified grouting specialist or grouting foreman whose qualifications have been provided to the Contracting Officer. The foreman or specialist shall supervise the performance of the work in compliance with these specifications.

PART 2 PRODUCTS

2.1 GROUTING MATERIALS

Provide grout of a nonshrink type and normally composed of water, cement, and fluidifier with shrinkage compensators (expanding agents). Use sand, admixtures to vary grout properties, and mineral fillers as specified or approved. The grout mixes will be designed or approved by the Contracting Officer and will be varied to meet the characteristics of each hole or situation as determined by the conditions encountered. The various materials furnished shall conform to the following paragraphs.

2.1.1 Water

[Furnish the water used in the grout. It shall be fresh, clean, and free of sewage, oil, or organic matter and injurious amounts of acid, alkali,
and salts or other damaging substances as determined by COE CRD-C 400. [Water suitable for use in the work will be furnished by the Government. Provide any necessary connections and extensions to the Government supply line.]

2.1.2 Cement

**************************************************************************
NOTE: Designer should insert the Section number and title that specifies the storage requirements for cement.
**************************************************************************

Provide cement used in grout conforming to the requirements of ASTM C150/C150M, portland cement Type [_____]_. Store cement in accordance with Section [03 30 00 CAST-IN-PLACE CONCRETE] [03 30 53 MISCELLANEOUS CAST-IN-PLACE CONCRETE] [_____]_. Employ methods of handling, transporting, and storage that are satisfactory to the Contracting Officer. Only cement furnished in cloth or paper bags will be accepted for use in the work unless bulk cement is approved. Store a sufficient quantity of cement at or near the site of the work to ensure that grouting operations will not be delayed due to shortage of cement. Care shall be taken in storage and handling to protect the cement from contamination and moisture. In the event the cement contains lumps or foreign matter that will not pass through a standard #100 mesh screen, remove the cement from the work site and replace it at no cost to the Government.

2.1.3 Sand

Sand for grout shall consist of hard, tough, durable, uncoated particles. It may be composed of [natural sand][manufactured sand][a combination of natural and manufactured sand]. The shape of the particles shall be generally rounded or cubical and shall not contain more than 5 percent of flat or elongated pieces having a maximum dimension in excess of five times the minimum dimension. If the sand is a combination of separately processed sizes, classification, or a combination of natural and manufactured sands, the different components shall be batched separately, or, subject to written approval, blended prior to delivery to the mixing plant. The sand shall be well-graded from fine to coarse, and the gradation, as determined in accordance with ASTM C136/C136M and ASTM C117, shall conform to the following requirements:

<table>
<thead>
<tr>
<th>SIEVE DESIGNATION (U.S. STANDARD SQUARE MESH)</th>
<th>CUMULATIVE PERCENTAGE BY WEIGHT</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>PASSING</td>
</tr>
<tr>
<td>8</td>
<td>100</td>
</tr>
<tr>
<td>16</td>
<td>95-100</td>
</tr>
<tr>
<td>30</td>
<td>60-85</td>
</tr>
<tr>
<td>50</td>
<td>20-50</td>
</tr>
<tr>
<td>100</td>
<td>10-30</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>RETAINED</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>0-5</td>
</tr>
<tr>
<td>15-40</td>
</tr>
<tr>
<td>50-80</td>
</tr>
<tr>
<td>70-90</td>
</tr>
</tbody>
</table>
In addition to the grading limits shown, all sand used in the work shall have a fineness modulus within the range of 1.50 to 2.00. The grading of the sand as delivered to the mixes, during any 24-hour period of operation, shall be controlled so that the fineness moduli of samples taken will not vary more than 0.10 from the average fineness modulus. The results of previous tests and the service record may be used to determine the acceptability of the sand. Sand shall be stored in a manner to facilitate drainage and avoid the inclusion of any foreign materials in the grout. The storage piles shall be constructed to prevent segregation and contamination.

2.1.4 Admixtures

An admixture is any material other than water, sand, and cement added to the grout immediately before or during its mixing to alter its chemical or physical properties to a desired characteristic during its fluid or plastic state. Admixtures shall conform to ASTM C494/C494M at the time of acceptance testing sample submittal; furnish certification from the manufacturer that the material meets all the requirements of these specifications. All admixtures to be used in each batch of grout shall be separately packaged and weighed prior to use. Grout fluidifier and expanding agents shall conform to the requirements of ASTM C937. Accelerator additive shall be calcium chloride (CaCl₂) in amounts up to 2 percent of the cement by weight or an approved product manufactured for the specific purpose of accelerating grout set-up time. The calcium chloride shall be granular or flaked and added to the grout by dissolving it in a portion of the mix water.

2.1.5 Mineral Filler

Fillers used in grout as replacement for a portion of the cement shall be fly ash composed of finely divided siliceous residue and in accordance with ASTM C618, Class F. The maximum amount of fly ash should not exceed 30 percent of the cement by weight.

2.1.6 Chemical Grouting Materials

**************************************************************************
NOTE: Designers should seek information from chemical grout suppliers and manufacturers and other reference material on the subject about which type(s) of chemical grout is best suited for their particular application and job.
**************************************************************************

Grouting materials shall be nonflammable and the type used in grouts that are either water-based (gel forming) or water-reactive (foam forming). Only the following water-based chemical types shall be used; silicates, acrylates, polyacrylamides, acrylamides (only certain products), modified tannin, and epoxy resins. Only the following water-reactive chemical types
shall be used; polyurethanes and elastomers. Chemical compounds shall be EPA approved. A sufficient quantity of chemical grouting materials shall be stored at or near the work site to ensure that grouting operations will not be delayed due to storage of these materials. Storage requirements, mixing, and handling of all component materials as well as the grout mixture itself shall be in accordance with the manufacturer's or supplier's recommendations.

2.2 EQUIPMENT

Drilling and grouting equipment shall be of a type, capacity, and mechanical condition suitable for the work, as approved by the Contracting Officer. Power, compressed air, all other equipment, and the layout thereof shall meet the requirements of local, State, and Federal regulations and codes, both with respect to safety and otherwise. The use of gasoline internal combustion engines for operation of drilling and grouting equipment underground is not permitted. Internal combustion engines shall be diesel powered fitted with suitable and efficient scrubbers and in compliance with EM 385-1-1.

2.2.1 Drilling Equipment

Use standard drilling equipment of the rotary, percussion, or rotary-percussion type to perform grout hole, drain hole, and exploratory hole drilling. The use of hand-held equipment, such as jackhammer or jackleg percussion-type drills for drilling holes above the horizontal, is not permitted. The equipment shall be of a type and condition that will allow a drilling rate which will not delay the work and will be adequate to maintain an alignment within a tolerance of 4 percent or less of the depth. All drilling equipment shall be properly maintained and a sufficient supply of bits, tools, and spare parts shall be kept at the job site to avoid delays. In the case of equipment breakdown, repairs shall be made promptly. Exploratory drilling shall be accomplished using rotary core drilling rigs and equipment. A standard ball bearing, swivel type, triple-tube, or double-tube core barrel shall be used at all times when drilling exploratory holes. The core barrel shall be of a length, generally 1.5 or 3 meters 5 or 10 feet, appropriate for the working space and the type of material being drilled. Appropriate coring bits for exploratory holes and drain holes shall be NW size except wire line bits shall be NQ in size or as directed. Grout hole sizes shall be EW. A wire line system shall be used on downward inclined holes that are [15][_____] meters [50][_____] feet or greater in depth.

2.2.2 Grouting Equipment

2.2.2.1 Cement Grouting Equipment

Submit a plan of the proposed grouting equipment types and layout for approval. An example of a typical grouting equipment layout is included at the end of this section. The grout plant shall be capable of supplying, mixing, stirring, and pumping the grout as specified. The plant shall have a minimum capacity of [0.11][_____] cubic meters per minute [4][_____] cubic feet per minute (cfm) of grout injected at a pressure not greater than [690][_____] kPa [100][_____] pounds per square inch (psi). It shall be maintained in first-class operating condition at all times, and any grout hole lost or damaged due to mechanical failure of equipment or inadequacy of grout supply shall be replaced at no expense to the Government. Grouting equipment to be furnished shall include the following:
2.2.2.1.1 Grout Pump

Air or electrically powered grout pump(s) of the progressive cavity (helical screw) type that is free of surging are capable of pumping a great range of grout consistencies, provide close control of pumping pressures and variable rates of injection, and can be easily and quickly serviced during grouting operations. A minimum of one spare grout pump and spare pump parts shall be available on site during all grouting operations.

2.2.2.1.2 Grout Mixer

Grout mixers either mechanically driven, high-speed, shear-type tub mixers with either vertical or horizontal drum, or high-speed colloidal mixers. Mixers shall be capable of effectively mixing and stirring a capacity of at least 0.11 cubic meters 4 cubic feet of grout with water to cement ratios from 0.6:1 to 6.0:1 and achieve mixing by constant rapid circulation of grout. The mixer shall be equipped with a suitable volume-measuring water metering device for batching water for the grout mix. The water meter shall be calibrated to read in cubic meters and thousandths cubic feet and tenths and designed in a manner that after each delivery the hands can be conveniently set back to zero. The water meter shall have a certificate of calibration from an independent laboratory. Prior to each use, the water meter shall be checked for accuracy and, if necessary, recalibrated.

2.2.2.1.3 Holding Tank or Sump

Holding tank(s) or sump(s) of the mechanically agitated type to provide a high volume and continuous injection of grout. The sump shall be capable of holding the solids of the mix in suspension and have a capacity of at least 0.34 cubic meters 12 cubic feet of grout or three times the capacity of the mixing system. Volume of grout used from the agitator holding tank(s) or sump(s) shall be measured by a vertical graduated stick or marks at different levels in the tank(s)/sump(s).

2.2.2.1.4 Supply and Pressure Control

Valves, pressure gauges, grout lines, header arrangements, and accessories as necessary to provide a continuous supply of grout and accurate pressure control. Grout shall be conveyed between the pump and the hole using a [single-line system consisting of a pipe or hose or combination of both extending from the pump discharge to the header at the hole collar with grout injection rate controlled by the pump speed] [or ] [circulating double-line system composed of a supply line to the header at the hole collar and a return line from the header to the grout pump, sump, or holding tank]. Grout lines shall consist of either black steel pipe or reinforced rubber or plastic hose or a combination of both. The maximum inside diameter of all grout lines shall be 25 millimeters 1 inch. The grout injection rate for the single-line system shall be controlled by the pump speed so that settlement of solids within the lines will not occur when pumping at or above the minimum discharge capacity of the pump. The pressure in the double-line system shall be controlled by one or more valves on the control line. The distance between the hole and the pump or holding tanks shall be as short as possible to minimize the accumulation of solids and possible clogging. Pressure gauges shall be high precision, graduated with divisions not greater than 10 kPa 2 psi on the dial face, calibrated and certified correct prior to use. Gauges shall be tested for accuracy[daily] during the work by cross comparison with a standard set of oil-filled gauges. The moving parts of all gauges shall be protected from dust, grit, and direct contact with grout.
2.2.1.5 Flow Cone

Flow cone(s) to ascertain the fluidity of grout mixtures. The flow cone and method of test shall be in accordance with ASTM C939/C939M.

2.2.1.6 Communications

Telephone or radio communications between the grout plant and the hole being grouted when the site conditions such as distance, noise level, or visual obstructions negatively impact on the proper control of grouting operations.

2.2.2 Chemical Grouting Equipment

The chemical grout plant shall be of the continuous mixing and pumping type. Provide all chemical grouting equipment in strict compliance with the grout manufacturer or supplier recommendations for the specific grout and the method to be used in grout application approved by the Contracting Officer. All equipment shall be of a type, capacity, and mechanical condition suitable for doing the work, compatible with the chemical to be handled, and maintained in first-class operating conditions throughout the job.

2.3 GROUT

2.3.1 Cement Grout

Design the grout mixture to expand [3 to 5 percent][2 to 4 percent] when tested in accordance with ASTM C940. Grout flow time-of-efflux, when tested in accordance with ASTM C939/C939M shall be [between 10 and 30 seconds]. The unconfined compressive strength of the solidified grout shall range between [3.5 and 13.8][13.8 and 20] MPa [500 and 2,000][2,000 and 3,000] psi when tested in accordance with ASTM C942/C942M.

2.3.2 Chemical Grout

Chemical grout shall be composed of commercially available materials consisting of base material, reactant, water, and accelerator if required. Set times for chemical grout shall be controllable from 1 to 30 minutes following injection. All components shall be compatible with each other and with the rock or soil and groundwater. The Contractor and manufacturer shall certify that the proposed grout is chemically stable and will not render surrounding groundwater unpotable. The grout mix shall be such that when injected in medium dense Ottawa 20-30 sand and tested by an approved method, the unconfined compressive strength of the grouted sand shall average at least 690 kPa 100 psi.

2.3.3 Grouting Material Samples

**************************************************************************
NOTE: The Designer should insert the name and address of the Division Laboratory where material samples are to be shipped and tested.
**************************************************************************

Ship grouting material samples for acceptance laboratory testing to:

[_____] Division Laboratory
The samples shall include:

<table>
<thead>
<tr>
<th>Material</th>
<th>Quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cement</td>
<td>5 sacks (or 213 kg 470 pounds)</td>
</tr>
<tr>
<td>Additive(s)</td>
<td>2.25 kg 5 pounds of each</td>
</tr>
<tr>
<td>Sand</td>
<td>0.75 cubic meter 1 cubic yard</td>
</tr>
<tr>
<td>Mineral Filler</td>
<td>68 kg 150 pounds</td>
</tr>
<tr>
<td>Chemical Grout (to include reactant and catalyst)</td>
<td>4 L 1 gallon</td>
</tr>
</tbody>
</table>

Each sample shall be from the manufacturer or supplier and representative of the materials to be used in the work or from the shipment received at the work site. Shipment shall be made to permit arrival at the lab 28 calendar days before the earliest start of grouting. Any substitution of materials after mix design is approved will require a new mix design and an additional 28 days. State the intended grout pumping temperature range. Grout mixes will be designed and approved only for the stated temperature range.

2.4 PIPE AND FITTINGS

All pipe shall conform to ASTM A53/A53M standard weight. The fittings shall be malleable iron Type I in accordance with ASME B16.3, ASME B16.5, and ASME B16.9, Class 150. Pipe shall be black steel of the diameter shown or as directed.

PART 3 EXECUTION

3.1 GROUT, DRAINAGE, AND EXPLORATORY HOLES

Holes through shotcrete or concrete or into the surrounding rock, for the purpose of injecting grout or air release and providing drainage, shall be at the location in the direction and to the depths shown or as directed or approved. Form holes by embedding pipe in the concrete or shotcrete at the time of placing or made by drilling through the concrete, shotcrete, or rock as indicated below for the various kinds of holes. All grout, drainage, and exploratory holes shall be drilled using only water or compressed air.

3.1.1 Embedded Pipe

Provide all metal pipe and fittings required for constructing grout holes, grout hole connections, and air vents. All pipe and fittings embedded in concrete shall be cleaned thoroughly of dirt, grease, grout, and mortar immediately before embedding and shall be firmly held in position and protected from damage or displacement while the concrete is being placed. Great care shall be taken to avoid premature clogging of pipes and any pipe that becomes clogged or obstructed before completion of operations shall be cleaned out in a satisfactory manner or replaced at the expense of the Contractor. All piping required for the work shall be cut, threaded, fabricated, and installed, as required.
3.1.2 Grout and Vent Hole Drilling

Grout and vent holes shall be located as shown and as directed. Grout holes drilled through shotcrete or concrete shall be of sufficient size to permit the caulking or grouting of short lengths of 40 mm 1-1/2 inch diameter pipe into the hole for attachment of the grout supply line. Grout hole diameters in rock shall be as shown within a tolerance of 6 mm 0.25 inch and not less than 35 mm 1-3/8 inch at the point of deepest penetration. The size of completed grout holes shall be checked frequently during the work to assure proper hole diameters are achieved. It is anticipated that the required depth of [ring][tunnel and shaft] grout holes will not exceed [15][_____] m [50][_____] feet. Protect each hole drilled from becoming clogged or obstructed by means of a cap or other suitable device on the collar. The use of greases, "rod dope," or other lubricants on the drill rods or in grout holes will not be permitted. No core recovery will be required, and the drilling fluid shall be water or compressed air. During the drilling of grout holes, take all precautionary measures to control dust, fumes, and noise in conformity with [other sections of these specifications and] the applicable local, State, and Federal laws, codes, and regulations. No drilling of tunnel and shaft or ring grout holes shall be accomplished until all contact grouting within [60][_____] m [200][_____] feet has been completed.

3.1.3 Drain Hole Drilling

Drainage holes shall be located as shown and as directed, and drilled through the permanent liner after all grouting from holes within [60][_____] m [200][_____] feet has been completed. Drain hole diameters shall be as shown but not less than [50][_____] mm [2][_____] inches with a tolerance of 6 mm 0.25 inch for their full lengths.

3.1.4 Exploratory Hole Drilling

Perform exploratory drilling as directed when required to determine the condition of the rock prior to grouting or the effectiveness of the grouting operations. Such drilling may be required at any inclination and in advance of the excavation face or from the perimeter of the tunnel or shaft. Exploratory drill hole depths may vary but will not exceed a maximum of [15][_____] m [50][_____] feet. The entire length of each exploratory hole shall be core drilled using water or compressed air. Core size shall be either NW (54 mm 2-1/8 inch diameter) or HQ (54 mm 2-1/2 inch diameter). Core drilling shall be performed by competent and experienced drillers and special care shall be taken to obtain cores in as good condition as possible. Core logging shall be performed by [the Government Representative][a qualified geologist experienced in core logging]. Suitable wooden core boxes will be furnished by the Government as shown in Section [02 32 13 SUBSURFACE DRILLING AND SAMPLING] [03 37 29 CONCRETE FOR CONCRETE CUTOFF WALLS] shall be furnished by the Contractor for core storage in a suitable area on site. Core boxes shall be protected from the weather prior to being delivered to the storage area upon completion of each exploratory drill hole. Place the core in the boxes in the correct sequence with each run marked by accurately labeled wooden blocks according to the measured distances in the holes. No box shall contain cores from more than one hole.

3.1.5 Disposal of Drill Cuttings

Remove drill cuttings and water produced during the drilling process from the tunnel or shaft area on a routine basis to avoid buildup that may
impede the function of temporary or permanent drainage system components such as slotted pipe, sumps, and pumps. Drill cuttings shall be disposed of at an approved location outside the tunnel or shaft.

3.2 GROUTING PROCEDURES

Perform grouting in the presence and under the direction of the Contracting Officer. Remove cement grout, which is not injected into the hole within 1 hour after mixing (30 minutes if the mix contains fluidifier with expanding agent), from the mixer, sump, and supply line and waste it.

3.2.1 Washing and Pressure Testing Holes

**************************************************************************
NOTE: Develop the appropriate form to record test results and attach it to the end of this section.
**************************************************************************

Immediately before the injection of grout into any hole drilled for the purpose of tunnel and shaft grouting or exploratory drilling, the hole shall be thoroughly washed under pressure and then pressure tested to provide an indication of potential grout take.

a. All intersected rock seams and crevices containing clay or other washable materials shall be washed with water and air under pressure to remove as much of these materials as practicable (normally this means until the return wash water runs clean). The maximum pressure at which air and water are introduced for any separate washing operation shall be as directed.

b. All holes sufficiently tight to build up the maximum required pressure shall be washed at such pressure, and the washing shall continue as long as there is any increase in the rate of flow or drop in pressure when the pump is delivering a capacity flow. Open holes in which no pressure can be built up shall be washed for a period of 5 minutes or for such a period of time as fracture-filling is being removed, as determined by the venting of muddy water through surface openings or other grout holes. Water pressure testing shall also be required in grout holes and exploration holes for the purpose of either assessing the grout take potential or the imperviousness of a grouted area.

c. The necessary fittings, a gauge for measuring hydraulic water pressure up to \( [690][\_____] \text{kPa} \ [100][\_____] \text{psi} \) and a meter large enough to measure \( 0.14 \text{ cubic meter per minute} \) to the nearest \( 0.001 \text{ cubic meter} \) \( 5 \text{ cfm} \) to the nearest \( 0.1 \text{ cubic foot} \) shall be provided. The volume of water available at the drill hole shall be a minimum of \( [0.11][\_____] \text{cubic meters per minute} \) \( [4][\_____] \text{cfm} \). Drill holes shall be tested as directed with clean water under a continuous pressure as determined in the field. After the waterline or header has been secured to the collar of the hole, water shall be pumped into the system until approximately \( [100][\_____] \text{kPa} \ [15][\_____] \text{psi} \) pressure is obtained. The pressure shall be maintained by control of a bypass valve and the flow test continued for 5 minutes. If no flow occurs, the pressure shall be shut in and held for 5 minutes and any pressure drop recorded. Both the hold test and the flow test may be repeated in the same interval if necessary to confirm indications of grout take or
tightness of an already grouted area. During each test, record the data on the Government supplied form [___ Form ___, dated ______]. Drilling, washing, and water pressure testing in previously grouted areas shall not take place before 24 hours following the completion of all the planned grouting in that particular area.

3.2.2 Contact Grouting

Contact grouting is defined as the injection of grout behind cast-in-place concrete lining (shaft and/or tunnel), or grouting behind the initial support system, to achieve continuous contact between the lining and the surrounding rock or soil. Tunnel plug contact grouting is also included in this definition. Perform contact grouting in such a manner as to ensure that all voids between the concrete or initial support members and the rock or soil face will be filled with grout. No pressure washing or testing is required prior to injecting grout. Cast-in-place concrete final lining shall have been in place at least [7] days before grouting commences. Grout shall be a [neat] [sanded] [cement] [chemical] grout mixture. The grouting of any hole shall not be terminated until all voids have been filled to the maximum extent practicable and the Government Representative directs the Contractor to stop grouting. Vent pipes, for the release of air and water during grouting of crown overbreak cavities which may not be filled with concrete, shall be provided as shown and in such locations as directed or approved. The installation requirements of paragraph EMBEDDED PIPE shall apply to vent pipes. Contact grouting shall be done at the highest safe pressure as directed but initially not exceeding [69] kPa [10] psi. Grouting shall be initiated from the lower end and at the invert of a tunnel and the grout behind the liner displaced upward. Grouting in the tunnel crown area may require secondary grouting to completely fill all the void space due to overbreak. Such secondary grouting shall be done with expansive grout mixtures after the initial contact grout has been injected and set up. For shaft linings, grout holes or nipples shall be radially located and grouted from inside the shaft. Split spaced grout injection holes or nipples may be necessary in shaft liner grouting.

[3.2.3 Grouting Behind a Steel Liner]

This type of grouting, often called "skin" grouting, shall consist of placing neat cement grout in the annular space surrounding a steel liner or "can" to fill the void between the steel liner and the cast-in-place concrete final lining. Grouting procedures are the same as those described in paragraph CONTACT GROUTING with the following exceptions:

a. Grout holes and sealing plugs shall be provided in the steel liner plates during fabrication. The pattern shall be as shown.

b. Grouting equipment shall be such that sudden surges in pressure at refusal do not occur.

c. Grout hole plugs shall be ground flush with the steel liner and finished smooth.

d. After grouting is completed, the Government Representative will sound the liner with hammer blows to determine if all voids are filled. If directed, additional grout holes shall be drilled and tapped to receive a nipple. The use of a cutting torch to cut-in and weld-on a nipple is prohibited.
3.2.4 Tunnel, shaft, and Ring Curtain Grouting

**************************************************************************
NOTE: Tunnel, shaft, and ring curtain grouting are defined as the grouting in areas of the work including, but not limited to, ahead of the tunnel or shaft face or along any reach of tunnel or shaft to control water flows or aid in stabilizing and filling voids in the formation.
**************************************************************************

Accomplish tunnel, shaft, and ring curtain grouting at the locations shown and/or as directed. Any grout hole that is lost or damaged due to mechanical failure of equipment, inadequacy of grout supply, or Contractor error shall be replaced by another hole or holes at the Contractor's expense.

3.2.4.1 Grout Injection (Cement Grout)

a. If the water pressure testing indicates a relatively tight hole, start grouting with a thin grout mixture. For an open hole condition, the water-cement ratio shall be reduced accordingly and, with the grout pump operating as nearly as practicable at constant speed at all times, the ratio shall be reduced further, if necessary, until the required pressure has been reached. If the pressure tends to rise too high, as determined by the Government Representative, the water-cement ratio shall be changed as directed. Grout mixes shall be in the proportions directed by the Government Representative who will direct changes to suit the conditions existing in the particular grout hole. The water-cement ratio by volume will be varied to meet the characteristics of each hole as revealed by the pressure washing and testing operations and will normally range between [3.0:1.0 and 0.6:1.0].

b. Grouting pressures shall be varied as directed with conditions encountered in the respective holes. If it is found impossible to reach the required pressure after pumping a reasonable volume of grout at the minimum workable water-cement ratio, a sanded grout mix shall be used, the pumping speed shall be reduced, or pumping stopped temporarily and intermittent grouting shall be performed, allowing sufficient time between grout injections for the grout to stiffen. If necessary to relieve premature stoppage, periodic applications of water under pressure shall be made at the direction of the Government Representative. If the desired results are not obtained with this mix, grouting in the hole shall be discontinued, if so directed.

c. In such event, the hole shall be cleaned, the grout allowed to set, and additional drilling and grouting be done in this hole or in the adjacent area, as directed, until the desired resistance is built up. Under no conditions shall the pressure or rate of pumping be increased suddenly, because either may produce a water-hammer effect which may promote stoppage. After the grouting of any hole is completed, the pressure shall be maintained by means of a stopcock or other suitable device until the grout has set to the extent that it will be retained in the hole.

3.2.4.2 Refusal

The grouting of any hole shall not be considered complete until that hole
refuses to take grout at a rate of less than \(0.015 \text{ cubic meter} \div 0.5 \text{ cubic foot}\) of solids (cement) per 1/2 hour] \(0.03 \text{ cubic meter} \div 1.0 \text{ cubic foot}\) of solids (cement) per 10 minutes] at whatever grout mixture and pressure is being used.

3.2.4.3 Grout in Drains

If leakage of grout into drains occurs, immediately stop the grouting operations and remove all grout from the drains by washing, to the satisfaction of the Contracting Officer. No separate payment will be made for such work. Such stopping of grouting operations and washing of drains shall be repeated as often as required to complete the grouting.

3.2.4.4 Stage Grouting

Stage grouting is the procedure by which a grout hole or a ring curtain hole is drilled, pressure tested, and grouted in successive stages within progressively deeper zones from the top of the grout hole, either from the ground surface or from the tunnel or shaft wall, to the depth shown or as directed, prepared for grouting, and then grouted. After the grout has achieved an initial set, the hole shall be washed, cleaned, and deepened and then grouted to the bottom of the next stage. If the Contractor allows the grout to harden within the grout hole, no payment will be made for redrilling the grout hole. A minimum period of \(24\) hours shall elapse between the completion of grouting in one stage and the start of drilling for the next stage. This procedure shall be repeated for the full depth of the grout application. Grouting pressures shall be increased \(\text{as directed}\) \(\text{as shown}\) as successive stages deepen the grout holes. Normally the grout holes shall be split spaced by locating secondary holes midway between two previously drilled and grouted primary holes, and the stage grouting process shall be repeated until the desired results are attained for the full depth of the grout application. Tertiary and succeeding series of split spaced holes shall also be drilled and grouted in stages if directed by the Government Representative.

3.2.4.5 Grout Injection (Chemical Grout)

In the zones to be chemically grouted, chemical grouting shall be performed in such a way as to produce a continuous cylinder or mass of chemically grouted ground outside the excavation perimeter of the tunnel or shaft in either soils or finely fissured rock strata, increasing the strength and reducing the permeability of the material. Grout in place shall be chemically stable and nontoxic for the environment in which it is placed. Excavation through grouted areas shall not commence until the grouting work has been completed and approved by the Government Representative. Regrouting shall be performed if the required degree of waterproofing and/or stabilization is not achieved by the first application. The method of injection shall be the continuous mixing method, with the proper amounts of grout base material, water, reactant, and accelerator automatically proportioned and continuously supplied at proper flow rates and pressures. The batch system of mixing grout shall not be permitted unless high volumes of chemical grout with shortened gel times are necessary in flowing water conditions. The base material and the water-accelerator-catalyst solution shall pass through parallel separate hoses to a suitable baffling chamber near the top of the hole. A sampling cock, to allow frequent gel time checks, shall be placed after the baffling chamber. Suitable check valves shall be placed in the grout lines at the proper locations to prevent backflow and unintentional gelations. All mixing, handling, pumping, and injection operations shall be in accordance with the manufacturer's
recommendations. A technical representative of the manufacturer or supplier shall be present at the work site during the initial grouting operations.

3.2.4.6 Grout Injection Pipes

**************************************************************************

NOTE: The following paragraph may be specified for grouting when it is desirable to exercise maximum control over the grout injection process, i.e., to grout or regROUT AT ANY SPECIFIC DEPTH.

**************************************************************************

Grout pipes are commercially available or field fabricated as illustrated by the attached sketch. Perform installation with care to assure the sealing grout encapsulates the entire pipe and completely fills the annulus. Grout used to fill the annulus shall consist of portland cement, bentonite and fly ash, be thick enough to prevent infiltration into the soil or rock, and be of low strength and brittle.

3.2.5 Waste Water and Grout

Waste grout that cannot be placed or injected prior to initial set or maximum specified time limit. If such grout is mixed at the direction or approval of the Government Representative, it will be paid for at the applicable contract unit prices for the material constituents of the wasted grout. During the progress of the work, provide for adequate disposal of all wash and waste water and remove all waste grout, on a daily basis if necessary, to maintain a safe and effective grouting operation.

3.3 PATCHING AND CLEANUP

Upon completion of the grouting operations, remove all grout supply connections from embedded pipe to a minimum depth of 25 mm 1-inch, measured from the face of the concrete [shotcrete]. Holes or depressions thus formed shall be patched with a damp-pack mortar composed of water, one part portland cement to two parts sand. One teaspoonful of aluminum powder will be added to each sack of cement used in the mortar mix to compensate for shrinkage. An unpolished, nonleafing powder of high purity and low grease will be used. Damp-pack mortar shall be just moist enough to form a ball in the hands. It shall be thoroughly tamped into the hole using hard wooden tools. The patching shall be done in a neat workmanlike manner to provide a surface smoothness at least equal to undisturbed areas of the final lining. Exploratory holes which have not been grouted shall be packed to the full depth of the final lining with tightly rammed dry mortar and then patched as described above. Prior to final acceptance of the work, the interior surface of the final lining shall be cleaned of excess cement or chemical grout, mortar, oil, and grease to the greatest extent practicable, as determined by the Government Representative.

3.4 RECORDS

**************************************************************************

NOTE: Attach ENG FORM 1836 to the end of this section.

**************************************************************************

Prepare, on a daily basis, records of all grout hole and drain hole drilling operations, all pressure washing and pressure testing operations.
and all cement and chemical grouting operations. These records shall include: driller's logs of all grout holes, drain holes, and exploratory holes; pressure washing information and pressure testing results; grouting data including time of each change of operation, rate of pumping, grouting pressures, changes in water-cement ratio, changes in proportions of additives such as fluidifier, accelerator, or sand, and amounts of various materials injected; core logging data on Government provided ENG FORM 1836 at a vertical scale of 1 inch equals 1 foot; and other data considered necessary as determined by the Government Representative. Blank report forms of the type to be used are attached at the end of this specification.

Duplicate records of all grout hole and drain hole drilling operations, all pressure washing and pressure testing operations, and all cement and chemical grouting operations. The Government must receive the originals of all such records before final payment will be processed.

3.5 CONTRACTOR QUALITY CONTROL

In accordance with Section 01 45 00.00 1001 45 00.00 2001 45 00.00 40 QUALITY CONTROL, establish and maintain quality control that specifically includes, but is not limited to, inspections to assure that:

a. The specified qualification requirements are met.

b. Drilling and grouting equipment is provided as specified and maintained in satisfactory condition.

c. The required amount of [cement is] [chemical grout materials are] kept on hand during grouting operations.

d. Grouting is performed in the presence of a Government Representative.

e. Required records are kept and submitted as specified.

f. Accurate [cement] [chemical] grout mixture proportions are maintained [as directed] [as recommended by the manufacturer or supplier].

g. Materials are properly protected from moisture and contamination after delivery and transportation to the site.

h. Only approved materials are used.

i. The quantity of bulk materials used equals the computed amount.

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for removal of rubber deposits and paint from asphalt concrete or portland cement concrete airfield pavements.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

NOTE: It is recommended that friction and/or texture testing be performed for affected pavement areas after hydroblast operations are performed for rubber and/or paint removal work. This is recommended because the effective friction level may be reduced by polishing of the aggregates within the pavement surface.

NOTE: On the project drawings, show:

1. Locations and dimensions of areas applicable to removal work.
2. Type and general condition of pavement and any joints or markings for each removal area.

3. Indication of whether rubber, paint, or both are to be removed in each work area.

4. Locations of Government hydrants to be provided for Contractor use.

PART 1 GENERAL

1.1 UNIT PRICES

1.1.1 Measurement

[Rubber] [and] [paint] removal is measured by the number of square meters feet of [rubber] [and] [paint] to be removed.

1.1.2 Payment

[Rubber] [and] [paint] removal is paid for at the contract unit price per square meter feet of [rubber] [and] [paint] to be removed.

1.2 REFERENCES

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

U.S. NATIONAL ARCHIVES AND RECORDS ADMINISTRATION (NARA)

29 CFR 1910 Occupational Safety and Health Standards

1.3 ADMINISTRATIVE REQUIREMENTS

Submit a schedule of work to the Contracting Officer. Describe the work to
be accomplished; noting the location of work, distances from the ends of runways, taxiways, buildings, and other structures; and indicating dates and hours during which the work will be accomplished. Schedule the work to conform to aircraft operating schedules. The Government will try to schedule aircraft operations so as to permit the maximum amount of time for the Contractor's work. However, in the event of any emergency, intense operational demands, adverse wind conditions, and other unforeseen difficulties, discontinue all work at locations in the aircraft operational area. Keep the approved schedule of work current and notify the Contracting Officer of any changes prior to beginning each day's work.

1.4 SUBMITTALS

**************************************************************************

NOTE: Review Submittal Description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G". Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy, Air Force, and NASA projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy, Air Force and NASA projects, or choose the second bracketed item for Army projects.

**************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.] [for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-01 Preconstruction Submittals
Schedule of work; G[, [_____]]

[Rubber] [and] [Paint] Removal Process Plan; G[, [_____]]

Waste Collection, Identification and Disposal Plan; G[, [_____]]

SD-03 Product Data

Mechanical [rubber] [and] [paint] removal equipment

Chemical [rubber] [and] [paint] removal equipment

[Rubber] [and] [Paint] Removal Detergents or Chemicals ; G[, [_____]]

SD-06 Test Reports

Test Section Results

1.5 MECHANICAL REMOVAL EQUIPMENT

**************************************************************************
NOTES: Shotblasting is prohibited for use on airfield pavements.
**************************************************************************

Submit product data for mechanical [rubber] [and] [paint] removal equipment including area of coverage per pass, range of water pressures, and water tank capacity.

**************************************************************************
NOTE: For Navy, delete sandblasting. The use of sandblasting is prohibited for use on Navy airfield pavements.
**************************************************************************

Mechanical removal equipment includes waterblasting[, sandblasting], grinding or scarifying, or other approved non-chemical systems. [Control the equipment used on asphalt or tar concrete to remove [rubber] [and] [paint] accumulations while minimizing disturbances to asphalt or tar mixtures.] [Control the equipment used on portland cement concretes to remove [rubber] [and] [paint] accumulations and prevent removal of hardened paste from the concrete.] Basic hand tools and the following major types of mechanical equipment are considered acceptable for this project:

a. Waterblasting Equipment.

b. Grinding or Scarifying Equipment.[

c. Sandblasting Equipment.]

1.5.1 Waterblasting Equipment

Provide mobile waterblasting equipment capable of producing a pressurized stream of water that effectively removes [rubber] [and] [paint] from the pavement surface without significantly damaging the pavement. Provide equipment, tools, and machinery which are safe and in good working order at all times. Provide equipment interlocks to prohibit high pressure water discharge when the vehicle or cleaning head is stationary (not moving
forward or side to side).

[1.5.2 Sandblasting Equipment

**************************************************************************
NOTE: For Navy, delete sandblasting. The use of sandblasting is prohibited for use on Navy airfield pavements.
**************************************************************************

Provide mobile sandblasting equipment capable of producing a pressurized stream of sand and air that effectively removes [rubber] [and] [paint] from the pavement surface without filling voids with debris in asphalt or tar pavements or removing joint sealants in portland cement concrete pavements. Include with the equipment an air compressor, hoses, and nozzles of adequate size and capacity for removing [rubber] [and] [paint]. Equip the compressor with traps and coalescing filters that maintain the compressed air free of oil and water.

1.5.3 Grinding or Scarifying Equipment

Provide equipment capable of removing surface contaminants, paint build-up, or extraneous markings from the pavement surface without leaving any residue. If a weed torch is used to remove paint, the surface must be cleaned by hydro blast afterwards to remove surface contaminants and ash.

1.6 CHEMICAL REMOVAL EQUIPMENT

Submit product data for chemical [rubber] [and] [paint] removal equipment. Use chemical equipment capable of applying and removing chemicals from the pavement surface while leaving only non-toxic biodegradable residue.

1.7 TEST SECTION

Prior to the start of work, remove [rubber] [and] [paint] on designated test areas not less than 15 m 50 feet in length. Use procedures, water pressures, nozzle height, nozzle spacings, nozzle angle, and equipment movement rate to achieve the required degree of [rubber] [and] [paint] removal in accordance with Paragraph [RUBBER] [AND] [PAINT] REMOVAL. Methods included in paragraph COMPLIANCE TESTING will be used to determine if the [rubber] [and] [paint] was successfully removed from the test section. The test will examine seven random locations within the test section. Submit the test section results before conducting any further removal work. Provide photos of seven random locations within the test area taken before and after the removal. Provide photos of four random locations at joint seals within the test area taken before and after removal.

1.8 DELIVERY, STORAGE, AND HANDLING

Deliver required materials in original manufacturer's containers labeled with appropriate EPA, OSHA, or other agency warnings, if applicable, and Safety Data Sheets. Protect materials from degrading until their use is required during execution of the work.
1.9 PROJECT/SITE CONDITIONS

1.9.1 Environmental Requirements

**************************************************************************
NOTE: For Navy, delete sandblasting. The use of sandblasting is prohibited for use on Navy airfield pavements.
**************************************************************************

Ensure pavement surface is free of snow, ice or slush. Ensure surface temperature is at least 5 degrees C 40 degrees F and rising at the beginning of operations[ except those involving sandblasting for which a lower surface temperature may be approved]. Cease operation during thunder and lightning storms. Cease operation during rainfall except for waterblasting and removal of previously applied chemicals. Cease waterblasting where surface water accumulation alters the effectiveness of material removal.

1.9.2 Airfield Traffic Control

Coordinate performance of all work in the controlled zones of the airfield with the Contracting Officer and with the [Flight Operations Officer or Airfield Manager] [control tower]. Neither equipment nor personnel can use any portion of the airfield without permission of these officers unless the runway is closed. Runways will be closed during the following times:

<table>
<thead>
<tr>
<th>Day or Date</th>
<th>Runway Closing Time</th>
<th>Runway Opening Time</th>
<th>Important Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>(____)</td>
<td>(____)</td>
<td>(____)</td>
<td>(____)</td>
</tr>
</tbody>
</table>

1.9.3 Radio Communication

No personnel or equipment will be allowed in the controlled zones of the airfield until radio contact has been made with the control tower and permission is granted by the control tower. A radio for this purpose [will be provided by the Government. The Contractor is responsible for the radio and must reimburse the Government for repair or replacement of the radio if it is lost, damaged, or destroyed] [is to be provided by the Contractor and approved by the Contracting Officer]. Maintain contact with the control tower at all times during work in vicinity of the airfield. Notify the control tower when work is completed and all personnel, equipment and materials have been removed from all aircraft operating surfaces.

1.9.4 Emergency Landing and Takeoff

Emergencies take precedence over all operations. Upon notification from the Control Tower of an emergency landing or imminent takeoff, stop all operations immediately and evacuate all personnel and equipment to an area not utilized for aircraft traffic which is at least 76 m 250 feet measured perpendicular to and away from the near edge of the runway unless otherwise authorized by the Contracting Officer or the Contracting Officer's Representative. Equipment and chemicals or detergents as well as excess water must be able to clear the work area within 3 minutes.
1.9.5  Airfield Lighting

When night operations are necessary, provide all necessary lighting and equipment. Direct or shade lighting to prevent interference with aircraft, the air traffic control tower, and other base operations. Provide lighting and related equipment capable of being removed from the runway within 15 minutes of notification of an emergency. Night work must be coordinated with the Flight Operations Manager or Airfield Manager and approved in advance by the Contracting Officer or authorized representative.

1.9.6  Water

Water to be used for high-pressure water equipment will be made available from Government hydrant[s] [as shown on the drawings,] [within [_____] m feet of all points of the work area,] [at no cost to the Contractor] [at the prevailing rates]. Furnish equipment and labor for delivery of water from the hydrant to the job site. Notify the Contracting Officer on location of fire hydrant[s] to be used and the respective times of use. The Contracting Officer will notify the Fire Department of fire hydrants to be used and designated times of use. Connections to a fire hydrant will be subject to the Contracting Officer's inspection and approval. The Contractor must provide and use a backflow prevention device for filling water tanks. The Contractor is responsible for testing, treating, and filtering the water to ensure it will not interfere with the rubber removal or damage or clog the rubber removal equipment.

1.10  SAFETY

PART 2  PRODUCTS

2.1  [RUBBER] [AND] [PAINT] REMOVAL DETERGENTS OR CHEMICALS

The use of environmentally acceptable detergents or chemical agents must be considered on a case-by-case basis. Submit the Safety Data Sheet (SDS) for detergents or chemicals in the [rubber] [and] [paint] removal process. Use of any detergents or chemicals in the [rubber] [and] [paint] removal process must be approved in advance by the Contracting Officer. The Government specifically reserves the right to reject the use of any process which the Contracting Officer determines may pose unnecessary risks to human health, the environment, the pavement, aircraft or NAVAIDS due to corrosion or foreign object damage (FOD) potential as a result of its use, storage, or disposal.

PART 3  EXECUTION

******************************************************************************
NOTE: The Contracting Officer's Representative, the airfield manager and the pavements engineer will jointly develop guidelines and requirements for rubber and paint removal operations; and will jointly evaluate the feasibility of the Contractor's methods and project compliance with applicable regulations.
******************************************************************************
3.1 [RUBBER] [AND] [PAINT] REMOVAL

**************************************************************************
NOTE: The following provides recommended rubber and paint removal percentages based on visual estimation of pavement area required to be exposed by the removal process. The degree of removal possible without damaging the pavement surface will depend on pavement condition. Portland cement concrete pavements can withstand more water pressure impact than asphaltic concrete pavements before aggregates are exposed. Do not specify 100 percent removal, as this will result in excessive exposure of pavement aggregates.

2. Rubber removal from asphaltic concrete pavements: 85 percent.

NOTE: The drawings should indicate areas surfaced with a porous friction course.
**************************************************************************

Prior to any work being completed, submit a [Rubber] [and] [Paint] Removal Process Plan for approval by the Contracting Officer.

a. The pavement surface type is [Portland cement concrete] [and] [asphalt mixture] [as indicated].

b. [Remove 90 percent of all visible rubber on Portland cement concrete pavements and 85 percent of all visible rubber on asphaltic concrete pavements.] [Remove 85 percent of paint on Portland cement and asphaltic concrete pavement. Remove all paint that is loose, flaking, chalky, or not to be re-marked or does not comply with size or pattern standards.]

c. Chemical methods used must be compatible with pavement materials, the environment and working personnel.

d. Exercise close control of water pressure and blasting time/duration to prevent damage to joints, existing markings that are not intended for removal, or the wearing surface. [Neither hydroblasting or abrasive blasting may be used for rubber removal on porous friction courses.]

e. Demonstrate the ability to remove rubber at a touchdown area of the runway selected by the Contracting Officer; at least one site per runway will be chosen. Rubber removal must not damage the pavement surface. The surface texture of the cleaned demonstration area will be compared to that of non-rubber traffic areas to determine satisfactory completion of the removal operation.

f. After approval of the Contractor's operations by the Contracting Officer, the cleaned sample area will become the standard for rubber
removal and final surface texture for the remainder of work.

g. Compliance testing for the amount of rubber and paint to be removed must conform to the requirements in paragraph COMPLIANCE TESTING.

3.2 RATE OF REMOVAL

[Remove rubber at a minimum rate of 929 square meter 10,000 square feet per hour.] [Remove paint at a minimum rate of 93 square meter 1,000 square feet per hour.] Do not permit high-pressure water application to remove the existing pavement surface, joint seals or crack seals.

3.3 WATER PRESSURE

**************************************************************************
NOTE: The optimum water pressure to be used for rubber and paint removal will be determined by the test specified in paragraph entitled "Rubber and Paint Removal."
**************************************************************************

Provide water pressure impact upon the indicated pavement areas sufficient to remove the designated [rubber] [and] [paint] to the required degree of removal without damaging the existing pavement, joint sealant, or other airfield appurtenances. The Contractor is responsible for repairing any damage caused by the removal work.

3.4 CLEANUP AND WASTE DISPOSAL

**************************************************************************
NOTE: The Contractor is normally responsible for total contract performance. However, at geographically isolated airfields, it may be necessary to furnish Government equipment and personnel for cleanup operations.
**************************************************************************

Keep the worksite clean of by-products, debris and waste from [rubber] [and] [paint] removal operations. Perform cleanup operations continuously. [Residue will be removed from the pavement by Government-furnished sweepers and personnel. Notify the Contracting Officer for coordination.] [Remove all residue from the pavement. Obtain the approval of residue removal and disposal method from the Contracting Officer prior to beginning work.] Submit a Waste Collection, Identification and Disposal Plan describing proposed actions regarding waste collection, control, identification, and disposal to the Contracting Officer's Representative for approval prior to the start of work. The plan will address disposal methods and requirements for hazardous and non-hazardous wastes.

3.5 COMPLIANCE TESTING

a. Compliance with the [rubber] [and] [paint] removal requirements must be determined by direct testing within the designated work area.

b. Use a 0.1 square meter one square foot section of transparent material inscribed with a grid of 100 equal squares as a tool for quantitative measure of the percent removal. Place the grid pattern on the pavement surface at random locations. Then count the squares which contain
rubber and/or paint deposits. The number of squares containing rubber and/or paint deposits must not exceed the allowed percentage in each of the randomly selected locations.

c. Divide each work area designated for [rubber] [and] [paint] removal into at least four equal zones for the purpose of compliance testing. The layout of each zone must be approved by the Contracting Officer. Within each zone, a minimum of seven random locations must be evaluated. The amount of [rubber] [and] [paint] removed at each of the randomly selected test locations within each zone must meet the requirement described in paragraph [RUBBER] [AND] [PAINT] REMOVAL. Evaluate each zone independently. A zone not meeting the required percentage must be recleaned by the Contractor at the Contractor's expense.

d. Deposits of [rubber or rubber buildup] [and] [paint] are defined as any surface deposit that can be removed by scratching the deposit with a flat sharp object (such as a pocket knife) without damaging the pavement surface. Stains are defined as materials in the pavement surface microtexture that cannot be removed without damaging the pavement surface. Stain is generally embedded in the surface of the pavement below the horizontal plane of the surface texture. The Contractor is not responsible for stain removal.

3.6 DAMAGE REPAIR

Repair any damage to the pavement surface, joint, joint and crack seals, or other Government property caused during the performance of the work at the Contractor's expense. Submit a repair plan to include methods and material to the Contracting Officer's Representative for approval prior to performance of the repairs. Complete the repairs within the performance period of the Contract.

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for single and double bituminous surface treatment of pavements for airfields, roads, streets, parking areas, and other general applications.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1 GENERAL

1.1 UNIT PRICES

NOTE: Delete this paragraph when lump sum bidding is used.

The bituminous material and aggregate to be paid for will be the measured quantities used in the accepted work.
1.1.1 Measurement

1.1.1.1 Bituminous Material

The amount of bituminous material to be paid for will be measured in [metric 2000 pounds tons] [the number of liters gallons of material used in the accepted work, corrected to liters at 15.6 degrees C gallons at 60 degrees F in accordance with ASTM D1250, using a coefficient of expansion of 0.00045 per degree C 0.00025 per degree F for asphalt emulsion].

1.1.1.2 Aggregate

The amount of aggregate paid for will be the number of [metric 2000 pounds tons] [cubic meters yards] of aggregate placed and accepted in the completed work or placed in authorized stockpiles.

1.1.1.3 Quantity Limits

**************************************************************************
NOTE: Only the appropriate application rates consistent with the gradations of paragraph "Mineral Aggregate" will be retained.
**************************************************************************

Spread the bituminous material and aggregate within the quantity limits shown in PART 2; base bids on the mean of the values in the tables. The individual quantities of bituminous material and aggregate may be varied to meet specific field conditions at all times during progress of the work, as directed, without adjustments to contract unit prices.

1.1.2 Payment

**************************************************************************
NOTE: Delete this paragraph when lump sum bidding is used.
**************************************************************************

The quantities of aggregates and bituminous material, determined as specified in paragraph MEASUREMENT, will be paid for at the respective contract unit prices. Payment will constitute full compensation for all operations necessary to complete the work as specified herein.

1.1.3 Waybills and Delivery Tickets

Submit copies of waybills and delivery tickets during progress of the work. Before the final statement is allowed, file with the Contracting Officer certified waybills and delivery tickets for aggregate and bituminous material used in the bituminous surface treatment. Do not remove bituminous material from the tank car or storage tank until initial outage and temperature measurements have been taken. Do not release the car or tank until final outage has been taken.

1.2 REFERENCES

**************************************************************************
NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in
this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

**************************************************************************

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

ASTM INTERNATIONAL (ASTM)

ASTM D1139/D1139M (2015) Aggregate for Single or Multiple Bituminous Surface Treatments

API MPMS Chapter 11.1

ASTM D2028/D2028M (2015) Cutback Asphalt (Rapid-Curing Type)

ASTM D2995 (1999; R 2009) Determining Application Rate of Bituminous Distributors

1.3 SUBMITTALS

**************************************************************************
NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy, Air Force, and NASA projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy, Air Force and NASA projects, or choose the second bracketed item for Army projects.

**************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a
Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

**SD-03 Product Data**
- Waybills and Delivery Tickets
- Cutback Asphalt
- Emulsified Asphalt
- Asphalt Cement

**SD-06 Test Reports**

**Tests**

1.4 QUALITY CONTROL

1.4.1 Safety Precautions

Smoking or open flames will not be permitted within 8 m (25 feet) of heating, distributing, or transferring operations of bituminous materials other than bituminous emulsions.

1.4.2 Sampling and Testing

Sampling and testing is the responsibility of the Contractor. Perform sampling and testing using an approved commercial testing laboratory, or by the Contractor, subject to approval. Sampling must be in accordance with ASTM D75/D75M for aggregates and ASTM D140/D140M for bituminous material, unless otherwise directed. Perform aggregate gradation tests on each sample in accordance with ASTM C136/C136M. Perform all other aggregate tests on the initial source samples and repeat tests when there is a change of source. Perform sieve analyses daily from material samples including an analysis of each gradation of material. Perform tests in sufficient number to ensure that materials meet specified requirements. Submit copies of test results, within 24 hours after completion of each test. Repeat aggregate testing (wear, soundness, deleterious material and stripping) for each 18,000 metric tons (20,000 tons) of aggregate used in the project.

1.4.3 Wear Test

Perform the wear test in accordance with ASTM C131/C131M to ensure that aggregates have a percentage of wear not exceeding 40 percent after 500 revolutions.

1.4.4 Soundness Test

--------------------------------------------------------------------------------
NOTE: The magnesium-sulfate soundness test is to be used in excluding aggregates known to be unsatisfactory or for evaluating aggregates from new sources. The maximum allowable percentage of loss will be inserted in the blank and normally should be within the range of 10 to 20 percent. The values used will be based on knowledge of aggregates in the area that have been previously approved or that have a satisfactory service record in bituminous pavement construction for at least 5 years and will assure that aggregates from new sources will be equal to or...
better than these aggregates. Default value should be 18 for magnesium sulfate and 12 for sodium sulfate.

Perform the soundness test as specified by ASTM C88 to ensure that aggregates have a weight loss not greater than \[____\][18] percent when subjected to five cycles of the magnesium sulfate test or \[____\] [12] percent when subjected to five cycles of the sodium sulfate test.

1.4.5 Stripping Test

Perform stripping tests meeting the requirements of ASTM D3625/D3625M. Deleterious substances must not exceed the requirements of ASTM D1139/D1139M.

1.5 DELIVERY, STORAGE, AND HANDLING

Inspect the materials delivered to the site for contamination and damage. Unload and store the materials with a minimum of handling. Store aggregates preventing segregation and contamination.

1.6 EQUIPMENT, TOOLS AND MACHINES

Provide equipment dependable and adequate for the purpose intended and properly maintained in satisfactory and safe operating condition at all times. Discontinue the use of equipment which fails to produce satisfactory work and replace with satisfactory equipment. Equipment such as asphalt distributors, scales, batching equipment, spreaders and similar equipment, must have been calibrated by an approved calibration laboratory within \[12\] \[____\] months prior to commencing work [and every \[____\] months thereafter, by such laboratory from the date of last calibration, during the term of the contract].

1.6.1 Bituminous Distributors

Provide a self propelled distributor with pneumatic tires of such size and number to prevent rutting, shoving or otherwise damaging the surface being sprayed. Calibrate the distributor in accordance with ASTM D2995. Design and equip the distributor to spray the bituminous material in a uniform coverage at the specified temperature, at readily determined and controlled total liquid rates from \(0.14\) to \(4.5\) L/square meter \(0.03\) to \(1.0\) gallons per square yard, with a pressure range of \(172.4\) to \(517.1\) kPa \(25\) to \(75\) psi and with an allowable variation from the specified rate of not more than plus or minus 5 percent, and at variable widths. Include with the distributor equipment a separate power unit for the bitumen pump, full-circulation spray bars, tachometer, pressure gauges, volume-measuring devices, adequate heaters for heating of materials to the proper application temperature, a thermometer for reading the temperature of tank contents, and a hand hose attachment suitable for applying bituminous material manually to areas inaccessible to the distributor. The distributor will be capable of circulating and agitating the bituminous material during the heating process.

1.6.2 Single-Pass, Surface-Treatment Machines

Use only machines capable of spraying bituminous material and spreading aggregate in one pass. Use only bituminous spraying equipment conforming to the requirements given above for a bituminous distributor. Use only machines capable of spreading aggregates at controlled amounts per square
yard as specified. In addition, only use single-pass, surface-treatment machines capable of placing a surface treatment adjacent to an existing surface treatment, forming a joint of the same thickness and uniformity as other portions of the surface treatment. Ridges or blank spaces will not be permitted. Form joints in the second application at least 300 mm 1 foot from those formed in the first application.

1.6.3 Heating Equipment for Storage Tanks

Use equipment consisting of coils and equipment for producing steam or hot oil and designed to prevent the introduction of steam or hot oil into the material. Affix an armored thermometer with a range of 35 to 200 degrees C 100 to 400 degrees F to the tank so the temperature of the bituminous material may be determined at all times.

1.6.4 Power Rollers

Use only steel-wheeled or pneumatic-tired type power rollers conforming to the following requirements:

a. Use only steel-wheeled rollers having at least one steel drum and weigh a minimum of 4.5 metric tons 5 tons. Equip steel wheels of the rollers with adjustable scrapers.

b. Use only self-propelled pneumatic-tired rollers having wheels mounted on two axles in such manner that the rear tires will not follow in the tracks of the forward group. Maintain uniform tire inflation to not less than 414 kPa 60 psi nor more than 552 kPa 80 psi pressure. Equip pneumatic-tired rollers with boxes or platforms for ballast loading. Load rollers so that the tire print width of each wheel is not less than the clear distance between tire prints.

1.6.5 Mechanical Spreaders

Use only adjustable spreaders capable of spreading aggregate at controlled amounts per square yard, as specified.

1.6.6 Brooms and Blowers

Use only power type brooms and blowers capable of cleaning surfaces to be treated.

1.6.7 Scales

Use standard truck scales of the beam type equipped with a weight-recording device. Use scales with sufficient size and capacity to accommodate the trucks used in hauling aggregates. The scales must be tested and approved by an inspector of the State Inspection Bureau charged with scale inspection within the state in which the project is located. If an official of the inspection bureau is not available, test the scales in accordance with state specifications and in the presence of the Contracting Officer. Keep the necessary number of standard weights on hand, at all times, for testing the scales.

1.6.8 Weighhouse

Provide a weatherproof weighhouse constructed in a manner to afford adequate protection for the indicating and recording devices of the scales.
1.7 ENVIRONMENTAL REQUIREMENTS

Apply bituminous surface treatment only when the existing surface or base course is dry or contains moisture not in excess of the amount that will permit uniform distribution of the asphalt material and provide the desired adhesion between the asphalt material and the materials underneath and above. Do not apply bituminous surface treatment when either the atmospheric temperature, in the shade, is below [10][15.5] degrees C [50][60] degrees F or the pavement surface to be treated is below 20 degrees C 70 degrees F unless otherwise directed.

PART 2 PRODUCTS

**************************************************************************
NOTE: Delete designations, materials, grades, and aggregate sizes which are not available or desirable for the project. In selecting alternate materials, consider the cost effect of competition between materials along with engineering considerations.
**************************************************************************

Use mineral aggregate and bituminous material of the following types, gradations, grades, and consistencies that meet the requirements of stripping, wear, deleterious materials and soundness tests as specified in paragraph SAMPLING AND TESTING.

2.1 MINERAL AGGREGATE

**************************************************************************
NOTE: The desired gradations to be used for the project will be specified. For single surface treatment, select the required gradation from the table for single bituminous surface treatment. For double surface treatment, select the required gradations (either No. 1 and No. 2 or No. 3 and No. 4) from the table for double bituminous surface treatment.
**************************************************************************

Provide aggregate consisting of crushed stone, crushed gravel, or crushed slag of such nature that thorough coating of bituminous material, used in the work, will not strip off upon contact with water when testing using ASTM D3625/D3625M. Maintain aggregate moisture content so that the aggregate will be readily coated with the bituminous material. Drying may be required, as directed. Use aggregate conforming to the gradation shown below. Determine gradation of the aggregates by ASTM C136/C136M.

| AGGREGATE GRADATION SINGLE BITUMINOUS SURFACE TREATMENT (PERCENT BY WEIGHT PASSING) |
|-----------------|--------|--------|--------|
| Sieve Designation (mm) | No. 1 | No. 2 | No. 3 |

2.1.1 Crushed Stone

Provide crushed stone consisting of clean, sound, durable particles, free of soft or disintegrated pieces, dust, or foreign matter.

2.1.2 Crushed Gravel

Provide crushed gravel consisting of clean, sound, durable particles, free of soft or disintegrated pieces or foreign matter. At least 90 percent by weight of the particles must have at least two fractured faces.

2.1.3 Crushed Slag

Provide crushed slag which is an air-cooled blast-furnace product having a dry weight of not less than 1120 kg/cubic meter 70 pcf, and consists of angular particles uniform in density and quality and free of dust and foreign matter. Determine the weight of a cubic meter foot of slag aggregate by ASTM C29/C29M.

2.1.4 Aggregate Quantities

Spread the bituminous material and aggregate within the quantity limits.
shown below. The individual quantities of bituminous material and aggregate may be varied to meet specific field conditions at all times during progress of the work, as directed, without adjustments to contract unit prices. Aggregate weights shown are for aggregates having a specific gravity of 2.65. Adjust the number of kg pounds required if the specific gravity of the aggregate used is other than 2.65 in order to ensure a constant volume of aggregate per square meter yard of treatment.

2.2 BITUMINOUS MATERIALS

**************************************************************************
NOTE: In some states and localities, the use of cutback asphalt is prohibited or curtailed by local air pollution regulations. In areas where cutback asphalt is restricted by air pollution regulations, asphalt cement or emulsified asphalt should be used. RC-800 is most commonly recommended for surface treatments. Where cooler temperatures are anticipated, use of RC-250 may be desirable. The type of cutback or emulsion to be used will depend on local conditions and temperature; and these factors must be carefully considered in making the selection for surface treatments. Penetration graded and performance graded asphalt cements can also be used. A majority of surface treatments utilize asphalt emulsion as the binder.

**************************************************************************
2.2.1 Cutback Asphalt

Use rapid curing cutback asphalt conforming to ASTM D2028/D2028M, Designation [RC-250] [RC-800] [RC-3000]. Submit temperature-viscosity relationship of cutback asphalt.

2.2.2 Emulsified Asphalt

Use rapid-setting emulsified asphalt conforming to ASTM D977, Grade RS-1 or RS-2 or ASTM D2397/D2397M, Grade CRS-1 or CRS-2.

2.2.3 Asphalt Cement

Use asphalt cement conforming to ASTM D946/D946M, Penetration Grade [120-150] [200-300] or ASTM D6373, Performance Graded Asphalt Binder [PG 64-22] [PG 58-28] [PG 52-34]. Submit temperature-viscosity relationship of asphalt cement.

PART 3 EXECUTION

3.1 SURFACE PREPARATION

Immediately before applying the first course of bituminous material, clean the surface of loose material with power brooms or power blowers. Take care to remove all dirt, clay, and other loose or foreign matter. Flush the surface with water, when necessary to achieve a clean surface, only when directed by the Contracting Officer; allow the surface to dry after flushing.

3.2 APPLICATION OF FIRST COURSE

3.2.1 Bituminous Material

**************************************************************************
NOTE: Application temperatures will vary with the grade of asphalt used. Recommended materials and application temperatures may be found in paragraph APPLICATION TEMPERATURE OF MATERIALS, below and in Asphalt Institute Publications: Asphalt Surface Treatments - Specifications (publication No. ES-11) and Asphalt Surface Treatments - Construction Techniques (publication No. ES-12).
**************************************************************************

Apply bituminous material by means of a bituminous distributor at the temperature specified in paragraph APPLICATION TEMPERATURE OF MATERIALS, below or as directed; and within the limits specified in paragraph QUANTITY LIMITS in PART 1. Apply bituminous material in such a manner that uniform distribution is obtained over all surfaces treated. Unless the distributor is equipped to obtain a satisfactory result at the junction of previous and subsequent applications, spread building paper on the surface for a sufficient distance back from the ends of each application so that flow through the sprays may be started and stopped on the paper in order that all sprays will operate at full force on the surface treated. Immediately after application, remove and destroy the building paper. Properly treat areas inaccessible to the distributor with bituminous material using the hose attachment. Protect adjacent buildings, structures, and trees to prevent their being spattered or marred.
3.2.2 Spreading of Aggregate

Immediately following application of bituminous material, spread aggregate uniformly over the surface within the limits of the quantities specified in paragraph QUANTITY LIMITS in PART 1 using mechanical spreaders. Spread aggregate evenly by hand on all areas missed by the mechanical spreader. Operate equipment spreading aggregate so that the bituminous material will be covered ahead of the truck wheels. When hand spreading is employed on inaccessible areas, spread aggregate directly from trucks. Spread additional aggregate by hand over areas having insufficient cover. Continue spreading during these operations when necessary.

3.2.3 Brooming and Rolling

Roll the surface with a pneumatic-tired and a steel-wheeled roller after sufficient aggregate is spread. Continue rolling until no more aggregate can be worked into the treated surface. The use of the steel-wheeled roller will be discontinued, or a lighter weight steel wheel roller substituted, as directed, if the roller being used causes excessive crushing and shattering of the aggregate. If the aggregate is not distributed properly, broom the surface as soon as possible after the first coverage by the roller, but not until the surface has set sufficiently to prevent excessive marking. Continue brooming, rolling, and supplemental spreading of aggregate until the surface is cured and rolled sufficiently to key and set the aggregate. In places not accessible to rollers, compact the aggregate with pneumatic tampers. Remove aggregate that has become contaminated with foreign matter and replace with clean aggregate and reroll as directed. Maintain and protect the treated areas by use of barricades until properly cured.

3.3 APPLICATION OF SECOND COURSE

3.3.1 Bituminous Treatment

Apply the bituminous material for the second course within 48 hours after construction of the first course, weather permitting. Remove excess aggregate prior to the second application of bituminous material. If the treated surface is excessively moistened by rain, allow the surface to dry for such time as deemed necessary. Perform the second application of bituminous material in the manner specified in paragraph APPLICATION OF FIRST COURSE, including temperature and QUANTITY LIMITS.

3.3.2 Aggregate

Immediately following the second application of bitumen, spread aggregate conforming to the gradation and limits specified in paragraph QUANTITY LIMITS uniformly over the bituminous material and process in the manner specified for the first course.

3.3.3 Brooming and Rolling Second Course

Roll and broom the surface in the manner specified for the first course until a thoroughly bonded, smooth, even-textured surface is produced. Sweep off the surface surplus aggregate and remove it prior to final acceptance.
3.4 APPLICATION TEMPERATURE OF MATERIALS

3.4.1 Cutback Asphalt

Apply cutback asphalt in the range of 38 to 93 degrees C 100 to 200 degrees F.

3.4.2 Emulsified Asphalt

Apply asphalt emulsions in the range of 32 to 71 degrees C 90 to 160 degrees F.

3.4.3 Asphalt Cement

Apply asphalt cement in the range of 163 to 191 degrees C 325 to 375 degrees F.

3.5 TRIAL APPLICATION

**************************************************************************
NOTE: This paragraph will be deleted if project size does not warrant trial application.
**************************************************************************

Preliminary to providing a complete surface treatment, treat [three] [_____] lengths of at least 30.5 m 100 feet each for the full width of the distributor bar. Use the appropriate typical application rates specified herein for one surface treatment trial. Make other surface treatment trials using various amounts of materials as may be deemed necessary.

3.6 PROTECTION

Keep all traffic off surfaces freshly treated with bituminous material. Provide sufficient warning signs and barricades so that traffic will not travel over freshly treated surfaces. Protect the treated areas from traffic for at least 24 hours after final application of bituminous material and aggregate, or for such time as necessary to prevent picking up. Immediately prior to opening to traffic, roll the entire treated area with a self-propelled pneumatic-tired roller.

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for gilsonite modified asphalt surface coatings (not coal tars products, only Gilsonite modified asphalt emulsion seal coats with a bituminous base residue containing no less than 20 percent Uintaite or Gilsonite, hereafter referred to as Gilsonite modified asphalt emulsion) for low volume roads, parking areas, airfield secondary and tertiary pavements (low-speed taxiways, shoulders, overruns), and other general applications with or without aggregate applied on the applied coating. An asphalt seal coat without aggregate, more commonly called a 'fog seal', can be considered for use on pavements with low to moderate weathered surfaces (as defined by ASTM D5340). The use of Gilsonite modified asphalt emulsion should be used whenever possible. The use of this product on a runway must be approved by cognizant NAVFAC (Echelon III), AFCEC, MAJCOM or TSMCX Pavement Engineer.

This specification can be used for high volume or high speed roads, taxiways and runways only with the incorporation of a suitable aggregate in order to maintain adequate surface friction and only with the written approval of the cognizant NAVFAC (Echelon III), AFCEC, MAJCOM or TSMCX Pavement Engineer. At present, only the Gilsonite modified asphalt emulsion, seal coat product with aggregate should be considered for use on airfield runway pavements.

If used on Design/Build projects involving high volume or high speed roads or any airfield pavement, this section must be prepared by the Government RFP preparer and must not be further edited by the Contractor's Designer of Record.

Adhere to **UFC 1-300-02** Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project
specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1  GENERAL

UFC 3-250-03, "Standard Practice Manual for Flexible Pavements" should be used for guidance in preparing these specifications.

1.1  MEASUREMENT AND PAYMENT PROCEDURES

NOTE: Payment and Measurement must be made on a unit price bases with the test section determined application rate for emulsion and aggregate. Therefore, this requires that the contract documents reflect unit pricing for the asphalt emulsion and aggregate, if used.

Measure the quantities of gilsonite modified asphalt emulsion and aggregate used in the accepted work and to be paid for, provided that the measured quantities are not more than 10 percent over the test section determined application rate. Any amount of gilsonite modified asphalt emulsion and aggregate more than 10 percent over the test section determined application rate for each application will be deducted from the measured quantities except for irregular areas where hand spraying of the bituminous material and hand spreading of the aggregate is necessary.

1.1.1  Gilsonite Seal Coat Measurement Methods

The area of applied emulsion and aggregate to be paid for will be measured in square meters square yards.

1.1.2  Payment

The approximate amounts of materials per square meter square yard for gilsonite modified asphalt emulsion and aggregate used in production must be as provided in Table 6 for the treatment area[s] at the specified dilution rate[s] as noted. The actual application rates will vary within the range specified to suit field conditions and will be recommended by the manufacturer's representative and approved by the Contracting Officer from test areas and sections evaluated.
1.2 REFERENCES

**************************************************************************
NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.
**************************************************************************

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

ASTM INTERNATIONAL (ASTM)

1.3 SYSTEM DESCRIPTION

**************************************************************************
NOTE: Retain equipment units required for the project and delete all others.
**************************************************************************

1.3.1 Equipment, Plant and Tools

Equipment, plant and tools used in the work are subject to Government approval and must be maintained in a satisfactory working condition at all times. Provide equipment which is adequate and has the capability of producing the results specified. Provide calibrated equipment, such as asphalt distributors, spreaders and similar equipment, that has been recalibrated by an approved calibration laboratory within 12 months prior to commencing work and every 6 months thereafter, by such laboratory from the date of recalibration, during the term of the contract. Submit an equipment list with calibration reports.

1.3.2 Asphalt Distributors

The emulsion must be applied with an equipment manufacturer-approved computer rate-controlled bituminous distributor. The equipment must be in good working order and contain no contaminants or diluents in the tank when product to be applied is added to the tank. Spreader bar tips must be clean, free of burrs, and of a size to maintain an even distribution of the emulsion. Any type of tip or pressure source is suitable that will maintain predetermined flow rates and constant pressure during the application process with application speeds under 13 kilometers per hour, eight miles per hour or 213 meters per minute, 700 feet per minute. Test the equipment under pressure for leaks and to ensure it is in good working order before use.

The distributor truck must be equipped with a 3.66 meter 12 foot, minimum, spreader bar with individual nozzle control. The distributor truck must be capable of specific application rates in the range of 0.15 to 0.80 liters per square meter 0.05 to 0.25 gallons per square yard. These rates must be computer-controlled rather than mechanical. The distributor truck must have an easily accessible thermometer that constantly monitors the temperature of the emulsion.
In the event of a temperature problem with the material, a distributor truck will be provided that is equipped to effectively heat and mix the material to the required temperature prior to application. Heating and mixing will be done in accordance with the manufacturer's recommendations. Care must be taken not to overheat or over mix the material.

The distributor must be equipped to hand spray the emulsion in areas identified either on the plans or by the Contracting Officer.

1.3.3 Aggregate Spreader

The asphalt distributor truck will be equipped with an aggregate spreader that can apply sand to the emulsion in a single pass operation without driving through wet emulsion. The aggregate spreader must be equipped with a variable control system capable of uniformly distributing the sand at the specified rate at varying application widths and speeds. Spinner type equipment will be acceptable. The sander must have a minimum hopper capacity of at least 1,360 kilograms 3,000 pounds of sand. Push-type hand sanders will be allowed for use around lights, signs and other obstructions.

1.3.4 Power Brooms and Power Blowers

A power broom or blower must be provided for removing loose material from the surface to be treated.

1.3.5 Vacuum Sweepers

Provide self-propelled, vacuum pickup sweepers capable of removing loose sand, water, and debris from pavement surface.

1.3.6 Equipment Calibration

For the calibration of the aggregate spreader, only option b. is permitted unless aggregate spreader has been calibrated with the same aggregate within the last six months. Equipment calibration for emulsion may be achieved by either one of the two following procedures:

a. First Procedure: Contractor to furnish a State Calibration Certification for the asphalt emulsion distributor, from any state providing that service, or other acceptable agency certification at the approval of the Contracting Officer, and the calibration date must have been within 6 months of the contract award, or up to 12 months if supporting documents substantiate continuous work using the same distributor.

b. Second Procedure: Furnish all equipment, materials and labor necessary to calibrate the asphalt emulsion distributor and the aggregate spreader. Perform all calibrations with the approved job materials and prior to applying the specified coatings to the prepared surface. Perform calibration of the asphalt emulsion distributor in accordance with ASTM D2995. Perform work to calibrate the tank and measuring devices of the distributor. Perform inspection and calibration at the beginning of the work and at least once a day during construction.

1.4 SUBMITTALS

********************************************************************

NOTE: Review Submittal Description (SD) definitions

********************************************************************
in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy, Air Force, and NASA projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy, Air Force, and NASA projects, or choose the second bracketed item for Army projects.

**************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

**SD-03 Product Data**

Contractor Qualifications; G[, [____]]

Provide copies of Qualifications.

Manufacturer Representative’s Experience

Material Performance

Equipment List; G[, [____]]

List of equipment used in the project along with calibration reports.

Aggregates

Provide in accordance with Field Quality Control.

SD-06 Test Reports

Manufacturer's Certificate of Compliance for Bituminous Material,

Manufacturer's Certificate of Compliance for Aggregates

Recommendation by contractor/manufacturer from results of test section application.

Any additional testing as requested by Contracting Officer

Bituminous Materials; G[, [____]]

1.5 QUALITY ASSURANCE

Provide copies of Contractor Qualifications for applicators, personnel and equipment, Certified by Manufacturer to apply product and to have made three (3) applications similar to this project in past two (2) years. Include details of previous work, schedule adherence, quality of workmanship, materials and name and work phone of contracting officer's points of contact.

Obtain Manufacturer's Certificate of Compliance for emulsion and aggregates. Obtain samples at time of delivery to the field as necessary to satisfy the requirements herein.

******************************************************************************
NOTE: The requirement for the Contractor to require a manufacturer's authorized representative on the job site at the beginning of the work is recommended for all DoD projects.
******************************************************************************

1.5.1 Manufacturer's Representation

The manufacturer’s representative must have knowledge of the material, procedures, and equipment described in the specification and must be responsible for determining the application rates and must oversee the preparation and application of the seal coat product. Documentation of the manufacturer representative’s experience and knowledge for applying the seal coat product must be furnished to the Contracting Officer a minimum of 10 work days prior to placement of the test sections. The cost of the manufacturer’s representative must be included in the bid price.
1.5.2 Samples

Take aggregate samples for laboratory tests in accordance with ASTM D75/D75M. Take samples of gilsonite modified asphalt emulsion in accordance with ASTM D140/D140M.

1.5.3 Aggregates Source

Select sources from which aggregates are to be obtained and notify the Contracting Officer within [15] days after the award of the Contract. Perform tests for the evaluation of aggregates by using an approved commercial laboratory at no expense to the Government. Tests for determining the suitability of aggregate must include: gradation in accordance with ASTM C136/C136M, and ASTM C117 and must be within the last six months. Independent laboratory testing is required for all new aggregate sources.

1.5.4 Gilsonite Modified Asphalt Emulsion Source

The Contractor must furnish the vendor’s certified test reports for bituminous materials, in its concentrated form, to the Contracting Officer, showing that the material meets the properties of Table 1. Bituminous materials must meet the properties of Table 2 and Table 3.

1.6 DELIVERY, STORAGE, AND HANDLING

Deliver gilsonite modified asphalt emulsion to the site in a homogenous and undamaged condition. Inspect the materials for contamination and damage. Unload and store the materials with a minimum of handling. Protect stored aggregate from contamination and segregation. Replace defective or damaged materials.

1.7 ENVIRONMENTAL REQUIREMENTS

Apply the coating when the existing surface is dry, and when the weather is not foggy, rainy, or when the wind velocity will prevent the uniform application of the material. Apply gilsonite modified asphalt emulsion seal coat only when both the atmospheric temperature and the pavement surface temperature are above 15.5 degrees C 60 degrees F, unless otherwise directed.

PART 2 PRODUCTS

**************************************************************************

NOTE: The quantities of material shown in the table above cover an average range of conditions. The quantity of sand, the dilution rate of the emulsified asphalt and its rate of spread should take into consideration local conditions and experience. The Designer of Record should select the dilution rate(s) reflecting the local condition of the pavement such as surface texture, porosity, and age of the asphalt pavement to be sealed.

A dilution rate of one (1) part emulsified asphalt to one (1) part water is recommended for most applications. A dilution rate of two (2) parts emulsified asphalt to one (1) part water is recommended for grooved, rough or course surfaces,
or where the pavement is highly oxidized or badly cracked.

Application rates can vary from 0.36 to 0.68 l per m² 0.08 to 0.15 gallons per square yard. For a 1:1 dilution, 0.45 to 0.68 l per m² 0.10 to 0.15 gallons per square yard is recommended. For a 2:1 dilution, 0.36 to 0.68 l per m² 0.08 to 0.15 gallons per square yard is recommended. Exceeding recommended application rates is not advisable without consulting a responsible manufacturer’s representative.

If the manufacturer's representative cannot consult on the appropriate dilution and rate to apply it is recommended that the manufacturer's representative is contacted during the design phase to discuss the appropriate dilution and rate to select.

**************************************************************************

2.1 GILSONITE MODIFIED ASPHALT EMULSION

The bituminous material must be a gilsonite modified asphalt emulsion. The material must meet the following requirements of the applicable portions of Table 1, 2, and 3.: 

Table 1: Concentrated Bituminous Material Properties

<table>
<thead>
<tr>
<th>Properties</th>

| pH, cationic (see Note 1)           |               | 6.5 percent maximum  

Note 1: pH may be used in lieu of the particle charge test which is sometimes inconclusive in slow setting, bituminous emulsions.

The bituminous material concentrate must be diluted with heated water prior to application. The bituminous material, when diluted in the volumetric proportion of [one part hot water to one part concentrate] [one part hot water to two parts concentrate] must meet the requirements shown in Table 2.: 

[...]
Table 2: 1 Part Bitumen : 1 Part Water Dilution Emulsion Properties (see Note 2)

Note 2: In ready-to-apply form by volume.

Note 3: Pumping stability is tested by pumping 475 ml 1 pint of diluted material at 25 deg C 77 deg F, through a 6 mm 1/4 inch gear pump operation 1,750 rpm for 10 minutes with no significant separation or coagulation.

The bituminous base residue must contain not less than 20 percent uintaite or gilsonite, and must not contain any tall oil pitch or coal tar material. This must be stated in the Manufacturer's Certificate of Compliance for bituminous material. The material must be compatible with asphaltic concrete, and have a 5-year minimum proven performance record at airports with similar climatic conditions. Curing time, under recommended application conditions, must not exceed eight hours.

The Contractor must furnish vendor's certified test reports showing that the material is the type, grade and quality specified for each load of bituminous material delivered to the project. The certification must also show the shipment number, refinery, consignee, destination, contract number and date of shipment. The test reports and certification must be delivered to the Contracting Officer before permission is granted to use the material. The furnishing of the vendor's certified test report for the bituminous material must not be interpreted as a basis for final acceptance. The manufacturer's material test report certification may be subject to verification by testing the material delivered for use on the project.

The bituminous material storage and handling temperature must be between $10 \text{ deg C} - 71 \text{ deg C}$ and the material must be protected from freezing, or whenever outside temperature drops below $5 \text{ deg C}$ for prolonged time periods.

2.2 AGGREGATE

**************************************************************************
NOTE: Aggregate should be used on runways and where friction may also be an issue. Where friction is not an issue the sand requirement can be removed.

The gradations in the table represent the limits in determining aggregate suitability for use in the emulsified asphalt surface treatment. The sand gradation used, within the limits designated in the table, must provide sufficient friction levels to meet or exceed the Maintenance Planning Friction Level in Table 3-2, “Friction Level Classification for Runway Pavement Surfaces” of AC 150/5320-12, Measurement, Construction, and Maintenance of Skid Resistant Airport Pavement Surfaces.

Locally available sand or abrasive material may be available that is slightly outside of the gradation requirements listed below. These may be submitted for review and approval by the Contracting Officer. It is recommended to obtain concurrence for use by the seal coat manufacturer; and the Designer of...
Record and manufacturer’s field representative should verify acceptance during application of test sections

The aggregate material must be a dry, clean, dust and dirt free, sound, durable, angular shaped manufactured specialty sand, such as that used as an abrasive, with a Mohs hardness of 6 to 8. The Contractor must submit manufacturer’s technical data and a manufacturer’s certification indicating that the specialty sand meets the requirements of the specification to the Contracting Officer prior to start of construction. The sand must be approved for use by the Contracting Officer and must meet the following gradation limits when tested in accordance with ASTM C136/C136M and ASTM C117:

Table 4: Aggregate Material Gradation Requirements

</tr>
<tr>
<td>No. 100</td>
<td>0-7</td>
</tr>
<tr>
<td>No. 200</td>
<td>0-2</td>
</tr>
</tbody>
</table>

The Contractor must submit gradation and manufacturer's specification for review at or prior to the pre bid for approval. The gradations in the chart represent the limits in determining aggregate source suitability for use in the bituminous surface treatment. The final gradations approved, within the limits designated in Table 4, must provide sufficient friction levels to meet the Minimum Friction Level in Table 3-2, "Friction Level Classification for Runway Pavement Surfaces" of FAA AC 150/5320-12.

2.2.1 Material Performance

NOTE: The following Material Performance submittal must be required for airfield runways and taxiways.

Friction tests previously performed in accordance with FAA Advisory Circular, FAA AC 150/5320-12, at 40 and 60 mph-wet, must be submitted showing, as a minimum; friction value of pavement surface prior to sealant application; two values, test between 24 and 96 hours after application,
with a minimum of 24 hours between tests; and one value test at no less than 90 days or greater than 360 days after the application. The results of the two tests between 24 and 96 hours must indicate friction is increasing at a rate to obtain similar friction value on the 90th day as the original friction value, and the long term test must indicate no apparent adverse effect with time relative to friction values and existing pavement surface.

The contractor must submit a list of airports which meet the above requirements, as well as technical details on application rates, aggregate rates, and point of contact at these airports to confirm use and success of sealer with aggregate. Friction tests must be submitted from no less than one of the airports on the list and each set of tests described above, must be from one project.

Seal coat material submittal without required friction performance will not be approved. Friction tests performed on this project, if any, cannot be used as a substitute of this requirement.

2.2.2 MOHS Hardness

MOHS hardness must be within 6-8 in accordance with ASTM D1474/D1474M.

2.3 POLYMER

**********************************************************
NOTE: If the Designer of Record determines that polymer is required, the Designer of Record must verify that the vinyl acrylic polymer is approved for use by the asphalt material manufacturer. Polymer will generally increase cost, but it also increases durability. A lifecycle cost analysis may justify its use.
**********************************************************

Vinyl acrylic polymer must be approved for use by the manufacturer of the bituminous material for compatibility and must meet the requirements provided in Table 5:

<table>
<thead>
<tr>

The Contractor must submit manufacturer's specifications for the vinyl acrylic polymer with the bituminous materials submittal for review and approval.

2.4 WATER

Water used in diluting the emulsion must be potable, free from harmful soluble salts and chemicals, and at least 38 deg C 100 deg F.

PART 3 EXECUTION

3.1 PREPARATION OF SURFACE

**************************************************************************
NOTE: If the surface to be treated requires repairs, the method of repairs and extent of work involved should be shown or described. For substantial amounts of repair work use applicable UFGS sections.

Removal of paint and rubber deposits are generally accomplished by high pressure water blasting. Few approved chemicals are effective and sandblasting is not permitted by air pollution regulations at some locations. Mechanical abrasion generally causes damage to the pavement.
**************************************************************************

Provide Inspection Reports of; air and surface temperature during application of seal coat, emulsion temperature and rate of application, dilution rate used, adequacy of surface cleaning and preparation, aggregate rate of application, and protection of site facilities as applicable, each day of application.

Repair and patch all major pavement defects in accordance with [Section 32 01 17.61 SEALING CRACKS IN ASPHALT PAVING][the following subparagraphs]. All cracks sealed with a joint sealant compatible with the emulsion prior to application of the emulsion.

[3.1.1 Hairline Cracks

Cracks that are less than 6 mm 1/4 inch wide do not need to be sealed.

3.1.2 Small Cracks

Cracks that are 6 to 20 mm 1/4 to 3/4 inch wide must be routed to a nominal width 3 mm 1/8 inch greater than the existing nominal width and to a depth not less than 20 mm 3/4 inch, waterblasted and cleaned using compressed air.
3.1.3 Medium Cracks

Cracks that are 20 to 50 mm 3/4 to 2 inches wide must be waterblasted and cleaned using compressed air.

3.1.4 Large Cracks

Cracks that are greater than 50 mm 2 inches wide must be repaired using pothole repair techniques instead of sealing.

3.1.5 Cleaning Operations

Provide a clean surface for the seal coat. If considered necessary by the manufacturer's representative and is approved by the Contracting Officer, flushing with water will be permitted. Water will be made available for the contractor's use from a hydrant location within [_____] km(s) mile(s) of the project site [at prevailing Government rates]. The contractor must provide tools, hoses and hauling equipment for providing and dispensing of the water.

Immediately before applying the sealcoat, the asphalt surface to be treated must be free of all dirt, sand, vegetation, loose paint, excessive oil or grease, rubber deposits or other objectionable material. The surface must be cleaned with a power broom or power blower supplemented by hand sweeping or any other means required to remove deleterious matter to the satisfaction of the Contracting Officer.

3.1.6 Weather Limitations

The asphalt emulsion shall be applied only when the existing pavement surface is dry and when the weather is not foggy, rainy, or when the wind velocity will prevent the uniform application of the material. No material shall be applied when dust or sand is blowing or when rain is anticipated within eight hours of application completion. The atmospheric temperature and the pavement surface temperature shall both be above 16 deg C 60 deg F. During application, account for wind drift.

3.1.7 Protection of Site Facilities

Cover existing buildings, structures, runway edge lights, taxiway edge lights, informational signs, retro-reflective marking and in-pavement duct markers as necessary before applying the emulsion. Should emulsion get on any light or marker, clean property promptly. If cleaning is not satisfactory to the Contracting Officer, the Contractor must replace any light, sign or marker with equivalent equipment at no cost to the Government.

3.2 GILSONITE EMULSION MIXING

The application emulsion must be obtained by blending bituminous material concentrate, polymer and water. Always add heated water to the bituminous material concentrate; never add bituminous material concentrate to heated water. Add one percent polymer, by volume, to the emulsion mix. If the polymer is added to the emulsion mix at the plant, submit weigh scale tickets to the Contracting Officer. As an option, the polymer may be added to the emulsion mix at the job site provided the polymer is added while the circulating pump is running. The mix must be agitated for a minimum of 15 minutes or until the polymer is mixed to the satisfaction of the Contracting Officer.
3.3 QUANTITIES OF MATERIAL PER SQUARE METER YARD

The approximate amounts of materials per square meter yard for the bituminous surface treatment must be as provided in Table 6 for the treatment area(s) at the specified dilution rate(s) as noted on the plans. The exact amounts to be used must be determined by the results of the test section program as directed by the Contracting Officer. Pavements with more progressive deterioration issues may require heavier than normal application rates for emulsion and aggregate. In such cases a manufacturer's representative should be consulted as directed by the Contracting Officer.

</tr>
</tbody>
</table>

3.3.1 Application of Gilsonite Modified Asphalt Emulsion

The emulsion must be applied upon the properly prepared, clean and dry surface at the application rate approved by the Contracting Officer for each designated treatment area. The emulsion temperature must be at a temperature at or above 54 deg C 130 deg F, but not exceeding 71 deg C 160 deg F or in accordance with the manufacturer's recommendation using a pressure distributor to obtain uniform distribution at all points.

During all applications, the surfaces of adjacent structures must be protected in such manner as to prevent their being spattered or marred. Bituminous materials must not be discharged into borrow pits or gutters or upon the airport area.

3.3.2 Application of Aggregate

The emulsion, along with sand at the rate specified for each designated application area must be spread uniformly over the emulsion in a single pass from a sanding attachment to the asphalt distributor. The aggregate must be spread in the same width of application as the bituminous material and must not be applied in such thickness as to cause overspreading.

Sprinkling of additional aggregate material, and spraying additional bituminous material over areas that show up having insufficient cover or bitumen, must be done by hand whenever necessary. In areas where hand work is necessitated, the sand must be applied before the sealant begins to break.

Sanding must be performed in a manner so as to prevent appreciable amounts of sand from going onto any pavement prior to the emulsion being applied. The Contractor must clean up areas with excess or loose sand and dispose of off airport property.
3.4 TEST SECTIONS AND AREAS

**************************************************************************

NOTE: Note to designer: There may be more than one test section needed. Specify the number based upon the pavement surface conditions, slope, and texture.

For projects calling for application of the asphalt surface treatment on runway and high speed exit taxiway, the Designer of Record must document skid resistance in accordance with AC 150/5320-12, Measurement, Construction, and Maintenance of Skid-Resistant Airport Pavement Surfaces, prior to full application.

The test areas/sections afford the Contractor and the Designer of Record an opportunity to determine the quality of the mixture in place as well as the performance of the equipment.

If operational conditions preclude placement of a test section on the pavement to be seal coated, it may be applied on a pavement with similar surface texture.

**************************************************************************

Prior to production seal coating applying the seal coat, place up to 3[_____] test sections at a location determined by the Contracting Officer approximately 15 meters 50 feet long by a minimum of 2.5 meters 8 feet wide in a single pass of equipment using the approved job materials in accordance with the specification requirements, unless noted otherwise. Perform tests to determine the application rates of the asphalt emulsion and aggregate. Test sections must be performed on pavement areas that are not considered critical to operations. Vary the application rates along the longitudinally along the test section in order to effectively evaluate the pavement absorption rates. If the tests indicate that the seal coat test section does not conform to the specification requirements, make necessary adjustments to the application equipment and to the spreading procedures, and construct additional test sections for conformance to the specifications. Where test sections do not conform to specification requirements, repair or remove seal coat at no expense to the Government; no separate payment will be made for seal coat materials and labor, either in placement or removal of any test section. Removal of seal coat must be performed only if 500 feet of length or greater on a runway surface do not meet the friction requirements of FAA AC 150/5320-12. Perform quality control sampling and testing during construction as specified in paragraph FIELD QUALITY CONTROL. Test sections must be performed in the presence of the Contracting Officer and the Seal Coat Manufacturer's Representative (SCMR). Notify the Contracting Officer 7[_____] days prior to the planned test section date. The SCMR must recommend to the Contracting Officer application rates of materials used in production seal coating. The Contracting Officer must approve the application rates prior to production seal coating.

A qualified manufacturer's representative must be present in the field to assist the Contractor in applying test areas or test sections to determine the optimum rate of application of both sealant and sand.
A test area or section must be applied for each differing HMA pavement surface identified in the project. The test area or sections must be used to determine the material application rate(s) of both sealant and sand prior to full production. The same equipment and method of operations must be utilized on the test section(s) as will be utilized on the remainder of the work.

a. For Taxiway, Taxilane and Apron Surfaces - Prior to full application, the Contractor must place test areas at application rate(s) stipulated by the Contracting Officer or judged necessary by the manufacturer's representative to determine proper application rate. The area to be tested will be designated by the Contracting Officer and will be located on a representative section of the pavement to receive the bituminous surface coat.

If the test area should prove to be unsatisfactory, necessary adjustments to the application rate, placement operations, and equipment must be made. Additional test areas must be placed and evaluated, if required. Full production must not begin without the Contracting Officer's approval.

b. For Runway and High Speed Taxiway Exit Surfaces - If friction testing is required by the contract, the Contractor will test according to FAA AC 150/5320-12. The contractor must place a series of friction test sections a minimum of 90 meters long by 2.5 meters wide (300 feet long by 8 feet wide) at application rate(s) determined by application test sections and areas. The area to be tested will be located on a representative section of the pavement to receive the bituminous surface coat.

The Contractor must perform tests for skid resistance of the test sections after a time frame determined by the contractor, manufacturers representative (if present), and the Contracting Officer. Full application can proceed when the results of the friction evaluation are equal to or greater than the Maintenance Minimum levels provided in Table 3-2, "Friction Level Classification for Runway Pavement Surfaces," in FAA AC 150/5320-12. Documentation will be provided by the manufacturer that demonstrates a history of rapid increase of pavement friction to above Maintenance Planning levels provided in Table 3-2 and returning to pre-application numbers shortly thereafter.

If the test section should prove to be unsatisfactory, necessary adjustments to the application rate, placement operations, and equipment must be made. Additional test sections must be placed and evaluated, if required. Full production must not begin without the Contracting Officer's approval.

3.5 FIELD QUALITY CONTROL - SEAL COAT

3.5.1 Aggregate Gradation

Perform gradation tests in accordance with ASTM C136/C136M when directed by the Contracting Officer. When the source of materials is changed or deficiencies are found, the gradation must be repeated and the material already placed must be retested to determine the extent of the unacceptable material where friction issues exist. Replace all in-place unacceptable material or re-apply seal coat material conforming to the specification as directed by Contracting Officer at no additional expense to the Government.
3.5.2 Gilsonite Modified Asphalt Emulsion Sample

Obtain a sample of the asphalt emulsion used under the supervision of the Contracting Officer. The sample will be retained by the contractor until the completion of the project and must be turned over to the government upon request of the Contracting Officer.

3.5.3 Water Compatibility Test

In some localities an incompatibility may exist between the asphalt emulsion and the water to be used for dilution due to their characteristics. Clear, potable water should be used. No less than thirty days prior to commencing work, 0.24 liter one half pint of the proposed asphalt emulsion and 0.24 liter one half pint of the proposed water must be combined, agitated, and allowed to sit for a period of 24 hours to test their compatibility. If they prove to be incompatible, indicated by separation of the emulsion, clotting, particles settling or other adverse properties from mixing with water, an approved chemical treatment must be provided for all water used for dilution or a different and compatible source of water must be selected. Report results to the Contracting Officer.

3.5.4 Application Inspection

Inspect application of seal coat for uniformity. Furnish a written report within 24 hours of testing citing air and surface temperature during application, emulsion temperature during application, dilution rate, and rate of emulsion application determined from testing compared to the approved production rates.

3.6 TRAFFIC CONTROL

Protect freshly placed coatings from damage by traffic. Provide sufficient warning signs and barricades to prevent traffic over freshly treated surfaces. Protect treated areas from traffic for at least [2][_____] hours after final application of seal coat material, or for such time as necessary to prevent picking up. Immediately prior to opening for subsequent construction operations (markings) or traffic, broom and vacuum to remove loose material only after material has completely cured. Provide warning signs and barricades for proper traffic control in accordance with MUTCD.

NOTE: This guide specification covers the requirements for rejuvenation of bituminous pavements using a liquid rejuvenator material.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1  GENERAL

1.1  UNIT PRICES

NOTE: Delete these paragraphs when lump sum bidding is used.

1.1.1  Measurement

1.1.1.1  Quantity of Rejuvenator

The quantity of rejuvenator to be paid for will be the number of liters used in the accepted work as determined by the Contracting Officer, corrected to liters at 15 degrees C gallons at 60 degrees F in accordance with ASTM D1250, and provided that the measured quantities are not 20...
percent over the approved application rate. Any amount of rejuvenator exceeding the approved application rate by more than 20 percent will be deducted from the measured quantities except for irregular areas where hand spraying of the rejuvenator is necessary. The actual application rate will be determined by the Contracting Officer by dividing the number of liters gallons of rejuvenator actually applied by the number of square meters square yards of pavement treated.

1.1.1.2 Treated Pavement

The quantity of pavement treated with rejuvenator to be paid for will be the number of square meters square yards completed and accepted as determined by the Contracting Officer. The number of square meters square yards of treated pavement will be determined by measuring the length and width of the specified work area. Measurements to determine the number of square meters square yards will be along the surface of the pavement.

1.1.2 Payment

Quantities of rejuvenator and treated pavement will be paid for at respective unit prices. Payment will not be made for quantities of rejuvenator and treated pavement when actual application rate of rejuvenator is more than 20 percent below the approved application rate until deficiency is corrected in accordance with paragraph Insufficient Rejuvenator Material.

1.2 REFERENCES

**************************************************************************

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

**************************************************************************

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

ASTM INTERNATIONAL (ASTM)

ASTM D92 (2012a) Standard Test Method for Flash and
1.3 SUBMITTALS

NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy, Air Force, and NASA projects.
The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy, Air Force and NASA projects, or choose the second bracketed item for Army projects.

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

**SD-04 Samples**

**Bituminous Rejuvenator**

1.4 QUALITY ASSURANCE

Apply the rejuvenator so that the test properties of binder extracted from samples of the upper 9 mm 3/8 inch of the surface of the test section show that viscosities have decreased by at least 40 percent. Compute the percent decrease in viscosity as follows:

\[
100 \left( \frac{\text{Viscosity of untreated sample}}{\text{Viscosity of untreated samples}} - \text{Viscosity of treated sample}\right)
\]

1.5 DELIVERY, STORAGE, AND HANDLING

Protect rejuvenator material from excessively high or low temperatures. Store the rejuvenator at temperatures recommended by the manufacturer. Smoking, fire or flames other than heaters that are part of the equipment will not be permitted in the vicinity of heating, distributing or transferring operations for rejuvenators that are flammable.

1.6 EQUIPMENT, TOOLS, AND MACHINES

Maintain equipment, tools, and machines used in the performance of the work in a satisfactory working condition.

1.6.1 Bituminous Storage Tank

Provide bituminous storage tanks capable of heating the bituminous material under effective and positive control at all times to the required temperature. Accomplish heating by steam coils, hot oil, electricity, or other suitable method. Affix an armored thermometer to the tank so that the temperature of the bituminous material may be read at all times.

1.6.2 Bituminous Distributor

Provide a bituminous distributor designed and equipped to spray the bituminous material in a uniform double or triple lap at the temperature recommended by the manufacturer, at variable widths, and at readily determined and controlled rates from 0.10 to 1.0 L/square meter 0.04 to 0.2
gallon/square yard with an allowable variation from the specified rate of not more than plus or minus 5 percent. Include with the distributor equipment a separate power unit for the bitumen pump, full-circulation spray bars, tachometer, pressure gauges, volume-measuring devices, adequate heaters for heating of materials to the proper application temperature, a thermometer for reading the temperature of tank contents, and a hand hose attachment suitable for applying bituminous material manually to areas inaccessible to the distributor. Equip the distributor for circulation and agitation of the bituminous material during the heating process.

1.6.3 Brooms and Blowers

Furnish power type brooms and blowers suitable for cleaning the surfaces of bituminous pavements.

1.7 ENVIRONMENTAL REQUIREMENTS

Apply the rejuvenator to a dry surface and only when the atmospheric temperature in the shade is 10 degrees C 50 degrees F or above. Delay application if rain appears imminent within 8 hours following planned time of application.

PART 2 PRODUCTS

2.1 REJUVENATOR

Provide chemical rejuvenator having a proven record of satisfactory performance based on the ability of the material to decrease the viscosity of the binder material, to reduce the rate of loss of fines, and to retard crack propagation. Select a material that neither permanently damages nor obscures pavement markings. Approval of specific application specifications recommended by the manufacturer is required by the Contracting Officer. Sample the rejuvenating material according to ASTM D140/D140M. Provide rejuvenator conforming to the following test requirements:

<table>
<thead>
<tr>
<th>Property</th>
<th>Requirement</th>
<th>Test Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>Residue, percent</td>
<td>55 minimum</td>
<td>ASTM D244 (1)</td>
</tr>
<tr>
<td>Viscosity at 60 degrees C, sq mm/sec 140 degrees F, centistokes (2)</td>
<td>80-500</td>
<td>ASTM D2170/D2170M</td>
</tr>
<tr>
<td>Flash Point (3) Cleveland Open Cup (COC), degrees C degrees F</td>
<td>177 350 minimum</td>
<td>ASTM D92</td>
</tr>
</tbody>
</table>

(1) Modify ASTM D244 evaporation test for percent residue by heating 50 gram samples to 150 degrees C 300 degrees F until foaming ceases, cooling immediately, and calculating the results.

(2) Viscosity on the residue obtained from evaporation test.

(3) Flash point on residue from evaporation test.
2.2 AGGREGATE

Determine gradation of mineral aggregate in accordance with ASTM C136/C136M and meet the following gradation requirements:

<table>
<thead>
<tr>
<th>Sieve Designation (mm)</th>
<th>Percent by Weight Passing</th>
</tr>
</thead>
<tbody>

<td>4-12</td>
</tr>
<tr>
<td>0.15 No. 100</td>
<td>0-5</td>
</tr>
</tbody>
</table>

PART 3 EXECUTION

3.1 PREPARATION OF SURFACE

Immediately before applying the rejuvenator, remove loose material, dirt, clay, or other objectionable material from the surface to be treated. After the cleaning operation and prior to application of the rejuvenator, the Contracting Officer will inspect the area to be treated to determine fitness of the area to receive the rejuvenator.

3.2 APPLICATION OF REJUVENATOR MATERIAL

Following preparation and subsequent inspection of the surface, uniformly apply the rejuvenator over the surface to be treated at the approved rate with an allowable variation from the approved rate of application of plus or minus 20 percent and at the temperature recommended by the supplier. To obtain uniform application of the rejuvenator on the surface treated at the junction of previous and subsequent applications, spread building paper on the surface at a sufficient distance back from the ends of each application so that application of the rejuvenator may be started and stopped on the paper. Immediately after application, remove the building paper and properly dispose of it. Properly treat areas missed by the distributor with the hand spray. Do not disturb the surface for a period of at least 24 hours following application of the rejuvenator.

3.2.1 Excess Rejuvenator Material

Provide approved mineral aggregate for spreading, in sufficient quantity, to effectively blot up any excess rejuvenator material remaining on the treated pavement surface after 24 hours.

3.2.2 Ponding and Puddling of Rejuvenator Material

If low spots and depressions in the pavement surface cause ponding or puddling of the rejuvenating agent, broom the pavement surface with a broom drag. Continue brooming until the pavement surface is free of any pools of excess material.

3.2.3 Excess Runoff of Rejuvenator

Treat pavement surfaces, which have excessive runoff of rejuvenator due to
surface grade, in 2 or more applications. Perform each additional application after the prior application of material has penetrated into the pavement.

3.2.4 Insufficient Rejuvenator Material

When it is determined by the Contracting Officer that the actual application rate of the rejuvenator is more than 20 percent below the approved application rate, make subsequent applications of rejuvenator to bring the actual application rate up to the approved rate with penetration into the pavement surface occurring within 24 hours after application.

3.3 TEST SECTION

Prior to application of the rejuvenator, prepare representative test sections on the pavement to be treated. Treat the test sections with various amounts of rejuvenator, and conduct tests on samples obtained from the top 9 mm 3/8 inch of each of these treated areas to measure viscosity and thus determine desired application rate. Obtain the samples of treated material no sooner than 24 hours after application of rejuvenator. Select an application rate to obtain the specified reduction in asphalt viscosity and to ensure that all rejuvenator material penetrates into the pavement surface within 24 hours. Do not apply rejuvenator at a rate what will exceed that which the pavement can absorb within 24 hours. Do not begin application of the rejuvenator until the test sections have been evaluated and the required application rate has been approved.

3.4 SAMPLING AND TESTING

3.4.1 Sampling

Perform sampling of the test section before and after the pavement has been rejuvenated. Take samples from the treated test section areas no sooner than 24 hours after application of the rejuvenator.

3.4.2 Testing

Conduct tests to extract the bituminous rejuvenator according to ASTM D2172/D2172M and recover according to ASTM D1856. Submit samples of sufficient size to provide enough bituminous binder for determination of viscosity. Measure viscosity of the bituminous material in accordance with ASTM D2170/D2170M or ASTM D2171/D2171M, as applicable, and conducted at 60 degrees C140 degrees F unless otherwise specified. Determine the change in viscosity for each application rate of rejuvenator in the test section from tests conducted on samples taken before and samples taken after the pavement surface has been rejuvenated. Sampling and testing [are the responsibility of the Contractor] [will be by the Government].

3.4.3 Calibration Test

Furnish all equipment, materials and labor necessary to calibrate the bituminous distributor. Perform the calibration with approved job material, prior to applying the rejuvenator to the prepared surface, and in accordance with ASTM D2995.

PART 1  GENERAL

1.1  UNIT PRICES

NOTE: This paragraph will be deleted if the work is included in one lump sum contract price for the entire work covered by the invitation for bids. This paragraph may be revised to combine the payment for cold-mix recycled mixture, rejuvenator (if needed), and emulsified asphalt cement, when separate payment for emulsified asphalt cement material is not considered warranted based on local experience and job conditions. Lump sum contracts can be used when the total job does not exceed 17,000 square meters 20,000 square yards or 1000 metric tons tons.
1.1.1 Measurement

**************************************************************************
NOTE: Where in place mixing is used, measurement will be in square meters yards of accepted work.
**************************************************************************

Cold-mix recycling paid for will be the number of [metric tons tons] [square meters yards] used in the accepted work. Aggregates will be paid for by the number of [metric tons tons] [square meters yards] used in the accepted work. The recycling agent will be paid for by the number of [liters gallons] [metric 2000-pound tons] of material used in accepted work. The emulsified asphalt cement will be paid for by the number of [liters gallons] [metric 2000-pound tons] of material used in accepted work. Determine the number of liters gallons of emulsified asphalt cement used either by measuring the material at a temperature of 15.6 degrees C 60 degrees F or by correcting the amount measured at another temperature to liters gallons at 15.6 degrees C 60 degrees F, using a coefficient of expansion of 0.00045 per degree C 0.00025 per degree F for the emulsified asphalt.

1.1.2 Payment

The quantities of recycled paving mixture, aggregates, recycling agent, and emulsified asphalt cement, determined as provided above, will be paid for at respective contract unit prices per [metric ton ton] [square meter yard] for paving mixture and aggregates and per [liter gallon] [metric ton ton] for recycling agent and emulsified asphalt cement. If deficiencies in the finished product exceed specified tolerances, no payment will be made for such areas of pavement until the defective areas are corrected and accepted by the Contracting Officer.

1.2 REFERENCES

**************************************************************************
NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.
**************************************************************************

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

**************************************************************************

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.
AASHTO T 88 (2013) Standard Method of Test for Particle Size Analysis of Soils

ASTM INTERNATIONAL (ASTM)

ASTM D2041/D2041M (2011) Theoretical Maximum Specific Gravity and Density of Bituminous Paving Mixtures

1.3 SUBMITTALS

NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy.
Air Force, and NASA projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy, Air Force and NASA projects, or choose the second bracketed item for Army projects.

**************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-03 Product Data

   Aggregates
   Asphalt Emulsion
   Recycling Agent
   Job-Mix Formula (JMF); G[, [_____]}

SD-04 Samples

   Samples
   Cold Recycled Mixtures

SD-06 Test Reports

   Testing

1.4 QUALITY CONTROL

1.4.1 Sampling and Testing

Perform sampling and testing by using a commercial testing laboratory or Contractor facilities, upon approval by the Contracting Officer. No work requiring testing will be permitted until the testing facilities have been inspected and approved. The first inspection will be at the expense of the Government. Cost incurred by the Government for any subsequent inspection required because of failure of the facilities to pass the first inspection will be charged to the Contractor.

1.4.2 Samples

Submit samples from the existing pavement obtained from at least two locations to provide representative samples of the pavement. Take recyclable asphalt pavement and aggregate samples for laboratory tests in accordance with ASTM D75/D75M. Take samples of the emulsified asphalt cement (bituminous material) [and recycling agent] in accordance with ASTM D140/D140M.
1.4.3 Sampling and Testing During Construction

Perform quality control sampling and testing as required in paragraph ACCEPTABILITY OF WORK.

1.5 EQUIPMENT, TOOLS AND MACHINES

Allow the Contracting Officer access, at any time, to all equipment used to produce the cold-recycled mixture; this can involve checking the adequacy of the equipment used, inspecting the operation of the equipment, and verifying weights, mixture proportions, and the character and physical properties of the materials used for construction. Plant, machines, tools, and miscellaneous equipment to be used on the production and placement of the cold recycled mixture must be approved by the Contracting Officer. Tentative approval of specific items will be made only after adequacy of the plant, machines, tools, and miscellaneous equipment has been demonstrated in full-scale production.

1.5.1 Central Plant Mixing

**************************************************************************
NOTE: This paragraph and paragraph In-Place Mixing should be left in only when it is desired to give the Contractor a choice between central plant mix and in-place methods.
**************************************************************************

Provide a mixing plant designed, coordinated, operated to produce mixture within the JMF, and capable of producing recycled mixture at a minimum rate of \[136\] \[_____] Mg \[150\] \[_____] tons per hour. Equip the plant with a positive means to control the amount of asphalt, water, [recycling agent,] and time of mixing.

1.5.2 In-Place Mixing

Use equipment for in-place mixing construction that will produce mixture within the JMF. Use mixing equipment that is equipped with positive means to control the amount of asphalt[, recycling agent,] and water added and is capable of producing a homogeneous mixture.

1.5.3 Straightedge

Furnish and maintain at the site, in good condition, one 3.66 meter 12 foot straightedge for each mechanical spreader. Make straightedge available for Government use. Use straightedges constructed of aluminum or other lightweight metal with blades of box or box-girder cross section and with flat bottom reinforced to insure rigidity and accuracy. Use straightedge with handles to facilitate movement on pavement.

1.6 ENVIRONMENTAL REQUIREMENTS

Do not construct recycled cold-mix course in rain or on a layer which contains free water either within the layer or on its surface. Construct recycled cold-mix courses only when the atmospheric temperature is 10 degrees C 50 degrees F or above.
PART 2   PRODUCTS

2.1 RECLAIMED ASPHALT PAVEMENT (RAP)

**************************************************************************
NOTE: Cold-mix recycling could include the use of existing RAP material stockpiles. If this condition exists, the desired material properties must be included below. The gradation of the existing stockpile will need to be determined.
**************************************************************************

Provide RAP consisting of material obtained from cold milling or from removal and crushing of the existing asphalt pavement. The maximum particle size of the RAP material must never exceed half the thickness of the compacted cold mix layer. When lifts of 75 mm 3 inches or more are used, the maximum particle size of the RAP material must not exceed a maximum of 38 mm 1-1/2 inch and a minimum of 90 percent of the RAP must pass a 25 mm 1 inch sieve.

2.2 AGGREGATES

**************************************************************************
NOTE: Delete this paragraph when new or additional aggregates are not required as part of the recycling project. When required, new aggregates may be added to produce an aggregate gradation that meets the desired end product. Gradations for base course, stabilized base course or intermediate asphalt mixture course should be specified in Table I below. For airfields, cold recycled mixture will only be used for base course material or lower levels in the pavement structure. The choice of which gradation to specify should be based on the type, quality, and uniformity of the RAP material available for use. The gradation of the recycled mixture must be determined on the aggregate recovered from an extraction or ignition test.

The gradation may require only that a maximum aggregate particle size not be exceeded or it may be more detailed, requiring further processing or adjustment with new aggregates to meet the desired gradation. The tolerances applied to this gradation should follow standard tolerances given for aggregates or asphalt aggregate mixtures when used in similar situations. When the recycled mixture is intended to be used as an intermediate or binder course (for non airfield areas), the gradation tolerances should follow those given in UFC 3-250-03, Table "Aggregate Gradations for Bituminous Concrete Pavements," for low-pressure tires. When the recycled mixture is to be used as a base course, an exact JMF aggregate gradation is not normally given and therefore tolerances are not required. The only requirement is that the gradation must stay within the gradation range specified.
**************************************************************************
Provide aggregates consisting of crushed stone, crushed gravel, crushed slag, screening, natural sand, and mineral filler, as required. The portion of materials retained on the 4.75 mm No. 4 sieve will be known as coarse aggregate, the portion passing the 4.75 mm No. 4 sieve and retained on the 0.075 mm No. 200 sieve will be known as fine aggregate, and the portion passing the 0.075 mm No. 200 sieve will be known as mineral filler. The combined recycled aggregate gradation must conform to the gradation specified in TABLE I. TABLE I is based on aggregates of uniform specific gravity; the percentage passing various sieves may be changed by the Contracting Officer when aggregates of varying specific gravities are used. Adjustments of percentage passing various sieves may be changed by the Contracting Officer when the specific gravity of the aggregates varies by more than 0.2.

<table>
<thead>
<tr>
<th>TABLE I. COMBINED RECYCLED AGGREGATE GRADATION</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sieve Size</td>
</tr>
<tr>
<td>[_____]</td>
</tr>
</tbody>
</table>

2.2.1 Coarse Aggregate

---------------------------------------------------------------------------------------------------------------------
NOTE: The values of percentage of loss will be based on knowledge of aggregates in the area which have been previously approved or that have a satisfactory service record in bituminous pavement construction for at least 5 years. Typically, RAP will come from existing pavement being repaved and aggregate from RAP will not be tested except for gradation. New aggregates will meet required properties described in this section. Cold mix layers will always be overlaid with hot mix layers or bituminous surface treatment.
---------------------------------------------------------------------------------------------------------------------

New coarse aggregate will consist of clean, sound, durable particles meeting the following requirements.

a. Percentage of loss not exceeding 40 after 500 revolutions, as determined in accordance with ASTM C131/C131M.

b. Percentage of loss not exceeding [_____] after five cycles performed in accordance with ASTM C88, using magnesium sulfate.

c. Dry weight of crushed slag not less than 1200 kg/cubic m 75 pcf, as determined in accordance with ASTM C29/C29M.

d. Crushed gravel retained on the 4.75 mm No. 4 sieve and each coarser sieve containing at least 75 percent by weight of crushed pieces having one or more fractured faces with the area of each face equal to at least 75 percent of the smallest midsectional area of the piece. When two fractures are contiguous, the angle between planes of fractures must be at least 30 degrees to count as two fractured faces.

e. Essentially cubical particle shape of crushed aggregates. Provide aggregate that contains no more than 20 percent by weight of flat and
elongated particles in any sieve size when determined in accordance with ASTM D4791.

2.2.2 Fine Aggregate

Provide new fine aggregate consisting of clean, sound, durable particles including natural sand or crushed stone, slag, or gravel that meets requirements for wear and soundness specified for coarse aggregate. Fine aggregate produced by crushing gravel must have at least 90 percent by weight of crushed particles having two or more fractured faces in the portion larger than the 0.600 mm No. 30 sieve. This requirement applies to the material before blending with natural sand, when blending is necessary. Quantity of new natural sand to be added to the intermediate course mixtures must not exceed 25 percent by weight of new coarse and new fine aggregate and material passing the 0.075 mm No. 200 sieve. Provide natural sand that is clean and free from clay and organic matter. The percentage of loss must not exceed [_____] after five cycles of the soundness test performed in accordance with ASTM C88, using magnesium sulfate.

2.2.3 Mineral Filler

Use mineral filler conforming to ASTM D242/D242M. Determine grain size in accordance with AASHTO T 88.

2.3 ASPHALT EMULSION

**************************************************************************
NOTE: The material being recycled may contain sufficient asphalt binder to meet the specification requirements. In this case, only water will be added as a lubricant to improve compaction. When additional asphalt binder is needed grade SS-1 or CSS-1 should be specified in moderate or cold climates. Grade SS-1h or CSS-1h should be specified in hotter climates such as the southern or southwestern areas of the United States. Medium set, high float, or other types of emulsions may be used with open graded mixtures or in instances where previous experience with these types of emulsions has provided good results.
**************************************************************************

Asphalt, if required, must be an emulsified asphalt, Grade [_____] conforming to [ASTM D977] [ASTM D2397/D2397M].

2.4 WATER

Generally, any potable water will be acceptable for diluting the asphalt emulsion. Prior to construction, mix a sample of the water intended for use on the job with a sample of the emulsion at the ratio to be used in the project. If any adverse effect is observed on the emulsion, use a new source of water.

2.5 RECYCLING AGENT

**************************************************************************
NOTE: Depending on the material properties of the
existing asphalt cement binder and the type and method of recycling used, an appropriate type of recycling agent (rejuvenator) will be selected. An emulsified recycling agent should be selected according to ASTM D5505. The type of rejuvenator specified must match the recycling process used. The recycling agent selected should be capable of decreasing the viscosity of the reclaimed asphalt cement to levels that approach the viscosity values of asphalt cement in new asphalt concrete pavements for that area or region. Delete this paragraph if a recycling agent is not required.

**************************************************************************
Use [_____] recycling agent selected in accordance with ASTM D5505. Submit notification on sources from which aggregates, emulsified asphalt cement and recycling agent are to be obtained within 15 days after contract award.

2.6 JOB-MIX FORMULA (JMF)

**************************************************************************

NOTE: The mix design primarily establishes the amount of asphalt binder and recycling agent (if used) to be added to the mixture, and then establishes the amount of water to insure optimum compaction conditions. The optimum asphalt content (this includes the recycling agent, if used) is determined based on hot compacted samples because this produces the density that will ultimately be obtained in the field. Ideally, the water content should be selected to provide maximum density based on samples compacted at the mixture temperature (ambient air temperature) which will be encountered during construction.

Prior to bidding the contract, the designer may want to sample and obtain the material properties of the asphalt and aggregates in the existing pavement. This information is required to allow the development of a JMF and to allow for estimates of emulsified asphalt cement and/or recycling agent type and quantities required. The need for new aggregates to meet JMF requirements may also be determined. For lump sum bidding, a reasonable estimate of required quantities of materials will be needed.

**************************************************************************

Submit the JMF for the recycled mixture to the Contracting Officer for acceptance after the award of the contract and at least [30] [_____] days prior to placement of recycled mixture. Samples will be compacted using 50 blows with Marshall equipment or 50 gyrations with the Superpave gyratory compactor. Prior to compaction mixes will be heated to temperatures equivalent to hot mix asphalt and the mix will be designed to provide 3-4 percent air voids in the compacted mixture. Mixes will be compacted at expected construction temperature to determine optimum moisture content. No payment will be made for cold recycled mixtures produced prior to the completion and acceptance of the JMF. The formula will indicate the gradation of the aggregate and a definite percentage of water [,recycling
agent] and asphalt emulsion to be added to the mixture.

2.6.1 Gradation Tolerances

**************************************************************************
NOTE: Eliminate the corresponding material size and tolerance values to agree with sieve sizes specified in Table 1. Eliminate these completely if no new aggregate is added and no specific JMF gradation is developed.
**************************************************************************

The tolerances allowed on the gradation are as follows:

<table>
<thead>
<tr>
<th>Material</th>
<th>Tolerance, Plus or Minus</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aggregate passing the 4.75 mm No. 4 or larger sieve</td>
<td>4 percent</td>
</tr>
<tr>
<td>Aggregate passing the 2.36, 1.18, 0.6, and 0.3 mm Nos. 8, 16, 30, and 50 sieves</td>
<td>3 percent</td>
</tr>
<tr>
<td>Aggregate passing the 0.15 and 0.074 mm Nos. 100 and 200 sieves</td>
<td>1 percent</td>
</tr>
</tbody>
</table>

2.6.2 Asphalt Content

The JMF will be allowed an asphalt content tolerance of 0.3 percent. The asphalt content may be adjusted by the Contractor to improve paving mixture, without adjustment in contract unit price when approved by the Contracting Officer. Select the optimum asphalt content to provide the tabulated properties when samples are compacted at 120 degrees C 250 degrees F using 50 blows of the Marshall hammer or 50 gyrations with the Superpave gyratory compactor.

<table>
<thead>
<tr>
<th>Property</th>
<th>Requirement (50 blows)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Voids in total mix, percent</td>
<td>3-5</td>
</tr>
<tr>
<td>Voids filled with bitumen, percent</td>
<td>75-85</td>
</tr>
</tbody>
</table>

2.6.3 Water Content

Select the water content to provide maximum dry density when samples are prepared at the optimum asphalt content and compacted with 50 blows/gyrations at ambient temperature. When no asphalt binder is added to the mixture, select the water content to provide maximum dry density. Prepare samples with water contents, in 0.5 percent intervals, from 0 to 2.5 percent (water content may be increased to achieve maximum density). After compaction, place the samples in an oven at 60 degrees C 140 degrees F for 96 hours. After cooling to ambient temperature, determine the dry density according to ASTM D2726/D2726M. Select the optimum moisture content as the moisture content that provides maximum density.
PART 3  EXECUTION

3.1  CONDITION OF EXISTING SURFACE

Correct areas in the existing pavement that provide indications of underlying structural deficiencies (alligator cracking or depressions) prior to the completion of the recycling process.

3.2  CONSTRUCTION METHODS

**************************************************************************
NOTE: Depending on the type of recycling desired the following paragraphs should be edited to remove the undesired method. The following can remain in its entirety when the type of construction used is to be a Contractor's option.
**************************************************************************

Use only RAP material that meets the requirements given in paragraph RECLAIMED ASPHALT PAVEMENT prior to mixing.

3.2.1  Central Plant Mixing

Introduce the required amount of bituminous material for each batch, or calibrated amount of continuous mixing, into the mixer to meet the requirements of the JMF. Mix the material in a manner that provides a uniform dispersion of the emulsified asphalt, recycling agent if used, and water and achieves a thorough coating (visually) of all aggregate particles. If this process requires excessive mixing, resulting in premature breaking of the emulsified asphalt, shorten the mixing times as approved by the Contracting Officer. Use a mixing process that thoroughly coats all particles.

3.2.2  Test Section

**************************************************************************
NOTE: Use of a test section is recommended for all recycled mixtures, especially for central-plant mix recycling. The following paragraph is written for placing central-plant mix with a paver and must be edited when another type of recycling is used.
**************************************************************************

Prior to the start of the recycling project, prepare a sufficient quantity of mixture to construct a test section at least 15 meters 50 feet long, two spreader widths wide and of thickness to be used in the project. Place, spread, and roll the mixture with the equipment to be used in the project and in accordance with requirements specified above. This test section will be tested and evaluated as a lot conforming to all specification requirements. If approved by the Contracting Officer, the test section may be located in one of the less critical areas of the project. Otherwise, it will be located outside the project area. If tests results are satisfactory, the test section will remain in place as part of the completed pavement if constructed in the project pavement area. If tests indicate that the pavement does not conform to specification requirements, remove the test section and dispose of the material offsite. Make necessary adjustments to the plant and placing operations and rolling procedures immediately, and construct another test section, all at no
additional cost to the Government. Construct additional test sections, as necessary and as directed. Sample and test additional test sections for conformance with specification requirements. In no case will full production of the recycled mixture begin without approval of the Contracting Officer.

3.2.3 In-Place-Mixing

**************************************************************************
NOTE: In-place recycling can be divided into either partial- or full-depth recycling. Partial-depth recycling involves only a portion of the asphalt bound layers and normally involves recycling to a depth of 50 to 100 mm (2 to 4 inches). Full-depth recycling involves all asphalt bound layers and often portions of the underlying base course layer.
**************************************************************************

Produce a uniform blend of the RAP, new aggregate (when required), asphalt emulsion, recycling agent, water, and a mixture containing the required amounts of emulsified asphalt and water as given in the JMF when using the in-place recycling process.

3.3 PLACEMENT

3.3.1 Spreaders

Provide spreading equipment capable of spreading material uniformly; and resulting in a surface that meets the grade and smoothness requirements when compacted. Unless otherwise directed, begin spreading along the centerline of areas paved on a crowned section, or on the high side of areas with a one-way slope, in the direction of major traffic flow. Spray contact surfaces of previously constructed pavement, curbs, manholes, and other structures with a thin coat of bituminous material conforming to Section 32 12 13 BITUMINOUS TACK AND PRIME COATS. Place the recycled mixture without segregation. When segregation occurs during placement, suspend the spreading operation until the cause is determined and corrected. When placing by hand, dump and distribute the mixture into place and spread with lutes in a uniformly loose layer of such thickness to conform to the required grade and thickness when compacted. During hand spreading, carefully place each shovelful of mixture by dropping the material in place by turning the shovel over in a manner to prevent segregation. Do not place the mixture by throwing or broadcasting.

3.3.2 Placement with a Paver

Place the recycled asphalt mixture with a self-propelled asphalt paver or similar equipment containing a vibrating or tamping screed. Operate the paver so that the course being laid will be smooth and continuous without pulling or tearing.

3.3.3 Layer Thickness and Curing

**************************************************************************
NOTE: The minimum layer thickness allowed should be at least twice the size of the maximum aggregate particle of the RAP or aggregate. The maximum layer thickness may vary from 100 to 150 mm (4 to 6 inches). However, it is typically recommended to not exceed...
100 mm 4 inch layer unless there is a good reason to use a thicker layer. Constructing layers thicker than 100 mm 4 inches makes it more difficult to compact, more difficult to control smoothness, and more time to cure. The curing period should range from 7 to 14 days, depending on climatic conditions. The hotter and drier the weather, the shorter the curing period. Generally, the cure period should be about 2 days for each 25 mm 1 inch of lift thickness. The water content of the recycled mixture should be below 1.5 percent prior to placing additional layers or a wearing surface.

Construct each layer of compacted mixture at least [_____] mm inches but no more than [_____] mm inches in thickness. Allow each layer of recycled mixture to cure for [_____] days before placing a succeeding layer, unless a shorter curing period is approved in writing by the Contracting Officer.

3.3.4 Windrows

When windrows are used, construct them of such size and shape to allow adequate mixing of materials without segregation, ensuring that the required thickness of pavement can be constructed.

3.4 COMPACTION OF MIXTURE

Conduct compaction of the mixture to satisfy density, grade, and smoothness requirements. Roll bituminous mixtures until all roller marks are eliminated, and a field density of at least 98 percent of the theoretical maximum density has been obtained when tested in accordance with ASTM D2041/D2041M.

3.4.1 Operation of Rollers and Tampers

Provide the sufficient number, weight, and type of rollers to obtain the required density. Begin initial rolling of the recycled mixture as the emulsion is starting to break. Vibratory rolling will be allowed to achieve required density. Use finish rolling with a steel-wheel roller to remove any existing roller marks.

3.4.2 Correcting Deficient Areas

Remove mixture that becomes contaminated with foreign material, or is defective in any way, to the full thickness of the course. Cut the hole with sides vertical and perpendicular to each other, with one side parallel to the direction of traffic. Do not skin patch rolled areas to correct low areas and do not be mill rolled areas to correct high areas. Place fresh paving mixture in holes in sufficient quantity to produce a finished surface conforming to grade and smoothness requirements. Paving mixture shall be aerated, if necessary, and shall be compacted to the density specified herein. Provide competent workmen capable of performing all work incidental to the correction of deficiencies and defects.

3.5 JOINTS

Joints shall present the same texture, density, and smoothness as other sections of the course. Carefully make joints between old and new pavements or between successive days' work to ensure continuous bond.
between old and new sections of the course.

3.5.1 Transverse Joints

Pass the roller over the unprotected end of freshly laid mixture only when laying of the course has been discontinued. Cut back the edge of the previously laid course to expose even, vertical surface for the full thickness of the course. The fresh mixture shall be raked against the joints, thoroughly tamped, and then rolled.

3.5.2 Longitudinal Joints

Construct longitudinal joints which are uniform, and without mixture segregation. When directed by the Contracting Officer, cut back the longitudinal joint to expose an even, vertical surface for the full thickness of the course.

3.6 EDGES OF PAVEMENT

Edges of pavement shall be straight and true to required lines. After final rolling, cut off and square excess material and dispose of as directed.

3.7 TRAFFICKING

 Trafficking on newly placed cold recycled mixtures will not be allowed prior to completion of compaction and the curing period.

3.8 ACCEPTABILITY OF WORK

3.8.1 Testing

Perform field tests in sufficient numbers to ensure that the specifications are being met. Submit copies of test results within 24 hours of completion of tests. Submit copies of test reports for aggregate source, not less than [30] [_____] days before the material is required in the work. Certified copies of the emulsified asphalt cement and/or recycling agent manufacturer's test reports indicating compliance with applicable specified requirements, will be placed not less than [30] [_____] days before material is required in the work. Testing is the Contractor's responsibility and performed by an approved commercial laboratory. Perform the following tests at the appropriate time, as the minimum acceptable for each type of operation.

3.8.1.1 Mixture Properties

***********************************************************************
NOTE: The mixture should normally be sampled and tested twice a day or for every 4 hours of production or placement.
***********************************************************************

Obtain a sample of the recycled mixture for every [_____] hours of placement of the mix. Determine the asphalt content of the mix according to ASTM D2172/D2172M or ASTM D6307. The asphalt content of the recycled material shall be within the tolerance given in paragraph JOB-MIX FORMULA. Determine the gradation of the extracted aggregate in accordance with ASTM C117 and ASTM C136/C136M. The extracted gradation shall meet the JMF and the corresponding tolerances.
3.8.1.2 Density Testing

**NOTE:** The frequency of testing for the maximum theoretical density (ASTM D2041/D2041M) should be tied to the frequency of the field nuclear test readings. Depending on the anticipated construction methods used, a nuclear density test should be performed about every 500 square meters yards of recycled mixture placed. Generally, one ASTM D2041/D2041M test should be conducted for every 4 nuclear tests and four ASTM D2041/D2041M tests should be performed for each full day of production.

Conduct field density tests in accordance with ASTM D6938 or ASTM D1556/D1556M. When ASTM D6938 is used, the testing shall be by the direct transmission method. Accomplish the calibration of the nuclear test device by testing in accordance with ASTM D1556/D1556M as described in paragraph "Calibration" of ASTM D6938. Tests performed in accordance with ASTM D6938 result in a wet unit weight of material. Determine the moisture content of the recycled mixture by ASTM D2216, ASTM D4643, ASTM D4944, or ASTM D4959. The calibration testing shall occur in an area representative of the entire project in regards to materials and compactive effort. Perform a minimum of three of these tests and at least three nuclear readings shall be taken near each of these areas. Calibrate each nuclear device accordingly. Each day the used nuclear devices shall be recalibrated in the manner stated above or the selected area preserved and the devices calibrated in the same approximate locations each day. The field density shall be expressed as a percentage of the maximum theoretical density in accordance with ASTM D2041/D2041M. Furnish all tools, labor, and materials for obtaining samples and refilling sample locations. Perform a minimum of one nuclear field density test for every \[\text{[____]} \text{metric tons tons} \text{][square meters yards]} \text{of mixture placed.}

3.8.1.3 Grade Conformance

**NOTE:** For cold-recycled mixtures used only as a base course in aircraft traffic areas, such as airfield runways and taxiways, intervals between grade-conformance tests should not exceed 8 m 25 feet. This should be the procedure for wide non airfield pavement such as parking lots. For roads, the intervals between grade-conformance tests should not exceed 8 m 25 feet longitudinally and should be at transverse intervals as appropriate.

Take measurements for deviation from grade by running lines of levels at intervals of \[\text{[____]} \text{meters feet} \text{longitudinally and [____]} \text{meters feet transversely} \text{to determine the elevation of the completed pavement. The finished and completed surface shall conform within 15 mm 0.05 foot to lines, grades, cross section, and dimensions shown on the drawings.}

3.8.1.4 Surface Smoothness

Take measurements for deviation from surface smoothness with a 3.66 meter...
12 foot straightedge. The finished surface of the layer shall not deviate more than 10 mm 3/8 inch from the testing edge of the straightedge in the transverse or longitudinal direction. Place the straightedge parallel to the centerline of each lane paved at intervals of [_____] meters feet and perpendicular to the centerline at intervals of [_____] meters feet. Record the locations and deviations from the straightedge of all measurements. Remove defective areas and replace them with fresh paving mixture at no additional cost to the Government.

3.8.2 Material Samples

Obtain a sample of all materials used in the recycled mixture under the supervision of the Contracting Officer. The sample will be retained by the Government.

-- End of Section --

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for cold milling of bituminous pavement for airfields, roads, streets, parking areas, and other general applications.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1 GENERAL

NOTE: This guide specification can be used to specify cold milling alone on structurally sound pavements for surface texturing to increase skid resistance of a worn pavement, or for pavement removal to restore roadway geometry. Cold milling can also be used in conjunction with mill and fill operations.

On the project drawings, show:

1. Location and extent of milling operation.
2. Required elevation of milled surface and finish
surface of new pavement.

3. Section indicating in \textit{mm inches} the depth that existing pavement has to be removed.

4. Location of existing manholes, valve boxes and utility lines.

**************************************************************************

1.1 UNIT PRICES

**************************************************************************

\textbf{NOTE: Delete these paragraphs when lump sum bidding is used.}

**************************************************************************

1.1.1 Measurement

The quantity of milled pavement will be the number of square \textit{meters yards} completed and accepted as determined by the Contracting Officer. Determine the number of square \textit{meters yards} of milled pavement by measuring the length and width of the milled surface within the specified work area. Measure the width of the area to the closest \textit{mm inch} and measure the length of the area to the closest \textit{meter foot}.

1.1.2 Payment

Payment will be to the nearest square \textit{meter yard}. No payment will be made for milling outside the specified area of work.

1.2 QUALITY ASSURANCE

1.2.1 Grade

Mill pavement such that the finished surface conforms to the lines, grades, and cross sections indicated. The maximum allowable deviation of the finished milled pavement surfaces from the established plan grade line and elevation will be [0] \textit{[6] mm [0] [1/4] inch}. The deviations from the plan grade line and elevation will not be permitted in areas of pavements where closer conformance with planned grade and elevation is required for the proper functioning of appurtenant structures involved.

1.2.2 Surface Smoothness

The maximum allowable deviation of the finished surfaces from the testing edge in the transverse or longitudinal direction will be \textit{6 mm 1/4 inch}.

1.2.3 Traffic Control

Provide all necessary traffic controls during milling operations.

1.3 EQUIPMENT, TOOLS, AND MACHINES

Maintain in a satisfactory working condition equipment, tools, and machines used in the performance of the work.

1.3.1 Cold-Milling Machine

Provide a cold-milling machine which is self-propelled, capable of milling
the pavement to a specified depth and smoothness and of establishing grade
control; with means of controlling transverse slope and dust produced
during the pavement milling operation. Machine will have capability of
adding water in front of equipment to minimize dust during milling
operation. The machine will have the ability to [windrow the millings or
cuttings] [remove the millings or cuttings from the pavement and load them
into a truck]. The milling machine will not damage any part of the
pavement structure that is not to be removed.

1.3.2 Cleaning Equipment

Provide cleaning equipment suitable for removing and cleaning loose
material from the pavement surface.

1.3.3 Straightedge

Furnish and maintain at the site, in good condition, one \( 3.66 \) meter 12 foot
straightedge or other suitable device for each milling machine, for testing
the finished surface. Make straightedge available for Government use. Use
straightedges constructed of aluminum or other lightweight metal, with
blades of box or box-girder cross section with flat bottom reinforced to
insure rigidity and accuracy. Use straightedges with handles to facilitate
movement on the pavement.

1.4 ENVIRONMENTAL REQUIREMENTS

Do not perform milling when there is accumulation of snow or ice on the
pavement surface.

PART 2 PRODUCTS

Not Used

PART 3 EXECUTION

3.1 MILLING OPERATION

When the milled material (cutting) is to be cold recycled, the maximum size of the cuttings should be
equal to or less than one-half of the recycled pavement thickness. Generally, the maximum size for
a single 100 mm 4 inch lift of pavement will be 50 mm 2 inches or less. For hot recycling the
recommended maximum size of the milled material is 50 mm 2 inches.

If design does not include removal of base course material and it is desired not to disturb the base
course then the following may be included in this paragraph:

Conduct cold-milling operation to ensure that only bituminous pavement is removed and base course is
not disturbed. Leave in place a layer of bituminous pavement, 25 mm 1 inch thick, over the undisturbed base course.
A minimum of seven days notice is required, prior to start work, for the Contracting Officer to coordinate the milling operation with other activities at the site. Make sufficient passes so that the designated area is milled to the grades and cross sections indicated. Mill the pavement in depth increments that will not damage the pavement below the designated finished grade. If scabbing occurs, the surface will not meet smoothness requirements. Take steps to modify the process as needed to prevent scabbing from occurring. Repair or replace, as directed, items damaged during milling such as manholes, valve boxes, utility lines, pavement that is torn, cracked, gouged, broken, or undercut. Remove the milled material. Remove the milled material from the pavement and load into trucks.

3.2 GRADE AND SURFACE-SMOOTHNESS TESTING

3.2.1 Grade-Conformance Tests

NOTE: For pavements in aircraft traffic areas such as airfield runways and taxiways, lines of levels to determine elevation of the milled pavement will be run longitudinally and transversely at intervals not exceeding 8 meters 25 feet.

Test the finished milled surface of the pavement for conformance with the plan-grade requirements and for acceptance by the Contracting Officer by running lines of levels at intervals of [7.5] [_____] meters [25] [_____] feet longitudinally and [7.5] [_____] meters [25] [_____] feet transversely to determine the elevation of the completed pavement. Correct variations from the designated grade line and elevation in excess of the plan-grade requirements as directed. Skin patching for correcting low areas will not be permitted. Remove and replace the deficient low area. Remove sufficient material to allow at least 25 mm 1 inch of asphalt concrete to be placed.

3.2.2 Surface-Smoothness Tests

After completion of the final milling, the finished milled surface will be tested by the Government with a straightedge. Other approved devices may be used, provided that when satisfactorily and properly operated, such devices reveal all surface irregularities exceeding the tolerances specified. Correct surface irregularities that depart from the testing edge by more than 6 mm 1/4 inch. Skin patching for correcting low areas will not be permitted. Remove and replace the deficient low area. Remove sufficient material to allow at least 25 mm 1 inch of asphalt concrete to be placed.

3.3 REMOVAL OF MILLED MATERIAL

[Place material that is removed [in the disposal area as specified] [into traveling mixing plant for cold-mix recycling].] [Transport material that is removed to central plant for hot-mix or cold-mix recycling.] [Stockpile material that is removed as specified and in such a manner to prevent segregation or contamination.] [Material that is removed will become the property of the Contractor and removed from the site.]

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for the hot in-place recycling of existing bituminous pavement using either single- or multiple-pass methods.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1 GENERAL

NOTE: Experience and data indicate that scarifying is feasible only on existing asphalt pavements that are structurally sound but in need of surface leveling or exhibit superficial distresses. In the single-pass method, new asphalt mixture is placed over the recycled asphalt at the time of construction. When using a multiple-pass in-place recycling process, apply an asphalt overlay or surface treatment to the recycled pavement after construction of the in-place recycled mixture. Hot in-place recycling is a good method for roads in poor surface condition, but approval of the responsible government agency's member on the
Pavements Discipline Working Group is required for use on airfields.

1.1 UNIT PRICES

**NOTE:** When other methods of measurement are desired or are necessary, this paragraph will be modified accordingly. Delete paragraph NEW ASPHALT MIXTURE when new asphalt is not added to the mixture. The term "recycling agent" is used in this section to mean any product used to decrease the viscosity of old asphalt binders as specified in ASTM D4552.

1.1.1 Measurement

1.1.1.1 In-Place Recycled Mixture

The quantity of hot in-place recycled mixture paid for will be the number of square meters yards completed and accepted as determined by the Contracting Officer. The number of square meters yards of planed pavement will be determined by measuring the length and width of the specified work area. Recycling agent will be paid for by the number of liters gallons of material used in the accepted work.

1.1.1.2 New Asphalt Mixture

New asphalt mixture will be paid for by the number of metric tons short tons of material used in accepted work.

1.1.2 Payment

The quantities of recycled asphalt mixture, new asphalt mixture, and recycling agent as determined in paragraph IN-PLACE RECYCLED MIXTURE and paragraph NEW ASPHALT MIXTURE, will be paid for at contract unit prices per square meter yard for recycled mixture [and per metric ton short ton for new asphalt mixture] and per liter gallon for recycling agent. If deficiencies in the finished product exceed specified tolerances, no payment will be made for such areas of pavement until the defective areas are corrected and accepted by the Contracting Officer.

1.2 REFERENCES

**NOTE:** Paragraph REFERENCES is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in paragraph REFERENCES by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.
References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

SECTION 32 01 16.74  Page 5
1.3 SUBMITTALS

**************************************************************************
NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a “G” to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy, Air Force, and NASA projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy, Air Force and NASA projects, or choose the second bracketed item for Army projects.

**************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-03 Product Data
1.4 EQUIPMENT, TOOLS, AND MACHINES

Maintain equipment, tools, and machines used in the performance of the work in a satisfactory working condition at all times, and in conformance with applicable governing regulations for local air pollution controls. Provide equipment capable of performing recycling operations at a minimum rate of 600 square meters 720 square yards per hour to the depth required.

1.4.1 Heating Units

Provide heating units that use radiant heat with no flame directly on the pavement. Provide combustion chamber(s) that is(are) insulated and totally enclosed. Shield the heating units with an enclosed hood to hold in the heat and to protect workers and surrounding areas.

1.4.2 Scarifying/Milling Equipment

Provide scarifying or hot milling equipment that is able to penetrate the pavement surface and cut to the depth as shown on the plans, without fracturing the aggregate in the pavement. When used for this purpose, the scarifiers or hot milling heads have to be able to mix the recycled mixture with any material that is added as part of the recycling process. Provide equipment with height adjustments to clear obstacles in the pavement.

1.4.3 Distribution and Mixing Equipment

Provide at least one unit of the recycling equipment capable of uniformly distributing and thoroughly mixing the recycling agent [and new asphalt mixture] with the recycled material. The distribution system(s) of the added material is(are) required to have a positive feed and shut-off linked to the movement of the unit.

1.4.4 Vibratory Screed

Cross slope and grade can be adjusted when additional asphalt materials are added to the mixture. When only the recycling agent is added to the mixture, there is little opportunity to adjust the existing slope and grade.
Provide a unit with a vibratory screed capable of spreading, leveling, and finishing the recycled mixture uniformly across the processed width.

1.4.5 **Straightedge**

Provide and maintain at the site, in good condition, one 3.66 meter 12 foot straightedge for each finishing unit (paver) for testing the finished surface. Make straightedges available for Government use. Straightedges have to be constructed of aluminum or other lightweight metal, with blades of box or box-girder cross section with flat bottom, reinforced to insure rigidity and accuracy, and with handles to facilitate movement on the pavement.

1.5 **QUALITY CONTROL**

**************************************************************************

NOTE: The amount of sampling and testing required depends upon the type of hot in-place recycling performed. Processes that do not add additional asphalt mixture only require testing for the amount of recycling agent added to the mixture. Processes that add additional asphalt material require gradation, asphalt content, and mixture volumetric testing.

**************************************************************************

1.5.1 **Initial Sampling and Testing**

Perform sampling and testing using a commercial testing laboratory or Contractor's facilities, upon approval by the Contracting Officer. Do not perform any work that requires testing until the testing facilities have been inspected and approved. The first inspection of the testing facilities will be at the expense of the Government. Cost incurred by the Government, for any subsequent inspection required because of failure of the facilities to pass the first inspection, will be charged to the Contractor.

1.5.2 **Samples**

Take samples of existing asphalt pavement from at least two locations to the expected depth of milling for laboratory tests in accordance with ASTM D979/D979M. Take samples of existing aggregate stockpiles in accordance with ASTM D75/D75M. Take samples of asphalt cement in accordance with ASTM D140/D140M and take samples of recycling agent in accordance with ASTM D140/D140M. Use the samples of asphalt pavement to determine the job-mix formula (JMF).

1.6 **ENVIRONMENTAL REQUIREMENTS**

Perform hot in-place recycling procedures only when the existing pavement is dry and the pavement surface temperature is above 15 degrees C 60 degrees F.

PART 2 **PRODUCTS**

**************************************************************************

NOTE: Delete the inapplicable paragraphs. Develop a mix design or JMF containing the type and amount
of new aggregates and asphalt cement for processes requiring additional new asphalt mixture. The material requirements for the new aggregates and asphalt cement used to produce the new asphalt mixture have to be listed below. The requirements listed are as given in Section 32 12 15.13 HOT-MIX ASPHALT AIRFIELD PAVING or Section 32 01 13.62 ASPHALT SURFACE TREATMENT.

2.1 RECYCLING AGENTS

NOTE: Select the appropriate grade of recycling agent based upon the ability of the recycling agent to provide the desired asphalt binder properties in the designed mixture.

Provide and use a hot-mix recycling agent of the appropriate grade conforming to ASTM D4552/D4552M.

2.2 JOB-MIX FORMULA

NOTE: When additional asphalt mixture is added to the mixture, the Government will have to sample and provide information concerning the material properties (asphalt content and gradation) of the existing pavement to the bidding parties. Add an edited version of either Section 32 12 16.16 ROAD-MIX ASPHALT PAVING or Section 32 12 15.13 HOT-MIX ASPHALT AIRFIELD PAVING to the project specifications in order to provide the material and mixture properties required in the JMF. The grade of asphalt specified ought to be that which is specified by the State DOT for that location.

Furnish the JMF to the Contracting Officer for review at least 14 days prior to the start of recycling operations. Do not begin demolition or recycling operations until the mix design has been approved by the Contracting Officer.

a. No payment will be made for hot in-place recycled mixtures produced prior to the completion and acceptance of the JMF. Provide [the gradation of the aggregate] [and] [the percentage of [asphalt and] recycling agent to be added to the mixture] in the JMF submitted for approval. Also provide, with the JMF, the amount of [asphalt and] recycling agent given per square yard of recycled material.

NOTE: Specify 50 gyrations for pavements designed for low tire pressures (less than or equal to 690 kPa 100 psi). Specify 75 gyrations for pavements designed for high tire pressures (greater than 690 kPa 100 psi).
b. Develop the JMF by combining various percentages of the selected recycling agent with the existing pavement material. Increase the amount of recycling agent in the recycled mixture until the void content of specimens made according to ASTM D6925 or ASTM D6926 using [50] [75] gyrations/blows reaches 3.5 percent. This reveals the maximum amount of recycling agent that can be added to the mixture. If the voids in the mixture are at 3.5 percent or lower with no recycling agent added, then no recycling agent will be used unless new asphalt mixture is added. At the selected amount of recycling agent and new asphalt mixture, if used, extract the asphalt cement from the samples made and recovered according to ASTM D2172/D2172M and ASTM D5404/D5404M, respectively.

c. Obtain the viscosity of the recovered asphalt cements in accordance with either ASTM D2170/D2170M or ASTM D2171/D2171M. The grade of recycling agent used in the recycled mixture has to be one that results in a dynamic shear rheometer measurement approaching the value indicated by ASTM D6373 for the high temperature PG grade requirements in the project location.

d. List the asphalt content tolerance as plus or minus 0.5% of the developed asphalt content target value in the JMF. [The in-place hot reused asphalt paving will be covered with hot mix asphalt meeting the requirements given in Section [32 12 16.16 ROAD-MIX ASPHALT PAVING] [32 12 15.13 HOT-MIX ASPHALT AIRFIELD PAVING]] [The in-place hot reused asphalt paving will be covered with surface treatment meeting the requirements given in Section 32 01 13.62 ASPHALT SURFACE TREATMENT].

PART 3 EXECUTION

3.1 PREPARATION OF SURFACE

Prior to recycling, clean the pavement surface of all loose and foreign or objectionable material with brooms or other suitable methods. Localized patching, structural corrections, and adjustments to existing structures (i.e., manhole covers) have to be completed prior to the recycling process.

3.2 HEATING

**************************************************************************
NOTE: Control the amount of heat applied to the pavement sufficiently to avoid damaging the heated pavement. Excess heat burns and therefore damages the asphalt binder. Experience has shown that a dense graded asphalt mix that is relatively lean in asphalt cement content is easiest to heat.
**************************************************************************

Provide heating units of sufficient number and size to heat the pavement surface as required for successful scarifying or hot milling to the required depth. Do not allow these units to overheat the existing pavement. Generate sufficient heat to result in a minimum recycled mixture temperature of 115 degrees C 240 degrees F as the mixture is being placed. Do not allow the maximum temperature of the recycled mixture to exceed 143 degrees C 300 degrees F at any time during the recycling process. Dispose of any recycled mixture that exceeds 143 degrees C 300 degrees F in accordance with approved waste disposal procedures and locations/facilities and replace the recycled mixture at no cost to the Government.
3.3 RECYCLING PROCEDURE

NOTE: Based on the requirements of the project, select either a single- or multiple-pass method of recycling. The single-pass method is further broken down into remix and repave procedures. The multiple-pass method requires a wearing surface that can be applied at any time from immediately prior to compaction of the recycled mixture to several weeks later.

Edit the following paragraphs according to the type of recycling to be accomplished.

3.3.1 Single-Pass Method

Perform the single-pass method using self-contained, self-propelled, automated units capable of heating, scarifying or hot rotary mixing, and redistributing the recycled mixture. The mixture consists of the existing pavement, recycling agent, [and new asphalt mixture] to the specified depth and design. Automatically feed the reclaimed material into a mixing unit. Add a recycling agent [and new asphalt mixture] to the reclaimed material in the mixer. Apply the recycling agent within the range required for the project and control the application within plus or minus 0.023 L/square meter 0.05 gallons/square yard. Heat the recycling agent, at the time of application, to within plus or minus 14 degrees C 25 degrees F of the temperature of the recycled mixture. Specify the [type and quantity of the new asphalt mixture as well as the proportion of new material and] reclaimed material in the JMF. Thoroughly mix all materials while maintaining the minimum temperature of 115 degrees C 240 degrees F. After mixing, the combined bituminous material [the addition of the recycling agent], gather the reclaimed material using a leveling device equipped with augers for mixing and placing to a uniform depth over the width being processed (Repaving). Place a layer of new hot mix asphalt conforming to the JMF over the recycled mix while it still has a residual minimum temperature of 107 degrees C 225 degrees F. Automatically feed the layer of new hot mix asphalt (meeting the requirements of Section 32 12 16.16 or Section 32 12 15.13) into a finishing unit (paver) that has automatic screed control for longitudinal leveling of the homogeneous recycled mixture to the required thickness in conformance with the specified cross-section.

3.3.2 Multiple-Pass Method

Perform the multiple-pass method consisting of self-contained, self-propelled or towed, automated units capable of heating, scarifying or hot rotary mixing, redistributing, and screeding. The equipment used in the method has to also provide for controlled leveling at the crown and across the screed to insure a cross-section that conforms to the pavement profile specified. Control the heating to provide a minimum recycled mixture temperature of 115 degrees C 240 degrees F behind the screed. The unit shall be able to uniformly distribute the specified amount of recycling agent throughout the recycled mixture. Apply the recycling agent within the range required for the project and control the application within plus or minus 0.023 L/square meter 0.05 gallons/square yard. Heat the recycling agent, at the time of application, to within plus or minus 14 degrees C 25 degrees F of the temperature of the recycled mixture. Apply a
wearing course meeting the requirements of Section [32 12 16.16 ROAD-MIX ASPHALT PAVING] [32 12 15.13 HOT-MIX ASPHALT AIRFIELD PAVING] [32 01 13.62 ASPHALT SURFACE TREATMENT] following completion of the recycling process.

3.4 JOINTS

Heat the existing pavement a minimum of 100 mm 4 inches beyond the width of the recycling. When recycling adjacent to an existing hot-mix recycled pavement mat, the heating has to extend 150 mm 6 inches into the existing mat and at least 100 mm 4 inches of the mat has to be recycled with the new mat.

3.5 COMPACTION

**************************************************************************
NOTE: The amount of compaction required for the in-place recycled asphalt mixture depends on the pavement application. Pavements subjected to high tire pressure (over 690 kPa 100 psi) vehicles, heavy loads, or numerous application of loads require a minimum density or degree of compaction of 93 percent of the theoretical maximum specific gravity of the recycled mixture. Pavements subjected to low tire pressure (equal to or less than 690 kPa 100 psi) vehicles, lighter loads, or fewer applications of loads will require a minimum density or degree of compaction of 92 percent of the theoretical maximum specific gravity of the recycled mixture.
**************************************************************************

Uniformly compact the in-place recycled asphalt mixture to a density of greater than or equal to [93] [92] percent of the theoretical maximum specific gravity but less than or equal to 96 percent of the theoretical maximum specific gravity as determined according to ASTM D2041/D2041M. Provide and utilize the type, size and number of rollers using the rolling pattern that produced the approved test section in production paving. Use a pneumatic-tire roller to seal the surface. Use additional rollers as required to remove any roller marks. Use only water or an approved release agent on rollers, tamps, and other compaction equipment. Operate rollers in vibratory mode only when doing so does not damage the pavement. Establish a new rolling pattern when changes occur in the recycled mix or placement conditions. Adjust or cease compaction when cracking or displacement occurs. Repair cracked pavement before sealing, overlaying or applying surface treatments. Ensure that pavement is fully compacted before allowing rollers to park on the pavement. Suspend operations when the density is found to be outside the specified range. Provide a written corrective action plan to the Contracting Officer that will ensure future operations will result in pavement densities within the specified range. Do no restart recycling operations until operations have been adjusted so that density requirements are met. Correct pavement with density lower than the minimum specified by either removing and replacing or reheating with an infrared heater with no open flame and recompacting at no additional cost to the Government. Pavement can only be reheated and recompacted once. If its density remains below the minimum specified, remove and replace the pavement mixture having inadequate density at no additional cost to the government.
3.6 TEST SECTION

**************************************************************************
NOTE: Use of a test section is recommended for all hot in-place recycling projects, especially for single-pass methods of construction. Placement of test sections in two adjacent paving lanes is required for recycling of pavement areas where extensive longitudinal construction joints are required, i.e. parking lots.
**************************************************************************

Prior to the start of the recycling, recycle a length of pavement at least 30 meters 100 feet long to the depth required in the project. If possible, at the direction of the Contracting Officer, place this test section in two adjacent paving lanes to demonstrate joint construction. In accordance with requirements specified in paragraph PREPARATION OF SURFACE, paragraph HEATING, paragraph RECYCLING PROCEDURE and paragraph COMPACTION, place or spread the recycled mixture and then roll the recycled mixture with the equipment to be used in the project. Test and evaluate this test section as a full day's production. The test section may be located in one of the less critical areas of the project pavement construction, as directed by the Contracting Officer. Begin full production if test results are satisfactory, and as approved by the Contracting Officer. If the test section was constructed within the project boundaries and demonstrates satisfactory test results, keep it in place as part of the completed pavement. If tests indicate that the pavement does not conform to specification requirements, make necessary adjustments to operations and procedures immediately and construct another test section, all at no additional cost to the Government. Construct additional test sections, as necessary and as directed by the Contracting Officer, to be sampled and tested for conformance with specification requirements. Do not start full production without test section approval by the Contracting Officer.

3.7 ACCEPTABILITY OF WORK

3.7.1 Field Testing and Sampling

Perform the tests described in paragraph MIXTURE PROPERTIES and paragraph DENSITY TESTING on one set of samples taken at the rates and times specified in these sub paragraphs. Submit copies of all test results within 24 hours of material sampling. Submit copies of test reports on material properties of existing asphalt pavement [and new asphalt mixture], not less than [30] [_____] days before the material is required in the work. Include with the test reports all of the information establishing compliance with the requirements detailed in this section and in referenced publications. Certified copies of the recycling agent manufacturer's test reports indicating compliance with applicable specified requirements, have to be received no less than [30] [_____] days before the material is required for the project. Perform sampling and testing using a commercial testing laboratory or Contractor's facilities, upon approval by the Contracting Officer.

3.7.1.1 Mixture Properties

**************************************************************************
NOTE: Select the information in the first set of brackets when the single-pass remix process is used and select the information in the second set of
brackets when the multiple-pass process is used. Sample and test the mixture twice a day, or once for every 4 hours, of production or placement.

[Obtain a sample of the recycled mixture for every [_____] hours of mix production. Extract the asphalt cement from the mix according to ASTM D2172/D2172M. The asphalt content of the recycled material has to be within the tolerance given in paragraph JOB-MIX FORMULA. Determine the gradation of the extracted aggregate according to ASTM C117 and ASTM C136/C136M. The extracted gradation has to meet the JMF and the corresponding tolerances.] [Record and report to the Contracting Officer the amount of recycling agent used per day along with the square meter yard area recycled. Use these values to verify that the correct amount of recycling agent is being added to the recycled mixture.]

3.7.1.2 Density Testing

NOTE: A 100 mm 4 inch core or 150 mm 6 inch core sample is required for each 1,700 to 5,000 square meters 2,000 to 6,000 square yards of hot in-place recycled mixture. Default area of sampling is 1,700 square meters 2,000 square yards.

Obtain one 100 or 150 mm 4 or 6-inch diameter core sample for each [_____] square meters yards of hot in-place recycled mixture. Determine the location of the core samples according to ASTM D3665. Determine the density of the cores in accordance with ASTM D2726/D2726M. Report the density as a percent of the theoretical maximum specific gravity, as determined by ASTM D2041/D2041M, of the cores. Correct pavement with density lower than the minimum specified by either removing and replacing or reheating with an infrared heater with no open flame and recompacting at no additional cost to the Government.

3.7.2 Grade Conformance

NOTE: Run lines of levels to determine elevation of the planed pavement longitudinally and transversely at intervals not exceeding 7.6 meters 25 feet for pavements subject to aircraft traffic, such as airfield runways and taxiways. Grade measurements for roads will be 7.6 m 25 feet longitudinally along centerline and as appropriate transversely.

Test the finished surface of the recycled pavement, for conformance with the plan-grade requirements and acceptance in the presence of the Contracting Officer, by running lines of levels at intervals of [_____] meters feet longitudinally and [_____] meters feet transversely to determine the elevation of the completed pavement. Correct the finished surface where it varies more than 15 mm 0.6 inch from the established plan-grade line and elevation. Correct the finished surfaces at junctures with other pavements where the surface does not coincide with the finished surfaces of abutting pavements.
3.7.3 Surface-Smoothness

During construction of the recycled pavement, the finished surface will be tested by the Contractor using a straightedge. The measurements of any deviations from the straightedge and the locations of those deviations will be recorded. Other approved devices may be used provided that, when satisfactorily and properly operated, such devices reveal all surface irregularities exceeding the tolerances specified. Correct surface irregularities that depart from the testing edge by more than 6 mm 1/4 inch as directed.

NOTE: This guide specification covers the requirements for heater scarifier procedures for bituminous pavements in connection with surface treatments or asphalt overlays.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1 GENERAL

NOTE: Experience and data indicate that scarifying is feasible only on existing asphalt concrete pavements which are structurally sound but in need of surface leveling or sealing, for example, pavements disturbed for utility trenches or other openings or where patches have settled and surface deterioration exists. This specification covers the use of heater scarifiers for the maintenance of bituminous pavements. Heater scarification should not be used on airfields but is useful for relatively low volume roads when applying surface treatments or thin overlays. Heater scarifying is to be used in conjunction with surface treatments...
and asphalt overlays; therefore, a surface treatment or asphalt overlay section should be included in the project specifications.

NOTE: When other methods of measurement are desired or are necessary, this paragraph will be modified accordingly.

1.1 UNIT PRICES

NOTE: When other methods of measurement are desired or are necessary, this paragraph will be modified accordingly.

1.1.1 Measurement

Determine quantities of [bituminous material] [recycling agent] applied and area of pavement treated in the accepted work by the following methods.

1.1.1.1 Bituminous Material and Recycling Agent

The quantity of [bituminous material] [recycling agent] to be paid for will be the number of liters gallons used in the accepted work as determined by the Contracting Officer, corrected to liters at 15.6 degrees C gallons at 60 degrees F in accordance with ASTM D1250 and using a coefficient of expansion of 0.00045 per degree C 0.00025 per degree F for asphalt emulsion.

1.1.1.2 Treated Pavement

The quantity of pavement treated with [bituminous material] [recycling agent] is the number of square meters yards completed and accepted as determined by the Contracting Officer. Determine the number of square meters yards of treated pavement by measuring the length and width of the specified work area. Take measurements to determine the number of square meters yards along the surface of the pavement and to the closest mm inch for width and the closest meter foot for length.

1.1.1.3 Heater Scarifying

The quantity of heater scarifying of bituminous concrete surfaces is the number of square meters yards completed and accepted, as determined by the Contracting Officer. Determine the number of square meters yards of scarified pavement by measuring the length and width of the specified work area. Take measurements along the surface of the pavement.

1.1.2 Payment

Quantities of heater scarifying, treated pavement and [bituminous material] [recycling agent] will be paid for at respective contract unit prices.

1.2 REFERENCES

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.
Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

**AMERICAN ASSOCIATION OF STATE HIGHWAY AND TRANSPORTATION OFFICIALS (AASHTO)**

AASHTO T 102 (2009; R 2013) Standard Method of Test for Spot Test of Asphaltic Materials

**ASTM INTERNATIONAL (ASTM)**

ASTM D92 (2012a) Standard Test Method for Flash and Fire Points by Cleveland Open Cup Tester

### 1.3 SUBMITTALS

**NOTE:** Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that
require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy, Air Force, and NASA projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy, Air Force and NASA projects, or choose the second bracketed item for Army projects.

**************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-04 Samples

Materials; G[, [____]]

SD-06 Test Reports

Testing

1.4 EQUIPMENT, TOOLS, AND MACHINES

Maintain equipment, tools, and machines used in the performance of the work in a satisfactory working condition at all times and conforming to applicable governing regulations for local air pollution controls.

1.4.1 Heater Scarifier

Provide a heater scarifier that is: 1) a self-propelled machine having, in combination, the means of heating and scarifying the existing asphalt concrete surface and spreading the scarified material in a uniform layer. 2) capable of producing a minimum thickness of 19 mm 3/4 inch of uncompacted reclaimed mix without damaging the asphalt binder or violating pollution standards of the area. 3) capable of working at a rate of speed
that allows heating and scarifying the pavement to meet the specified requirements. Provide a machine that heats, scarifies, and spreads material in equal widths.

1.4.2 Bituminous Distributor

Provide a bituminous distributor mounted on pneumatic tires of such size and number to prevent rutting, shoving, or other damage to the base, surface, or other layers in the pavement structure. Design and equip the bituminous distributor to spray the bituminous material in a uniform double or triple lap at the temperature recommended by the manufacturer, at variable widths up to at least 3.7 meter (12 feet), and at readily determined and controlled rates from 0.09 to 2.3 L/square meter (0.02 to 0.5 gallon/square yard) with an allowable variation from the specified rate of not more than plus or minus 5 percent. Include with the distributor equipment a separate power unit for the bitumen pump, full circulation spray bars, tachometer, pressure gauges, volume measuring devices, adequate heaters for heating of materials to the proper application temperature, a thermometer for reading the temperature of tank contents, and a hand hose attachment suitable for applying bituminous material to areas inaccessible to the distributor. Equip the distributor to circulate and agitate the bituminous material during the heating process.

1.4.3 Cleaning Equipment

Use power brooms, power blowers, and power vacuuming equipment suitable for cleaning the surface and cracks in the existing pavement prior to treatment.

1.5 ENVIRONMENTAL REQUIREMENTS

Perform heater scarifying procedures only when the existing pavement is dry and the pavement surface temperature is above 15 degrees C (60 degrees F).

PART 2 PRODUCTS

*************************************************************************
**NOTE: Designer will specify either bituminous asphalt emulsion or recycling agent to be used for treating the scarified surface, and will delete the inapplicable paragraph and renumber all subsequent paragraphs accordingly. When bituminous asphalt emulsion is to be used, grade SS-1 or CSS-1 asphalt emulsion should be specified in moderate or cold climates and grade SS-1h or CSS-1h should be specified in hotter climates such as the southern or southwestern areas of the United States.**************************************************************************

2.1 BITUMINOUS MATERIAL

Provide an emulsified asphalt, Grade [___], conforming to [ASTM D977] [ASTM D2397/D2397M]. The asphalt from which emulsion is required to have a negative spot when tested in accordance with AASHTO T 102.

2.2 RECYCLING AGENTS

Provide recycling agents composed of a petroleum base oil uniformly emulsified with water, conforming to the requirements of the table below, and having a proven record of satisfactory service for at least two years.
prior to use in this contract.

<table>
<thead>

(1)  Modify ASTM D244 evaporation test for percent residue by heating 50-gram samples to 148 degrees C 300 degrees F until foaming ceases; then cool immediately and calculate results.

(2)  Viscosity on the residue obtained from evaporation test.

(3)  Flash point on residue from evaporation test.

2.3  SAMPLING AND TESTING

2.3.1  Sampling

Take all samples of [bituminous material] [recycling agent] in accordance with the requirements of ASTM D140/D140M, unless otherwise specified. All materials will be subject to approval before use. Submit samples of proper size for approval, not less than [_____] days before commencing the work. Furnish additional samples of materials as required during construction.

2.3.2  Testing

Testing [will be the Government's responsibility] [is the responsibility of the Contractor. Perform testing using an approved commercial testing laboratory or by the Contractor's testing laboratory, subject to the approval of the Contracting Officer]. Test the materials to establish compliance with the specified requirements. Before delivery of materials, submit certified copies of the test reports establishing compliance with specifications detailed herein and in referenced publications. Submit test results on materials prior to and during construction.

PART 3  EXECUTION

3.1  PREPARATION OF SURFACE

*********************************************************************************************************************************************
NOTE: If the surface to be treated contains utility accesses, drainage systems, etc., which require repairs, the method of repairs and extent of work involved should be shown on plans and described in a separate section of the specifications.
*********************************************************************************************************************************************
Repair all potholes, defective base areas, utility cuts, and large cracks. Adjust manhole covers, valve boxes, and like structures to the desired grade prior to pavement surface repair operations.

3.2 SCARIFYING OPERATION

**************************************************************************
NOTE: Control the amount of heat applied to the pavement so that the heated pavement is not checked, charred, or otherwise damaged. The scarified pavement will not be heated while in a loosened, scarified condition. Experience has indicated that loose material on the surface tends to insulate the pavement, and thus less heat is absorbed by the pavement. Excess heat will burn the asphalt binder; however, sufficient heat should be applied to hold the temperature of the scarified material to a minimum of 90 degrees C 200 degrees F prior to the application of an overlay.
**************************************************************************

Use a heater scarifier to scarify the existing bituminous surface as shown. The temperature at which the work is performed, the nature and condition of the equipment, and the manner of performing the work should be such that no pavement damage occurs during the heating and scarifying operation. Accomplish heating with a unit or units that uniformly heat the pavement to the depth to be scarified. Uniformly spread the scarified material with the scarifier unit. Scarify the surface to a depth of at least 19 mm 3/4 inch. Do not heat the pavement while in a loosened, scarified condition.

3.3 APPLICATION OF BITUMINOUS EMULSION AND RECYCLING AGENTS

Uniformly apply the [bituminous emulsion] [recycling agent] with a bituminous distributor or other approved equipment at a temperature between 23 and 54 degrees C 75 and 130 degrees F in quantities of not less than 0.20, nor more than 1.40 L/square meter 0.05, nor more than 0.30 gallon/square yard. The exact quantities, which may be varied to suit field conditions, will be determined by the Contracting Officer. Apply the [emulsion] [recycling material] while the scarified material is hot. The bituminous material or recycling agent should be added after the heating process and before the scarification process.

3.4 COMPACTION

When a surface treatment is to be added, compact the scarified surface to provide a density that results in less than 8% air voids. When a thin asphalt overlay is to be applied the overlay asphalt material will be added on top of the scarified surface behind the scarifier. This can be placed prior to compaction of the scarified material and all material compacted together or it can be added after the scarified material has been compacted. Compact the entire area including the overlay and scarified material to a density that provides less than 7% air voids.

3.5 COMPLETION OF PAVEMENT

After application of [bituminous emulsion] [recycling agents] complete pavement construction.

NOTE: This guide specification covers the requirements for sealing cracks in bituminous pavements.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1 GENERAL

NOTE: Treatment of cracks in asphalt pavements can consist of sealing or filling the crack. There are differences in both materials and methods for crack sealing or crack filling. Crack sealing uses specialized sealants to seal working cracks and prevent moisture infiltration into the pavement substructure. Crack filling uses ordinary materials (asphalt cement and emulsions) to fill non-working cracks and reduce moisture infiltration into the pavement substructure. Working cracks are typically transverse or reflective cracks that move more than 3 mm 1/8 inch due to seasonal temperature variations. Non-working cracks are typically longitudinal cracks and block cracks. This
specification covers crack sealing using routed and cleaned cracks sealed with joint sealant.

For additional information concerning crack sealing and filling of bituminous pavements see UFC 3-270-01, "O&M Manual: Asphalt and Concrete Pavement Maintenance and Repair"

**************************************************************************

1.1 UNIT PRICES

**************************************************************************

NOTE: Delete paragraphs Measurement and Payment for lump sum bidding. If cracks of different widths are measured and paid separately, revise the following paragraphs to properly describe each crack condition found within the repair area.

**************************************************************************

1.1.1 Measurement

Determine the quantity of each sealing item to be paid for by actual measurement of the number of linear meters feet of approved in-place material.

1.1.2 Payment

Payment will be made at the contract unit bid prices per linear meter foot for the sealing items scheduled. Include in the unit bid prices the cost of all labor, materials, and the use of all equipment and tools required to complete the work.

1.2 REFERENCES

**************************************************************************

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

**************************************************************************

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.
1.3 SUBMITTALS

***********************************************************************************************************************************************

NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy, Air Force, and NASA projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy, Air Force and NASA projects, or choose the second bracketed item for Army projects.

***********************************************************************************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:
1.4 QUALITY ASSURANCE

Test the crack sealant and backup materials for conformance with the referenced applicable material specification. Perform testing of the materials in an approved, independent laboratory; submit certified copies of the test reports for approval [_____] days prior to the use of the materials at the job site. Submit reports of all tests. Samples will be retained by the Government for possible future testing, if the materials appear defective during or after application. Furnish samples of materials, in sufficient quantity to be tested by the Government upon request. Conformance with the test requirements of the laboratory tests specified will not constitute final acceptance of the materials. Final acceptance will be based on the performance of materials that have been satisfactorily installed.

1.5 DELIVERY, STORAGE, AND HANDLING

Inspect materials delivered to the job site for defects; unload, and store them with a minimum of handling to avoid damage. Provide storage facilities at the job site to protect materials from weather and maintain them at the temperatures recommended by the manufacturer.

1.6 ENVIRONMENTAL REQUIREMENTS

Apply the materials only when the ambient air temperature and the pavement temperature within the joint wall are at least 4 degrees C 40 degrees F and rising. Do not apply sealant if moisture is observed in the crack.

1.7 ACCEPTANCE

1.7.1 Crack Sealant

Inspect the crack sealant for proper cure and rate of set, tack free surface, bonding to the bituminous pavement, cohesive separation within the sealant, reversion to liquid, and entrapped air and voids. Remove sealants exhibiting any of these deficiencies, at any time prior to the final acceptance of the project, and replace as specified herein.

1.7.2 Test Section

Prior to the cleaning and sealing of the cracks for the entire project, construct a test section at least 60 m 200 feet long using the specified materials and approved equipment to demonstrate the proposed preparation
and sealing of all cracks of the project. Following the completion of the test section and before any other crack is sealed, inspect the test section to determine that the materials and installation meet the requirements specified. If materials or installation do not meet requirements, remove the materials and reclean and reseal the cracks. [When the test section meets the requirements, it can be incorporated into the permanent work and accepted for payment. Seal all other cracks in the manner approved and successfully completed for sealing the test section.]

PART 2 PRODUCTS

2.1 SEALANTS

**************************************************************************
NOTE: Use the state DOT guidance to specify the Performance Grade (PG) asphalt binder for roads and streets in the project vicinity. The sealant manufacturer will use this PG value to determine the ASTM D 6690 Type (I through IV) suitable for the project. Type III sealant is equivalent to the cancelled Federal Spec SS-S-1401C grade requirement, which includes evaluation of immersed bond at -29 degrees C -20 degrees F.

Additional guidance on selecting the asphalt binder PG grade includes the following: Asphalt Institute MS-26, The Asphalt Binder Handbook; the Asphalt Institute's State Binder Specification Database, or the FHWA LTPPBind software.

If the bituminous pavement is covered by a fuel-resistant pavement sealer, seal the cracks using the above mentioned sealants and then cover with a fuel-resistant pavement sealer. Do not use fuel-resistant crack sealants in asphalt pavements for compatibility reasons.

**************************************************************************
Provide crack sealant conforming to ASTM D6690, Type as suitable over the Performance Grade [_____] temperature range for sealing cracks.

2.2 BACKER ROD MATERIALS

**************************************************************************
NOTE: The use of backer rod materials in bituminous pavements is to control the routed crack width to depth (W/D) ratio and minimize waste of sealant material. Backer rod material is not required in cracks with a sealant reservoir depth of less than 20 mm 3/4 inch.

**************************************************************************
Provide backer rod material that is a compressible, nonshrinking, nonstaining, nonabsorptive material and nonreactive with the crack sealant. Use backer rod with a melting point temperature of at least 2 degrees C 5 degrees F greater than the maximum pouring temperature of the sealant being used, when tested in accordance with ASTM D789. Use material that has a water absorption of not more than 5 percent by weight when tested in accordance with ASTM C509. Use backer rod material that is 25
percent (plus or minus 5 percent) larger in diameter than the nominal width of the crack.

2.3 EQUIPMENT, TOOLS, AND MACHINES

Equipment, tools, and machines used in performance of the work are subject to approval by the Government. Maintain in a satisfactory working condition at all times.

2.3.1 Routing Equipment

**************************************************************************
NOTE: Rotary impact routers that are equipped with vertical sided, carbide tipped bits have been used successfully to rout cracks in bituminous pavements. Impact routers that are not equipped with carbide tipped bits normally chip and damage the surrounding pavement and are not be permitted.
**************************************************************************

Provide routing equipment which is a self-powered machine operating a power driven tool or bit specifically designed for routing bituminous pavements. Use a bit rotating about a vertical axis at sufficient speed to cut a smooth vertical-walled reservoir in the pavement surface and maintain accurate cutting without damaging the sides or top edges of the reservoir. Provide a router capable of following the trace of the crack without deviation. The use of rotary impact routing devices [will not be permitted for cleaning cracks.] [can be permitted if vertical-sided carbide tipped bits are used.]

2.3.2 Air Compressor

Provide air compressor capable of furnishing not less than 0.071 cubic meters per second 150 cubic feet per minute and maintaining a line pressure of not less than 621 kPa 90 psi at the nozzle. Equip the compressor with filters that maintain the compressed air free of oil and water.

2.3.3 Heat Lance

**************************************************************************
NOTE: Specify a heat lance if temperatures less than 4 degrees C 40 degrees F or moisture in the cracks are anticipated.
**************************************************************************

Provide a heat lance operating with propane and compressed air in combination to provide flame-free high temperature hot air up to 1650 degrees C 3000 degrees F with exit velocities of 915 meters per second 3000 feet per second.

2.3.4 Hand Tools

Hand tools can be used, when approved, for removing defective sealant from cracks and repairing or cleaning the crack faces.

2.3.5 Crack Sealing Equipment

Provide unit applicators, used for heating and installing the hot-poured crack sealant materials, that are mobile and equipped with a double-boiler,
agitator-type kettle with an oil medium in the outer space for heat transfer; a direct-connected pressure-type extruding device with a nozzle shaped for inserting in the prepared crack to be filled; positive temperature devices for controlling the temperature of the transfer oil and sealant; and a recording type thermometer for indicating the temperature of the sealant. Allow the sealant to circulate through the delivery hose and return to the inner kettle when not in use.

PART 3 EXECUTION

3.1 PREPARATION OF CRACKS

**************************************************************************

NOTE: In bituminous pavements that have large quantities of hairline cracks or cracks less than 6 mm 1/4 inch, use a bituminous fog coat or a bituminous seal coat to prevent water intrusion into the base material. See UFC 3-270-01, "O&M Manual: Asphalt and Concrete Pavement Maintenance and Repair", UFGS 32 01 13.62 ASPHALT SURFACE TREATMENT and UFGS 32 12 36.13 ASPHALTIC SEAL AND FOG COAT. Fog coats, seal coats and other asphalt surface treatments are suitable for airfield pavement shoulders. UFC 3-270-01 requires approval by the Pavements DWG for the use of surface treatments on runways or taxiways.

If the pavement being sealed is to receive a hot asphalt concrete overlay, do not seal small cracks. Medium and large cracks can be sealed but maintain the top of the sealant 6 mm 1/4 inch below the pavement surface to prevent "bleeding" of the material through the overlay. If the cracks are overfilled, the sealant material will be tracked onto the pavement.

**************************************************************************

Immediately before the installation of the crack sealant, thoroughly dry and clean the cracks to remove oxidized pavement, loose aggregate and foreign debris. Prepare cracks as follows:

3.1.1 Cracks

3.1.1.1 Hairline Cracks

[Cracks that are less than 6 mm 1/4 inch wide do not need to be sealed.] [Seal cracks that are less than 6 mm 1/4 inch wide in accordance with Section [_____] .]

3.1.1.2 Small and Medium Cracks

Rout cracks that are 6 to 37 mm 1/4 to 1-1/2 inches wide to a nominal width 3 mm 1/8 inch greater than the existing nominal width and to a depth not greater than 20 mm 3/4 inch. Clean and dry using compressed air or a heat lance.

**************************************************************************

NOTE: Repairs of large cracks greater than 37 mm 1-1/2 inches wide are not covered by this

3.1.1.3 Large Cracks

Do not seal cracks that are greater than 37 mm 1-1/2 inches wide. [Refer to the drawings for repair methods for large cracks].

3.1.2 Existing Sealant Removal

NOTE: Delete this paragraph if the cracks have never been sealed in the past.

Cut loose the in-place sealant from both crack faces and to a depth shown on the drawings. Remove sealant to a depth sufficient to accommodate any backer rod material that is required to maintain the depth of new sealant to be installed. Prior to further cleaning operations, remove all old loose sealant remaining in the crack opening by blowing with compressed air.

3.1.3 Routing

Perform routing of the cracks using a rotary router with a bit that is at least 3 mm 1/8 inch wider than the nominal width of the crack to remove all residual old sealant (resealing), oxidized pavement and any loose aggregate in the crack wall.

3.1.4 Cleaning

Use compressed air or a heat lance to clean the crack faces and the pavement surfaces extending a minimum of 13 mm 1/2 inch from the crack edges. Use a multiple-pass technique until the surfaces are free of dust, dirt, old sealant residue, moisture, or foreign debris that might prevent the sealant material from bonding to the asphalt pavement. Use a heat lance when pavement temperature is less than 4 degrees C 40 degrees F. Do not burn the pavement, a slight darkening is acceptable. Immediately follow the heat lance with the sealing operation.

3.1.5 Backer Rod Material

When required, use backer rod material in all cracks that otherwise would require excessive sealant or exceed the sealant reservoir depth. Insert the backer rod material into the lower portion of the crack as shown on the drawings. Place the backer rod so that the top of the backer rod is a maximum of 19 mm 3/4 inch and a minimum width to depth ratio of 1 below the top of the pavement. Ensure that the backer rod material is placed evenly at the specified depth and is not stretched or twisted during installation.

3.1.6 Rate of Progress of Crack Preparation

Limit the stages of crack preparation, which include routing, air pressure or heat lance cleaning and placing of the backer rod material, to only that linear footage that can be sealed during the same day.
3.2 PREPARATION OF SEALANT

Do not heat hot-poured sealants in excess of the safe heating temperature recommended by the manufacturer, as shown on the sealant containers. Withdraw and waste sealant that has been overheated or subjected to application temperatures for over 4 hours or that has remained in the applicator at the end of the day's operation.

3.3 INSTALLATION OF SEALANT

Submit manufacturer's instructions [_____] days prior to the use of the material on the project. Installation of the material will not be allowed until the instructions are received.

3.3.1 Time of Application

Seal cracks immediately following final cleaning and drying of the crack walls and following the placement of the backer rod material (when required). Place sealant only when cracks are dry. Reclean cracks that cannot be sealed under the conditions specified, or when rain interrupts sealing operations, and allow to dry or dry by mechanical means prior to installing the sealant.

3.3.2 Sealing the Crack

**************************************************************************

NOTE: Slightly underfill cracks to preclude tracking the material onto the pavement surface.

For airfield pavements, recess the sealant 3 mm 1/8 inch below the pavement surface; for roads, streets and parking lots, recess the sealant 6 mm 1/4 inch.

For pavements that are to receive an overlay, recess the sealant a minimum of 6 mm 1/4 inch and a maximum of 13 mm 1/2 inch below the pavement surface.

**************************************************************************

Immediately preceding, but not more than 15 m 50 feet ahead of the crack sealing operations, perform a final cleaning and drying with compressed air or heat lance. This distance can be increased if demonstrated and approved during the test section. Fill the cracks from the bottom of reservoir formed by the routing or the top of the backer rod up to [3] [6] mm [1/8] [1/4] inch below the pavement surface. Remove excess or spilled sealant from the pavement by approved methods and discard it. Install the sealant in a manner which prevents the formation of voids and entrapped air. Make multiple passes with the applicator wand as necessary to obtain the specified sealant depth from the pavement surface. Do not use gravity methods or pouring pots to install the sealant material. Do not permit traffic over newly sealed pavement until authorized. Check sealed cracks frequently to ensure that the newly installed sealant is cured to a tack-free condition within 3 hours.

3.4 CLEANUP

Upon completion of the project, remove unused materials from the site and leave the pavement in a clean condition.
3.5 QUALITY CONTROL PROVISIONS

3.5.1 Crack Cleaning

Provide quality control provisions during the crack cleaning process to correct improper equipment and cleaning techniques that damage the bituminous pavement in any manner.

3.5.2 Crack Seal Application Equipment

Inspect the application equipment to ensure conformance to temperature requirements and proper installation. If evidence of bubbling, improper installation, and failing to cure or set are identified, suspend operations until causes of the deficiencies are determined and corrected.

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for geosynthetic paving fabric interlayer for asphaltic overlays and surface treatments for roads, streets, and airfield pavements.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

NOTE: To achieve maximum performance with the use of paving fabrics in asphalt pavement, do not overextend their range of application. Consult UFC 3-250-01, Chapter 15-8, for additional guidance on geosynthetic paving fabrics. The paving fabric not only retards or reduces low-severity reflection cracking but prevents surface infiltration of water. Paving fabrics have performed well when used on pavements with oxidation cracking, on longitudinal construction joint cracks in asphalt pavement, and on the longitudinal joint between portland cement concrete pavement widened with flexible pavement. Cracks that are greater than 6 mm 1/4 inch wide should be filled with a suitable crack filler prior to installing the paving fabric.
Cover the paving fabric with a hot-mix asphalt overlay or an asphalt surface treatment.

PART 1   GENERAL

1.1   UNIT PRICES

1.1.1   Measurement

Measure the as-built surface area, covered by geosynthetic paving fabrics, in square meters or square yards. No allowance will be made for waste, overlaps, damaged materials, repairs, or materials used for the convenience of the Contractor.

1.1.2   Payment

Geosynthetic paving fabric installed and accepted will be paid for at the respective contract unit price in the bidding schedule. This unit price will include the cost of geosynthetic paving fabric, asphalt binder, equipment, installation, testing, and other costs associated with placement of the geosynthetic paving fabric.

1.2   REFERENCES

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.
STATE STANDARD SPECIFICATIONS

NOTE: Where SSS-[] is found in the text, insert the appropriate State Standard Specification. Do not specify state standards for airfield paving projects.

Provide materials and workmanship specified herein with the reference State Standard specifications (SSS) in accordance with the referenced articles, sections and paragraphs of the standard except that contractual and payment provisions do not apply. Where the term "Engineer" is used, it means the Contracting Officer. Where the term "state" is used, it means "Federal Government."

1.4 SUBMITTALS

NOTE: Review Submittal Description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy.
Air Force, and NASA projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy, Air Force, and NASA projects, or choose the second bracketed item for Army projects.

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-03 Product Data
- Plant, Equipment, Machines, And Tools
SD-06 Test Reports
- Asphalt Distributor Calibration Documentation
SD-07 Certificates
- Asphalt Cement; G[, [____]]
- Geosynthetic Paving Fabric; G[, [____]]

1.5 QUALITY CONTROL

1.5.1 Design Conformance

NOTE: Cover the paving fabric with a hot-mix asphalt overlay or an asphalt surface treatment. Select the choice in brackets and delete the other.

Check with agency Subject Matter Expert before specifying an asphalt surface treatment for airfield paving projects.

[Provide an asphalt concrete conforming to the requirements of Section 32 12 16.16 ROAD-MIX ASPHALT PAVING.][Provide an asphalt surface treatment conforming to the requirements of Section 32 01 13.62 ASPHALT SURFACE TREATMENT.][Provide an asphalt concrete conforming to the requirements of Section 32 12 15.13 ASPHALT PAVING FOR AIRFIELDS.]

1.6 DELIVERY AND STORAGE

Deliver materials to job site in original unopened rolls, packages, cartons, bundles, or containers. Handle and store geosynthetic paving fabric in accordance with ASTM D4873/D4873M. Prevent damage to materials...
during loading, transporting, and unloading. Inspect materials for contamination. Protect geosynthetic materials against sunlight, UV radiation, moisture, rain, dust, or rodents. Replace defective or damaged materials. Remove rejected materials from Government property.

1.7 PROJECT/SITE CONDITIONS

1.7.1 Placement Conditions

Place geosynthetic paving fabric under the following conditions:

a. Ambient air temperature for asphalt cements above 10 degrees C 50 degrees F and rising.

b. Dry pavement surface temperature above 4.5 degrees C 40 degrees F and rising.

1.8 ACCEPTANCE

1.8.1 Tolerances

Acceptance of the paving fabric interlayer is based on compliance with the tolerances presented in Table 1. Remove and replace paving fabric interlayer represented by the failing tests or submit repair plan for approval.

PART 2 PRODUCTS

2.1 MATERIALS

2.1.1 Asphalt Cement

******************************************************************************
NOTE: Specify Performance Grade (PG) asphalt wherever available. When selecting PG asphalt cements, the asphalt cement grade should be the same as specified for the hot mix asphalt overlay or surface treatment.
******************************************************************************

******************************************************************************
NOTE: Add appropriate State Standard specification (SSS) in the blanks below.
******************************************************************************

Asphalt cement binder conforming to [ASTM D6373] [Section [_____] of
SSS-[

2.1.2 Geosynthetic Paving Fabric

**************************************************************************

NOTE: Paving fabrics are fabrics designed with higher ultimate elongation and are manufactured with synthetic polymers. All paving fabrics available that meet these specifications are nonwoven. Check properties against any other manufacturers' literature or information or data that may be more current.

**************************************************************************

Geosynthetic paving fabric conforming to AASHTO M 288, Type II. The numeric values in AASHTO M 288 are Minimum Average Roll Values (MARV) in the weaker principal direction.

2.2 EQUIPMENT

Submit list of proposed equipment to be used in performance of construction work, including descriptive data. Plant, equipment, machines, and tools used in the work are subject to approval. Maintain in a satisfactory working condition at all times.

2.2.1 Asphalt Distributor

Provide a distributor capable of spraying asphalt binder at the prescribed temperature and application rate without streaking, skipping, or dripping. Equip distributor with hand spray having single nozzle and positive shut-off valve. Check and clean the filters at the start of each day during the installation. Provide calibrated instruments to determine temperature of asphaltic binder in both the distributor and its application site as well as instrumentation for securing uniformity at the junction of the two loads. Submit current asphalt distributor calibration documentation for all calibrated equipment, certified by an approved calibration laboratory within [12] [_____] months prior to commencing work[ and every [_____] month, thereafter during the term of the contract].

2.2.2 Geosynthetic Paving Fabric Handling Equipment

Provide mechanical or manual laydown equipment capable of laying fabric smoothly with minimum wrinkles or folds.

2.2.3 Vacuum Sweeper

Provide a Self-propelled, vacuum pickup capable of completely removing loose material and debris from pavement surface.

2.2.4 Miscellaneous Equipment

Additional equipment includes, but not limited to, stiff bristle brooms; squeegees to spread asphalt binder; rollers to smooth paving fabric; scissors or blades to cut paving fabric; and brushes for applying binder at paving fabric overlaps.

2.2.5 Condition of Equipment

Keep storage tanks, piping, retorts, booster tanks, and distributors used
in storing and handling asphalt material clean and in good operating condition throughout the duration of the work. Do not allow contamination of asphaltic material with foreign material in equipment during operation. Provide and maintain a recording thermometer in good working order in storage heating unit. Submit calibration documentation as required in paragraph: Asphalt Distributor.

PART 3 EXECUTION

3.1 PREPARATION

**************************************************************************
NOTE: Consult UFC 3-270-01 for methods and materials used to repair underlying asphalt concrete pavement. Do not seal cracks under 6 mm 1/4 inch wide.
**************************************************************************

3.1.1 Cracks

Seal all cracks wider than 6 mm 1/4 inch in accordance with 32 01 17.61 SEALING CRACKS IN ASPHALT PAVING

3.1.2 Potholes

Remove surface pavement and base course as indicated. Make saw cuts to provide a square or rectangular shape with vertical straight faces around the pothole. Make one pair of faces at right angles to traffic flow. Spray vertical surfaces with emulsified asphalt. Fill with asphalt concrete, and compact patch level with existing pavement using a vibratory plate compactor for small patches or a roller for large patches.

3.1.3 Surface Preparation

[Cold-mill existing pavement in accordance with Section 32 01 16.71 COLD MILLING ASPHALT PAVING. Use micro-milling equipment if required by the geosynthetic manufacturer. ]Clean pavement surfaces immediately prior to application of asphalt binder by using a power broom followed by a power blower using compressed air.

3.2 PAVING FABRIC INSTALLATION

3.2.1 Asphalt Binder

**************************************************************************
NOTE: The amount of asphalt cement required depends on the condition and texture of the asphaltic surface on which the paving fabric is to be placed and on the type of paving fabric. Most common paving fabrics require about 0.9 - 1.58 L/sq.m 0.20 - 0.35 gal/sq.yd. of residual asphalt to achieve installation. Use 1.13 - 1.36 L/sq.m 0.25 - 0.30 gal/sq.yd. for cracked and weathered surface of existing asphalt pavement. Use 1.36 - 1.58 L/sq.m 0.30 - 0.35 gal/sq.yd. for heavily distressed, oxidized, or milled surfaces.
**************************************************************************

Spray area to receive paving fabric with asphalt binder at a rate of
residual asphalt content of [1.0 - 1.31] [_____] L per square meter [0.22-0.29] [_____] gallon per square yard. Maintain the application temperature within the range of 135 to 175 degrees C 275 to 350 degrees F for asphalt cement. Where the paving fabric will be joined with another layer of paving fabric, apply asphalt binder to cover a minimum width of the paving fabric plus 150 mm 6 inches. Minimize time interval between placing asphalt binder and placing paving fabric so that temperature loss of asphalt binder due to dust, wind, or cooler temperatures does not cause loss of adhesion. Keep newly placed paving fabric free of traffic and debris until asphalt overlay or surface treatment is complete.

3.2.2 Paving Fabric Placement

Place paving fabric with minimal wrinkles and folds. In cold and windy conditions, shorten the incremental length of paving fabric that is placed to accommodate the rapid cooling of the applied asphalt cement. Place paving fabric manually on areas where it cannot be mechanically installed. In the event of improper alignment during placement which causes the paving fabric to wrinkle or fold in excess of the tolerances provided in Table 1, slit the paving fabric and realign by overlapping the previous material and proceed as before. Overlap the paving fabric not to exceed the tolerances shown in Table 1 at all joints[, except as otherwise shown]. Do not lap joints with more than two paving fabric layers. Construct transverse joints by shingling in the direction of placement to prevent paving fabric disturbance by paver. Use a pneumatic tire roller to roll the paving fabric to remove air bubbles that form under the paving fabric. In case binder bleeds through paving fabric, blot binder with sand before overlay is placed. Remove excess sand before placing overlay. Neatly cut and contour paving fabric at joints. Remove and replace damaged paving fabric before resurfacing.

3.2.2.1 Traffic Control

Prohibit vehicles, except handling equipment, from traveling on paving fabric. Limit equipment speed to 8 kph 5 miles per hour. During construction and at intersections and corners, turn equipment gradually to avoid damaging paving fabric.

3.2.2.2 Additional Asphalt Binder

If the paving fabric does not stay bonded with the underlying surface, apply additional binder at a residual asphalt content of at least 0.09 L per square meter 0.02 gallon per square yard to paving fabric surface.

3.2.3 [Asphalt Concrete Overlay][Asphalt Surface Treatment]

**************************************************************************
NOTE: Cover the paving fabric with a hot-mix asphalt overlay or an asphalt surface treatment.
Select the choice in brackets and delete the other.
**************************************************************************

[Place overlay in accordance with [Section 32 12 16.16 ROAD-MIX ASPHALT PAVING] [Section 32 12 15.13 ASPHALT PAVING FOR AIRFIELDS]. ][Construct asphalt surface treatment in accordance with Section 32 01 13.62 ASPHALT SURFACE TREATMENT. ]Do not place paving fabric that cannot be covered with overlay the same day. If rain is imminent, and the paving fabric cannot be
covered in time, use a pneumatic tire roller on top of the installed paving fabric. After the rainfall stops, if water is displaced while walking on the paving fabric, do not proceed with paving. If the paving fabric is still wet, but no free water is visible underfoot, paving can proceed.

NOTE: This guide specification covers the requirements for providing grooves in airfield pavements to increase the safe performance of aircraft.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1   GENERAL

NOTE: If an active runway is to be grooved, allowances such as Contractor reaction time, minimum distance equipment must be removed from the runway, and an estimated cost to the Contractor for each interruption must be addressed.

If unit prices are used, the following are designer options:

The unit of measurement for grooving the [runway] [taxiway] surface will be the lump sum. The unit of measurement for aircraft traffic interruptions will be each.
A lump sum price will be paid for grooving and cleaning the pavement. The minimum payment for each interruption will be one hour.

**************************************************************************

1.1 SUBMITTALS

**************************************************************************

NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy, Air Force, and NASA projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy, Air Force and NASA projects, or choose the second bracketed item for Army projects.

**************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.] [for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-03 Product Data

   Equipment; G[, [_____]]
   Procedures; G[, [_____]]
1.2 EQUIPMENT, TOOLS, AND MACHINES

1.2.1 Grooving Machine

Provide a grooving machine that is power driven, self-propelled, specifically designed and manufactured for pavement grooving, and has a self contained and integrated continuous slurry vacuum system as the primary method for removing waste slurry. Equip the grooving machine with diamond-saw cutting blades capable of making at least 457 mm 18 inches in width of multiple parallel grooves in one pass of the machine. Use cutting blades capable of making the required width and depth of grooves in one pass of the machine. A mixture of new and worn blades or blades of unequal wear or diameter are not permitted in the cutting head. Match the blade type and configuration with the hardness of the existing airfield pavement. Use wheels on the grooving machine that will not scar or spall the pavement. Provide the machine with devices to control depth of groove and alignment within the specified tolerances.

Submit a list of proposed equipment to be used in performance of this work, including descriptive data and safety precautions required for the equipment operation.

1.3 ENVIRONMENTAL REQUIREMENTS

Grooving operations will not be permitted when freezing conditions prevent the immediate removal of debris and/or drainage of water from the grooved area. The Contractor is responsible for discharge and disposal of waste slurry. Waste slurry discharge pits may be constructed along side the pavement to be grooved, as directed by the Contracting Officer. Provide and maintain temporary storm drainage, pollution control, and erosion control features at each discharge pit in accordance with base environmental regulations. Excavate and dispose of hardened waste slurry [off base] [in accordance with the base waste disposal requirements] after it has been dewatered. Regrade and restore to original condition all disposal pit areas.

PART 2 PRODUCTS

Not used.

PART 3 EXECUTION

3.1 PREPARATION

******************************************************************************

NOTE: Limits of the grooved area should be as described in UFC 3-260-02. Grooves will be continuous for the entire length of the usable runway and will be perpendicular to the runway centerline. Grooves should terminate within 1.5 to 3 meters 5 to 10 feet of the pavement edge to allow for the operation of grooving equipment. Grooves will also be terminated within 75 to 230 mm 3 to 9 inches of the runway centerline joint, transverse joints, in-runway lighting fixtures (or similar items). Joint seals (compression or field molded) shall be installed such that they will have proper...
relief below the bottom of the groove cuts. The following areas should not be grooved: overruns, UAS only runways, rotary-wing runways, 3m 10 feet of runway ends, and 3m 10 feet either side of an arresting barrier cable that requires hook engagement for operation. Figures 2-10 and 2-11 of -FAAAC 150/5320-12A- show examples of saw-cut step patterns at the intersection of secondary runways and exit taxiways to primary runways, respectively. Characteristics of the existing pavement will be described in sufficient detail to allow the Contractor to select the most economical and effective cutting blades for grooving the pavement. Pavements should not be grooved until they are at least 30 days old.

**************************************************************************

3.1.1 Existing Pavements

Do not groove bumps, depressed areas, bad or faulted joints, and badly cracked and/or spalled areas in the pavement until such areas are adequately repaired or replaced.

3.1.2 New Pavements

Allow new asphalt concrete pavements to cure for a minimum of 30 days before grooving, to allow the material to become stable enough to prevent closing of the grooves under normal use. Permit new portland cement concrete pavements to cure for a minimum of 28 days before grooving.

3.2 WATER SUPPLY

**************************************************************************

NOTE: If transportation of the water by surface laid pipe is permitted, routing of the pipe should be shown. Identify the available source location on the drawings.

**************************************************************************

[Provide water for the grooving operation] [The Government will provide water for the grooving operation].

3.3 GROOVING

3.3.1 Procedures

Submit grooving sequence and method of placing guide lines to control grooving operation. Cut grooves in the [asphalt] [portland cement] areas as indicated on the drawings. Begin the grooving at one side of the usable [runway] [taxiway] and continue for the full width of the area. Take all reasonable precautions to prevent damage to or roughening of the pavement between grooves. Spalling along or tearing or raveling of the groove edges will not be allowed. Cut grooves that are 6 mm, plus 2 mm, minus 0 mm 1/4 inch, plus 1/16 inch, minus 0 inch wide by 6 mm, plus or minus 2 mm 1/4 inch, plus or minus 1/16 inch deep and 38 mm, plus 0 mm, minus 3 mm 1-1/2 inches, plus 0 inches, minus 1/8 inch center to center spacing. Cut grooves that are [_____] meters feet plus or minus 75 mm 3 inches long and normal to the longitudinal axis of the centerline of the [runway]
[taxiway]. The transverse alignment of the grooves must not vary more than 75 mm 3 inches plus or minus on a 23 m 75 foot length of grooving. Do not groove within 150 mm plus or minus 75 mm 6 inches plus or minus 3 inches of the runway centerline. Do not groove within 150 mm 6 inches of transverse joints or working cracks, through compression seals, in-runway lighting fixtures or similar items, the first 3 m 10 feet either side of an arresting barrier cable or the first and last 3 m 10 feet of the runway.

3.3.2 Clean-Up

Continuously clean-up debris from the grooving operation. Flush debris produced by the equipment to the edge of the grooved area or pick it up before it dries and hardens. Flush the remaining dust coating to the edge of the area if the resultant accumulation is not detrimental to the vegetation or storm drainage system. Accomplish all flushing operations in a manner to prevent erosion on the shoulders, damage to vegetation, or plugging of storm drainage.

3.3.3 Repair of Damaged Pavement

Repair at the Contractor's expense, [as specified in Section [_____]],[] any damage, which in the opinion of the Contracting Officer will be detrimental to aircraft operations and/or pavement performance, occurring to the pavement as a result of the grooving operations.

3.4 CONTRACTOR QUALITY CONTROL

3.4.1 Test Section

Groove a test section [_____] m feet long by two lanes wide in an area of the pavement outside of the trafficked area, as approved by the Contracting Officer. Demonstrate the setup and alignment process, the grooving operation, and the waste slurry disposal.

3.4.2 Inspections

At the beginning of each work shift, furnish a full complement of grooving blades with each saw that are capable of cutting grooves of the specified width, depth, and spacing. If during the work, a single grooving blade on a machine becomes incapable of cutting a groove, continue work for the remainder of the work shift. The Contractor is not required to cut the groove omitted because of the failed blade. Should two or more grooving blades on a machine become incapable of cutting grooves, cease operating the machine until it is repaired.

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for field molded sealants in sealing or resealing joints in rigid pavements on airfields, roads, streets, and other areas.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

NOTE: When crack repair is involved, edit accordingly, including the section title. This specification should not be used for liquid oxygen compatible joint seals.

NOTE: The following information shall be shown on the project drawings:

1. Spacing, width, and type of joints in concrete pavements to be sealed.

2. Typical details of existing joints.
3. Depth of existing sealant to be removed for each type of joint, if not specified.

4. Detail of type of joint to be refaced or widened with a concrete saw. Show extent of new width and depth of sawing to provide the proper shape factor of the void space in the joint. For materials other than silicone, the ratio of the depth to width (d/w) of the sealant reservoir should generally be not less than 1 nor greater than 1.5. For silicone sealant a depth to width ratio of approximately 0.5 is preferred. Depending upon the width of the refaced joint, the thickness of the sealant bead should be between 6 and 13 mm and 1/2 in. Following are the recommended details for silicone sealants:

<table>
<thead>
<tr>
<th>Refaced Joint Width</th>
<th>10 mm</th>
<th>13 mm</th>
<th>19 mm</th>
<th>25 mm</th>
</tr>
</thead>
<tbody>

| Total Depth of Joint| 1"   | 1 1/8"| 1 1/2"| 2 1/4"

5. Location and type of bond breaker or back-up.

6. Identify type of sealant based on proposed use of pavements. (See note in paragraph entitled "Joint Sealant.")

7. For joint details see UFC 3-260-02, "Pavement Design for Airfields".

******************************************************************************
PART 1   GENERAL
******************************************************************************

NOTE: In preparing Contract specifications for concrete pavements, use UFC 3-250-04 Standard Practice for Concrete Pavements.

******************************************************************************
1.1 UNIT PRICES

**************************************************************************
NOTE: Delete this paragraph when lump sum bidding is used.
**************************************************************************

1.1.1 Measurement

Determine the quantity of each sealing item to be paid for by actual measurement of the number of linear \text{m ft} of in-place material that has been approved.

1.1.2 Payment

Make payment at the Contract unit bid prices per linear \text{meter foot} for the sealing items scheduled. Include the cost of labor, materials, and the use of equipment and tools required to complete the work in the unit bid price.

1.2 REFERENCES

**************************************************************************
NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.
**************************************************************************

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

ASTM INTERNATIONAL (ASTM)

ASTM C792  (2015; R 2020) Effects of Heat Aging on Weight Loss, Cracking, and Chalking of Elastomeric Sealants

1.3 SUBMITTALS

**************************************************************************

NOTE: Review Submittal Description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a “G” to an item if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy, Air Force, and NASA projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy, Air Force, and NASA projects, or choose the second bracketed item for Army projects.

**************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-03 Product Data
Sealants

Submit catalog cuts, specifications, Safety Data Sheets and other information documenting conformance to Contract requirements.
Manufacturer's Recommendations

SD-04 Samples

**************************************************************************
NOTE: Liquid joint sealer proposed for use in airfield pavements should be tested by the U.S. Army Corps of Engineer, Waterways Experiment Station, P. O. Box 631, Vicksburg, MS 39180, Attn: Larry Lynch, telephone: (601) 634-4274, before acceptance. Project Managers should assure that sufficient funds (approximately $1500) are available and that the 45 day testing time requirement has been taken into account when establishing contract completion time. For small projects involving approximately less than 3,000 m (10,000 linear ft) of joint sealing, the requirement for testing may be waived provided that a Factory Test Report is submitted. In no case should materials not meeting the applicable specification be accepted.
**************************************************************************

Sealants

Provide for testing a 19-L 5-gal sample of each sealant with associated primer to the Contracting Officer a minimum of 60 days prior to its use on the job. Provide factory-sealed containers with a factory applied label showing the following information:

Name of sealant
Identification of component, or primer
Specification number and type
Manufacturer's name
Manufacturer's lot and batch number
Date of Manufacture (month and year)
Shelf life retest date (month and year)
List of hazardous components
Quantity of material in container (volume)
Storage instructions
Instructions for use

Blocking Media/Backup Materials

Backer Rod

Bond Breaking Tapes

SD-06 Test Reports
NOTE: Liquid joint sealer proposed for use in airfield pavements should be tested by the U.S. Army Corps of Engineer, Waterways Experiment Station, P. O. Box 631, Vicksburg, MS 39180, Attn: Larry Lynch, telephone: (601) 634-4274, before acceptance. Project Managers should assure that sufficient funds (approximately $1500) are available and that the 45 day testing time requirement has been taken into account when establishing contract completion time. For small projects involving approximately less than 3,000 m (10,000 linear ft) of joint sealing, the requirement for testing may be waived provided that a Factory Test Report is submitted. In no case should materials not meeting the applicable specification be accepted.

NOTE: Factory test report should be required for joint seals on projects when the Government testing is waived.

Sealants

SD-07 Certificates

Equipment List

SD-08 Manufacturer's Instructions

Sealants

Provide instructions that include, but not limited to: storage requirements, ambient temperature and humidity ranges, and moisture condition of joints for successful installation; requirements for preparation of joints; safe heating temperature; mixing instructions; installation equipment and procedures; application and disposal requirements; compatibility of sealant with filler material; curing requirements; and restrictions to be adhered to in order to reduce hazards to personnel or to the environment. Submit instructions at least 30 days prior to use.

1.4 QUALITY ASSURANCE

1.4.1 Test Requirements

NOTE: Select the applicable statement for testing and determining specification compliance and delete the inapplicable statement. Select the first statement for projects except where the project is less than 200 L (50 gal) or 200 kg (440 lbs) of material. When the project requires less than 200 L (50 gal) or 200 kg (440 lbs) of sealant, the first statement can be deleted and the sealant and back-up material may be accepted on certified certificate that contains the test data showing compliance with
Test the sealant and backup or separating material for conformance with the referenced material specification. The materials will be tested by the Government. Do not use material at the project prior to receipt of written notice that the materials meet the laboratory requirements. The cost of the first test of samples will be borne by the Government. If the samples fail to meet specification requirements, replace the materials represented by the sample and test the new materials at the Contractor's expense.

Perform testing of the materials in an approved independent laboratory and submit certified copies of the test reports for approval [_____] days prior to the use of the materials at the job site. Submit samples to be retained by the Government for possible future testing if the materials appear defective during or after application. Conformance with the requirements of the laboratory tests specified does not constitute final acceptance of the materials. Base final acceptance on the performance of the in-place materials. Submit samples of the materials (sealant, primer if required, and backup material), in sufficient quantity for testing and approval [_____] days prior to the beginning of work. Do not use material until it has been approved.

1.4.2 Trial Joint Sealant Installation

Prior to cleaning and sealing the joints for the entire project, prepare a test section at least 60 m 200 ft long using the specified materials and approved equipment, so as to demonstrate the proposed joint preparation and sealing of the types of joints in the project. Following the completion of the test section and before any other joint is sealed, inspect the test section to determine that the materials and installation meet the requirements specified. Inspect joint seal test section.[ Provide written notice of deficiencies and required corrections or adjustments in the joint seal installation procedures.] Correct deficiencies and obtain approval of test section prior to installing joint seals. If it is determined that the materials or installation do not meet the requirements, remove the materials, and reclean and reseal the joints at no cost to the Government. Permit the test section meeting the requirements to be incorporated into the permanent work and paid for at the Contract unit price per linear foot for sealing items scheduled. Prepare and seal other joints in the manner approved for sealing the test section. Notify the Contracting Officer upon completion of the test section.

1.5 DELIVERY, STORAGE, AND HANDLING

Inspect materials delivered to the site for visible damage, and unload and store with a minimum of handling. Deliver joint materials in original sealed containers and protect from freezing or overheating. Provide jobsite storage facilities capable of maintaining temperature ranges within manufacturers recommendations.

1.6 ENVIRONMENTAL REQUIREMENTS

Do not proceed with work when weather conditions detrimentally affect the quality of cleaning joints or applying sealants. Proceed with joint preparation and sealing only when weather conditions are in accordance with manufacturer's instructions. Install joint sealant to dry surfaces and
1.7 TRAFFIC CONTROL

Do not permit vehicular or heavy equipment traffic on the pavement in the area of the joints being sealed during the protection and curing period of the sealant. Permit traffic on the pavement at the end of the curing period.

PART 2 PRODUCTS

2.1 SEALANTS

******************************************************************************
NOTE: Select joint sealants based on the proposed use and local experience. Specify ASTM D6690 (Type II or Type III) sealants for areas that do not receive fuel spillage, engine blast and heat exposure (i.e., areas where aircraft warm up the engines). Type III contains the requirements of Type II and has additional requirements for a water immersed bond test and an oven-aged resilience test. ASTM D6690 (Type II or Type III) sealants are normally used on roadways, vehicle parking lots, and on some aircraft taxiways. Test ASTM D6690 sealants in accordance with ASTM D5329 and COE CRD-C 525 in addition to the appropriate specification.

Permit ASTM D5893/D5893M sealants to be specified in place of ASTM D6690 sealants. ASTM D5893/D5893M covers silicone sealants that provide improved life-cycle cost benefits. Permit silicone sealant to be used for general purpose sealing and re-sealing of joints in concrete pavements not subject to severe jet fuel or lubricant spillage. Silicone swells up under fuel spills. This may result in an unsatisfactory seal in aircraft or vehicle servicing areas where spillage is frequent.
******************************************************************************

Use materials for sealing cracks in accordance with ASTM D6690 and ASTM D5893/D5893M based on the type of area as follows:

<table>
<thead>
<tr>
<th>Area</th>
<th>Sealing Material</th>
</tr>
</thead>
<tbody>
<tr>
<td>[_____]</td>
<td>[ASTM D6690, Type II and ASTM D5329/COE CRD-C 525]</td>
</tr>
<tr>
<td>[_____]</td>
<td>[ASTM D6690, Type III and ASTM D5329/COE CRD-C 525]</td>
</tr>
<tr>
<td>[_____]</td>
<td>[ASTM D5893/D5893M]</td>
</tr>
</tbody>
</table>

Use self leveling, non-acid curing silicone sealant meeting the following requirements in accordance with ASTM C920 or ASTM C1193:
<table>
<thead>
<tr>
<th>TEST</th>
<th>TEST METHOD</th>
<th>REQUIREMENTS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Weight Loss</td>
<td>ASTM C792 Modified (see Note 1 below)</td>
<td>10 percent max.</td>
</tr>
<tr>
<td>Flow</td>
<td>ASTM C639 (Type I)</td>
<td>Smooth and level</td>
</tr>
<tr>
<td>Extrusion Rate</td>
<td>ASTM C603</td>
<td>30 sec. max.</td>
</tr>
<tr>
<td>Tack Free Time</td>
<td>ASTM C679</td>
<td>5 hours max.</td>
</tr>
<tr>
<td>Hardness (Shore 00) (see Note 2 below)</td>
<td>ASTM C661</td>
<td>30 - 80</td>
</tr>
<tr>
<td>Tensile Stress at 150 Percent Elongation (see Note 2 below)</td>
<td>ASTM D412 (Die C)</td>
<td>200 kPa 30 psi max.</td>
</tr>
<tr>
<td>Percent Elongation (see Note 2 below)</td>
<td>ASTM D412 (Die C)</td>
<td>700 min.</td>
</tr>
<tr>
<td>Accelerated Weathering</td>
<td>ASTM C793</td>
<td>Pass 5000 hours</td>
</tr>
<tr>
<td>Bond and Movement Capability</td>
<td>ASTM C719</td>
<td>Pass 10 cycles at plus 50 percent movement (no adhesion or cohesion failure)</td>
</tr>
<tr>
<td>Peel</td>
<td>ASTM D903</td>
<td>Minimum 140 kPa 20 psi of width with at least 75 percent cohesive failure</td>
</tr>
</tbody>
</table>

NOTES:
1. Percent weight loss of wet (uncured) sample after placing in forced-draft oven maintained at 70 degrees plus 2 degrees C 158 degrees plus 1 degree F for two hours.

2. Specimen cured 21 days at 23 degrees C plus 2 degrees C 73 degrees plus 1 degree F and 50 percent plus 5 percent humidity.

ACCELERATED WEATHERING FACTORY TEST REPORT. For the Accelerated Weathering test, in lieu of testing of actual sealant to be used on the project, it is permitted to submit a report of a factory test, performed within two years of Contract award.

2.2 PRIMERS

Use primers in accordance with the recommendation of the manufacturer.

2.3 BOND BREAKERS

2.3.1 Blocking Media/Backup Materials

**************************************************************************
NOTE: The use of a bond breaking separation tape or backup material in the joint may prevent an adverse reaction between incompatible materials, maintain the desired configuration (shape factor of the material), and act as a bond breaker to prevent excessive stresses from being placed on the sealant during pavement movement. Therefore, the separating or backup material should be carefully selected and
installed to form an effective and durable support for the sealant. Separating or blocking media should be placed to a depth below the pavement approximately equal to the width of the joint. This is to achieve a shape factor (ratio of the depth of the sealant to the width of the joint) of 1. ASTM D5893/D5893M sealants sometimes require a shape factor of 0.5 instead of 1. This is equivalent to a width-to-depth ratio of 2:1 and requires the standard joint detail to be modified. If an ASTM D5893/D5893M sealant is to be used the placement depth of the bond breaking separating tape or backup material should be adjusted accordingly. Drawings should be included in the Contract drawings to indicate application details.

**************************************************************************

Provide backup (joint filler) material that is a compressible, nonshrinking, nonstaining, nonabsorbing, nonreactive material with the sealant. Use backup material compliant with ASTM D5249. Use material with a melting point at least 3 degrees C 5 degrees F greater than the pouring temperature of the sealant being used when tested in accordance with ASTM D789. Use material with a water absorption of not more than 5 percent of the sample weight when tested in accordance with ASTM C1016. Use backup (joint filler) material that is 25 plus or minus 5 percent larger in diameter than the nominal width of the crack. Use blocking media consistent with the sealant manufacturer's installation instructions.

2.3.2 Bond Breaking Tapes

Provide a bond breaking tape or separating material that is a flexible, nonshrinking, nonabsorbing, nonstaining, and nonreacting adhesive-backed tape. Use material with a melting point at least 3 degrees C 5 degrees F greater than the pouring temperature of the sealant being used when tested in accordance with ASTM D789. Use bond breaker tape approximately 3 mm 1/8 in wider than the nominal width of the joint and that does not bond to the sealant. Use bond breaking tape consistent with the sealant manufacturer's installation instructions.

PART 3 EXECUTION

3.1 EXECUTING EQUIPMENT

Submit equipment list and description of the equipment to be used and a statement from the supplier of the sealant that the proposed equipment is acceptable for installing the specified sealant. Use equipment for heating, mixing, and installing seals in accordance with the instructions provided by the sealant manufacturer. Provide equipment, tools, and accessories necessary to clean existing joints and install liquid joint sealants. Maintain machines, tools, and other equipment in proper working condition. Submit a list of proposed equipment to be used in performance of construction work including descriptive data, [_____] days prior to use on the project.

3.1.1 Joint Cleaning Equipment
3.1.1.1 Tractor-Mounted Routing and Plowing Tool

Use routing tools for removing old sealant from the joints, of such shape and dimensions and so mounted on the tractor that do not damage the sides
of the joints. Use tools designed to be adjusted to remove the old material to varying depths and widths as required. Use equipment capable of maintaining accurate cutting depth and width control. Use a joint plow equipped with a spring or hydraulic mechanism to release pressure on the tool prior to spalling the concrete. Do not permit the use of V-shaped tools or rotary impact routing devices. Permit the use of hand-operated spindle routing devices to clean and enlarge random cracks.

3.1.1.2 Concrete Saw

Provide a self-propelled power saw, with water-cooled diamond or abrasive saw blades, for cutting joints to the depths and widths specified, for refacing joints, cleaning sawed joints where sandblasting does not provide a clean joint, widening, or deepening existing joints as specified without damaging the sides, bottom, or top edge of joints. Permit single or gang type blades with one or more blades mounted in tandem for fast cutting. Select saw adequately powered and sized to cut specified opening with not more than two passes of the saw through the joint.

3.1.1.3 Sandblasting Equipment

NOTE: Sandblasting equipment with a 6 mm 1/4 in nozzle requires at least 65 L per second 137 cubic ft per minute of air to function efficiently.

Include with the sandblasting equipment an air compressor, hose, and long-wearing venturi-type nozzle of proper size, shape and opening. Do not permit the maximum nozzle opening to exceed 6 mm 1/4 in. Use a portable air compressor capable of providing not less than 71 L/s 150 cfm and maintaining a line pressure of not less than 620 kPa 90 psi at the nozzle while in use. Demonstrate compressor capability, under job conditions, before approval. Use a compressor equipped with traps that maintain the compressed air free of oil and water. Use a nozzle with an adjustable guide that holds the nozzle aligned with the joint approximately 25 mm 1 in above the pavement surface. Adjust the height, angle of inclination and the size of the nozzle to secure satisfactory results.

3.1.1.4 Waterblasting Equipment

NOTE: Waterblasting equipment varies considerably with respect to design of wand, nozzle, water pressure, and water volume, depending upon the manufacturer. Consequently, the effectiveness of a particular set of equipment cannot be predicted. Delete this paragraph if waterblasting is not used.

Include with the waterblasting equipment a trailer-mounted water tank, pumps, high-pressure hose, wand with safety release cutoff control, nozzle, and auxiliary water re-supply equipment. Provide water tank and auxiliary re-supply equipment of sufficient capacity to permit continuous operations. Use a nozzle with an adjustable guide that holds the nozzle aligned with the joint approximately 25 mm 1 in above the pavement surface. Adjust the height, angle of inclination and the size of the nozzle to obtain satisfactory results. Use a pressure gauge mounted at the pump that shows the pressure in kPa psi at which the equipment is operating.
3.1.1.5 Air Compressor

Use a portable air compressor capable of operating the sandblasting equipment and capable of blowing out sand, water, dust adhering to sidewalls of concrete, and other objectionable materials from the joints. Use a compressor that provides air at a pressure not less than 620 kPa (90 psi) and a minimum rate of 0.07 cubic m of air per second (150 cubic ft of air per minute) at the nozzles and free of oil.

3.1.1.6 Vacuum Sweeper

Use a self-propelled, vacuum pickup sweeper capable of completely removing loose sand, water, joint material, and debris from pavement surface.

3.1.1.7 Hand Tools

Permit the use of hand tools, such as brooms and chisels, when approved, for removing defective sealant from a crack and repairing or cleaning the crack faces.

3.1.2 Sealing Equipment

Use joint sealing equipment of a type required by the sealant manufacturer's installation instructions. Use equipment capable of installing sealant to the depths, widths and tolerances indicated. Do not proceed with joint sealing when malfunctions are noted until the malfunctions are corrected.

3.1.2.1 Hot-Poured Sealing Equipment

Use mobile unit applicators equipped with a double-boiler, agitator-type kettle with an oil medium in the outer space for heat transfer for heating and installing ASTM D6690 joint sealant materials; a direct-connected pressure-type extruding device with a nozzle shaped for inserting in the joint to be filled; positive temperature devices for controlling the temperature of the transfer oil and sealant; and a recording thermometer for indicating the temperature of the sealant. Use an applicator unit designed so that the sealant circulates through the delivery hose and returns to the inner kettle when not in use.
3.1.2.2 Cold-Applied, Single-Component Sealing Equipment

NOTE: Some ASTM D5893/D5893M sealants cure when exposed to moisture. When the sealant is moisture sensitive it is necessary to use Teflon-lined hoses to prevent the sealant from curing in the hoses.

Use equipment for installing ASTM D5893/D5893M single component joint sealants that consists of an extrusion pump, air compressor, following plate, hoses, and nozzle for transferring the sealant from the storage container into the joint opening. Use a nozzle with dimensions that allows the tip of the nozzle to extend into the joint to allow sealing from the bottom of the joint to the top. Maintain the initially approved equipment in good working condition, serviced in accordance with the supplier's instructions, and unaltered in any way without obtaining prior approval. Use lined hoses and seals to prevent moisture penetration and withstand pumping pressures. Use equipment free of contamination from previously used or other type sealant. Permit use of small hand-held air-powered equipment (i.e., caulking guns) for small applications.

3.2 SAFETY

NOTE: Delete this paragraph if liquid oxygen (LOX) equipment, storage, or piping is not within the project area. Joint sealant should not be used within 8 m (25 ft) of any LOX equipment or storage.

If LOX equipment, storage, or piping is within the project area, use continuously reinforced concrete slabs in the 8 m (25 ft) clear area of LOX to reduce the number of joints. If joints cannot be eliminated within the 8 m (25 ft) clear area, clean the joints in the area and leave unsealed. DO NOT PERMIT LOX TO MIX WITH ANY ORGANIC MATERIAL.

Specify sandblasting of joint walls as a light cleaning method following sawing of joints. Sandblasting sometimes causes minor deterioration around the joint area. Secure station permission before sandblasting. If necessary, insert a cross-reference to Section 01 57 19 TEMPORARY ENVIRONMENTAL CONTROLS.

Do not place sealant within 8 m (25 ft) of LOX equipment, LOX storage, or LOX piping. Clean joints in this area and leave them unsealed.

In accordance with the provisions of the Contract respecting "Accident Prevention," take appropriate measures to control worker exposure to toxic substances during the work. Provide personnel protective equipment as required. Make Material Safety Data Sheets (Department of Labor Form OSHA-20 or comparable form) available on the site.

Perform sandblasting operations in accordance to paragraph entitled "Abrasive Blasting" of Section 01 57 19 TEMPORARY ENVIRONMENTAL CONTROLS.
3.3 PREPARATION OF JOINTS

**************************
NOTE: The proper preparation of joints with respect to size of joint opening, required cleanliness of concrete surfaces to be bonded, and proper separation of noncompatible materials from the joint sealant cannot be overemphasized. The same applies to storage, preparation, proportioning, mixing and placement of sealants. The neglect of any facet of these operations can result, and has resulted, in poor performance of the joint sealant.

Provide details of the existing joints and the required depth of removal of old sealant on the drawings.

**************************

Unless otherwise indicated, remove existing material, saw, clean and reseal joints. Do not proceed with final cleaning operations by more than one working day in advance of sealant. Clean joints by removing existing joint sealing compound, bond-breakers, dirt, laitance, curing compound, filler, and protrusions of hardened concrete from the sides and upper edges of the joint space to be sealed and other foreign material with the equipment. Do not permit cleaning procedures that damage joints or previously repaired patches by chipping or spalling. Remove existing sealant to the required depth. Precise shape and size of existing joints vary, and conditions of joint walls and edges vary and include but are not limited to rounding, square edges, sloping, chips, voids, depressions, and projections.

3.3.1 Existing Sealant Removal

**************************
NOTE: Delete this paragraph if the joints have never been sealed and renumber the subsequent paragraphs. Specify and show on the plans the depth to remove the old sealant from the joints. Show typical existing joint dimensions. Waterblasters have been used successfully to remove sealants that still have some resilience. A nozzle that puts out a thin stream of water is required to cut the sealant loose from the joint walls. Do not use the concrete saw if it widens the joint to a width greater than 25 mm 1 in.

**************************

Cut loose the in-place sealant from both joint faces and to the required depth, using the [tractor-mounted routing equipment] [concrete saw] [waterblaster] as specified in paragraph EQUIPMENT. Provide a depth sufficient to accommodate blocking media and bond breakers that are required to maintain the depth of new sealant to be installed. For expansion joints, remove existing sealant to a depth of not less than [the indicated depth.][ 25 mm 1 in.] When existing preformed expansion-joint material is more than 25 mm 1 in below the surface of the pavement, remove existing sealant to the top of the preformed joint filler. Prior to further cleaning operations, remove loose old sealant remaining in the joint opening by blowing with compressed air. Permit use of hand tools to remove sealant from random cracks. Do not permit chipping, spalling, or
other damage to the concrete. Clean pavement surface with vacuum sweeper. Protect previously cleaned joints from being contaminated by subsequent cleaning operations.

3.3.2 Sawing

**************************************************************************
NOTE: Joints often need to be refaced or widened to provide vertical faces and remove damaged concrete. Care should be used when refacing or widening joints so that the joint's width does not exceed 25 mm 1 in. If the joint width exceeds 25 mm 1 in, rebuilding of the joint should be considered. Joint walls should be vertical. The edges should not be rounded or beveled unless required by design.
**************************************************************************

3.3.2.1 Refacing of Joints

**************************************************************************
NOTE: Specify refacing of joints by sawing for the following reasons:

1. To widen the joint space or change the shape factor.

2. To straighten the vertical walls inside the joints and remove old sealant.

If the joints have never been sealed, change the title of this paragraph to Facing of Joints and the appropriate words and sentences used. If "dry" sawing is used to face or reface the joints, remove the debris using compressed air.
**************************************************************************

Accomplish [refacing] [facing] of joints using a concrete saw as specified in paragraph EQUIPMENT [to remove residual old sealant and a minimum of concrete from the joint face to provide exposure of newly cleaned concrete, and, if required, to enlarge the joint opening to the width and depth shown on the drawings.] [to saw through sawed and filler-type joints to loosen and remove material until the joint is clean and open to the full specified width and depth.] Provide exposure of newly clean concrete through removal. Remove burrs and irregularities from sides of joint faces. Stiffen the blade with a sufficient number of dummy (used) blades or washers. Clean, immediately following the sawing operation, the joint opening using a water jet to remove saw cuttings and debris and adjacent concrete surface. Protect adjacent previously cleaned joint spaces from receiving water and debris during the cleaning operation.

a. Joint Widening (Except Expansion Joints): Saw joints having grooves less than 10 mm 3/8 in wide and less than 25 mm 1 in deep to a minimum width of [10] [13] [_____] mm [3/8] [1/2] [_____] in and to the minimum depth, [of] [25 mm] [38 mm] [1 in] [1-1/2 in] [as indicated].

3.3.2.2 Refacing of Random Cracks

**************************************************************************
NOTE: Use a vertical spindle routing device to
clean random cracks. Sandblast clean random cracks that are approximately 25 mm 1 in wide to prevent additional widening of the crack instead of sawing or routing.

Accomplish sawing of the cracks using a power-driven concrete saw as specified in paragraph EQUIPMENT. Use a saw blade 150 mm 6 in or less in diameter to enable the saw to follow the trace of the crack. Stiffen the blade with dummy (or used) blades or washers. Immediately following the sawing operation, clean the crack opening using a water jet to remove saw cuttings and debris.

3.3.3 Final Cleaning of Joints

3.3.3.1 Sandblasting

NOTE: Specify sandblasting of joint walls following sawing of joints. Sandblasting may cause some minor deterioration around the joint area. Secure station permission before sandblasting. If necessary, insert a cross-reference to Section 01 57 19 TEMPORARY ENVIRONMENTAL CONTROLS.

Do not permit sandblasting of joints under certain conditions. Blowing sand and dust may either violate atmospheric pollution statutes or may drift into areas where it is objectionable. When sandblasting is prohibited, substitute cleaning the joints with a waterblaster or wire brushes. Wire brushes do not clean as well as the sandblaster or waterblaster; use only for small areas. When wire brushes are used, provide attention to ensure worn brushes are not used and that the joints are being adequately cleaned. When waterblasting is required instead of sandblasting, replace the word sandblasting with waterblasting.

Following removal of existing sealant, and sawing, and immediately before resealing, clean newly exposed concrete joint faces and pavement surface extending to a minimum of 13 mm 1/2 in up to 50 mm 2 in from each joint edge by sandblasting until concrete surfaces in the joint space are free of sealants, dust, dirt, water and other foreign materials that prevent bonding of new sealants to the concrete. Use sand particles of the proper size and quality for the work. Perform sandblasting with specified nozzles, air compressor, and other appurtenant equipment. Position nozzles to clean the joint faces. Make at least two passes; one for each joint face. Make as many passes as required for proper cleaning. Immediately prior to sealing the joint, blow out the joint spaces with compressed air until completely free of sand, water, and dust. Install joint sealants to dry joints. Replace expansion joint filler material damaged in performing the work with new materials of the same type and dimensions as the existing material, or with appropriate blocking media.

3.3.4 Bond Breaker

At the time the joints receive the final cleaning and are dry, install bond
breaker material as indicated with a steel wheel or other approved device.

3.3.4.1 Blocking Media (Backer Rod) (Except for Expansion Joints)

When the joint opening is of a greater depth than indicated for the sealant depth, plug or seal off the lower portion of the joint opening using a blocking media/back-up material to prevent the entrance of the sealant below the specified depth. Take care to ensure that the blocking media/backup material is placed at the specified depth and is not stretched or twisted during installation.

3.3.4.2 Bond Breaking Tape

Where inserts or filler materials contain bitumen, or the depth of the joint opening does not allow for the use of a backup material, insert a bond breaker separating tape to prevent incompatibility with the filler materials and three-sided adhesion of the sealant. Bond the tape to the bottom of the joint opening to prevent it from floating up into the new sealant.

3.3.5 Rate of Progress of Joint Preparation

Limit the stages of joint preparation, including sandblasting, air pressure cleaning and placing of the back-up material to only that lineal footage that can be sealed during the same day.

3.3.6 Disposal of Debris

**************************************************************************
NOTE: Specify location of disposal of debris.
**************************************************************************

Sweep pavement surface to remove excess joint material, dirt, water, sand, and other debris by vacuum sweepers or hand brooms. Remove the debris immediately [to a point off station.] [to a designated area.] [in accordance with Section 02 41 00 [DEMOLITION] [ AND ] [DECONSTRUCTION]].

3.4 PREPARATION OF SEALANT

**************************************************************************
NOTE: Delete the inappropriate paragraphs.
**************************************************************************

3.4.1 Hot-Poured Sealants

Heat hot-poured sealing materials in accordance with ASTM D6690 and with safe heating temperature ranges recommended by the manufacturer. Withdraw and waste sealant that has been overheated or subjected to heating for over 3 hours or that remain in the applicator at the end of the day's operation. Heat sealant in specified equipment.

3.4.2 Single-Component, Cold-Applied Sealants

Inspect the ASTM D5893/D5893M sealant and containers prior to use. Reject materials that contain water, hard caking of any separated constituents, nonreversible jell, or materials that are otherwise unsatisfactory. Do not reject sealants that exhibit settlement of constituents in a soft mass that can be readily and uniformly remixed in the field with simple tools.
3.5 INSTALLATION OF SEALANT

3.5.1 Time of Application

After approval of the test section, seal joints immediately following final cleaning and placing of bond breakers. Commence sealing joints when walls are dust free and dry, and when weather conditions meet sealant manufacturer's instructions. If the above conditions cannot be met, or when rain interrupts sealing operations, reclean and permit the joints to dry prior to installing the sealant.

3.5.2 Sealing Joints

**************************************************************************
NOTE: Joints should be slightly underfilled to preclude extrusion of the material above the surface of the pavement at summertime temperatures. For airfield pavements, the sealant should be recessed 3 mm 1/8 in below the pavement surface; for roads, streets and parking lots, the sealant should be recessed 6 mm 1/4 in. For pavements that receive tracked vehicle traffic, the sealant should be recessed a minimum of 6 mm 1/4 in below the pavement surface after it has cured or cooled to ambient temperature.
**************************************************************************

Do not install joint sealant until joints to be sealed have been inspected and approved. Install bond breaker just prior to pouring sealant. Fill the joints with sealant from bottom up until joints are uniformly filled solid from bottom to top using the specified equipment for the type of sealant required. Fill joints to 3 mm 1/8 in plus or minus 1.5 mm 1/16 in below top of pavement, and without formation of voids or entrapped air. Do not permit gravity methods or pouring pots to be used to install the sealant material. Except as otherwise permitted, tool the sealant immediately after application to provide firm contact with the joint walls and to form the indicated sealant profile below the pavement surface. Remove excess sealant that has been inadvertently spilled on the pavement surface. Do not permit traffic over newly sealed pavement until authorized. When a primer is recommended by the manufacturer, apply it evenly to the joint faces in accordance with the manufacturer's recommendations. Check sealed joints frequently to ensure that newly installed sealant is cured to a tack-free condition within the specified time. Protect new sealant from rain during curing period.

3.6 INSPECTION/FIELD QUALITY CONTROL

3.6.1 Joint Cleaning

Inspect joints during the cleaning process to correct improper equipment and cleaning techniques that damage the concrete pavement in any manner. Approve cleaned joints prior to installation of the separating or back-up material and joint sealant.

3.6.2 Sampling Sealant

Obtain a 4-L one gal sample of each type of sealant on the project from material used for each 3000 m 10,000 linear ft or less of joints sealed. Store samples according to manufacturer's instructions. Retain
samples until final acceptance of the work.

3.6.3 Sealant Application Equipment

Inspect the application equipment to ensure conformance to temperature requirements, proper proportioning and mixing (if two-component sealant) and proper installation. Suspend operations if there is evidences of bubbling, improper installation, or failure to cure or set until causes of the deficiencies are determined and corrected.

3.6.4 Joint Sealant

Inspect the joint sealant for proper rate of cure and set, bonding to the joint walls, cohesive separation within the sealant, reversion to liquid, entrapped air and voids. Remove sealants exhibiting these deficiencies prior to the final acceptance of the project from the joint, wasted, and replace at no additional cost to the Government. Obtain approval for each joint seal installation.

3.7 ACCEPTANCE

Reject sealer that fails to cure properly, or fails to bond to joint walls, or reverts to the uncured state, or fails in cohesion, or shows excessive air voids, blisters, surface defects, swelling, or other deficiencies, or is not properly recessed within indicated tolerances. Remove rejected sealer and reclean and reseal joints. Perform removal and reseal work promptly by and at the expense of the Contractor.

3.8 CLEAN-UP

Upon completion of the project, remove unused materials from the site and leave the pavement in a clean condition.

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for partial depth patching of spalled concrete and popout areas of rigid paving. The work involves removal of spalled concrete, preparing the area to be repaired, and placing, finishing, and curing (as needed) the repair material. It is emphasized that this specification is for rehabilitation applications only and is not to be used with new construction.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1   GENERAL

NOTE: This specification is not intended for repair of heat resistant concrete pavements. See second note in paragraph entitled "Cement."

For details, drawings and illustrations related to partial depth patching, refer to UFC 3-270-03, "Concrete Crack and Partial-Depth Spall Repair" for
NOTE: For full-depth repairs of PCC pavements for roads and streets only, use Section 32 13 13.06 PORTLAND CEMENT CONCRETE PAVEMENT FOR ROADS AND SITE FACILITIES. For full-depth patches or slab removal and replacement of airfield pavements, use Section 32 13 14.13 CONCRETE PAVING FOR AIRFIELDS AND OTHER HEAVY DUTY PAVEMENTS.

NOTE: As a minimum, show the following information on the drawings:

1. Plans showing layout and identification of each affected joint and joint type. Include identification of joints with dowels and with tie-bars. Identify pavements or slabs that are reinforced and the reinforcement. Include location of each random crack where spall repairs are needed.

Spalling along a longitudinal joint in older concrete pavements may be a result of a broken keyway. Details for repairing broken keyways should be included in the project plans. Repair of broken keyways using the full-depth repair technique should be considered.

2. Show approximate location, length and width of each spall and location and size (usually average diameter) of popouts to be repaired. Dimensions of spalls and popouts need not be to scale. Identify by legend and symbol whether spall repair needed is approximately rectangular or circular or pentagonal (triangular spall). Specifically detail any special or unusual shapes or partial depth repairs.

3. If required spall repairs are extensive, provide a schedule showing scope of work and quantities for bid purposes in addition to the location plans. Identify feature areas where spalls or groups of spalls are located, area of spall repairs in square meter square feet, location and number or area of popouts, and other PCC pavement repairs which may be a part of the contract.

4. Provide details of spall and popout repairs. Refer to UFC 3-270-01 and UFC 3-270-03 for suggested details to be included on project drawings. Ensure
that these drawings include the required 50 mm 2 inch minimum horizontal beyond the unsound spalled areas in the length and width dimensions shown for each spall repair area.

5. In conducting field surveys to locate and size spalls needing repair, each suspect area must be sounded to determine extent of damage. Sounding may be done with a steel hammer, steel rod, or other suitable means for locating unsound areas that exhibit hollow sound, and indicator of potentially delaminated concrete that may develop into a spall. It is not unusual for delamination in a spall area to extend well beyond that visually obvious. Each existing partial depth patch should also be sounded to determine the performance of the patch. If soundings indicated that existing patches may be unsound, these patches should be included in the new patching program.

6. Indicate the maximum allowable time to return the repair area to aircraft/vehicle traffic. The pavement repair material that is required for the repairs may be dictated by the maximum allowable time to return the repair area to aircraft/vehicle traffic. Mixes based on the use of a standard Type I, II or V cement can be used when the time required to return the area to traffic is in excess of 3 days. Mixes based on the use of standard Type III cement can be used when the time required to return the area to traffic is in excess of 24 hours. Mixes which utilize blends of admixture in conjunction with standard cement types to further accelerate strength gains can be used when the time required to return the area to traffic is in excess of 4 hours; however, these blends are very sensitive to the mixing proportions and deviation as small as 5 percent can lead to a 6 to 8 hour increase in the cure times. When the time required to return the area to traffic is less than 4 hours use of proprietary or magnesium phosphate repair materials is required. In general, repairs using material designed for traffic after short curing periods have shorter life spans.

1.1 UNIT PRICES

***************

NOTE: When lump sum payment is used, delete this paragraph. If patching is a separate pay item, revise the paragraph accordingly.

1.1.1 Measurement

The quantity of concrete and proprietary repair products to be paid for is the number of [cubic meters feet][kgs lbs] placed in the completed and accepted patched areas.
1.1.2 Payment

The quantity of concrete and proprietary repair products, measured as specified, is paid for at the contract unit price. The unit price includes full compensation for furnishing labor; materials; and for performing work involved in patching the pavements as specified.

1.2 REFERENCES

1.3 SUBMITTALS

**************************************************************************
NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy, Air Force, and NASA projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy, Air Force and NASA projects, or choose the second bracketed item for Army projects.

**************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

1.4 QUALITY ASSURANCE

**************************************************************************
NOTE: Guidance for preparation of criteria to be used in inspection of laboratory facilities is contained in ASTM E329.
**************************************************************************

1.4.1 Preconstruction Testing Of Materials

Submit proposed concrete mix design at least [30] [_____] days prior to placement. Provide mix design evaluation and certification by a Government approved engineering testing laboratory, and indicate the weight of each ingredient of the mixture, aggregate gradation, slump, air content, water-cement ratio, time of trafficking and 3-day and 28-day compressive strength test results. Include a complete list of materials including admixtures and applicable reference specifications. Place no concrete prior to Government approval of the proposed mix design. No deviation from the approved mix design is permitted without prior Contracting Officer approval.

Within 24 hours of physical completion of laboratory testing, submit copies of laboratory test results for Contracting Officer approval.

1.4.1.1 Cement

Test cement as prescribed in the referenced specification under which it is furnished. Cement may be accepted on the basis of mill tests and the manufacturer's certification of compliance with the specification.
1.4.1.2 Aggregate

Take aggregate gradation samples for laboratory testing in conformance with ASTM D75/D75M.

1.4.1.3 Proprietary Repair Products

At least 30 days before the repair material is used, submit certified copies of test results for the specific lots or batches to be used on the project, not more than 6 months old prior to use in the work.

Manufacturer's certifications may be submitted rather than laboratory test results for proprietary repair products. Include in the submittals details for substrate preparation, mixing, placing, finishing, curing and testing of the material, as applicable. Include a minimum of three case histories documenting the use of the product in a similar freeze-thaw environment and pavement condition. Certify compliance with the appropriate specification referenced herein. Place no materials without prior approval from the Contracting Officer.

1.4.2 Equipment; Approval, Maintenance, and Safety

Provide and use only dependable and well maintained equipment that is appropriate to accomplish the work specified. Allow sufficient time for assembly of equipment requiring such at the work site to permit thorough inspection, calibration of weighing and measuring devices, adjustment of parts, and the making of any repairs that may be required prior to the start of work.

a. Submit volumetric mixer calibration and efficiency test results in accordance with the requirements of ASTM C685/C685M within 6 months of concrete placement. If applicable, submit concrete uniformity test data for the first load of the ready-mixed concrete to be used as the repair material.

b. Provide Safety Data Sheets (SDS) and Personal Protection Equipment (PPE) per 29 CFR 1910.

1.4.3 Shop Detail Drawings

**************************************************************************
NOTE: Delete this paragraph if the project scope does not require detailed shop drawings and staging plans from the Contractor.
**************************************************************************

Submit detailed Shop Drawings conforming to AASHTO SDDP-1-OL.

1.5 DELIVERY, STORAGE, AND HANDLING

1.5.1 Cement

Deliver cement in bulk or in suitable bags used for packaging cements and store in a manner to prevent absorption of moisture.

1.5.2 Aggregate

Deliver, handle, and store aggregates in a manner to avoid breakage,
seggregation, inter-mingling or contamination by foreign materials.

1.5.3 Other Materials

Deliver epoxy-resin, chemical admixtures and proprietary repair products to the site in such manner as to avoid damage or loss. Provide storage areas in a windowless and weatherproof, but ventilated, insulated noncombustible building, with provision nearby for conditioning the material to 20 to 30 degrees C 70 to 85 degrees F for a period of 48 hours prior to use. Keep the ambient temperature in the storage area no higher than 40 degrees C 100 degrees F.

1.6 Project/Site Conditions

Do not place concrete or other repair products when weather conditions detrimentally affect the quality of the finished product. Do not place concrete when the air temperature is below 5 degrees C 40 degrees F in the shade. When air temperature is likely to exceed 35 degrees C 90 degrees F, provide concrete having a temperature not exceeding 35 degrees C 90 degrees F when deposited. Keep the surface of placed concrete damp with a water fog until the approved curing medium is applied. Take similar precautions for placing other repair products, as directed by the product vendor's instructions. Do not place concrete or other repair products if the weather forecast indicates that the air temperature is expected to drop below 5 degrees C 40 degrees F over the next 7 days.

PART 2 PRODUCTS

2.1 MATERIALS

2.1.1 Coarse Aggregate

2.1.1.1 Composition

Provide coarse aggregate consisting of gravel, crushed gravel, crushed stone, or a combination thereof.

2.1.1.2 Quality

**************************************************************************

NOTE: Do not allow types of aggregate at locations where they have an unsatisfactory performance record. Specify aggregate to be washed in areas where deleterious substances are present and unsatisfactory performance has been observed.

If concrete is used for the repair, the concrete aggregates should be similar to aggregates in existing concrete pavement to ensure that there is thermal compatibility between the aggregate in the existing concrete pavement and the aggregate in the repair concrete.

**************************************************************************

Provide aggregate, as delivered to the mixers, consisting of clean, hard, unweathered, and uncoated particles. Remove dust and other coatings from the coarse aggregate by adequate washing. Meet the requirements of ASTM C33/C33M, Class 5S. Provide aggregates with an abrasion loss, when tested in accordance with ASTM C131/C131M, not exceeding 40 percent; the
maximum allowable percentage for clay lumps and friable particles is [1.5] percent. Provide documentation of aggregate conforming to ASTM C136/C136M.

2.1.1.3 Particle Shape

Provide spherical or cubical shaped coarse aggregate particles. Remove all coarse aggregates with the largest dimension that is equal to or larger than three times the smallest dimension.

2.1.1.4 Gradation

**************************************************************************
NOTE: The spall repair depth should be a minimum of 50 mm 2 inches. The 13 mm 1/2 inch maximum nominal size for coarse aggregate specified below is suitable for 50 mm 2 inches deep spall repair areas.
**************************************************************************

The maximum nominal size of the coarse aggregate is 13 mm 1/2 inch. Provide well graded coarse aggregate conforming to gradation size 7 in Table 3 of ASTM C33/C33M when tested in accordance with ASTM C136/C136M as delivered to the batching hoppers.

2.1.1.5 Alkali Silica Reactivity

**************************************************************************
NOTE: For small quantity patching projects, include the first paragraph and require the use of non-reactive aggregate.

For large quantity patching projects, include reference to Section 32 13 14.13 CONCRETE PAVING FOR AIRFIELDS AND OTHER HEAVY DUTY PAVEMENTS MORE THAN 10,000 CUBIC YARDS and include the second paragraph cross-referencing ASR evaluation and mitigation testing.
**************************************************************************

[Evaluate and test coarse aggregate, to be used in all concrete, for alkali-silica reactivity in accordance with ASTM C1260. Provide aggregate with a measured expansion not exceeding 0.08 percent at 28 days when tested. Aggregates with test data indicating an expansion greater than 0.08 percent will be rejected.]

[Evaluate coarse aggregate in accordance with Section 32 13 14.13, paragraph: Alkali-Silica Reactivity, with mitigation of reactive aggregate in accordance with the referenced paragraph.]

For proprietary repair products, provide documentation from the supplier that the repair product combination with the aggregates selected will not exhibit alkali-silica reactivity.

2.1.2 Fine Aggregate

2.1.2.1 Composition

Provide fine aggregate consisting of either natural sand, manufactured
sand, or a combination of natural and manufactured sand, and composed of clean, hard, durable particles; conforming to Table 2 of ASTM C33/C33M.

2.1.2.2 Particle Shape

Ensure particles of the fine aggregate are generally spherical or cubical in shape.

2.1.2.3 Grading

Provide fine aggregate as delivered to the mixer conforming to the gradation in Table 1 of ASTM C33/C33M when tested in accordance with ASTM C136/C136M.

In addition, provide fine aggregate, as delivered to the mixer, with a fineness modulus of not less than 2.40 nor more than 2.90, when calculated in accordance with ASTM C136/C136M.

2.1.2.4 Alkali Silica Reactivity

Evaluate and test fine aggregate to be used in all concrete for alkali-silica reactivity in accordance with Paragraph ALKALI SILICA REACTIVITY.

2.1.3 Admixtures

2.1.3.1 Air-Entraining Admixtures

Provide air-entraining admixtures conforming to ASTM C260/C260M.

2.1.3.2 Chemical Admixtures

ASTM C494/C494M. Where not shown or specified, the use of admixtures is subject to written approval of the Contracting Officer.

2.1.4 Cement

**************************************************************************
NOTE: Specify type of portland cement to suit project requirement and location. Specify Type III cement only when pavements are expected to be returned to active service in excess of 24 hours and less than 3 calendar days. Specify type of cement, including low-alkali, to suit local aggregate conditions. Types of cements other than those bracketed may be specified provided the designer knows that they have a satisfactory service record in partial depth repairs.
**************************************************************************

**************************************************************************
NOTE: In addition to portland cement, there are many types of cements, polymers, blends and modifications thereto, and other cementitious materials available for patching PCC. Some have performed very well in some cases but failed in others. Many are unusually sensitive to moisture,
**************************************************************************
temperature conditions, mixing criteria, curing techniques, quality of workmanship, or other critical processes. Some are suitable for use during cold weather. Many will develop a level of strength in excess of that needed for patching PCC pavements. Many are not as durable as PCC. Some have been introduced fairly recently and do not have a long term performance record. For patching PCC, most are less compatible, and more expensive than portland cement. Use of any of these materials will depend on the knowledge of the design engineer as well as project requirements and may necessitate significant modifications to this guide specification and attached details.

**************************************************************************
Provide portland cement conforming to ASTM C150/C150M, Type [____]. Provide low alkali cement if the proposed fine or coarse aggregate are found to have greater than 0.08 percent expansion when tested in accordance with ASTM C1260, as per paragraph: Alkali Silica Reactivity.

2.1.4.1 Portland Cement Concrete Mix Design

**************************************************************************
NOTE: The required time for strength gain and compressive tests needs to be adjusted based on the maximum time available to return traffic to the repaired pavement. Pavement materials must reach the minimum required strength requirements within the time available to return traffic to the repaired pavement. Retain the bracketed time of testing, based on the length of time from finishing the placement, not to the initial set of the concrete, that best represents the time available before returning the area to traffic. The maximum interval for required compressive strength and testing is 3 days.

The minimum allowable compressive strength at the time of trafficking is 17.5 MPa 2,500 psi for roads, streets and parking areas and 20.7 MPa 3,000 psi for airfield pavements.

A list of materials that can meet the 2 hour cure time to return to traffic can be found on the approved material list on the Pavement Repair Material Certification Program web page at Blockedhttps://transportation.erdc.dren.mil/cacsites/TriService/pavement_repair

Delete the bracketed portion of the second paragraph for patching airfield pavements.

**************************************************************************
Design the concrete mixture to produce a minimum compressive strength of [17.5] [20.7] [____] MPa [2,500] [3,000] [____] psi at [2] [4] [24] [72] [____] hrs from the time the material is screeded and finished in the repair area and a minimum compressive strength of [31] [35] MPa [4,500] [5,000] psi at 28 days of age, determined in conformance with ASTM C39/C39M and ASTM C192/C192M, using standard 150 by 300 mm 6 by 12 inch cylinder test specimens.
specimens; and providing an air content by volume of [5] [6] [_____] percent, plus or minus 1.5 percent, based on measurements made on concrete immediately after discharge from the mixer in conformance with ASTM C231/C231M.

The allowable range of slump is 13 to 50 mm 1/2 to 2 inches when tested in accordance with ASTM C143/C143M [except that maximum slump may be increased to 100 mm 4 inches when the Contractor has included an approved water-reducing, mid range, admixture conforming to ASTM C494/C494M in the mix design]. To minimize drying shrinkage, the maximum water-cement ratio by weight is limited to 0.45.

2.1.5 Curing Materials

**************************************************************************
NOTE: Use of curing material and curing type is dependent on the specific repair product used. Concrete and cementitious repair products must be cured using pigmented liquid membrane curing compound typically used for curing conventionally placed concrete pavement.

Polymer (epoxy) repair products will need to be cured as per the product vendor's instructions.

When time is critical and the curing time for concrete or cementitious repair material is not acceptable, specify use of rapid setting proprietary repair materials.
**************************************************************************

2.1.5.1 Pigmented Liquid Membrane-Forming Compound

**************************************************************************
NOTE: Delete reference to ASTM C309 when repairing airfield pavements. ASTM C309 may only be specified for repair of roads, streets, and parking areas only.
**************************************************************************

Provide pigmented liquid membrane-forming compound conforming to COE CRD-C 300 [or ASTM C309].

2.1.6 Bonding-Agents

**************************************************************************
NOTE: Bonding agents should be used only for proprietary repair materials that require their use. Use only bonding agents recommended by the manufacturer of the repair material. For concrete and cementitious repair materials, a saturated surface dry or damp contact area is sufficient and easier to manage under a range of ambient conditions. A grout scrub may be used on projects with slow setting materials placed in repair areas with irregular surfaces.
**************************************************************************
2.1.6.1 Epoxy-Resin

Provide two component epoxy-resin material formulated to meet the requirements of ASTM C881/C881M, Type III, grade and class as approved, for use in bond coat applications and as a component of epoxy-resin concrete or mortar.
