3.2.11 Firefighter Telephones

Mount telephone[ hand sets][ jacks] on the wall in each stair at each floor landing, in each emergency generator room, in each fire pump room, in each elevator machine room, in each elevator lobby, and in each elevator cab 1200 mm 4 feet above the finished floor.

3.2.12 Local Operating Console (LOC)

Locate the LOC(s) as required by NFPA 72 and as indicated. Mount the console so that the top message button and microphone is no higher than 1200 mm 4 feet above the floor and the bottom (lowest) message button and microphone is at least 1-meter3 feet above the finished floor.

3.2.13 Ceiling Bridges

Provide ceiling bridges for ceiling-mounted appliances. Ceiling bridges must be as recommended/required by the manufacturer of the ceiling-mounted notification appliance.

3.3 SYSTEM FIELD WIREFING

3.3.1 Wiring within Cabinets, Enclosures, and Boxes

Provide wiring installed in a neat and workmanlike manner and installed parallel with or at right angles to the sides and back of any box, enclosure, or cabinet. Conductors that are terminated, spliced, or otherwise interrupted in any enclosure, cabinet, mounting, or junction box must be connected to screw-type terminal blocks. Mark each terminal in accordance with the wiring diagrams of the system. The use of wire nuts or similar devices is prohibited. Wiring to conform with NFPA 70.
Indicate the following in the wiring diagrams:

a. Point-to-point wiring diagrams showing the points of connection and terminals used for electrical field connections in the system, including interconnections between the equipment or systems that are supervised or controlled by the system. Diagrams must show connections from field devices to the FMCU and remote fire alarm/mass notification control units, initiating circuits, switches, relays and terminals.

b. Complete riser diagrams indicating the wiring sequence of devices and their connections to the control equipment. Include a color code schedule for the wiring. Include floor plans showing the locations of devices and equipment.

3.3.2 Terminal Cabinets

*********************************************************************************************************************************************

NOTE: Provide terminal cabinets on each floor where the fire alarm system supply riser is located and where the fire alarm return riser is located.

*********************************************************************************************************************************************

Provide a terminal cabinet at the base of any circuit riser, on each floor at each riser, and where indicated on the drawings. Terminal size must be appropriate for the size of the wiring to be connected. Conductor terminations must be labeled and a drawing containing conductors, their labels, their circuits, and their interconnection must be permanently mounted in the terminal cabinet. Minimum size is 200 mm by 200 mm 8 inches by 8 inches. Only screw-type terminals are permitted. Provide an identification label, that displays "FIRE ALARM TERMINAL CABINET" with 50 mm 2-inch lettering, on the front of the terminal cabinet.

3.3.3 Alarm Wiring

*********************************************************************************************************************************************

NOTE: Do not penetrate SCIF perimeters with copper signal line circuits. SCIF penetrations should be either fiber optic cable or IDC. IDC circuits penetrating the SCIF must be filtered.

*********************************************************************************************************************************************

a. Voltages must not be mixed in any junction box, housing or device, except those containing power supplies and control relays.

b. Utilize shielded wiring where recommended by the manufacturer. For shielded wiring, ground the shield at only one point, in or adjacent to the FMCU.

c. [Pigtail or T-tap connections to initiating device circuits, supervisory alarm circuits, and notification appliance circuits are prohibited.][ T-tapping using screw terminal blocks is allowed for Class "B" initiating device circuits.]

d. Color coding is required for circuits and must be maintained throughout the circuit. Conductors used for the same functions must be similarly color coded. Conform wiring to NFPA 70.

e. Pull all conductors splice free. The use of wire nuts, crimped
connectors, or twisting of conductors is prohibited. Where splices are unavoidable, the location of the junction box or pull box where they occur must be identified on the as-built drawings. The number and location of splices must be subject to approval by the [_____]
Designated Fire Protection Engineer (DFPE).

3.3.4 Back Boxes and Conduit

In addition to the requirements of Section 26 20 00 INTERIOR DISTRIBUTION SYSTEM, provide all wiring in rigid metal conduit or intermediate metal conduit unless specifically indicated otherwise. Minimum conduit size must be 19 mm 3/4-inch in diameter. Do not use electrical non-metallic tubing (ENT) or flexible non-metallic tubing and associated fittings.

a. Galvanized rigid steel (GRS) conduit must be utilized where exposed to weather, where subject to physical damage, and where exposed on exterior of buildings. Intermediate metal conduit (IMC) may be used in lieu of GRS as allowed by NFPA 70.

b. Electrical metallic tubing (EMT) is permitted above suspended ceilings or exposed where not subject to physical damage. Do not use EMT underground, encased in concrete, mortar, or grout, in hazardous locations, where exposed to physical damage, outdoors or in fire pump rooms. Use die-cast compression connectors.

c. For rigid metallic conduit (RMC), only threaded type fitting are permitted for wet or damp locations.

d. Flexible metal conduit is permitted for initiating device circuits [_____]6 feet in length or less. Flexible metal conduit is prohibited for notification appliance circuits and signaling line circuits. Use liquid tight flexible metal conduit in damp and wet locations.

e. Schedule 40 (minimum) polyvinyl chloride (PVC) is permitted where conduit is routed underground or underground below floor slabs. Convert non-metallic conduit, other than PVC Schedule 40 or 80, to plastic-coated rigid, or IMC, steel conduit before turning up through floor slab.

f. Exterior wall penetrations must be weathertight. Conduit must be sealed to prevent the infiltration of moisture.

[g. For Class "A" or "X" circuits with conductor lengths of 10 feet 3 meters or less, the conductors must be permitted to be installed in the same raceway in accordance with NFPA 72.]

3.3.5 Conductor Terminations

Labeling of conductors at terminal blocks in terminal cabinets, FMCU[, and remote FMCP] and the LOC must be provided at each conductor connection. Each conductor or cable must have a shrink-wrap label to provide a unique and specific designation. Each terminal cabinet, FMCP, and remote FMCP must contain a laminated drawing that indicates each conductor, its label, circuit, and terminal. The laminated drawing must be neat, using 12 point lettering minimum size, and mounted within each cabinet, control unit, or unit so that it does not interfere with the wiring or terminals. Maintain existing color code scheme where connecting to existing equipment.
3.4 DISCONNECTION AND REMOVAL OF EXISTING SYSTEM

**************************************************************************
NOTE: Contact the Contracting Officer, Base Fire Prevention Office, and/or Base Maintenance Personnel to determine what action is appropriate for the salvaging of existing fire alarm equipment.
**************************************************************************

Maintain existing fire alarm/mass notification equipment fully operational until the new equipment has been tested and accepted by the Contracting Officer. As new equipment is installed, label it "NOT IN SERVICE" until the new equipment is accepted. Once the new system is completed, tested, and accepted by the Government, it must be placed in service and connected to the supervising station. Remove tags from new equipment and tag the existing equipment "NOT IN SERVICE" until removed from the building.

a. After acceptance of the new system by the Contracting Officer, remove existing equipment not connected to the new system, remove unused exposed conduit, and restore damaged surfaces. Remove the material from the site and dispose.

b. Disconnect and remove the existing fire alarm/mass notification and smoke detection systems where indicated and elsewhere in the specification.

c. Control units and fire alarm devices and appliances disconnected and removed must be turned over to the Contracting Officer.

d. Properly dispose of fire alarm outlet and junction boxes, wiring, conduit, supports, and other such items.

3.5 CONNECTION OF NEW SYSTEM

The following new system connections must be made during the last phase of construction, at the beginning of the pre-Government tests. New system connections must include:

a. Connection of new relays to existing magnetic door hold-open devices.

b. Connection of new elevator recall relays to existing wiring and conduit.

c. Connection of new system transmitter to existing installation fire reporting system.

Once these connections are made, system must be left energized. Report immediately to the Contracting Officer, coordination and field problems resulting from the connection of the above components.

3.6 FIRESTOPPING

Provide firestopping for holes at conduit penetrations through floor slabs, fire-rated walls, partitions with fire-rated doors, corridor walls, and vertical service shafts in accordance with Section 07 84 00 FIRESTOPPING.

3.7 PAINTING

a. In unfinished areas (including areas above drop ceilings), paint all exposed electrical conduit (serving fire alarm equipment), fire alarm
conduit, surface metal raceway, junction boxes and covers red. In lieu of painting conduit, the contractor may utilize red conduit with a factory applied finish.

b. In finished areas, paint exposed electrical conduit (serving fire alarm equipment), fire alarm conduit, surface metal raceways, junction boxes, and electrical boxes to match adjacent finishes. The inside cover of the junction box must be identified as "Fire Alarm" and the conduit must have painted red bands 19 mm3/4-inch wide at 3-meter10-foot centers and at each side of a floor, wall, or ceiling penetration.

c. Painting must comply with Section 09 90 00 PAINTS AND COATINGS.

3.8 FIELD QUALITY CONTROL

**************************************************************************
NOTE: Listed tests are minimum required.
Coordinate with the local Authority Having Jurisdiction (AHJ) for minimum requirements in excess of the NFPA 72 minimums or those recommend below. If additional tests are required, such tests must be added to the list.
**************************************************************************

3.8.1 Test Procedures

Submit detailed test procedures, prepared and signed by the NICET Level [III][ or ][IV] Fire Alarm Technician, and the representative of the installing company, [and reviewed by the QFPE] [60][____] days prior to performing system tests. Detailed test procedures must list all components of the installed system such as initiating devices and circuits, notification appliances and circuits, control devices/equipment, batteries, transmitting and receiving equipment, power sources/supply, annunciators, special hazard equipment, emergency communication equipment, interface equipment, and surge protective devices. Test procedures must include sequence of testing, time estimate for each test, and sample test data forms. The test data forms must be in a check-off format (pass/fail with space to add applicable test data; similar to the forma in NFPA 72 and NFPA 4.) The test procedures and accompanying test data forms must be used for the pre-Government testing and the Government testing. The test data forms must record the test results and must:

a. Identify the NFPA Class of all Initiating Device Circuits (IDC), and Notification Appliance Circuits (NAC), Voice Notification System Circuits (NAC Audio).

b. Identify each test required by NFPA 72 Test Methods and required test herein to be performed on each component, and describe how these tests must be performed.

c. Identify each component and circuit as to type, location within the facility, and unique identity within the installed system. Provide necessary floor plan sheets showing each component location, test location, and alphanumeric identity.

d. Identify all test equipment and personnel required to perform each test (including equipment necessary for smoke detector testing. The use of magnets is not permitted.
e. Provide space to identify the date and time of each test. Provide space to identify the names and signatures of the individuals conducting and witnessing each test.

3.8.2 Pre-Government Testing

3.8.2.1 Verification of Compliant Installation

Conduct inspections and tests to ensure that devices and circuits are functioning properly. Tests must meet the requirements of paragraph entitled "Minimum System Tests" as required by NFPA 72. The contractor and an authorized representative from each supplier of equipment must be in attendance at the pre-Government testing to make necessary adjustments. After inspection and testing is complete, provide a signed Verification of Compliant Installation letter by the QFPE that the installation is complete, compliant with the specification and fully operable. The letter must include the names and titles of the witnesses to the pre-Government tests. Provide all completion documentation as required by NFPA 72 including all referenced annex sections and the test reports noted below.

a. NFPA 72 Record of Completion.

b. NFPA 72 Record of Inspection and Testing.

d. Audibility test results with marked-up test floor plans.

e. Intelligibility test results with marked-up floor plans.

f. Documentation that all tests identified in the paragraph "Minimum System Tests" are complete.

3.8.2.2 Request for Government Final Test

When the verification of compliant installation has been completed, submit a formal request for Government final test to the [_____][Designated Fire Protection Engineer (DFPE)][Contracting Officer's Representative (COR)]. Government final testing will not be scheduled until the DFPE has received copies of the request for Government final testing and Verification of Compliant Installation letter with all required reports. Government final testing will not be performed until after the connections to the installation-wide fire reporting system and the installation-wide mass notification system have been completed and tested to confirm communications are fully functional. Submit request for test at least [15][_____] calendar days prior to the requested test date.

3.8.3 Correction of Deficiencies

If equipment was found to be defective or non-compliant with contract requirements, perform corrective actions and repeat the tests. Tests must be conducted and repeated if necessary until the system has been demonstrated to comply with all contract requirements.

3.8.4 Government Final Tests

The tests must be performed in accordance with the approved test procedures in the presence of the DFPE. Furnish instruments and personnel required
for the tests. The following must be provided at the job site for Government Final Testing:

a. The manufacturer's technical representative.

[b. The contractor's Qualified Fire Protection Engineer (QFPE).]

c. Marked-up red line drawings of the system as actually installed.

d. Loop resistance test results

e. Copy of pre-Government Test Certificate, test procedures and completed test data forms.

f. Audibility test results with marked-up floor plans.

g. Intelligibility test results with marked-up floor plans.

Government Final Tests will be witnessed by the [_____, Designated Fire Protection Engineer, Qualified Fire Protection Engineer (QFPE)]. At this time, any and all required tests noted in the paragraph "Minimum System Tests" must be repeated at their discretion.

3.9 MINIMUM SYSTEM TESTS

3.9.1 System Tests

Test the system in accordance with the procedures outlined in NFPA 72. The required tests are as follows:

a. Loop Resistance Tests: Measure and record the resistance of each circuit with each pair of conductors in the circuit short-circuited at the farthest point from the circuit origin. The tests must be witnessed by the Contracting Officer and test results recorded for use at the final Government test.

b. Verify the absence of unwanted voltages between circuit conductors and ground. The tests must be accomplished at the pre-Government test with results available at the final system test.

c. Verify that the control unit is in the normal condition as detailed in the manufacturer's O&M manual.

d. Test each initiating device and notification appliance and circuit for proper operation and response at the control unit. Smoke detectors must be tested in accordance with manufacturer's recommended calibrated test method. Use of magnets is prohibited. Testing of duct smoke detectors must comply with the requirements of NFPA 72 except disconnect at least 20 percent of devices. If there is a failure at these devices, then supervision must be tested at each device.

e. Carbon Monoxide Detector Tests: Carbon monoxide detectors must be tested in accordance with NFPA 72 and the manufacturer's recommended calibrated test method.

f. Test the system for specified functions in accordance with the contract drawings and specifications and the manufacturer's O&M manual.
g. Test both primary power and secondary power. Verify, by test, the secondary power system is capable of operating the system for the time period and in the manner specified.

h. Determine that the system is operable under trouble conditions as specified.

i. Visually inspect wiring.

j. Test the battery charger and batteries.

k. Verify that red-line drawings are accurate.

l. Measure the current in circuits to ensure there is the calculated spare capacity for the circuits.

m. Measure voltage readings for circuits to ensure that voltage drop is not excessive.

n. Measure the voltage drop at the most remote appliance (based on wire length) on each notification appliance circuit.

o. Verify the documentation cabinet is installed and contains all as-built shop drawings, product data sheets, design calculations, site-specific software data package, and all documentation required by paragraph titled "Test Reports".

3.9.2 Audibility Tests

Sound pressure levels from audible notification appliances must be a minimum of 15 dBa over ambient with a maximum of 110 dBa in any occupiable area. The provisions for audible notification (audibility and intelligibility) must be met with doors, fire shutters, movable partitions, and similar devices closed.

3.9.3 Intelligibility Tests

**************************************************************************
NOTE: Occasionally, large DoD buildings are designed to provide cavernous-type open areas to meet unique operational requirements. Such areas are typically designed with hard wall and ceiling surfaces (such as metal or concrete) without acoustical treatments, and this has been found to cause excessive sound reflections that prevent obtaining the normal, minimum required CIS value. In such facilities, the cavernous-type open area is permitted to have locations with a CIS value lower than the normal, minimum required CIS value when the following conditions are met:

The requirement for a deviation from the normal, minimum CIS criteria identified in the design phase.

Justification for the deviation from the normal, minimum CIS criteria is provided to the approving authority (i.e., the AHJ for the Navy and Marine Corps; the DoD installation in conjunction with the contracting officer for the Army and Air Force).
The justification must address all factors relevant to the request for deviation from normal, minimum CIS criteria, including, but not limited to: the operational requirements that restrict the installation of acoustical wall and ceiling treatments; the potential use of special speaker technologies such as directional speakers or stacked speaker systems; and, the availability of physically larger or higher-fidelity speakers even though such speakers might not be listed for fire alarm use.

Note: Deviation from normal, minimum CIS criteria should not be requested for the design of normal, large, open areas that are typically found in permanent DoD buildings, such as dining halls, theaters, and gymnasiums. The potential for deviation from normal criteria is intended to address the rare exception to normal criteria that is sometimes needed for DoD buildings with unique operational requirements.

Building occupants located in the large, cavernous area can adequately understand the message content in the voice signal being broadcast. Whether the voice message is adequately understood must be determined by the approving authority (i.e., the AHJ for the Navy and Marine Corps; the DoD installation in conjunction with the contracting officer for the Army and Air Force).

The CIS value is not less than 0.6 at any location within the large, cavernous area.

The building occupants in the large, cavernous area must walk no more than 30 m (98 feet) to find another location within the large, cavernous area having at least the normal, minimum required CIS value. Note: An STI score of 0.5 is considered equivalent to a CIS score of 0.7. An STI value of 0.7 is considered equivalent to a CIS value of 0.8.

All readings for Sound Pressure Level (SPL) and Intelligibility score must be recorded on the installation drawings next to the speaker symbol. The readings must then be added on the "as-Built" drawings to be submitted at the conclusion of the Final Government test.

Intelligibility testing of the System must be accomplished in accordance with NFPA 72 for Voice Evacuation Systems, and ASA S3.2. Following are the specific requirements for intelligibility tests:

a. Intelligibility Requirements: Verify intelligibility by measurement after installation.

NOTE: The minimum required value for Navy and Marine Corps is 0.7 CIS. The minimum required value for
Army and Air Force is 0.8 CIS, although rounding is permitted such that a value of 0.75 may be rounded to 0.8.

b. Ensure that a CIS value greater than the required minimum value is provided in each area where building occupants typically could be found. The minimum required value for CIS is [.7][.8]. Rounding of values is permitted.

NOTE: Edit the following paragraph as required for each specific project.

c. Areas of the building provided with hard wall and ceiling surfaces (such as metal or concrete) that are found to cause excessive sound reflections may be permitted to have a CIS score less than the minimum required value if approved by the DFPE, and if building occupants in these areas can determine that a voice signal is being broadcast and they must walk no more than 10 m 33 feet to find a location with at least the minimum required CIS value within the same area.

NOTE: Edit the following paragraph as required for each specific project.

d. Areas of the building where occupants are not expected to be normally present are permitted to have a CIS score less than the minimum required value if personnel can determine that a voice signal is being broadcast and they must walk no more than 15 m 50 feet to a location with at least the minimum required CIS value within the same area.

e. Take measurements near the head level applicable for most personnel in the space under normal conditions (e.g., standing, sitting, sleeping, as appropriate).

f. The distance the occupant must walk to the location meeting the minimum required CIS value must be measured on the floor or other walking surface as follows:

(1) Along the centerline of the natural path of travel, starting from any point subject to occupancy with less than the minimum required CIS value.

(2) Curving around any corners or obstructions, with a 300 mm 12 inches clearance there from.

(3) Terminating directly below the location where the minimum required CIS value has been obtained.

Use commercially available test instrumentation to measure intelligibility as specified by NFPA 72 as applicable. Use the mean value of at least three readings to compute the intelligibility score at each test location.

3.10 SYSTEM ACCEPTANCE

Following acceptance of the system, as-built drawings and O&M manuals must
be delivered to the Contracting Officer for review and acceptance. The drawings must show the system as installed, including deviations from both the project drawings and the approved shop drawings. These drawings must be submitted within two weeks after the final Government test of the system. At least one set of as-built (marked-up) drawings must be provided at the time of, or prior to the Final Government Test.

[a. The drawings must be prepared electronically and sized no less than the contract drawings.] [Furnish one set of CDs or DVDs containing software back-up and CAD based drawings in latest version of [MicroStation] [AutoCAD, ]DXF and portable document formats of as-built drawings and schematics.]

b. Include complete wiring diagrams showing connections between devices and equipment, both factory and field wired.

c. Include a riser diagram and drawings showing the as-built location of devices and equipment.

d. Provide Operation and Maintenance (O&M) Instructions.

[In existing buildings, the transfer of devices from the existing system to the new system and the permission to begin demolition of the old fire alarm system will not be permitted until the as-built drawings and O&M manuals are received.]

3.11 INSTRUCTION OF GOVERNMENT EMPLOYEES

3.11.1 Instructor

Provide the services of an instructor, who has received specific training from the manufacturer for the training of other persons regarding the operation, inspection, testing, and maintenance of the system provided. The instructor must train the Government employees designated by the Contracting Officer, in the care, adjustment, maintenance, and operation of the fire alarm system. The instructor must be thoroughly familiar with all parts of this installation. The instructor must be trained in operating theory as well as in practical O&M work. Submit the instructors information and qualifications including the training history.

3.11.2 Required Instruction Time

Provide [8][16][_____] hours of instruction after final acceptance of the system. The instruction must be given during regular working hours on such dates and times selected by the Contracting Officer. The instruction may be divided into two or more periods at the discretion of the Contracting Officer. The training must allow for rescheduling for unforeseen maintenance and/or fire department responses.

[3.11.2.1 Technical Training

Equipment manufacturer or a factory representative must provide [1][3][_____] days of on site[ and 5 days of technical training to the Government at the manufacturing facility]. Training must allow for classroom instruction as well as individual hands on troubleshooting and diagnostics exercises.[ Factory training must occur within [6][12][_____] months of system acceptance.]
3.11.3 Technical Training Manual

Provide, in manual format, lesson plans, operating instructions, maintenance procedures, and training data for the training courses. The operations training must familiarize designated government personnel with proper operation of the installed system. The maintenance training course must provide the designated government personnel adequate knowledge required to diagnose, repair, maintain, and expand functions inherent to the system.

3.12 EXTRA MATERIALS

3.12.1 Repair Service/Replacement Parts

Repair services and replacement parts for the system must be available for a period of 10 years after the date of final acceptance of this work by the Contracting Officer. During the warranty period, the service technician must be on-site within 24 hours after notification. All repairs must be completed within 24 hours of arrival on-site.

During the warranty period, the installing fire alarm contractor is responsible for conducting all required testing and maintenance in accordance with the requirements and recommended practices of NFPA 72 and the system manufacturer[s]. Installing fire alarm contractor is NOT responsible for any damage resulting from abuse, misuse, or neglect of equipment by the end user.

3.12.2 Spare Parts

Spare parts furnished must be directly interchangeable with the corresponding components of the installed system[s]. Spare parts must be suitably packaged and identified by nameplate, tagging, or stamping. Spare parts must be delivered to the Contracting Officer at the time of the Government testing and must be accompanied by an inventory list.

3.12.3 Document Storage Cabinet

Upon completion of the project, but prior to project close-out, place in the document storage cabinet copies of the following record documentation:

a. As-built shop drawings
b. Product data sheets
c. Design calculations
d. All documentation required by SD-06.

-- End of Section Table of Contents --
NOTE: This specification covers the requirements for an addressable integrated fire detection, fire alarm system.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

NOTE: For OCONUS projects, this specification section should be edited for specific Host Nation requirements. Coordinate compliance with Host Nation requirements with the Designated Fire Protection Engineer (DFPE).
NOTE: For Family Housing projects at NAVFAC NE use regional guide specification section 28 31 46.00 22 (N-13854N) HOUSEHOLD FIRE WARNING EQUIPMENT to specify residential fire warning systems in lieu of this section.

**************************************************************************
NOTE: This specification section includes requirements from UFC 3-600-01 (change 43, 7 February 2020)
**************************************************************************

NOTE: This guide specification covers carbon monoxide alarm detectors for protection in indoor locations where fuel-burning appliances/equipment are used.

**************************************************************************
PART 1   GENERAL
**************************************************************************

1. On the drawings, show location of control unit, batteries and charger (if remotely mounted), supervising station transmitter, annunciator, primary power supply, remote annunciator, detectors, notification appliances (unless performance requirements are specified), and each alarm initiating device including fire extinguishing system switches.

2. Show single-line fire alarm systems riser diagram. Each device on the riser should be identified by type. Indicate connection of equipment.

3. A fire alarm operating matrix must be placed on the drawings. Show actions of input devices such as detectors, manual stations, waterflow switches, initiating devices, etc. on one axis and output functions such as door releases, smoke control fans, elevator relays, indicating/notification appliances etc. on the other. Entries which require descriptions, explanation of processes, sequences, interfaces, etc. can be flagged by symbols keyed to supplementary notes. Alternately provide a zone-by-zone sequence of operation or a schedule identifying all initiators, outputs, and interfaces.

4. Addressable Fire Alarm Systems generally utilize Signal Line Circuits (SLC) for communication between devices. Normally all devices are addressable or will have an addressable interface device installed integrally with the device. Initiating Device Circuits (IDC) should be provided for interfacing to existing IDC loops or connection between non-addressable devices and the SLC.

**************************************************************************
1.1 REFERENCES

**************************************************************************
NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

[ Section 07 84 00 FIRESTOPPING for additional work related to firestopping.]

1.3 SUMMARY

1.3.1 Scope

a. This work includes designing and [providing a new, complete,][modifying the existing] fire alarm system as described herein and on the contract drawings[ for the ____________]. Include system wiring, raceways,
pull boxes, terminal cabinets, outlet and mounting boxes, control
equipment, initiating devices, notification appliances, supervising
station fire alarm transmitters, and other accessories and
miscellaneous items required for a complete operational system even
though each item is not specifically mentioned or described. Provide
system[s] complete and ready for operation.[ Existing interior fire
alarm system was manufactured by [______].] Design and installation
must comply with UFGS 25 05 11, UFC 4-010-06 and AFGM 2019-320-02.

b. Provide equipment, materials, installation, workmanship, inspection,
and testing in strict accordance with NFPA 72, except as modified
herein. [The system layout on the drawings show the intent of coverage
and suggested locations. Final quantity, system layout, and
coordination are the responsibility of the Contractor.]

c. Each remote fire alarm control unit must be powered from a wiring
riser specifically for that use or from a local emergency power panel
located on the same floor as the remote fire alarm control unit. Where
remote fire control units are provided, equipment for notification
appliances may be located in the remote fire alarm control units.]

d. Where a fire pump is provided, the fire alarm system must monitor and
transmit the fire pump controller signals in accordance with the
provisions of NFPA 72.]

e. Where an emergency generator provides standby power supply for life
safety system circuits, the generator must be monitored by the Fire
Alarm Control Unit (FACU) and transmit emergency generator signals in
accordance with NFPA 72.]

f. The fire alarm system must be independent of the building security,
building management, and energy/utility monitoring systems other than
for control functions.

1.3.2 Qualified Fire Protection Engineer (QFPE)

**************************************************************************

NOTE: UFC 3-600-01 requires that shop drawings must
bear the Review Stamp and professional engineering
stamp of the QFPE prior to submission to the
Government for approval.
**************************************************************************

**************************************************************************

NOTE: The term Qualified Fire Protection Engineer
(QFPE) should be considered interchangeable with the
terms "Fire Protection Designer of Record (FPDOR)"
and/or "Fire Protection QC Specialist" where
referred to in other applicable contract documents.
The intent of defining the QFPE roles and
responsibilities here is NOT to require personnel in
addition to the QFPE, FPDOR, and/or FPQC specialist
referred elsewhere in the applicable contract
documents.
**************************************************************************

Services of the QFPE must include:

a. Reviewing SD-02, SD-03, and SD-05 submittal packages for completeness
and compliance with the provisions of this specification. Construction (shop) drawings and calculations must be prepared by, or prepared under the immediate supervision of, the QFPE. The QFPE must affix their professional engineering stamp with signature to the shop drawings, calculations, and material data sheets, indicating approval prior to submitting the shop drawings to the DFPE.

b. Providing a letter documenting that the SD-02, SD-03, and SD-05 submittal package has been reviewed and noting any outstanding comments.

c. Performing in-progress construction surveillance prior to installation of ceilings (rough-in inspection).

e. Signing applicable certificates under SD-07.

1.4 DEFINITIONS

Wherever mentioned in this specification or on the drawings, the equipment, devices, and functions must be defined as follows:

1.4.1 Interface Device

An addressable device that interconnects hard wired systems or devices to an analog/addressable system.

1.4.2 Fire Alarm Control Unit (FACU)

A master control unit having the features of a fire alarm control unit (FACU).

1.4.3 Remote Fire Alarm Control Unit

A control unit, physically remote from the fire alarm control unit, that receives inputs from automatic and manual fire alarm devices; may supply power to detection devices and interface devices; may provide transfer of power to the notification appliances; may provide transfer of condition to relays or devices connected to the control unit; and reports to and receives signals from the fire alarm and mass notification control unit.

1.4.4 Terminal Cabinet

A steel cabinet with locking, hinge-mounted door where terminal strips are securely mounted inside the cabinet.

1.4.5 Control Module and Relay Module

Terms utilized to describe emergency control function interface devices as defined by NFPA 72.

1.4.6 Designated Fire Protection Engineer (DFPE)

The DoD fire protection engineer that oversees that Area of Responsibility for that project. This is sometimes referred to as the "cognizant" fire protection engineer. Interpret reference to "authority having jurisdiction" and/or AHJ in referenced standards to mean the Designated Fire Protection Engineer (DFPE). The DFPE may be responsible for review of
the contractor submittals having a "G" designation, and for witnessing final inspection and testing.

1.4.7 Qualified Fire Protection Engineer (QFPE)

A QFPE is an individual who is a licensed professional engineer (P.E.), who has passed the fire protection engineering written examination administered by the National Council of Examiners for Engineering and Surveying (NCEES) and has relevant fire protection engineering experience.

1.5 SUBMITTALS

**************************************************************************
NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES (or the particular specification section for submittal procedures in this project) and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G". Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.
**************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.]

Shop drawings (SD-02), product data (SD-03) and calculations (SD-05) must be prepared by the fire alarm designer and combined and submitted as one
complete package. The QFPE must review the SD-02/SD-03/SD-05 submittal package for completeness and compliance with the Contract provisions prior to submission to the Government. The QFPE must provide a Letter of Confirmation that they have reviewed the submittal package for compliance with the contract provisions. This letter must include their registered professional engineer stamp and signature. Partial submittals and submittals not reviewed by the QFPE will be returned by the Government disapproved without review.

Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

**SD-01 Preconstruction Submittals**

Qualified Fire Protection Engineer (QFPE); G[, [____]]

Fire alarm system designer; G[, [____]]

Supervisor; G[, [____]]

Technician; G[, [____]]

Installer; G[, [____]]

Test Technician; G[, [____]]

Fire Alarm System Site-Specific Software Acknowledgement; G[, [____]]

**SD-02 Shop Drawings**

Nameplates; G[, [____]]

Instructions; G[, [____]]

Wiring Diagrams; G[, [____]]

System Layout; G[, [____]]

Notification Appliances; G[, [____]]

Initiating devices; G[, [____]]

Battery Power; G[, [____]]

Voltage Drop Calculations; G[, [____]]

**SD-03 Product Data**

Fire Alarm Control Unit (FACU); G[, [____]]

Video Display Unit (VDU); G[, [____]]

LCD Annunciator; G[, [____]]

Manual Stations; G[, [____]]

Smoke Detectors; G[, [____]]
Duct Smoke Detectors; G[, [_____]]

Projected Beam Smoke Detector; G[, [_____]]

Air sampling smoke detectors; G[, [_____]]

Heat Detectors; G[, [_____]]

Flame Detectors; G[, [_____]]

Multi-Criteria Detectors; G[, [_____]]

Carbon monoxide detector; G[, [_____]]

Addressable Interface Devices; G[, [_____]]

Addressable Control Modules; G[, [_____]]

Isolation Modules; G[, [_____]]

Notification Appliances; G[, [_____]]

Batteries; G[, [_____]]

Battery Chargers; G[, [_____]]

Supplemental Notification Appliance Circuit Panels; G[, [_____]]

Auxiliary Power Supply Panels; G[, [_____]]

Surge Protective Devices; G[, [_____]]

Alarm Wiring; G[, [_____]]

Back Boxes and Conduit; G[, [_____]]

Ceiling Bridges for Ceiling-Mounted Appliances; G[, [_____]]

Terminal Cabinets; G[, [_____]]

Digital Alarm Communicator Transmitter (DACT); G[, [_____]]

Automatic Fire Alarm Transmitters (including housing); G[, [_____]]

Radio Transmitter and Interface Panels; G[, [_____]]

Electromagnetic Door Holders; G[, [_____]]

Environmental Enclosures or Guards; G[, [_____]]

Firefighter Telephone; G[, [_____]]

Printer; G[, [_____]]

Document Storage Cabinet; G[, [_____]]
1.6 SYSTEM OPERATION

**************************************************************************
NOTE: Circuit wiring must be Class "B" unless Class "A" or "X" is required by the local installation and as permitted by NFPA 72 (SLC: "A", "B", or "X"; IDC and NAC: "A" or "B").

Circuits and pathways must have survivability levels as defined by NFPA 72.
**************************************************************************

Fire alarm system components requiring power, except for the FACU(s) power supply, must operate on 24 volts DC unless noted otherwise in this section.

The interior fire alarm system must be a complete, supervised, noncoded, analog/addressable fire alarm system conforming to NFPA 72, and UL 864. Systems meeting UL 2017 only are not acceptable. The system must be activated into the alarm mode by actuation of an alarm initiating device. The system must remain in the alarm mode until the initiating device is reset and the control unit is reset and restored to normal.

1.6.1 Alarm Initiating Devices and Notification Appliances (Visual, Audible)

a. Connect alarm initiating devices to initiating device circuits (IDC) [Class "A"] [Class "B"], or to signaling line circuits (SLC) Class ["A"] ["B"] ["X"] and installed in accordance with NFPA 72.

b. Connect notification appliances to notification appliance circuits (NAC) [Class "A"] [Class "B"].
1.6.2 Functions and Operating Features

The system must provide the following functions and operating features:

a. Power, annunciation, supervision, and control for the system. Addressable systems must be microcomputer (microprocessor or microcontroller) based with a minimum word size of eight bits with sufficient memory to perform as specified.

b. Visual alarm notification appliances must be synchronized as required by NFPA 72.

c. Electrical supervision of the primary power (AC) supply, presence of the battery, battery voltage, and placement of system modules within the control unit.

d. An audible and visual trouble signal to activate upon a single break or open condition, or ground fault[ (or short circuit for Class "X")]. The trouble signal must also operate upon loss of primary power (AC) supply, absence of a battery supply, low battery voltage, or removal of alarm or supervisory control unit modules. After the system returns to normal operating conditions, the trouble signal must again sound until the trouble is acknowledged. A smoke detector in the process of being verified for the actual presence of smoke must not initiate a trouble condition.

e. A trouble signal silence feature that must silence the audible trouble signal, without affecting the visual indicator.

f. Program capability via switches in a locked portion of the FACU to bypass the automatic notification appliance circuits, [fire reporting system][air handler shutdown][smoke control operation][elevator recall][door release][door unlocking] features. Operation of this programmed action must indicate on the FACU display[ and printer output] as a supervisory or trouble condition.[ Notification appliance bypass must be selectable by floor.]

g. Alarm functions must override trouble or supervisory functions. Supervisory functions must override trouble functions.

h. The system must be capable of being programmed from the control unit keyboard. Programmed information must be stored in non-volatile memory.

i. The system must be capable of operating, supervising, and/or monitoring non-addressable alarm and supervisory devices.

j. There must be no limit, other than maximum system capacity, as to the number of addressable devices that may be in alarm simultaneously.

k. Where the fire alarm system is responsible for initiating an action in another emergency control device or system, such as [HVAC, ][atrium exhaust, ][smoke control, ][elevator recall, ][releasing service, ]the addressable fire alarm relay must be located in the vicinity of the emergency control device.

l. An alarm signal must automatically initiate the following functions:

   (1) Transmission of an alarm signal to [the fire department][a remote supervising station].
(2) Visual indication of the device operated on the FACU, [Video Display unit (VDU),] [and on the [graphic ]remote annunciator]. [Indication on the graphic annunciator must be by floor, zone or circuit, and type of device.]

(3) Record the event on the system printer.

(4) Actuation of alarm notification appliances.

(5) Recording of the event electronically in the history log of the FACU.

(6) Release of doors held open by electromagnetic devices.

(7) Operation of the [smoke control system][atrium exhaust system].

(8) Release of power to electric locks (delayed egress locks) on doors that are part of the means of egress.

(9) Elevator recall as described in this section.

**************************************************************************
NOTE: Use this paragraph only where a detector or detection system is to release a special fire extinguishing system.
**************************************************************************

(10) Operation of [_____] must release the [_____] fire extinguishing system after a [_____] second time delay.

(11) Operation of a sprinkler waterflow switch serving an elevator machinery room or elevator shaft must operate shunt trip circuit breaker(s) to shut down power to the elevators in accordance with ASME A17.1/CSA B44.

(12) Operation of an interface that operates vibrating pagers worn by hearing-impaired occupants.

m. A supervisory signal must automatically initiate the following functions:

(1) Visual indication of the device operated on the FACU, [Video Display unit (VDU),] [and on the [graphic ]remote annunciator]. [Indication on the graphic annunciator must be by floor, zone or circuit, and type of device.]

(2) Record the event on the system printer.

(3) Transmission of a supervisory signal to [the fire department][a remote supervising station].

(4) Operation of a duct smoke detector must shut down the appropriate air handler in accordance with NFPA 90A in addition to other requirements of this paragraph and as allowed by NFPA 72.

(5) Recording of the event electronically in the history log of the FACU.
n. A trouble condition must automatically initiate the following functions:

1. Visual indication of the device operated on the FACU, [Video Display unit (VDU),] [and on the [graphic ]][remote annunciator]. Indication on the graphic annunciator must be by floor, zone or circuit, and type of device.

2. Record the event on the system printer.

3. Transmission of a trouble signal to [the fire department][a remote supervising station].

4. Recording of the event electronically in the history log of the FACU.

o. Activation of a carbon monoxide alarm initiating device must automatically initiate the following functions:

1. Visual indication of the device operated on the ,[ LCD, LED Display unit (VDU),][ and on the [graphic ]][remote annunciator]. Indication on the graphic annunciator must be by floor and room number, device address, and device type.

2. Transmission of a carbon monoxide alarm signal to [the fire department][a remote supervising station].

3. Activation of all strobes and the carbon monoxide alarm signal throughout the building.

4. Recording of the event electronically in the history log of the FACU.

p. System control equipment must be programmed to provide a 60-minute to 180-minute delay in transmission of trouble signals resulting from primary power failure.

1.6.3 Elevator Recall

******************************************************************************
NOTE: Delete this paragraph if no elevator work is included in the project.
******************************************************************************

Provide elevator recall in accordance with ASME A17.1/CSA B44, Section [14 21 13 ELECTRIC TRACTION FREIGHT ELEVATORS][14 21 23 ELECTRIC TRACTION PASSENGER ELEVATORS][14 24 13 HYDRAULIC FREIGHT ELEVATORS][14 24 23 HYDRAULIC PASSENGER ELEVATORS], and as specified herein. Activation of any smoke detector in an elevator shaft, machine room, or lobby (except at designated recall level) must cause all elevators associated with that shaft, machine room, or lobby to return nonstop to the designated level. Activation of a smoke detector in the lobby or machine room at the designated level must cause all elevators associated with that lobby to return nonstop to the assigned alternate level. Activation of a detector in an elevator shaft, machine room, or lobby must also cause illumination of elevator cab warning signal (fire hat) and complete operation of fire alarm system as specified in paragraph titled "Functions and Operating Features".
1.7 TECHNICAL DATA AND SITE-SPECIFIC SOFTWARE

Technical data and site-specific software (meaning technical data that relates to computer software) that are specifically identified in this project, and may be required in other specifications, must be delivered, strictly in accordance with the CONTRACT CLAUSES. The fire alarm system manufacturer must submit written confirmation of this contract provision as "Fire Alarm System Site-Specific Software Acknowledgement". Identify data delivered by reference to the specification paragraph against which it is furnished. Data to be submitted must include complete system, equipment, and software descriptions. Descriptions must show how the equipment will operate as a system to meet the performance requirements of this contract. The site-specific software data package must also include the following:

a. Items identified in NFPA 72, titled "Site-Specific Software".

b. Identification of programmable portions of the system equipment and capabilities.

c. Description of system revision and expansion capabilities and methods of implementation detailing both equipment and software requirements.

d. Provision of operational software data on all modes of programmable portions for fire alarm.

e. Description of Fire Alarm Control Unit equipment operation.

f. Description of auxiliary and remote equipment operations.

g. Library of application software.

h. Operation and maintenance manuals.

1.8 EXISTING EQUIPMENT

**************************************************************************
NOTE: If an addition to an existing fire alarm system is required, the contract drawings or this section must include the make, model number, and other pertinent information of existing components that are to operate with the new equipment. Since new interfaces will have to be compatible with the existing system or to the central fire alarm reporting system, it may be necessary to edit major items out of this specification. If a new FACU is required, it has to be compatible with the existing central fire alarm reporting system. When an existing system is to be expanded, show the following information on the contract drawings:

1. Manufacturer and model of existing control unit.

2. Number of existing initiating circuits (zones), notification appliance circuits, and control circuits served by the control unit.

3. Number of existing alarm notification appliances on the system.
4. Total calculated current draw of all devices served by each existing standby battery under both supervisory (standby) and alarm conditions, including NAC/extender control units and subcontrol units.

5. Ampere-hour rating and type of each existing battery.

**************************************************************************

a. Equipment and devices must be compatible and operable with the existing fire alarm mass notification system and must not impair reliability or operational functions of existing supervising station fire alarm system. The proprietary type supervising station (PSS) is located [in Building [_____.][_____.][_____.]. The supervising equipment is existing and consists of the following brands and models: [supervising station control unit [_____.][_____.][signal reporting components [_____.]], [annunciator [_____.][_____.]].

b. Equipment and devices must be compatible and operable with the existing building fire alarm system. Equipment must not impair reliability or operational functions of the existing system. The existing building system control unit is [_____.].

1.9 QUALITY ASSURANCE

1.9.1 Submittal Documents

1.9.1.1 Preconstruction Submittals

Within 36 days of contract award but not less than [14 days][_____.] prior to commencing any work on site, the Contractor must submit the following for review and approval. SD-02, SD-03 and SD-05 submittals received prior to the review and approval of the qualifications of the fire alarm subcontractor and QFPE must be returned disapproved without review. All resultant delays must be the sole responsibility of the Contractor.

1.9.1.2 Shop Drawings

Shop drawings must not be smaller than [ISO A1][ANSI D][the Contract Drawings]. Drawings must comply with the requirements of NFPA 72 and NFPA 170. Minimum scale for floor plans must be 1/8"=1'.

1.9.1.3 Nameplates

Nameplate illustrations and data to obtain approval by the Contracting Officer before installation.

1.9.1.4 Wiring Diagrams

[_____.] copies of point-to-point wiring diagrams showing the points of connection and terminals used for electrical field connections in the system, including interconnections between the equipment or systems that are supervised or controlled by the system. Diagrams must show connections from field devices to the FACU and remote FACU, initiating circuits, switches, relays and terminals, including pathway diagrams between the control unit and shared communications equipment within the protected premises. Point-to-point wiring diagrams must be job specific and must not indicate connections or circuits not being utilized. Provide complete
riser diagrams indicating the wiring sequence of all devices and their connections to the control equipment. Include a color-code schedule for the wiring.

1.9.1.5 System Layout

[_____] copies of plan view drawing showing device locations, terminal cabinet locations, junction boxes, other related equipment, conduit routing, conduit sizes, wire counts, conduit fill calculations, wire color-coding, circuit identification in each conduit, and circuit layouts for all floors. Indicate candela rating of each visual notification appliance. Clearly identify the locations of isolation modules. Indicate the addresses of all devices, modules, relays, and similar. Indicate if the environment for the FACU is within its environmental listing (e.g. temperature/humidity).

Provide a complete description of the system operation in matrix format similar to the "Typical Input/Output Matrix" included in the Annex of NFPA 72.

[For air sampling smoke detection systems, provide floor plan layouts indicating location of fire alarm control unit, air sampling piping (lengths of pipe) and sampling ports (sizes and locations). Floor plan must also indicate geographic monitor zone boundaries, location of display control unit, bar level annunciation panels if separate, and all other associated equipment that is required to provide a complete operational system.]

1.9.1.6 Notification Appliances

Calculations and supporting data on each circuit to indicate that there is at least 25 percent spare capacity for notification appliances. Annotate data for each circuit on the drawings.

1.9.1.7 Initiating Devices

Calculations and supporting data on each circuit to indicate that there is at least [25][_____] percent spare capacity for initiating devices. Annotate data for each circuit on the drawings.

1.9.1.8 Battery Power

Calculations and supporting data as required in paragraph Battery Power Calculations for alarm, alert, and supervisory power requirements. Calculations including ampere-hour requirements for each system component and each control unit component, and the battery recharging period, must be included on the drawings.

1.9.1.9 Voltage Drop Calculations

Voltage drop calculations for each notification circuit indicating that sufficient voltage is available for proper operation of the system and all components, at a minimum rated voltage of the system operating on batteries. Include the calculations on the system layout drawings.

1.9.1.10 Product Data

[_____] copies of annotated descriptive data to show the specific model, type, and size of each item. Catalog cuts must also indicate the NRTL
listing. The data must be highlighted to show model, size, and options that are intended for consideration. Data must be adequate to demonstrate compliance with all contract requirements. Product data for all equipment must be combined into a single submittal.

Provide an equipment list identifying the type, quantity, make, and model number of each piece of equipment to be provided under this submittal. The equipment list must include the type, quantity, make and model of spare equipment. Types and quantities of equipment submitted must coincide with the types and quantities of equipment used in the battery calculations and those shown on the shop drawings.

[1.9.1.11 Air Sampling Smoke Detection System Calculations]

Submit air sampling detection system design analysis calculations consisting of battery capacity, loading calculations, and fan speed and air flow/transport calculations. Include schematic diagrams showing pipe segments, pipe diameters, lengths of pipe, node numbers, and sample port diameters to verify the requirements are met.

[1.9.1.12 Operation and Maintenance (O&M) Instructions]

[Six] copies of the Operation and Maintenance Instructions. The O&M Instructions must be prepared in a single volume or in multiple volumes, with each volume indexed, and may be submitted as a Technical Data Package. Manuals must be approved prior to training. The Interior Fire Alarm System Operation and Maintenance Instructions must include the following:

a. "Manufacturer Data Package [five]" as specified in [Section 01 78 23 OPERATION AND MAINTENANCE DATA].

b. Operating manual outlining step-by-step procedures required for system startup, operation, and shutdown. The manual must include the manufacturer's name, model number, service manual, parts list, and preliminary equipment list complete with description of equipment and their basic operating features.

c. Maintenance manual listing routine maintenance procedures, possible breakdowns and repairs, and troubleshooting guide. The manuals must include conduit layout, equipment layout and simplified wiring, and control diagrams of the system as installed.

d. Complete procedures for system revision and expansion, detailing both equipment and software requirements.

e. Software submitted for this project on CD/DVD media utilized.

f. Printouts of configuration settings for all devices.

g. Routine maintenance checklist. The routine maintenance checklist must be arranged in a columnar format. The first column must list all installed devices, the second column must state the maintenance activity or state no maintenance required, the third column must state the frequency of the maintenance activity, and the fourth column provided for additional comments or reference. All data (devices, testing frequencies, and similar) must comply with UFC 3-601-02.

h. A final Equipment List must be submitted with the Operating and
As-Built Drawings

The drawings must show the system as installed, including deviations from both the project drawings and the approved shop drawings. These drawings must be submitted within two weeks after the final Government test of the system. At least one set of the as-built (marked-up) drawings must be provided at the time of, or prior to the final Government test.

Qualifications

The National Institute for Certification in Engineering Technologies (NICET) establishes the qualifications of an individual as an Engineering Technologist with verification of experience by having a current NICET certification.

Fire Alarm System Designer

The fire alarm system designer must be certified as a Level III[IV] (minimum) Technician by National Institute for Certification in Engineering Technologies (NICET) in the Fire Alarm Systems subfield of Fire Protection Engineering Technology or meet the qualifications for a QFPE.

Supervisor

[A NICET Level III[ or ]IV] fire alarm technician must supervise the installation of the fire alarm system[, including the air sampling smoke detection system].[A fire alarm technician with a minimum of eight years of experience must supervise the installation of the fire alarm system.]

The fire alarm technicians supervising the installation of equipment must be factory trained in the installation, adjustment, testing, and operation of the equipment specified herein and on the drawings.

Technician

Fire alarm technicians with a minimum of four years of experience must be utilized to install and terminate fire alarm devices, cabinets and control units. The fire alarm technicians installing the equipment must be factory trained in the installation, adjustment, testing, and operation of the equipment specified herein and on the drawings[ and must be thoroughly experienced in the installation of air sampling detection systems].

Installer

[Fire alarm installer with a minimum of two years of experience utilized to assist in the installation of fire alarm devices, cabinets and control units] [NICET Level II technician to assist in the installation of fire alarm devices, cabinets and control units]. A licensed electrician must be allowed to install wire, cable, conduit and backboxes for the fire alarm system system. The fire alarm installer must be factory trained in the installation, adjustment, testing, and operation of the equipment specified herein and on the drawings.
1.9.2.5 **Test Technician**

Fire alarm technicians with a minimum of eight years of experience and NICET Level [III][ or ][IV] utilized in testing and certification of the installation of the fire alarm devices, cabinets and control units. The fire alarm technicians testing the equipment must be factory trained in the installation, adjustment, testing, and operation of the equipment installed as part of this project.

1.9.2.6 **Manufacturer**

Components must be of current design and must be in regular and recurrent production at the time of installation. Provide design, materials, and devices for a protected premises fire alarm system, complete, conforming to NFPA 72, except as specified herein.

1.9.3 **Regulatory Requirements**

Equipment and material must be listed or approved. Listed or approved, as used in this Section, means listed, labeled or approved by a Nationally Recognized Testing Laboratory (NRTL) such as UL Fire Prot Dir or FM APP GUIDE. The omission of these terms under the description of any item of equipment described must not be construed as waiving this requirement. All listings or approvals by testing laboratories must be from an existing ANSI or UL published standard. The recommended practices stated in the manufacturer's literature or documentation must be considered as mandatory requirements.

1.10 **DELIVERY, STORAGE, AND HANDLING**

Protect equipment delivered and placed in storage from the weather, humidity, and temperature variation, dirt and dust, and other contaminants.

1.11 **MAINTENANCE**

1.11.1 **Spare Parts**

Furnish the following spare parts in the manufacturers original unopened containers:

a. [Five][_____] complete sets of system keys.
b. [Two][_____] of each type of fuse required by the system.
c. [One][_____] manual stations.
d. [Two][_____] of each type of detector installed.]
e. [Two][_____] of each type of detector base and head installed.[

f. [One][_____] electromagnetic door holders.

g. One smoke detector manufacturer's test screen, card or magnet for each ten beam smoke detectors, or fraction thereof, installed in the system.

h. Two air sampling smoke detection system filter assemblies.
i. [Two][_____] of each type of audible and visual alarm device installed.
j. [Two][_____] of each type of addressable monitor module installed.

k. [Two][_____] of each type of addressable control module installed.

l. [Two][_____] low voltage, [one][_____] [telephone][internet][ethernet], and [one][_____] 120 VAC surge protective device.

[m. [Two][_____] spare reams of paper for the system printer, plus sufficient paper for testing.]

[n. [Two][_____] spare printer ribbons.]

1.11.2 Special Tools

Software, connecting cables and proprietary equipment, necessary for the maintenance, testing, and reprogramming of the equipment must be furnished to the Contracting Officer, prior to the instruction of Government employees.

PART 2 PRODUCTS

2.1 GENERAL PRODUCT REQUIREMENT

All fire alarm equipment must be listed for use under the applicable reference standards.

2.2 MATERIALS AND EQUIPMENT

2.2.1 Standard Products

Provide materials, equipment, and devices that have been tested by a nationally recognized testing laboratory and listed for fire protection service when so required by NFPA 72 or this specification. Select material from one manufacturer, where possible, and not a combination of manufacturers, for any particular classification of materials. Material and equipment must be the standard products of a manufacturer regularly engaged in the manufacture of the products for at least [2][_____] years prior to bid opening.

2.2.2 Nameplates

Major components of equipment must have the manufacturer's name, address, type or style, model or serial number, catalog number, date of installation, installing Contractor's name and address, and the contract number provided on a new name plate permanently affixed to the item or equipment. Major components include, but are not limited to, the following:

a. FACU

Nameplates must be etched metal or plastic, permanently attached by screws to control units or adjacent walls.

2.2.3 Keys

Keys and locks for equipment, control units and devices must be identical. [Master all keys and locks to a single key as required by the [Installation Fire Department][_____]]. [Keys must be CAT [60][_____]].
2.2.4 Instructions

Provide a typeset printed or typewritten instruction card mounted behind a Lexan plastic or glass cover in a stainless steel or aluminum frame. [Install the instructions on the interior of the FACU.][Install the frame in a conspicuous location observable from the FACU.] The card must show those steps to be taken by an operator when a signal is received as well as the functional operation of the system under all conditions, normal, alarm, supervisory, and trouble. The instructions and their mounting location must be approved by the Contracting Officer before being posted.

2.3 FIRE ALARM CONTROL UNIT

**************************************************************************
NOTE: The control unit must be located in an air conditioned space where the ambient temperature is maintained between 15 and 27 degrees C 60 and 80 degrees F.
**************************************************************************

Provide a complete fire alarm control unit (FACU) fully enclosed in a lockable steel cabinet as specified herein. Operations required for testing or for normal care, maintenance, and use of the system must be performed from the front of the enclosure. If more than a single unit is required at a location to form a complete control unit, the unit cabinets must match exactly.[ If more than a single unit is required, and is located in the lobby/entrance, notify the Contracting Officer's Designated Representative (COR), prior to installing the equipment.]

The system must be capable of defining any module as an alarm module and report alarm trouble, loss of polling, or as a supervisory module, and reporting supervisory short, supervisory open or loss of polling such as waterflow switches, valve supervisory switches, fire pump monitoring, independent smoke detection systems, relays for output function actuation.

  a. Each control unit must provide power, supervision, control, and logic for the entire system, utilizing solid state, modular components, internally mounted and arranged for easy access. Each control unit must be suitable for operation on a 120 volt, 60 hertz, normal building power supply. Provide each control unit with supervisory functions for power failure, internal component placement, and operation.

  b. Visual indication of alarm, supervisory, or trouble initiation on the FACU must be by liquid crystal display or similar means with a minimum of 80 characters.

2.3.1 Cabinet

Install control unit components in cabinets large enough to accommodate all components and also to allow ample gutter space for interconnection of control units as well as field wiring. The cabinet must be a sturdy steel housing, complete with back box, hinged steel door with cylinder lock, and [surface][semi-recessed] mounting provisions. The enclosure must be identified by an engraved phenolic resin nameplate. Lettering on the nameplate must say "Fire Alarm control unit" and must not be less than 25 mm 1-inch high. Provide prominent rigid plastic or metal identification plates for lamps, circuits, meters, fuses, and switches.
2.3.2 Silencing Switches

2.3.2.1 Alarm Silencing Switch

Provide an alarm silencing switch at the FACU that must silence the audible and visual notification appliances. Subsequent activation of initiating devices must cause the notification appliances to re-activate.

2.3.2.2 Supervisory/Trouble Silencing Switch

Provide supervisory and trouble silencing switch(es) that must silence the audible trouble and supervisory signal(s), but not extinguish the visual indicator. This switch must be overridden upon activation of a subsequent supervisory or trouble condition. Audible trouble indication must resound automatically every 24 hours after the silencing feature has been operated if the supervisory or trouble condition still exists.

2.3.3 Non-Interfering

Power and supervise each circuit such that a signal from one device does not prevent the receipt of signals from any other device. Initiating devices must be manually reset by switch from the FACU after the initiating device or devices have been restored to normal.

2.3.4 Memory

Provide each control unit with non-volatile memory and logic for all functions. The use of long life batteries, capacitors, or other age-dependent devices must not be considered as equal to non-volatile processors, PROMS, or EPROMS.

2.3.5 Field Programmability

Provide control units and control units that are fully field programmable for both input and output of control, initiation, notification, supervisory, and trouble functions. The system program configuration must be menu driven. System changes must be password protected. Any proprietary equipment and proprietary software needed by qualified technicians to implement future changes to the fire alarm system must be provided as part of this contract.

2.3.6 Input/Output Modifications

The FACU must contain features that allow the bypassing of input devices from the system or the modification of system outputs. These control features must consist of a control unit mounted keypad[ and a keyboard]. Any bypass or modification to the system must indicate a trouble condition on the FACU.

2.3.7 Resetting

Provide the necessary controls to prevent the resetting of any alarm, supervisory, or trouble signal while the alarm, supervisory or trouble condition on the system still exists.

2.3.8 Walk Test

The FACU must have a walk test feature. When using this feature, operation of initiating devices must result in limited system outputs, so that the
notification appliances operate for only a few seconds and the event is indicated in the history log[ and on the system printer], but no other outputs occur.

2.3.9 History Logging

The control unit must have the ability to store a minimum of 400 events in a log. These events must be stored in a battery-protected memory and must remain in the memory until the memory is downloaded or cleared manually. Resetting of the control unit must not clear the memory.

2.3.10 Manual Access

An operator at the control unit, having a proper access level, must have the capability to manually access the following information for each initiating device.

a. Primary status.
b. Device type.
c. Present average value.
d. Present sensitivity selected.
e. Detector range (normal, dirty).

[2.3.11 Heat Detector Self-Test Routines

Automatic self-test routines must be performed on each detector that will functionally check detector sensitivity electronics and ensure the accuracy of the value being transmitted. Any detector that fails this test must indicate a trouble condition with the detector location at the control unit.

][2.4 VIDEO DISPLAY UNIT (VDU)

**************************************************************************
NOTE: Contact the DFPE to determine if a VDU is to be provided.
**************************************************************************

a. The VDU must be the secondary operator-to-system interface for data retrieval, alarm annunciation, commands, and programming functions. The desk mounted VDU must consist of a LCD monitor and a keyboard. The VDU must have a [300][430][____]-mm [12][17][____]-inch minimum [touch ] screen, capable of displaying 25 lines of 80 characters each. Communications with the FACU must be supervised. Faults must be recorded in the history log[ and on the printer]. Power required must be 120 VAC, 60 Hz from the same source as the FACU.

b. To eliminate confusion during an alarm situation, the screen must have dedicated areas for the following functions:

(1) Alarm and return to normal.

(2) Commands, reports, and programming.

(3) Time, day, and date.
c. Use full English language throughout to describe system activity and instructions. Full English language descriptors defining system points must be 100 percent field programmable by factory trained personnel, alterable and user definable to accurately describe building areas.

d. Alarms and other changes of status must be displayed in the screen area reserved for this information. Upon receipt of alarm, an audible alarm must sound and the condition and point type must flash until acknowledged by the operator. Return to normal must also be annunciated and must require operator acknowledgment. The following information must be provided in full English:

   (1) Condition of device (alarm, trouble, or supervisory).
   (2) Type of device (for example, manual pull, waterflow)
   (3) Location of device plus numerical system address.

e. The system must have multiple levels of priority for displaying alarms to conform with UL 864. Priority levels must be as follows:

   (1) Level 1 - Fire Alarms Signals
   (2) Level 2 - Supervisory Signals
   (3) Level 3 - Carbon Monoxide Alarm Signals
   (4) Level 4 - Trouble Signals

f. Provide the system with memory so that no alarm is lost. A highlighted message must advise the operator when unacknowledged alarms are in the system.

g. Multiple levels of access must be provided for operators and supervisors via user-defined passwords. Provide the following functions for each level:

   (1) Operator level access functions:
      
      (a) Display system directory, definable by device.
      (b) Display status of an individual device.
      (c) Manual command (alarm device with an associated command must use the same system address for both functions).
      (d) Report generation, definable by device, output on the VDU[ or printer], as desired by the operator.
      (e) Activate building notification appliances.

   (2) Supervisor level access functions:
      
      (a) Reset time and date.
      (b) Enable or disable event initiated programs[, printouts,] and initiators.
      (c) Enable or disable individual devices and system components.
h. The above supervisor level functions must not require computer programming skills. Changes to system programs must be [recorded on the printer and ] maintained in the control unit as a trouble condition.

2.5 REMOTE ANNUNCIATOR

**************************************************************************
NOTE: Provide the annunciator at a location in accordance with NFPA 72. A suggested location should be near the door through which the first responders will enter the building as indicated in their pre-fire plan, typically the main entrance.
**************************************************************************

2.5.1 LCD Annunciator

Provide a [semi-recessed][flush] mounted annunciator that includes an LCD display. The display must indicate the device in trouble/alarm or any supervisory device. Display the device name, address[, and actual building location].

A building floor plan must be provided and mounted (behind Plexiglass or similar protective material) at the annunciator location. The floor plan must indicate all rooms by name and number including the locations of stairs and elevators. The floor plan must show all devices and their programmed address to facilitate identification of their physical location from the LCD display information.

2.5.2 Graphic Annunciator

**************************************************************************
NOTE: Graphic annunciators should be provided only when a large number of concealed devices are installed. Normally, exposed devices will be annunciated by zone only on the fire alarm control unit zone annunciator and remote zone annunciator. Edit accordingly. Locate graphic annunciator(s) at or near building entrance to allow fire department quick access to the annunciator.
**************************************************************************

Graphic annunciator must be of the [interior][weatherproof] type, [flush][surface][pedestal]-mounted. Annunciator must be provided with the [building][room] floor plan, drawn to scale, with alarm lamps mounted to represent the location of [each concealed detector][each initiating device]. Annunciator graphic must also show the locations of the annunciator and control unit, and must have a "you are here" arrow showing its location. Orient building floor plan on graphic to location of person viewing the graphic(i.e., the direction the viewer is facing must be toward the top of the graphic display). Provide a North arrow.[ Principal rooms and areas shown must be labeled with room numbers or titles.] Detectors mounted above ceilings, [on ceilings, ] and beneath raised floors and different types of initiating devices must have different symbols or lamps of different colors for identification. Lamps must illuminate upon activation of corresponding device and must remain illuminated until the system is reset. Annunciator must have a lamp test switch.
2.5.2.1 Materials

Construct the graphic annunciator face plate of [smoked Plexiglas][non-glare matte finish][anodized bronze][anodized aluminum]. The face plate must be backlit with LEDs. Control equipment and wiring must be housed in a [recessed][semi-recessed][surface mounted] back box. The exposed portions of the back box must be [chrome plated][anodized bronze][anodized aluminum] without knockouts.

2.5.2.2 Programming

Where programming for the operation of the graphic annunciator is accomplished by a separate software program other than the software for the FACU, the software program must not require reprogramming after loss of power. The software must be reprogrammable in the field.

2.5.3 Printer

**************************************************************************
NOTE: If the printer will be located in a SCIF or similar area, specify "no stored memory".
**************************************************************************

a. Provide a system printer [with no stored memory] to record alarm, supervisory, and trouble conditions without loss of any signal or signals. Printout must be by circuit, device, and function as provided in the FACU. Printer must operate on a 120 VAC, 60 Hz power supply.

b. The printer must have at least 80 characters per line and have a 96 ASCII character set. The printer must have a microprocessor-controlled, bi-directional, logic seeking head capable of printing 120 characters per second utilizing a 9 by 7 dot matrix print head. Printer must not contain internal software which is essential for proper operation.

c. When the FACU receives a signal, the alarm, supervisory, and trouble condition must be printed. The printout must include the type of signal, the circuit or device reporting, the date, and the time of the occurrence. The printer must differentiate alarm signals from other printed indications. When the system is reset, this condition must also be printed including the same information concerning device, location, date, and time. Provide a means to automatically print a list of existing alarm, supervisory, and trouble conditions in the system. If a printer is off-line when an alarm is received, the system must have a buffer to retain the data and it must be printed when the printer is restored to service. The printer must have an indicator to alert the operator that the paper has run out.

2.6 MANUAL STATIONS

**************************************************************************
NOTE: Architectural Barriers Act (ABA) requires that manual alarm stations be mounted at a maximum of 1.1 m 44 inches above finished floor (AFF).
**************************************************************************

Provide metal or plastic, [semi-flush][flush][surface] mounted, [single][double]-action, addressable manual stations, that are not subject to operation by jarring or vibration. Stations must be equipped with screw terminals for each conductor. Stations that require the replacement of any
portion of the device after activation are not permitted. Stations must be finished in red with molded raised lettering operating instructions of contrasting color. The use of a key must be required to reset the station.

2.7 **SMOKE DETECTORS**

**************************************************************************

**NOTE:** Provide smoke detectors only in spaces where they are specifically required by UFC 3-600-01, DESIGN: FIRE PROTECTION ENGINEERING FOR FACILITIES.

Smoke detectors provided in elevator machinery rooms are to be provided per requirements of UFC 3-600-01. Coordinate with Section 14 21 13 ELECTRIC TRACTION FREIGHT ELEVATORS, Section 14 21 23 ELECTRIC TRACTION PASSENGER ELEVATORS and/or Section 14 24 13 HYDRAULIC FREIGHT ELEVATORS, Section 14 24 23 HYDRAULIC PASSENGER ELEVATORS.

**************************************************************************

2.7.1 **Spot Type Detectors**

Provide addressable [photoelectric][ionization][laser] smoke detectors as follows:

a. Provide analog/addressable [photoelectric smoke detectors utilizing the photoelectric light scattering principle for operation in accordance with UL 268][smoke detectors that operate on the ionization principle and are actuated by the presence of visible or invisible products of combustion][laser smoke detectors utilizing laser diode and patented smoke sensing chamber, designed to amplify signals from smoke but diminish stray internal reflections and must, on command from the FACU, send data to the control unit representing the analog level of smoke density]. Smoke detectors must be listed for use with the FACU.

b. Provide self-restoring type detectors that do not require any readjustment after actuation at the FACU to restore them to normal operation. The detector must have a visual indicator to show actuation.

c. Vibration must have no effect on the detector's operation. Protect the detection chamber with a fine mesh metallic screen that prevents the entrance of insects or airborne materials. The screen must not inhibit the movement of smoke particles into the chamber.

d. Provide twist lock bases [with sounder that produces a minimum of 90 dBA at 3 m (10 feet)] with screw terminals for each conductor. The detectors must maintain contact with their bases without the use of springs.

e. The detector address must identify the particular unit, its location within the system[,] and its sensitivity setting]. Detectors must be of the low voltage type rated for use on a 24 VDC system.

f. Laser smoke detector must be listed for use with the FACU. Detector must be able to achieve sensitivities from 0.02 percent-per-foot to 2 percent-per-foot obscuration.

g. Laser smoke detector must provide point identification of the fire location through addressability, must experience no delay in response
time due to smoke dilution or smoke transportation time, and must offer complete supervision of wiring and detector.]

[2.7.2 Projected Beam Smoke Detector

Detectors must consist of [combined transmitter and receiver unit] [separate transmitter and receiver units]. The transmitter unit must emit an infrared beam to the receiver unit [the use of a supplied reflector is required for the combined unit]. When the signal at the receiver falls below a preset threshold, the detector must initiate an alarm. The receiver must contain an LED status indicator that illuminates when an alarm condition exists. Long-term changes to the received signal caused by environmental variations must be automatically compensated. Detectors must incorporate features to assure that they are operational; a trouble signal must be initiated if the beam is obstructed for more than 3 seconds, the limits of the compensation circuit are reached, or the housing cover is removed. Detectors must have multiple sensitivity settings in order to meet UL listings for the different distances covered by the beam.

[2.7.3 Duct Smoke Detectors

**************************************************************************
NOTE: The requirements for Duct Detectors will be coordinated with the HVAC requirements and Sections 23 09 00 INSTRUMENTATION AND CONTROL FOR HVAC. All required duct detectors will be shown on the contract drawings.
**************************************************************************

Duct-mounted addressable photoelectric smoke detectors must consist of a smoke detector, as specified in paragraph Spot Type Detectors, mounted in a special housing fitted with duct sampling tubes. Detector circuitry must be mounted in a metallic or plastic enclosure exterior to the duct. It is not permitted to cut the duct insulation to install the duct detector directly on the duct. Detectors must be listed for operation over the complete range of air velocities, temperature and humidity expected at the detector when the air-handling system is operating. Detectors must be powered from the FACU.

a. Sampling tubes must run the full width of the duct. The duct detector package must conform to the requirements of NFPA 90A, UL 268A, and must be listed for use in air-handling systems. The control functions, operation, reset, and bypass must be controlled from the FACU.

b. Lights to indicate the operation and alarm condition must be visible and accessible with the unit installed and the cover in place. Remote indicators must be provided where required by NFPA 72. Remote indicators as well as the affected fan units must be properly identified in etched plastic placards.

c. Detectors must provide for control of auxiliary contacts that provide control, interlock, and shutdown functions specified in Section 23 09 00 to INSTRUMENTATION AND CONTROL FOR HVAC. Auxiliary contacts provide for this function must be located within 1 m 3 feet of the controlled circuit or appliance. The auxiliary contacts must be supplied by the fire alarm system manufacturer to ensure complete system compatibility.
2.8 AIR SAMPLING SMOKE DETECTION SYSTEM

The addressable air sampling smoke system must consist of a detector assembly housing an integral aspiration fan, filter, laser-based detection chamber and control, output and supervision circuitry. Each sampling point must be capable of being independently addressable. The system must consist of a piping or tubing distribution network that runs from the detector assembly(s) to the protected area(s) and is supported by air sampling smoke detection system calculations from a computer-based design modeling tool. The system must include configurable alarm and trouble relay outputs for interface to other systems where required.

a. System must be complete in all ways. It must include all engineering, and electrical installation, all detection and control equipment, auxiliary devices and controls, alarm interface, functional checkout and testing, training and all other operations necessary for a functional system.

b. System base detectors and modules must each accommodate up to [40 addressable] microbore sampling tubes where each tube has a sampling point at the end. Additional modules may be used to provide up to [20 addressable] sampling holes per system.

c. Program alarm thresholds to the following values unless the results of the pre-Government system tests indicate a clear need to change them. In the event that such a need is indicated, notify the Contracting Officer and provide complete documentation concerning the need to deviate from these values. Include within the deviation documentation request, information that complies with the paragraph entitled "Sensitivity Verification Test". Ensure initial threshold levels are approved prior to the Government test.

(1) Alarm Level 1: set ALERT at [0.0250] percent obscuration/foot

(2) Alarm Level 2: set PRE-ALARM at [0.0500] percent obscuration/foot

(3) Alarm Level 3: set FIRE 1 at [0.1000] percent obscuration/foot

(4) Alarm Level 4: set FIRE 2 at [0.2000] percent obscuration/foot

d. All air sampling smoke detection devices and associated components must be new, standard products or the manufacturer's latest design and suitable to perform the functions intended.

e. The laser detection chamber must be of the mass light scattering type and capable of detecting a wide range of smoke particle types of varying size. A particle counting method must be employed for the purposes of:

(1) Preventing large particles from affecting the true smoke reading.

(2) Monitoring contamination of the filter (for example, dust and dirt) to automatically notify when maintenance is required. The particle counting method must not be used for the purpose of smoke density measurement.
f. Detector(s) must be self-monitoring for filter contamination and provide indication through system fault when replacement is necessary. Detectors which allow automatic reset of filter status upon removal and re-insertion are not permitted.

g. Detector(s) must contain relays for alarm and fault conditions. The relays must be software programmable to the required functions.

h. Detector(s) must permit configuration by programmers that are either integral to the system, portable or PC based.

i. Detector(s) must allow programming of:

1. Smoke threshold alarm levels; ALERT, PRE-ALARM, FIRE 1 and FIRE 2.

2. Time delays. Ensure the display control unit contains individual adjustable alarm time delay features for each of the alarm threshold levels. Provide an adjustment range between 0 and 60 seconds. Program the alarm threshold time delays to 30 seconds for alarm levels 1 and 2, and 15 seconds for alarm levels 3 and 4.

3. Faults, including airflow, detector, power, filter and network, as well as an indication of the urgency of the fault.

4. Configuration of relay outputs for remote indication of alarm and fault conditions.

5. General purpose input functionality.

2.9 HEAT DETECTORS

***********************************************************************
NOTE: Heat detectors provided in elevator machinery rooms are strictly for the warning sign in the elevator cab and must not alarm the FACU. Coordinate with Section 14 21 13 ELECTRIC TRACTION FREIGHT ELEVATORS, Section 14 21 23 ELECTRIC TRACTION PASSENGER ELEVATORS and/or Section 14 24 13 HYDRAULIC FREIGHT ELEVATORS, Section 14 24 23 HYDRAULIC PASSENGER ELEVATORS.
***********************************************************************

2.9.1 Heat Detectors

Heat detectors must be analog/addressable and designed for detection of fire by [fixed temperature][combination fixed temperature and rate-of-rise principle][rate-compensating principle] in accordance with UL 521. The alarm condition must be determined by comparing detector value with the stored values.. Detectors located in areas subject to moisture, exterior atmospheric conditions, or hazardous locations [as defined by NFPA 70][ and ][as indicated], must be types approved for such locations.

[2.9.1.1 Combination Fixed-Temperature and Rate-of-Rise Detectors

Detectors must be [surface][semi-flush] mounted in the [vertical][horizontal] orientation and supported independently of wiring connections. Detectors must be self-resetting. Detector must operate at [57.2][90] degrees C[135][194] degrees F. Detector must feature rate
compensation. [Detectors rated to operate at 57.2 degrees C 135 degrees F must not respond to momentary temperature fluctuations less than 16.7 degrees C per minute between 16 and 38 degrees C 60 and 100 degrees F.][ Detectors rated to operate at 90 degrees C 194 degrees F must not respond to momentary temperature fluctuations less than 27.8 degrees C 50 degrees F per minute between 16 and 66 degrees C 60 and 150 degrees F.][ The detector assembly must be [weatherproof][ and ][explosionproof].]

][2.9.1.2 Rate Compensating Detectors

Detector backbox must be [surface][flush] mounted in the [vertical][horizontal] orientation and supported independently of wiring connections. Detectors must be self-restoring and hermetically sealed.[ The detector assembly must be [weatherproof][ and ][explosionproof].]

][2.9.1.3 Line-Type Fixed Temperature Detectors

**************************************************************************
**NOTE: Specify line-type heat detectors only with approval of the EFD/EFA Fire Protection Engineer.**************************************************************************

Provide [thermostatic][ or ][thermistor] line-type heat detection cable [with weather-resistant outer covering] where indicated. Cable must be nominally rated for a temperature of [68][88][138] degrees C [155][190][280] degrees F and must operate on fixed temperature principle only.

][2.9.1.4 Fixed Temperature Detectors

Detectors must be [surface][semi-flush] mounted in the [vertical][horizontal] orientation and supported independently of wiring connections. Detectors must be self-restoring. The detectors must have a specific temperature setting [of [57.2][_____] degrees C [135][_____] degrees F][as shown].[ The detector assembly must be [weatherproof][ and ][explosionproof].]

][2.10 FLAME DETECTORS

**************************************************************************
**NOTE: Modify these paragraphs as necessary to indicate that detectors placed in an explosive environment will be approved for use in the appropriate class, division, and group environment as defined in NFPA 70 and as shown on drawings.**************************************************************************

Detectors must be sensitive to the micron range best suited for their intended use. Detectors must operate over electrically supervised wiring circuits and the loss of power to the detector must result in a trouble signal. A self-test feature must be provided for each detector to be individually tested.

[2.10.1 Infrared (IR) Single Frequency Flame Detector

**************************************************************************
**NOTE: The single frequency IR flame detector has the advantage of a fast response and is moderately sensitive. Its disadvantages are being affected by

SECTION 28 31 70 Page 36
temperature extremes and being subject to false alarms from a myriad of IR sources.

The detector must be sensitive in the range of [_____] to [_____] micrometers only.

][2.10.2 Infrared (IR) Multi Frequency Flame Detector

**************************************************************************

NOTE: The IR multi frequency flame detector has the advantages of a moderately fast response, moderate sensitivity, and a lower false alarm rate. Its disadvantage is being affected by temperature extremes.

**************************************************************************

The IR detector must consist of three or more IR sensors, each selected for a different IR frequency. The primary sensor must be sensitive in the range of [_____] to [_____] micrometers only. Secondary sensors are tuned to different IR wavelengths to null out the effect of black body radiation to the primary sensor.

][2.10.3 Ultraviolet (UV) Flame Detectors

**************************************************************************

NOTE: Ultraviolet (UV) flame detectors can be set to respond accurately to UV wavelength light produced by flame from both indoors and outdoors. UV flame detectors operate on the Geiger-Muller principle. These gas-filled vacuum tubes respond in the UV portion of the spectrum but can ignore UV radiation from the sun because the upper response range of the detector falls below the range of UV radiation that reaches the earth.

Solid-state UV detectors are available, but their spectral response extends into the sun's UV range and are not recommended for external use.

UV detectors have an 80 to 90 degree cone of vision. The UV detector has a fast response time and usually is not affected by rain, wind, snow, high humidity, or temperature and pressure extremes. UV units will produce false alarms if they are exposed to arc welding or X-ray and gamma radiation. They can also be blinded by oil film or smoke. UV flame detectors that are used in dirty and dusty environments should be equipped with automatic self-test and self-cleaning devices. The cleaning device uses a stream of clean air across the lens surface to minimize the build-up of contaminants.

**************************************************************************

UV flame detector must be of the narrow band response type which operates on radiated ultraviolet energy and must be sensitive in the range of [_____] to [_____] micrometers only. The cone of vision must be 80 degrees or greater. Each detector must be completely insensitive to light sources
in the visible frequency range.

][2.10.4 Combination UV/IR Flame Detector

******************************************************************************
NOTE: Combination UV/IR flame detectors have been used both inside and outside to detect fires, but are slower to react than individual units.
******************************************************************************

The UV/IR detector must provide discrimination against false alarms by requiring both UV and IR flame detection before an alarm is sent. The UV sensor must be sensitive in the range of 0.185 to 0.265 micrometers only. The IR sensor must be sensitive in the range of [_____] to [_____] micrometers only. Detectors must be completely insensitive to light sources in the visible frequency range.

][2.11 MULTI-CRITERIA DETECTORS

******************************************************************************
The designer must select the sensor required to initiate a fire alarm condition.
******************************************************************************

Multi-criteria detectors must contain [fixed temperature [_____] degrees C F heat sensor], [rate-of-rise heat sensor], [photoelectric smoke detector], [_____] elements in a single housing.

}][2.12 CARBON MONOXIDE DETECTOR

Analog/addressable carbon monoxide (CO) detectors must be listed to UL 2075 and set to respond to the sensitivity limits of UL 2034. Carbon monoxide detectors must be listed for use with fire alarm control units. Detectors must be [surface] [semi-flush] mounted in the [vertical][horizontal] orientation and supported independently of wiring connections. Detectors must be self-restoring. For FACU with no listed compatible addressable CO detectors, provide listed 4-wire detectors.[ Do not provide CO detectors with local alarms.] Detector must be provided with an LED status indicator.

a. Where 4-wire CO detectors are necessary, each 4-wire CO detector must be individually monitored via addressable interface modules for alarm and off normal/trouble conditions (including loss of power to the individual detector). Power circuits for 4-wire CO detectors must be dedicated to powering the CO detectors only. Battery powered and 120 VAC powered detectors are prohibited.

b. Wiring connections must be made by means of screw terminals and detectors must be equipped with trouble relays. Detectors must be able to mount a single-gang electrical box.

c. A trouble condition at an individual CO detector must not affect any other CO detectors. CO detectors must be powered by the FACU.

d. Detectors must be provided with a means to test CO gas entry into the CO sensing cell.

2.13 ADDRESSABLE INTERFACE DEVICES

The initiating device being monitored must be configured as a [Class
"A"] [Class "B"] initiating device circuits. The module must be listed as compatible with the control unit. The module must provide address setting means compatible with the control unit's SLC supervision and store an internal identifying code. Monitor module must contain an integral LED that flashes each time the monitor module is polled and is visible through the device cover plate. Pull stations with a monitor module in a common backbox are not required to have an LED. [Existing fire alarm system initiating device circuits must be connected to a single module to supervise the circuit.] Modules must be listed for the environmental conditions in which they will be installed.

2.14 ADDRESSABLE CONTROL MODULES

The control module must be capable of operating as a relay (dry contact form C) for interfacing the control unit with other systems, and to control door holders or initiate elevator fire service. The module must be listed as compatible with the control unit. The indicating device or the external load being controlled must be configured as [Class B][Class A] notification appliance circuits. The system must be capable of supervising, audible, visual and dry contact circuits. The control module must have both an input and output address. The supervision must detect a short on the supervised circuit and must prevent power from being applied to the circuit. The control model must provide address setting means compatible with the control unit's SLC supervision and store an internal identifying code. The control module must contain an integral LED that flashes each time the control module is polled and is visible through the device cover plate. Control Modules must be listed for the environmental conditions in which they will be installed.

2.15 ISOLATION MODULES

a. Provide isolation modules to subdivide each signaling line circuit into groups of not more than [20 addressable devices][___] [each floor][in accordance with NFPA 72] between adjacent isolation modules.

b. Isolation modules must provide short circuit isolation for signaling line circuit wiring.

c. Power and communications must be supplied by the SLC and must report faults to the FACU.

d. After the wiring fault is repaired, the fault isolation modules must test the lines and automatically restore the connection.

2.16 NOTIFICATION APPLIANCES

2.16.1 Audible Notification Appliances

******************************************************************************
NOTE: The designer must layout speakers to achieve both the required dBA levels requires by NFPA 72.

NOTE: Where horns or bells are used for fire alarm notification, calculate the proper locations for these devices as detailed in "Designing Fire Alarm Audibility," which is contained in the Society of Fire Protection Engineers (SFPE) Handbook of Fire Protection Engineering. Submit the calculations at the 35-percent design review.

SECTION 28 31 70 Page 39
Audible appliances must conform to the applicable requirements of UL 464. Appliances must be connected into notification appliance circuits. Surface mounted audible appliances must be painted [red][white][____]. Recessed audible appliances must be installed with a grill that is painted [red][white][____][with a factory finish to match the surface to which it is mounted].

2.16.1.1 Horns

Horns must be [semi-flush mounted][surface-mounted, with the matching mounting backbox surface mounted vibrating type suitable for use in an electrically supervised circuit]. Horns must produce a sound rating of at least 85 dBA at 3.1 meters 10 feet. Horns used in exterior locations must be specifically listed or approved for outdoor use and be provided with metal housing and protective grilles. Horns must be [weatherproof][explosionproof].

2.16.1.2 Bells

Bells must be surface mounted with the matching mounting backbox [surface mounted][recessed]. Bells must be suitable for use in an electrically supervised circuit. Bells must be the underdome type producing a minimum output rating of [85][____] dBA at 3.1 m 10 feet. Bells used in exterior locations must be specifically listed or approved for outdoor use and be provided with metal housing and protective grilles. Single stroke, electrically operated, supervised, solenoid bells must be used for coded applications.

2.16.1.3 Chimes

Chimes must be electrically operated, supervised, electronic type, with an adjustable frequency of 800 to 1200 Hertz. Chimes must have a minimum sound rating of [80][____] dBA at 3 m 10 feet. Chimes must ring the bell codes, as indicated.

2.16.2 Visual Notification Appliances

NOTE: ABA requires that Visual Notification Appliances be provided in buildings and facilities in each of the following areas: restrooms, and any general usage area (e.g., meeting rooms), hallways, lobbies, and any other area for common use and other areas stated at www.access-board.gov. The Visual Notification Appliance must be mounted as required by ABA that directs compliance with NFPA 72. In addition, alarms in guest rooms required to provide
communication features must comply with sections 18.5.5.7 of NFPA 72. Shop drawings must indicate location, dimensions, content, details, and other required information to indicate extent of complying with ABA requirements.

2. Currently NFPA 72 requires "clear color" strobes for Fire Alarm Notification. NFPA 72 requires the strobe must be marked "Fire" to clearly identify the function.

Visual notification appliances must conform to the applicable requirements of UL 1638, UL 1971, and conform to the Architectural Barriers Act (ABA). Visual Notification Appliances must have clear high intensity optic lens, xenon flash tubes, or light emitting diode (LED) and be marked "Alert" in letters of contrasting color. The light pattern must be disbursed so that it is visible above and below the strobe and from a 90 degree angle on both sides of the strobe. Strobe flash rate must be 1 flash per second and a minimum of [15][30][75][_____] candela based on the UL 1971 test. Strobe must be [surface][semi-flush] mounted.

2.17 ELECTRIC POWER

2.17.1 Primary Power

Power must be [120][_____] VAC [50][60] Hz service for the FACU from the AC service to the building in accordance with NFPA 72.

2.18 SECONDARY POWER SUPPLY

Provide for system operation in the event of primary power source failure. Transfer from normal to auxiliary (secondary) power or restoration from auxiliary to normal power must be automatic and must not cause transmission of a false alarm.

2.18.1 Batteries

Provide sealed, maintenance-free, [sealed lead acid][lead-calcium][gel cell] batteries as the source for emergency power to the FACU. Batteries must contain suspended electrolyte. The battery system must be maintained in a fully charged condition by means of a solid state battery charger. Provide an automatic transfer switch to transfer the load to the batteries in the event of the failure of primary power.

2.18.1.1 Capacity

Battery size must be the following capacity. This capacity applies to every control unit associated with this system, including supplemental notification appliance circuit panels, auxiliary power supply panels, and fire alarm transmitters.

a. Sufficient capacity to operate the fire alarm system under supervisory and trouble conditions, including audible trouble signal devices for 48 hours and audible and visual signal devices under alarm conditions for an additional 15 minutes.
2.18.1.2 Battery Power Calculations

a. Verify that battery capacity exceeds supervisory and alarm power requirements for the criteria noted in the paragraph "Capacity" above.

(1) Substantiate the battery calculations for alarm and supervisory power requirements. Include ampere-hour requirements for each system component and each control unit component, and compliance with UL 864.

(2) Provide complete battery calculations for both the alarm and supervisory power requirements. Submit ampere-hour requirements for each system component with the calculations.

(3) Provide voltage drop calculations to indicate that sufficient voltage is available for proper operation of the system and all components. Calculations must be performed using the minimum rated voltage of each component.

b. For battery calculations assume a starting voltage of 24 VDC for starting the calculations to size the batteries. Calculate the required Amp-Hours for the specified standby time, and then calculate the required Amp-Hours for the specified alarm time. Using 20.4 VDC as starting voltage, perform a voltage drop calculation for circuits containing device and/or appliances remote from the power sources.

2.18.2 Battery Chargers

Provide a solid state, fully automatic, variable charging rate battery charger. The charger must be capable of providing 120 percent of the connected system load and must maintain the batteries at full charge. In the event the batteries are fully discharged (20.4 Volts dc), the charger must recharge the batteries back to 95 percent of full charge within 48 hours after a single discharge cycle as described in paragraph CAPACITY above. Provide pilot light to indicate when batteries are manually placed on a high rate of charge as part of the unit assembly if a high rate switch is provided.

2.19 Surge Protective Devices

Surge protective devices must be provided to suppress all voltage transients which might damage fire alarm control unit components. Systems having circuits located outdoors, communications equipment must be protected against surges induced on any signaling line circuit. Cables and conductors, that serve as communications links, must have surge protection circuits installed at each end. The surge protective device must wire in series to the power supply of the protected equipment with screw terminations. Line voltage surge arrestor must be installed directly adjacent to the power panel where the FACU breaker is located.

a. Surge protective devices for nominal 120 VAC must be UL 1449 listed with a maximum 500 volt suppression level and have a maximum response time of 5 nanoseconds. The surge protective device must also meet IEEE C62.41.1 and IEEE C62.41.2 category B tests for surge capacity. The surge protective device must feature multi-stage construction and be provided with a long-life indicator lamp (either light emitting diode or neon) which extinguishes upon failure of protected components. Any unit fusing must be externally accessible.
b. Surge protective devices for nominal 24 VAC, fire alarm telephone dialer, or ethernet connection must be UL 497B listed, meet IEEE C62.41.1 and have a maximum response time of 1-nanosecond. The surge protective device must feature multi-stage construction and be self-resetting. The surge protective device must be a base and plug style. The base assembly must have screw terminals for fire alarm wiring. The base assembly must accept "plug-in" surge protective module.

c. All surge protective devices (SPD) must be the standard product of a single manufacturer and be equal or better than the following:

(1) For 120 VAC nominal line voltage: UL 1449 and UL 1283 listed, series connected 120 VAC, 20A rated, surge protective device in a NEMA 4x enclosure. Minimum 50,000 amp surge current rating with EMI/RFI filtering and a dry contact circuit for remote monitoring of surge protection status.

(2) For 24-volt nominal line voltage: UL 497B listed, series connected low voltage, 24-volt, 5A rated, loop circuit protector, base and replaceable module.

(3) For alarm telephone dialers: UL 497A listed, series connected, 130-volt, 150 mA rated with self-resetting fuse, dialer circuit protector with modular plug and play.

(4) For IP-DACTS: UL 497B listed, series connected, 6.4-volt, 1.5A rated with 20 kA/pair surge current, data network protector with modular plug and play.

2.20 WIRING

Provide wiring materials under this section as specified in Section 26 20 00 INTERIOR DISTRIBUTION SYSTEM with the additions and modifications specified herein.

2.20.1 Alarm Wiring

IDC and SLC wiring must be [fiber optic][ or ][solid copper] cable in accordance with the manufacturers requirements. Copper signaling line circuits and initiating device circuit field wiring must be No. [14][16][18][_____] AWG size conductors at a minimum. Visual notification appliance circuit conductors, that contain audible alarm appliances, must be copper No. 14 AWG size conductors at a minimum. Wire size must be sufficient to prevent voltage drop problems. Circuits operating at 24 VDC must not operate at less than the listed voltages for the detectors and/or appliances. Power wiring, operating at 120 VAC minimum, must be a minimum No. 12 AWG solid copper having similar insulation. Acceptable power-limited cables are FPL, FPLR or FPLP as appropriate with red colored covering. Nonpower-limited cables must comply with NFPA 70.

2.21 AUTOMATIC FIRE ALARM TRANSMITTERS

**************************************************************************

NOTE: State the make and model number of existing proprietary supervising station receiving equipment. The choice of code transmitter, or radio transmitter depends upon the type of existing fire reporting system at the activity. Determine the
type of activity reporting system (e.g., positive non interfering or shunt). In most cases a local energy-tripping device will be required. The facility Fire Dept. or Engineering office should be contacted to determine the type and amount of data to be supervised (monitored), e.g., -type: separate or common transmission of alarm, supervisory, and trouble type signals; -amount: all points, all zones, or the combined premises. Verify that existing monitoring equipment has sufficient capacity to support the additional premises or that it can be expanded as necessary to accommodate the new fire alarm system. Identify existing components.

2.21.1 Radio Transmitter and Interface Panels

Transmitters must be compatible with proprietary supervising station receiving equipment. Each radio alarm transmitter must be the manufacturer's recognized commercial product, completely assembled, wired, factory tested, and delivered ready for installation and operation. Transmitters must be provided in accordance with applicable portions of NFPA 72, Federal Communications Commission (FCC) 47 CFR 90 and Federal Communications Commission (FCC) 47 CFR 15. Transmitter electronics module must be contained within the physical housing as an integral, removable assembly. The proprietary supervising station receiving equipment is [_____] and the transmitter must be fully compatible with this equipment. At the contractors option, and if listed, the transmitter may be housed in the same control unit as the FAC. The transmitter must be narrowband radio, with FCC certification for narrowband operation and meets the requirements of the NTIA (National Telecommunications and Information Administration) Manual of Regulations and Procedures for Federal Frequency Management.

2.21.1.1 Operation

Operate each transmitter from 120-volt ac power. In the event of 120-volt ac power loss, the transmitter must automatically switch to battery operation. Switchover must be accomplished with no interruption of protective service, and must automatically transmit a trouble message. Upon restoration of ac power, transfer back to normal ac power supply must also be automatic.

2.21.1.2 Battery Power

Transmitter standby battery capacity must provide sufficient power to operate the transmitter in a normal standby status for a minimum of 72 hours and be capable of transmitting alarms during that period.

2.21.1.3 Transmitter Housing

Use NEMA Type 1 for housing. The housing must contain a lock that is keyed [identical to the fire alarm system for the building][identical to radio alarm transmitter housings on the Installation]. Radio alarm transmitter housing must be factory painted with a suitable priming coat and not less than two coats of a hard, durable weatherproof enamel.
2.21.1.4 Antenna

Antenna must be [omnidirectional, coaxial, halfwave dipole antennas][_____]
for radio alarm transmitters with a driving point impedance to match
transmitter output. The antenna and antenna mounts must be corrosion
resistant and designed to withstand wind velocities of 161 km/hour 100 mph.
Do not mount antennas to any portion of the building roofing system.
Protect the antenna from physical damage.

2.21.2 Digital Alarm Communicator Transmitter (DACT)

Provide DACT that is compatible with the existing supervising station fire
alarm system. Transmitter must have a means to transmit alarm,
supervisory, and trouble conditions via a single transmitter. Transmitter
must have a source of power for operation that conforms to NFPA 72.
Transmitter must be capable of initiating a test signal daily at any
selected time. Transmitter must be arranged to seize telephone circuits in
accordance with NFPA 72.

2.21.3 Signals to Be Transmitted to the Base Receiving Station

**************************************************************************
NOTE: The following paragraph is applicable only to
existing installations for connections to an
auxiliary (public) alarm system. Edit this for the
installation specific criteria.
**************************************************************************

The following signals must be sent to the base receiving station:

[a. Sprinkler waterflow]
[b. Manual pull stations]
[c. Smoke detectors]
[d. Duct smoke detectors]
[e. Sleeping room smoke detectors]
[f. Carbon monoxide detectors]
[g. Heat detectors]
[h. Fire extinguishing system]
[i. Sprinkler valve supervision]
[j. Fire pump running]
[k. Fire pump supervision]
[l. Water supply level and temperature]
[m. Combustion engine drive fire pump running
   (1) Selector switch in position than automatic
   (2) Engine over-speed

SECTION 28 31 70 Page 45
(3) Low fuel
(4) Low battery
(5) Engine trouble (for example, low oil, over temp]

2.22 SYSTEM MONITORING

2.22.1 Valves

Each valve affecting the proper operation of a fire protection system, including automatic sprinkler control valves, standpipe control valves, sprinkler service entrance valve, valves at fire pumps, isolating valves for pressure type waterflow or supervision switches, and valves at backflow preventers, whether supplied under this contract or existing, must be electrically monitored to ensure its proper position. Provide each tamper switch with a separate address[, unless they are within the same room, then a maximum of five can use the same address].

2.22.2 High/Low [Air][Nitrogen] Supervisory Switches

Provide monitoring of high and low supervisory [air][nitrogen] for [dry pipe][ and][ preaction] systems. Each air supervisory switch must have a separate address. Switches must be listed extinguishing system attachments. The device must contain double pole, double throw contacts. Operation of the switch must cause a supervisory signal to be transmitted to the FACU when [air][nitrogen] pressure in the system monitored sprinkler system increases more than 34.5 kPa 5 psi above the normal system pressure or drops halfway from the normal pressure to the tripping point.

2.22.3 Room Low Temperature Supervisory Switch

Provide [monitoring of the ]listed supervisory air temperature switch for the [fire pump][sprinkler riser] room[s]. Switch must cause a supervisory signal to be transmitted to the FACU whenever the temperature in the room drops to below 4.4 degrees C 40 degrees F. Device must reset when temperature rises above 4.4 degrees C 40 degrees F.

2.22.4 Electromagnetic Door Holders

Electromagnetic holding devices must operate on [120 VAC][24 VDC], and require not more than [3][_____] watts of power to develop 6.9 kPa25 psi of holding force. Under normal conditions, the magnets must attract and hold the doors open. Operation must be fail safe with no moving parts. Electromagnetic door hold-open devices must not be required to be held open during building power failure. The device must be listed based on UL 228 tests.

2.23 ENVIRONMENTAL ENCLOSURES OR GUARDS

Environmental enclosures must be provided to permit fire alarm components to be used in areas that exceed the environmental limits of the listing. The enclosure must be listed for the device or appliance as either a manufactured part number or as a listed compatible accessory for the component is currently listed. Guards required to deter mechanical damage must be either a listed manufactured part or a listed accessory for the category of the initiating device or notification appliance.
2.24 FIREFIGHTER TELEPHONE COMMUNICATION SYSTEM

**************************************************************************
NOTE: Provide a master control station at the FACU with remote telephone stations in each stair at each floor landing, in each elevator lobby on each floor, and in elevator cabs. In addition, provide them at specific locations containing essential fire protection equipment, such as the fire pump room and outside the emergency generator room.

NOTE: In lieu of firefighter telephones radio repeater equipment compatible with responding fire department may be used if approved by the responding fire department.
**************************************************************************

2.24.1 General

Provide a firefighter telephone communication system with complete, common talk, closed circuits. The system must include, but not be limited to, a master control station mounted in the fire alarm control unit, a power supply and standby battery system, and remote telephone stations.

2.24.2 Features

The system must include the following features:

a. A master control station which must provide power, supervision, and control for wiring, components, and circuits. The act of lifting any remote telephone hand set from its cradle must cause both a visual and audible signal to annunciate at the master control station. Removing the hand set at the master control station and depressing a button at the remote telephone hand set must cause the automatic silencing of the audible signal.

b. Communication between the master control station hand set and any/or all remote hand sets must require the depressing of a push-to-talk switch located on any/all remote hand sets. During the time that the master control hand set is removed from its cradle it must be possible to communicate between five remote hand sets and the master control station.

c. Hand sets must be able to monitor any conversation in progress and join the conversation by pressing the push-to-talk button. It must not be possible to communicate between two or more remote hand sets with the master control station hand set in its cradle.

d. The master control station hand set must be red in color and equipped with a 1.5 m (5-foot) long strain-relieved coiled cord.

e. The master control station must monitor wire and connections for any opens, shorts, or grounds which would render the system inoperable or unintelligible.

f. The master control station must be equipped with a silencing switch and ring-back feature such that any audible trouble signal can be silenced and must be so indicated by the lighting of an amber LED. Once any trouble condition has been corrected, the amber LED must be
The master control station must be equipped with a separate, LED annunciated switch for each telephone circuit. In addition, LEDs must provide for the annunciation of operating and supervisory power.

The loss of operating or supervisory power must cause an audible and visual indication at the master control station and must also cause the fire alarm trouble signal to sound on the FACU.

Switches, LEDs, and controls must be fully labeled.

2.24.3 Handsets

Handsets must have the following features:

a. Provide [surface][flush] mounted remote telephone stations.

b. Each station must be equipped with a hinged door that is magnetically locked.

c. Each hand set must be permanently wired in place with a coiled cord.

d. Each hand set must be red high-impact cycolac and must be equipped with a push-to-talk switch which, when operated, must signal the master control station and a switch-equipped, storage cradle.

e. Provide operating and supervising power from the same supply circuit(s) utilized for the FACU.

PART 3 EXECUTION

3.1 VERIFYING ACTUAL FIELD CONDITIONS

Before commencing actual work, examine all adjoining work on which the contractor's work is in any way dependent for perfect workmanship according to the intent of this specification section, and report to the Contracting Officer's Representative any condition which prevents performance of first class work. No "waiver of responsibility" for incomplete, inadequate or defective adjoining work will be considered unless notice has been filed before submittal of a proposal.

3.2 INSTALLATION

3.2.1 Fire Alarm Control Unit (FACU)

Locate the FACU [where indicated on the drawings][____]. [Recess][Semi-recess][Surface mount] the enclosure with the top of the cabinet 2 m 6 feet above the finished floor or center the cabinet at 1.5 m [5] feet, whichever is lower. Conductor terminations must be labeled and a drawing containing conductors, their labels, their circuits, and their interconnection must be permanently mounted in the FACU. Locate the document storage cabinet adjacent to the FACU unless the Contracting Officer directs otherwise.

3.2.2 Battery Cabinets

When batteries will not fit in the FACU, locate battery cabinets below or adjacent to the FACU. Battery cabinets must be installed at an accessible...
location when standing at floor level. Battery cabinets must not be installed lower than 300 mm 12 inches above finished floor, measured to the bottom of the cabinet, nor higher than 900 mm 36 inches above the floor, measured to the top of the cabinet. Installing batteries above drop ceilings or in inaccessible locations is prohibited. Battery cabinets must be large enough to accommodate batteries and also to allow ample gutter space for interconnection of control units as well as field wiring. The cabinet must be provided in a sturdy steel housing, complete with back box, hinged steel door with cylinder lock, and surface mounting provisions. The cabinet must be identified by an engraved phenolic resin nameplate. Lettering on the nameplate must indicate the control unit(s) the batteries power and must not be less than 25 mm 1-inch high.

3.2.3 Manual Stations

Locate manual stations as required by NFPA 72 and as indicated on the drawings. Mount stations so they are located no farther than 1.5 feet [1.5] m 5 feet from the exit door they serve, measured horizontally. Manual stations must be mounted at 1067 mm 42 inches measured to the operating handle.

3.2.4 Notification Appliances

******************************************************************************
NOTE: Locate strobes wall mounted in corridors no more than 4.5 m 15 feet from the end of a corridor with 30 m 100 feet maximum distance between strobes. Where there is an obstruction to the viewing path in the corridors, such as a cross-corridor door or ceiling elevation change, consider the obstruction as defining a new corridor. Provide ceiling mounted strobes in rooms accessible to the public, such as conference rooms, restrooms, courtrooms, cafeterias, and auditoriums in accordance with NFPA 72. In Child Development Centers only chimes must be used as the pre-alert tone prior to voice messages.
******************************************************************************

a. Locate notification appliance devices [as required by NFPA 72][where indicated] Where more than two visual notification appliances are located in the same room or corridor or field of view, provide synchronized operation. Devices must use screw terminals for all field wiring.[ Audible and visual notification appliances mounted in acoustical ceiling tiles must be centered in the tiles plus or minus 50 mm2 inches.].

b. Audible and visual notification appliances mounted on the exterior of the building, within unconditioned spaces, or in the vicinity of showers must be listed weatherproof appliances installed on weatherproof backboxes.

c. Speakers must not be located in close proximity to the FACU or LOC so as to cause feedback when the microphone is in use.

3.2.5 Smoke and Heat Detectors

Locate detectors [as required by NFPA 72 and their listing][as indicated on the drawings] on a 100 mm 4-inch mounting box. Install heat detectors not
less than 100 mm 4 inches from a side wall to the near edge. Heat
detectors located on the wall must have the top of the detector at least
100 mm 4 inches below the ceiling, but not more than 300 mm 12 inches below
the ceiling. Smoke detectors are permitted to be on the wall no lower than
300 mm 12 inches from the ceiling with no minimum distance from the
ceiling. [In raised floor spaces, install the smoke detectors to protect[ 21 square meters 225 square feet per detector][____].] Install smoke
detectors no closer than 1 m 3 feet from air handling supply diffusers.
Detectors installed in acoustical ceiling tiles must be centered in the
tiles plus or minus 50 mm 2 inches.

3.2.6 Carbon Monoxide Detectors

Locate detectors [as required by NFPA 72 and their listings][as indicated
on the drawings] on a 100-mm4-inch mounting box.[ Carbon monoxide
detectors must be installed separate from smoke and/or heat detectors.]

3.2.7 Air Sampling Smoke Detector

Locate air sampling smoke detectors in accordance with the manufacturer's
instructions. Air sampling smoke detectors must be installed as follows:

a. Air Sampling Smoke Detector Assembly:

(1) Detector assembly must be mounted to a wall at a height between 48
to 60 inches 1200 mm to 1800 mm to top of detector measured above
the finished floor.

(2) Mounting must be in a fully accessible and visible location.

(3) Mounting or attachment to site equipment, cable trays, movable
walls, other equipment or equipment supports is not permitted.

(4) Piping network insertion into the detector inlet must not be glued.

(5) Air sampling smoke detector assembly must be installed in
accordance with this specification section and the manufacturer's
installation and instruction manuals.

(6) Flexible tubing for termination of the sampling pipe network into
detector inlet is not permitted unless allowed by its listing.

(7) Provide red background with white lettering labels that are
plastic or phenolic type with a minimum of 0.25-inch 6.4 mm block
lettering to indicate detector and zone. For example: "AIR
SAMPLING SOME DETECTOR No. 1-1 No. 5".

(8) Provide a typeset printed or typewritten instruction card mounted
behind a Lexan plastic or glass cover in a stainless steel or
aluminum frame. Install the frame in a conspicuous location
observable from the ASD panel. The card must show those steps to
be taken by an operator when a signal is received as well as the
functional operation of the system under all conditions, normal,
alarm, supervisory, and trouble. The instructions must be
approved by the Contracting Officer before being posted.

b. Pipe and Sampling Tube Mounting:

(1) The pipe and sampling tubing detection network must be mounted as
per the design and manufacturer's specification. The hardware used for mounting will depend upon the design and site requirements.

(2) To minimize flexing, pipes must be secured every 1.5 m (5 feet).

(3) Pipes must be suspended between 25 mm and 100 mm (1 and 4 inches) below the ceiling. In areas with a suspended ceiling, the pipe network must be installed above the ceiling utilizing the manufacturer's capillary sample port supported by the ceiling.

(4) The sampling tubes must be of the same length or use the manufacturer's guidelines to run tubes of the required lengths.

(5) When installing a pipe network in areas subject to high temperature fluctuations allow for the contraction and expansion of pipes.

(6) Where expansion or contraction of pipes is likely either after installation or on a continuous basis, do not place pipe clips adjacent to couplings and socket unions as these may interfere with the movement of the pipe.

(7) No bends are permitted within the first 450 mm (18 inches) from the detector inlet.

(8) The routing of the piping and sample tube network must be coordinated with potential obstructions, including cable trays, grounding bars, and HVAC ductwork.

(9) All changes in direction must be made with standard elbows or tees.

(10) All joints must be air-tight and made by using solvent cement, except at the entry to the detector assembly. Refer to ASTM F402.

(11) All pipes must be supported by mechanical hangers attached to the structure of the building. Not more than 300 mm (1-foot) of pipe must extend beyond the last hanger of each sampling pipe. The final installation must result in no noticeable deflection in the piping network.

(12) Attachment of air sampling pipes to cable trays, "gray iron", and telecommunications equipment is prohibited.

(13) Clearly label pipe network to distinguish the pipe from other facility pipe work or protective cabling enclosures. For example: "SMOKE DETECTION SAMPLING TUBE - DO NOT DISTURB". In open rooms and exposed areas, provide labels at no greater than 6.1-m (20-foot) intervals. Provide labels every 3 m (10 feet) where piping is installed above suspended ceilings and every 609 mm (2 feet), centered in the floor panels, where piping is installed within the raised floor cavity.

(14) Placement of the sampling tube must take into consideration appropriate sampling point locations and spacing.

c. Air Sampling Points:

(1) Open area ceiling sampling points must be oriented downward and
must be within 25 mm to 100 mm to 4 inches below the underside of the ceiling above where the ceiling is smooth.

(2) Label all air sampling points with a round red label, each with a center hole to match the diameter of the drilled sampling point. For example: "AIR SAMPLING POINT DIA 3.2 MM 0.125 INCHES". Indicate fractional dimensions in decimal format with a minimum of three decimal places.

[3.2.8 Graphic Annunciator

Locate the graphic annunciator as shown on the drawings. Mount the annunciator, with the top 1830 mm 6 feet above the finished floor or center the annunciator at [1525][_____] mm [5][_____] feet, whichever is lower.

[3.2.9 LCD REMOTE Annunciator

Locate the LCD annunciator as shown on the drawings. Mount the annunciator, with the top 2 m 6 feet above the finished floor or center the annunciator at [1.5][_____] m [5][_____] feet, whichever is lower.

[3.2.10 Electromagnetic Door Holder Release

Doors must be held open at a minimum of 90 degrees so as not to impede egress from the space. Mount the armature portion on the door and have an adjusting screw for seating the angle of the contact plate. Wall-mount the electromagnetic release, with a total horizontal projection not exceeding 100 mm 4 inches. Ensure all doors release to close upon first stage (pre-discharge) alarm. Electrical supervision of wiring external of control unit for magnetic door holding circuits is not required.

[3.2.11 Firefighter Telephones

Mount telephone[ hand sets][ jacks] on the wall in each stair at each floor landing, in each emergency generator room, in each fire pump room, in each elevator machine room, in each elevator lobby, and in each elevator cab 1200 mm 4 feet above the finished floor.

[3.2.12 Ceiling Bridges

Provide ceiling bridges for ceiling-mounted appliances. Ceiling bridges must be as recommended/required by the manufacturer of the ceiling-mounted notification appliance.

3.3 SYSTEM FIELD WIRING

3.3.1 Wiring within Cabinets, Enclosures, and Boxes

Provide wiring installed in a neat and workmanlike manner and installed parallel with or at right angles to the sides and back of any box, enclosure, or cabinet. Conductors that are terminated, spliced, or otherwise interrupted in any enclosure, cabinet, mounting, or junction box must be connected to screw-type terminal blocks. Mark each terminal in accordance with the wiring diagrams of the system. The use of wire nuts or similar devices is prohibited. Wiring to conform with NFPA 70.

Indicate the following in the wiring diagrams:

a. Point-to-point wiring diagrams showing the points of connection and
terminals used for electrical field connections in the system, including interconnections between the equipment or systems that are supervised or controlled by the system. Diagrams must show connections from field devices to the FACU and remote fire alarm control units, initiating circuits, switches, relays and terminals.

b. Complete riser diagrams indicating the wiring sequence of devices and their connections to the control equipment. Include a color code schedule for the wiring. Include floor plans showing the locations of devices and equipment.

3.3.2 Terminal Cabinets

**************************************************************************
NOTE: Provide terminal cabinets on each floor where the fire alarm system supply riser is located and where the fire alarm return riser is located.
**************************************************************************

Provide a terminal cabinet at the base of any circuit riser, on each floor at each riser, and where indicated on the drawings. Terminal size must be appropriate for the size of the wiring to be connected. Conductor terminations must be labeled and a drawing containing conductors, their labels, their circuits, and their interconnection must be permanently mounted in the terminal cabinet. Minimum size is 200 mm by 200 mm 8 inches by 8 inches. Only screw-type terminals are permitted. Provide an identification label, that displays "FIRE ALARM TERMINAL CABINET" with 50 mm 2-inch lettering, on the front of the terminal cabinet.

3.3.3 Alarm Wiring

**************************************************************************
NOTE: Do not penetrate SCIF perimeters with copper signal line circuits. SCIF penetrations should be either fiber optic cable or IDC. IDC circuits penetrating the SCIF must be filtered.
**************************************************************************

a. Voltages must not be mixed in any junction box, housing or device, except those containing power supplies and control relays.

b. Utilize shielded wiring where recommended by the manufacturer. For shielded wiring, ground the shield at only one point, in or adjacent to the FACU.

c. [Pigtail or T-tap connections to signal line circuits, initiating device circuits, supervisory alarm circuits, and notification appliance circuits are prohibited.][ T-tapping using screw terminal blocks is allowed for Class "B" signaling line circuits.]

d. Color coding is required for circuits and must be maintained throughout the circuit. Conductors used for the same functions must be similarly color coded. Conform wiring to NFPA 70.

e. Pull all conductors splice free. The use of wire nuts, crimped connectors, or twisting of conductors is prohibited. Where splices are unavoidable, the location of the junction box or pull box where they occur must be identified on the as-built drawings. The number and location of splices must be subject to approval by the [_____]
3.3.4 Back Boxes and Conduit

In addition to the requirements of Section 26 20 00 INTERIOR DISTRIBUTION SYSTEM, provide all wiring in rigid metal conduit or intermediate metal conduit unless specifically indicated otherwise. Minimum conduit size must be 19 mm (3/4-inch) in diameter. Do not use electrical non-metallic tubing (ENT) or flexible non-metallic tubing and associated fittings.

a. Galvanized rigid steel (GRS) conduit must be utilized where exposed to weather, where subject to physical damage, and where exposed on exterior of buildings. Intermediate metal conduit (IMC) may be used in lieu of GRS as allowed by NFPA 70.

b. Electrical metallic tubing (EMT) is permitted above suspended ceilings or exposed where not subject to physical damage. Do not use EMT underground, encased in concrete, mortar, or grout, in hazardous locations, where exposed to physical damage, outdoors or in fire pump rooms. Use die-cast compression connectors.

c. For rigid metallic conduit (RMC), only threaded type fitting are permitted for wet or damp locations.

d. Flexible metal conduit is permitted for initiating device circuits [_____]6 feet in length or less. Flexible metal conduit is prohibited for notification appliance circuits and signaling line circuits. Use liquid tight flexible metal conduit in damp and wet locations.

e. Schedule 40 (minimum) polyvinyl chloride (PVC) is permitted where conduit is routed underground or underground below floor slabs. Convert non-metallic conduit, other than PVC Schedule 40 or 80, to plastic-coated rigid, or IMC, steel conduit before turning up through floor slab.

f. Exterior wall penetrations must be weathertight. Conduit must be sealed to prevent the infiltration of moisture.

g. For Class "A" or "X" circuits with conductor lengths of 10 feet 3 meters or less, the conductors must be permitted to be installed in the same raceway in accordance with NFPA 72.

3.3.5 Conductor Terminations

Labeling of conductors at terminal blocks in terminal cabinets, FACU, and remote FACU must be provided at each conductor connection. Each conductor or cable must have a shrink-wrap label to provide a unique and specific designation. Each terminal cabinet, FACU, and remote FACU must contain a laminated drawing that indicates each conductor, its label, circuit, and terminal. The laminated drawing must be neat, using 12 point lettering minimum size, and mounted within each cabinet, control unit, or unit so that it does not interfere with the wiring or terminals. Maintain existing color code scheme where connecting to existing equipment.

3.4 DISCONNECTION AND REMOVAL OF EXISTING SYSTEM

**************************************************************************

NOTE: Contact the Contracting Officer, Base Fire Prevention Office, and/or Base Maintenance Personnel

**************************************************************************
to determine what action is appropriate for the salvaging of existing fire alarm equipment.

Maintain existing fire alarm equipment fully operational until the new equipment has been tested and accepted by the Contracting Officer. As new equipment is installed, label it "NOT IN SERVICE" until the new equipment is accepted. Once the new system is completed, tested, and accepted by the Government, it must be placed in service and connected to the supervising station. Remove tags from new equipment and tag the existing equipment "NOT IN SERVICE" until removed from the building.

a. After acceptance of the new system by the Contracting Officer, remove existing equipment not connected to the new system, remove unused exposed conduit, and restore damaged surfaces. Remove the material from the site and dispose.

b. Disconnect and remove the existing fire alarm and smoke detection systems where indicated and elsewhere in the specification.

c. Control units and fire alarm devices and appliances disconnected and removed must be turned over to the Contracting Officer.

d. Properly dispose of fire alarm outlet and junction boxes, wiring, conduit, supports, and other such items.

3.5 CONNECTION OF NEW SYSTEM

The following new system connections must be made during the last phase of construction, at the beginning of the pre-Government tests. New system connections must include:

a. Connection of new relays to existing magnetic door hold-open devices.

b. Connection of new elevator recall relays to existing wiring and conduit.

c. Connection of new system transmitter to existing installation fire reporting system.

Once these connections are made, system must be left energized. Report immediately to the Contracting Officer, coordination and field problems resulting from the connection of the above components.

3.6 FIRESTOPPING

Provide firestopping for holes at conduit penetrations through floor slabs, fire-rated walls, partitions with fire-rated doors, corridor walls, and vertical service shafts in accordance with Section 07 84 00 FIRESTOPPING.

3.7 PAINTING

a. In unfinished areas (including areas above drop ceilings), paint all exposed electrical conduit (serving fire alarm equipment), fire alarm conduit, surface metal raceway, junction boxes and covers red. In lieu of painting conduit, the contractor may utilize red conduit with a factory applied finish.

b. In finished areas, paint exposed electrical conduit (serving fire alarm equipment), fire alarm conduit, surface metal raceways, junction boxes,
and electrical boxes to match adjacent finishes. The inside cover of the junction box must be identified as "Fire Alarm" and the conduit must have painted red bands 19 mm/3/4-inch wide at 3-meter/10-foot centers and at each side of a floor, wall, or ceiling penetration.

c. Painting must comply with Section 09 90 00 PAINTS AND COATINGS.

3.8 FIELD QUALITY CONTROL

**************************************************************************
NOTE: Listed tests are minimum required.
Coordinate with the local Authority Having Jurisdiction (AHJ) for minimum requirements in excess of the NFPA 72 minimums or those recommend below. If additional tests are required, such tests must be added to the list.
**************************************************************************

3.8.1 Test Procedures

Submit detailed test procedures, prepared and signed by the NICET Level [III][ or ][IV] Fire Alarm Technician, and the representative of the installing company, [and reviewed by the QFPE] [60][_____] days prior to performing system tests. Detailed test procedures must list all components of the installed system such as initiating devices and circuits, notification appliances and circuits, signaling line devices and circuits, control devices/equipment, batteries, transmitting and receiving equipment, power sources/supply, annunciators, special hazard equipment, emergency communication equipment, interface equipment, and surge protective devices. Test procedures must include sequence of testing, time estimate for each test, and sample test data forms. The test data forms must be in a check-off format (pass/fail with space to add applicable test data; similar to the forma in NFPA 72 and NFPA 4.) The test procedures and accompanying test data forms must be used for the pre-Government testing and the Government testing. The test data forms must record the test results and must:

a. Identify the NFPA Class of all Initiating Device Circuits (IDC), and Notification Appliance Circuits (NAC), and Signaling Line Circuits (SLC).

b. Identify each test required by NFPA 72 Test Methods and required test herein to be performed on each component, and describe how these tests must be performed.

c. Identify each component and circuit as to type, location within the facility, and unique identity within the installed system. Provide necessary floor plan sheets showing each component location, test location, and alphanumeric identity.

d. Identify all test equipment and personnel required to perform each test (including equipment necessary for smoke detector testing. The use of magnets is not permitted.

e. Provide space to identify the date and time of each test. Provide space to identify the names and signatures of the individuals conducting and witnessing each test.
3.8.2 Pre-Government Testing

3.8.2.1 Verification of Compliant Installation

Conduct inspections and tests to ensure that devices and circuits are functioning properly. Tests must meet the requirements of paragraph entitled "Minimum System Tests" as required by NFPA 72. The contractor and an authorized representative from each supplier of equipment must be in attendance at the pre-Government testing to make necessary adjustments. After inspection and testing is complete, provide a signed Verification of Compliant Installation letter by the QFPE that the installation is complete, compliant with the specification and fully operable. The letter must include the names and titles of the witnesses to the pre-Government tests. Provide all completion documentation as required by NFPA 72 including all referenced annex sections and the test reports noted below.

a. NFPA 72 Record of Completion.

b. NFPA 72 Record of Inspection and Testing.

d. Audibility test results with marked-up test floor plans.

e. Documentation that all tests identified in the paragraph "Minimum System Tests" are complete.

3.8.2.2 Request for Government Final Test

When the verification of compliant installation has been completed, submit a formal request for Government final test to the [_____] [Designated Fire Protection Engineer (DFPE)][Contracting Officer's Representative (COR)]. Government final testing will not be scheduled until the DFPE has received copies of the request for Government final testing and Verification of Compliant Installation letter with all required reports. Government final testing will not be performed until after the connections to the installation-wide fire reporting system has been completed and tested to confirm communications are fully functional. Submit request for test at least [15][_____] calendar days prior to the requested test date.

3.8.3 Correction of Deficiencies

If equipment was found to be defective or non-compliant with contract requirements, perform corrective actions and repeat the tests. Tests must be conducted and repeated if necessary until the system has been demonstrated to comply with all contract requirements.

3.8.4 Government Final Tests

The tests must be performed in accordance with the approved test procedures in the presence of the DFPE. Furnish instruments and personnel required for the tests. The following must be provided at the job site for Government Final Testing:

a. The manufacturer's technical representative.

[b. The contractor's Qualified Fire Protection Engineer (QFPE).]
c. Marked-up red line drawings of the system as actually installed.
d. Loop resistance test results.
e. Complete program printout including input/output addresses.
f. Copy of pre-Government Test Certificate, test procedures and completed test data forms.
g. Audibility test results with marked-up floor plans.

Government Final Tests will be witnessed by the [_____], [Designated Fire Protection Engineer][Contracting Officer's Representative (COR)][, Qualified Fire Protection Engineer (QFPE)]. At this time, any and all required tests noted in the paragraph "Minimum System Tests" must be repeated at their discretion.

3.9  MINIMUM SYSTEM TESTS

3.9.1  System Tests

Test the system in accordance with the procedures outlined in NFPA 72. The required tests are as follows:

a. Loop Resistance Tests: Measure and record the resistance of each circuit with each pair of conductors in the circuit short-circuited at the farthest point from the circuit origin. The tests must be witnessed by the Contracting Officer and test results recorded for use at the final Government test.

b. Verify the absence of unwanted voltages between circuit conductors and ground. The tests must be accomplished at the pre-Government test with results available at the final system test.

c. Verify that the control unit is in the normal condition as detailed in the manufacturer's O&M manual.

d. Test each initiating device and notification appliance and circuit for proper operation and response at the control unit. Smoke detectors must be tested in accordance with manufacturer's recommended calibrated test method. Use of magnets is prohibited. Testing of duct smoke detectors must comply with the requirements of NFPA 72 except disconnect at least 20 percent of devices. If there is a failure at these devices, then supervision must be tested at each device.

e. Carbon Monoxide Detector Tests: Carbon monoxide detectors must be tested in accordance with NFPA 72 and the manufacturer's recommended calibrated test method.

f. Test the system for specified functions in accordance with the contract drawings and specifications and the manufacturer's O&M manual.

g. Test both primary power and secondary power. Verify, by test, the secondary power system is capable of operating the system for the time period and in the manner specified.

h. Determine that the system is operable under trouble conditions as specified.
i. Visually inspect wiring.

j. Test the battery charger and batteries.

k. Verify that software control and data files have been entered or programmed into the FACU. Hard copy records of the software must be provided to the Contracting Officer.

l. Verify that red-line drawings are accurate.

m. Measure the current in circuits to ensure there is the calculated spare capacity for the circuits.

n. Measure voltage readings for circuits to ensure that voltage drop is not excessive.

o. Disconnect the verification feature for smoke detectors during tests to minimize the amount of smoke needed to activate the sensor. Testing of smoke detectors must be conducted using real smoke or the use of canned smoke which is permitted.

p. Measure the voltage drop at the most remote appliance (based on wire length) on each notification appliance circuit.

q. Verify the documentation cabinet is installed and contains all as-built shop drawings, product data sheets, design calculations, site-specific software data package, and all documentation required by paragraph titled "Test Reports".

3.9.2 Audibility Tests

Sound pressure levels from audible notification appliances must be a minimum of 15 dBA over ambient with a maximum of 110 dBA in any occupiable area. The provisions for audible notification (audibility and intelligibility) must be met with doors, fire shutters, movable partitions, and similar devices closed.

3.10 SYSTEM ACCEPTANCE

Following acceptance of the system, as-built drawings and O&M manuals must be delivered to the Contracting Officer for review and acceptance. The drawings must show the system as installed, including deviations from both the project drawings and the approved shop drawings. These drawings must be submitted within two weeks after the final Government test of the system. At least one set of as-built (marked-up) drawings must be provided at the time of, or prior to the Final Government Test.

[a. The drawings must be prepared electronically and sized no less than the contract drawings.] [Furnish one set of CDs or DVDs containing software back-up and CAD based drawings in latest version of MicroStation] [AutoCAD, ]DXF and portable document formats of as-built drawings and schematics.]

b. Include complete wiring diagrams showing connections between devices and equipment, both factory and field wired.

c. Include a riser diagram and drawings showing the as-built location of devices and equipment.
d. Provide **Operation and Maintenance (O&M) Instructions**.

[In existing buildings, the transfer of devices from the existing system to the new system and the permission to begin demolition of the old fire alarm system will not be permitted until the as-built drawings and O&M manuals are received.]

### 3.11 INSTRUCTION OF GOVERNMENT EMPLOYEES

#### 3.11.1 Instructor

Provide the services of an instructor, who has received specific training from the manufacturer for the training of other persons regarding the operation, inspection, testing, and maintenance of the system provided. The instructor must train the Government employees designated by the Contracting Officer, in the care, adjustment, maintenance, and operation of the fire alarm system. The instructor must be thoroughly familiar with all parts of this installation. The instructor must be trained in operating theory as well as in practical O&M work. Submit the instructors information and qualifications including the training history.

#### 3.11.2 Required Instruction Time

Provide [8][16][_____] hours of instruction after final acceptance of the system. The instruction must be given during regular working hours on such dates and times selected by the Contracting Officer. The instruction may be divided into two or more periods at the discretion of the Contracting Officer. The training must allow for rescheduling for unforeseen maintenance and/or fire department responses.

**3.11.2.1 Technical Training**

Equipment manufacturer or a factory representative must provide [1][3][_____] days of on site and 5 days of technical training to the Government at the manufacturing facility. Training must allow for classroom instruction as well as individual hands on programming, troubleshooting and diagnostics exercises. Factory training must occur within [6][12][_____] months of system acceptance.

**3.11.3 Technical Training Manual**

Provide, in manual format, lesson plans, operating instructions, maintenance procedures, and training data for the training courses. The operations training must familiarize designated government personnel with proper operation of the installed system. The maintenance training course must provide the designated government personnel adequate knowledge required to diagnose, repair, maintain, and expand functions inherent to the system.

### 3.12 EXTRA MATERIALS

#### 3.12.1 Repair Service/Replacement Parts

Repair services and replacement parts for the system must be available for a period of 10 years after the date of final acceptance of this work by the Contracting Officer. During the warranty period, the service technician must be on-site within 24 hours after notification. All repairs must be completed within 24 hours of arrival on-site.
During the warranty period, the installing fire alarm contractor is responsible for conducting all required testing and maintenance in accordance with the requirements and recommended practices of NFPA 72 and the system manufacturer[s]. Installing fire alarm contractor is NOT responsible for any damage resulting from abuse, misuse, or neglect of equipment by the end user.

3.12.2  Spare Parts

Spare parts furnished must be directly interchangeable with the corresponding components of the installed system[s]. Spare parts must be suitably packaged and identified by nameplate, tagging, or stamping. Spare parts must be delivered to the Contracting Officer at the time of the Government testing and must be accompanied by an inventory list.

3.12.3  Document Storage Cabinet

Upon completion of the project, but prior to project close-out, place in the document storage cabinet copies of the following record documentation:

a. As-built shop drawings
b. Product data sheets
c. Design calculations
d. Site-specific software data package
e. All documentation required by SD-06.

      2.24.1.2 Battery Power
      2.24.1.3 Transmitter Housing
2.24.1.4 Antenna
2.24.2 Digital Alarm Communicator Transmitter (DACT)
2.24.3 Signals to Be Transmitted to the Base Receiving Station

2.25 SYSTEM MONITORING
2.25.1 Valves
2.25.2 High/Low [Air][Nitrogen] Supervisory Switches
2.25.3 Room Low Temperature Supervisory Switch
2.25.4 Electromagnetic Door Holders

2.26 ENVIRONMENTAL ENCLOSURES OR GUARDS

2.27 FIREFIGHTER TELEPHONE COMMUNICATION SYSTEM
2.27.1 General
2.27.2 Features
2.27.3 Handsets

PART 3 EXECUTION

3.1 VERIFYING ACTUAL FIELD CONDITIONS
3.2 INSTALLATION
3.2.1 Fire Alarm and Mass Notification Control Unit (FMCU)
3.2.2 Battery Cabinets
3.2.3 Manual Stations
3.2.4 Notification Appliances
3.2.5 Smoke and Heat Detectors
3.2.6 Carbon Monoxide Detectors
3.2.7 Air Sampling Smoke Detector
3.2.8 Graphic Annunciator
3.2.9 LCD REMOTE Annunciator
3.2.10 Electromagnetic Door Holder Release
3.2.11 Firefighter Telephones
3.2.12 Local Operating Console (LOC)
3.2.13 Ceiling Bridges

3.3 SYSTEM FIELD WIRING
3.3.1 Wiring within Cabinets, Enclosures, and Boxes
3.3.2 Terminal Cabinets
3.3.3 Alarm Wiring
3.3.4 Back Boxes and Conduit
3.3.5 Conductor Terminations

3.4 DISCONNECTION AND REMOVAL OF EXISTING SYSTEM
3.5 CONNECTION OF NEW SYSTEM
3.6 FIRESTOPPING
3.7 PAINTING
3.8 FIELD QUALITY CONTROL
3.8.1 Test Procedures
3.8.2 Pre-Government Testing
3.8.2.1 Verification of Compliant Installation
3.8.2.2 Request for Government Final Test
3.8.3 Correction of Deficiencies
3.8.4 Government Final Tests

3.9 MINIMUM SYSTEM TESTS
3.9.1 System Tests
3.9.2 Audibility Tests
3.9.3 Intelligibility Tests

3.10 SYSTEM ACCEPTANCE

3.11 INSTRUCTION OF GOVERNMENT EMPLOYEES
3.11.1 Instructor
3.11.2 Required Instruction Time
3.11.2.1 Technical Training
3.11.3 Technical Training Manual

3.12 EXTRA MATERIALS
3.12.1 Repair Service/Replacement Parts
3.12.2 Spare Parts
3.12.3 Document Storage Cabinet

-- End of Section Table of Contents --
NOTE: This specification covers the requirements for an addressable integrated fire detection, fire alarm evacuation and mass notification system.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).
NOTE: For Family Housing projects at NAVFAC NE use regional guide specification section 28 31 46.00 22 (N-13854N) HOUSEHOLD FIRE WARNING EQUIPMENT to specify residential fire warning systems in lieu of this section.

**************************************************************************

NOTE: This specification section includes requirements from UFC 3-600-01 (change 43, 7 February 2020)

**************************************************************************

NOTE: This guide specification covers carbon monoxide alarm detectors for protection in indoor locations where fuel-burning appliances/equipment are used.

**************************************************************************

PART 1  GENERAL

**************************************************************************

1. On the drawings, show location of control unit, batteries and charger (if remotely mounted), supervising station transceiver, annunciator, primary power supply, remote annunciator, detectors, notification appliances (unless performance requirements are specified), and each alarm initiating device including fire extinguishing system switches.

2. Show single-line fire alarm/mass notification systems riser diagram. Each device on the riser should be identified by type. Indicate connection of equipment.

3. A fire alarm operating matrix/mass notification system must be placed on the drawings. Show actions of input devices such as detectors, manual stations, waterflow switches, initiating devices, etc. on one axis and output functions such as door releases, smoke control fans, elevator relays, indicating/notification appliances etc. on the other. Entries which require descriptions, explanation of processes, sequences, interfaces, etc. can be flagged by symbols keyed to supplementary notes. Alternately provide a zone-by-zone sequence of operation or a schedule identifying all initiators, outputs, and interfaces.

4. Addressable Fire Alarm Systems generally utilize Signal Line Circuits (SLC) for communication between devices. Normally all devices are addressable or will have an addressable interface device installed integrally with the device. Initiating Device Circuits (IDC) should be provided for interfacing to existing IDC loops or connection between non-addressable devices and the SLC.
1.1 REFERENCES

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

1.2 RELATED SECTIONS

Section 25 05 11 Cybersecurity for Facility-Related Control Systems, applies to this section, with the additions and modifications specified herein. In addition, refer to the following sections for related work and coordination:

[ Section 21 13 13 WET PIPE SPRINKLER SYSTEM, FIRE PROTECTION
 ][ Section 21 30 00 FIRE PUMPS
 ][ Section 21 23 00.00 20 WET CHEMICAL FIRE EXTINGUISHING for KITCHEN CABINET
 ][ Section 21 13 16 DRY PIPE FIRE SPRINKLER SYSTEMS
 ][ Section 21 13 18 PREACTION FIRE SPRINKLER SYSTEMS
 ][ Section 21 13 19 DELUGE FIRE SPRINKLER SYSTEMS
 ][ Section 23 30 00 HVAC AIR DISTRIBUTION
 ][ Section 21 13 24.00 10 AQUEOUS FILM-FORMING FOAM (AFFF) FIRE PROTECTION SYSTEM
 ][ Section 21 13 25 HIGH-EXPANSION FOAM SYSTEM, FIRE PROTECTION
 ][ Section 21 13 20.00 20 FOAM FIRE EXTINGUISHING FOR AIRCRAFT HANGARS
 ][ Section 21 21 01.00 20 CARBON DIOXIDE FIRE EXTINGUISHING (HIGH PRESSURE)
1.3 SUMMARY

1.3.1 Scope

a. This work includes designing and [providing a new, complete,][modifying the existing] fire alarm and mass notification (MNS) system as described herein and on the contract drawings[ for the __________]. Include system wiring, raceways, pull boxes, terminal cabinets, outlet and mounting boxes, control equipment, initiating devices, notification appliances, supervising station fire alarm transmitters/mass notification transceiver, and other accessories and miscellaneous items required for a complete operational system even though each item is not specifically mentioned or described. Provide system[s] complete and ready for operation.[ Existing interior fire alarm system was manufactured by [____].] Design and installation must comply with UFGS 25 05 11, UFC 4-010-06 and AFGM 2019-320-02.

b. Provide equipment, materials, installation, workmanship, inspection, and testing in strict accordance with NFPA 72, except as modified herein. [The system layout on the drawings show the intent of coverage and suggested locations. Final quantity, system layout, and coordination are the responsibility of the Contractor.]

c. Each remote fire alarm control unit must be powered from a wiring riser specifically for that use or from a local emergency power panel located on the same floor as the remote fire alarm control unit. Where remote fire control units are provided, equipment for notification appliances may be located in the remote fire alarm control units.

d. Where a fire pump is provided, the fire alarm and mass notification system must monitor and transmit the fire pump controller signals in accordance with the provisions of NFPA 72.

e. Where an emergency generator provides standby power supply for life safety system circuits, the generator must be monitored by the FMCU and transmit emergency generator signals in accordance with NFPA 72.

f. The fire alarm and mass notification system must be independent of the building security, building management, and energy/utility monitoring systems other than for control functions.

1.3.2 Qualified Fire Protection Engineer (QFPE)

**************************************************************************
NOTE: UFC 3-600-01 requires that shop drawings must bear the Review Stamp and professional engineering stamp of the QFPE prior to submission to the Government for approval.
NOTE: The term Qualified Fire Protection Engineer (QFPE) should be considered interchangeable with the terms "Fire Protection Designer of Record (FPDOR)" and/or "Fire Protection QC Specialist" where referred to in other applicable contract documents. The intent of defining the QFPE roles and responsibilities here is NOT to require personnel in addition to the QFPE, FPDOR, and/or FPQC specialist referenced elsewhere in the applicable contract documents.

Services of the QFPE must include:

a. Reviewing SD-02, SD-03, and SD-05 submittal packages for completeness and compliance with the provisions of this specification. Construction (shop) drawings and calculations must be prepared by, or prepared under the immediate supervision of, the QFPE. The QFPE must affix their professional engineering stamp with signature to the shop drawings, calculations, and material data sheets, indicating approval prior to submitting the shop drawings to the DFPE.

b. Providing a letter documenting that the SD-02, SD-03, and SD-05 submittal package has been reviewed and noting any outstanding comments.

c. Performing in-progress construction surveillance prior to installation of ceilings (rough-in inspection).

e. Signing applicable certificates under SD-07.

1.4 DEFINITIONS

Wherever mentioned in this specification or on the drawings, the equipment, devices, and functions must be defined as follows:

1.4.1 Interface Device

An addressable device that interconnects hard wired systems or devices to an analog/addressable system.

1.4.2 Fire Alarm and Mass Notification Control Unit (FMCU)

A master control unit having the features of a fire alarm control unit (FACU) and an autonomous control unit (ACU) where these units are interconnected to function as a combined fire alarm/mass notification system. The FACU and ACU functions may be contained in a single cabinet or in independent, interconnected, and co-located cabinets.

1.4.3 Remote Fire Alarm and Mass Notification Control Unit

A control unit, physically remote from the fire alarm and mass notification control unit, that receives inputs from automatic and manual fire alarm devices; may supply power to detection devices and interface devices; may
provide transfer of power to the notification appliances; may provide
transfer of condition to relays or devices connected to the control unit;
and reports to and receives signals from the fire alarm and mass
notification control unit.

1.4.4 Local Operating Console (LOC)

A unit designed to allow emergency responders and/or building occupants to
operate the MNS including delivery of recorded messages and/or live voice
announcements, initiate visual, textual visual, and audible appliance
operation and other relayed functions.

1.4.5 Terminal Cabinet

A steel cabinet with locking, hinge-mounted door where terminal strips are
securely mounted inside the cabinet.

1.4.6 Control Module and Relay Module

Terms utilized to describe emergency control function interface devices as
defined by NFPA 72.

1.4.7 Designated Fire Protection Engineer (DFPE)

The DoD fire protection engineer that oversees that Area of Responsibility
for that project. This is sometimes referred to as the "cognizant" fire
protection engineer. Interpret reference to "authority having
jurisdiction" and/or AHJ in referenced standards to mean the Designated
Fire Protection Engineer (DFPE). The DFPE may be responsible for review of
the contractor submittals having a "G" designation, and for witnessing
final inspection and testing.

1.4.8 Qualified Fire Protection Engineer (QFPE)

A QFPE is an individual who is a licensed professional engineer (P.E.), who
has passed the fire protection engineering written examination administered
by the National Council of Examiners for Engineering and Surveying (NCEES)
and has relevant fire protection engineering experience.

1.5 SUBMITTALS

**************************************************************************
NOTE: Review submittal description (SD) definitions
in Section 01 33 00 SUBMITTAL PROCEDURES (or the
particular specification section for submittal
procedures in this project) and edit the following
list, and corresponding submittal items in the text,
to reflect only the submittals required for the
project. The Guide Specification technical editors
have classified those items that require Government
approval, due to their complexity or criticality,
with a "G". Generally, other submittal items can be
reviewed by the Contractor's Quality Control
System. Only add a "G" to an item, if the submittal
is sufficiently important or complex in context of
the project.

For Army projects, fill in the empty brackets
following the "G" classification, with a code of up
to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.

**************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.]

Shop drawings (SD-02), product data (SD-03) and calculations (SD-05) must be prepared by the fire alarm designer and combined and submitted as one complete package. The QFPE must review the SD-02/SD-03/SD-05 submittal package for completeness and compliance with the Contract provisions prior to submission to the Government. The QFPE must provide a Letter of Confirmation that they have reviewed the submittal package for compliance with the contract provisions. This letter must include their registered professional engineer stamp and signature. Partial submittals and submittals not reviewed by the QFPE will be returned by the Government disapproved without review.

Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-01 Preconstruction Submittals

Qualified Fire Protection Engineer (QFPE); G[, [_____]]

Fire alarm system designer; G[, [_____]]

Supervisor; G[, [_____]]

Technician; G[, [_____]]

SD-10 Operation and Maintenance Data
Operation and Maintenance (O&M) Instructions; G[, [_____]]
1.6 SYSTEM OPERATION

**************************************************************************
NOTE: Circuit wiring must be Class "B" unless Class "A" or "X" is required by the local installation and as permitted by NFPA 72 (SLC: "A", "B", or "X"; IDC and NAC: "A" or "B").

Circuits and pathways must have survivability levels as defined by NFPA 72.
**************************************************************************

Fire alarm system/mass notification system including textual display sign control panel(s), components requiring power, except for the FMCU(s) power supply, must operate on 24 volts DC unless noted otherwise in this section.

The interior fire alarm and mass notification system must be a complete, supervised, noncoded, analog/addressable fire alarm and mass notification system conforming to NFPA 72, UL 864, and UL 2572. Systems meeting UL 2017 only are not acceptable. The system must be activated into the alarm mode by actuation of an alarm initiating device. The system must remain in the alarm mode until the initiating device is reset and the control unit is reset and restored to normal. The system may be placed in the alarm mode by local microphones, LOC, FMCU, or remotely from authorized locations/users.

1.6.1 Alarm Initiating Devices and Notification Appliances (Visual, Voice, Textual)

a. Connect alarm initiating devices to initiating device circuits (IDC) [Class "A"] [Class "B"], or to signaling line circuits (SLC) Class ["A"] ["B"] ["X"] and installed in accordance with NFPA 72.

b. Connect notification appliances to notification appliance circuits (NAC) [Class "A"] [Class "B"].

1.6.2 Functions and Operating Features

The system must provide the following functions and operating features:

a. Power, annunciation, supervision, and control for the system. Addressable systems must be microcomputer (microprocessor or microcontroller) based with a minimum word size of eight bits with sufficient memory to perform as specified.

b. Visual alarm notification appliances must be synchronized as required by NFPA 72.
c. Electrical supervision of the primary power (AC) supply, presence of the battery, battery voltage, and placement of system modules within the control unit.

d. An audible and visual trouble signal to activate upon a single break or open condition, or ground fault. The trouble signal must also operate upon loss of primary power (AC) supply, absence of a battery supply, low battery voltage, or removal of alarm or supervisory control unit modules. After the system returns to normal operating conditions, the trouble signal must again sound until the trouble is acknowledged. A smoke detector in the process of being verified for the actual presence of smoke must not initiate a trouble condition.

e. A trouble signal silence feature that must silence the audible trouble signal, without affecting the visual indicator.

f. Program capability via switches in a locked portion of the FMCU to bypass the automatic notification appliance circuits, fire reporting system, air handler shutdown, smoke control operation, elevator recall, door release, door unlocking features. Operation of this programmed action must indicate on the FMCU display and printer output as a supervisory or trouble condition. Notification appliance bypass must be selectable by floor.

g. Alarm functions must override trouble or supervisory functions. Supervisory functions must override trouble functions.

h. The system must be capable of being programmed from the control unit keyboard. Programmed information must be stored in non-volatile memory.

i. The system must be capable of operating, supervising, and/or monitoring non-addressable alarm and supervisory devices.

j. There must be no limit, other than maximum system capacity, as to the number of addressable devices that may be in alarm simultaneously.

k. Where the fire alarm/mass notification system is responsible for initiating an action in another emergency control device or system, such as HVAC, atrium exhaust, smoke control, elevator recall, releasing service, the addressable fire alarm relay must be located in the vicinity of the emergency control device.

l. An alarm signal must automatically initiate the following functions:

   (1) Transmission of an alarm signal to the fire department, a remote supervising station.

   (2) Visual indication of the device operated on the FMCU, Video Display unit (VDU), and on the graphic annunciator. Indication on the graphic annunciator must be by floor, zone or circuit, and type of device.

   (3) Record the event on the system printer.

   (4) Actuation of alarm notification appliances.

   (5) Recording of the event electronically in the history log of the FMCU.
(6) Release of doors held open by electromagnetic devices.

(7) Operation of the [smoke control system][atrium exhaust system].

(8) Release of power to electric locks (delayed egress locks) on doors that are part of the means of egress.

(9) Elevator recall as described in this section.

**************************************************************************
NOTE: Use this paragraph only where a detector or detection system is to release a special fire extinguishing system.
**************************************************************************

(10) Operation of [_____] must release the [_____] fire extinguishing system after a [_____] second time delay.

(11) Operation of a sprinkler waterflow switch serving an elevator machinery room or elevator shaft must operate shunt trip circuit breaker(s) to shut down power to the elevators in accordance with ASME A17.1/CSA B44.

(12) Operation of an interface that operates vibrating pagers worn by hearing-impaired occupants.

m. A supervisory signal must automatically initiate the following functions:

1. Visual indication of the device operated on the FMCU, [Video Display unit (VDU),] [and on the [graphic ]][remote ]annunciator]. [Indication on the graphic annunciator must be by floor, zone or circuit, and type of device.]

2. Record the event on the system printer.

3. Transmission of a supervisory signal to [the fire department][a remote supervising station].

4. Operation of a duct smoke detector must shut down the appropriate air handler in accordance with NFPA 90A in addition to other requirements of this paragraph and as allowed by NFPA 72.

5. Recording of the event electronically in the history log of the FMCU.

n. A trouble condition must automatically initiate the following functions:

1. Visual indication of the device operated on the FMCU, [Video Display unit (VDU),] [and on the [graphic ]][remote ]annunciator]. [Indication on the graphic annunciator must be by floor, zone or circuit, and type of device.]

2. Record the event on the system printer.

3. Transmission of a trouble signal to [the fire department][a remote supervising station].
(4) Recording of the event electronically in the history log of the FMCU.

- **o.** Activation of a carbon monoxide alarm initiating device must automatically initiate the following functions:
  1. Visual indication of the device operated on the FMCU, LCD, LED Display unit (VDU), and on the remote annunciator. (Indication on the graphic annunciator must be by floor and room number, device address, and device type.)
  2. Transmission of a carbon monoxide alarm signal to the fire department.
  3. Activation of all strobes and the audible carbon monoxide message throughout the building.
  4. Recording of the event electronically in the history log of the FMCU.

- **p.** System control equipment must be programmed to provide a 60-minute to 180-minute delay in transmission of trouble signals resulting from primary power failure.

- **q.** Activation of a LOC pushbutton must activate the audible and visual alarms in the facility. The audible message must be the one associated with the pushbutton activated.

1.6.3 Elevator Recall

******************************************************************************
NOTE: Delete this paragraph if no elevator work is included in the project.
******************************************************************************

Provide elevator recall in accordance with ASME A17.1/CSA B44, Section [14 21 13 ELECTRIC TRACTION FREIGHT ELEVATORS][14 21 23 ELECTRIC TRACTION PASSENGER ELEVATORS][14 24 13 HYDRAULIC FREIGHT ELEVATORS][14 24 23 HYDRAULIC PASSENGER ELEVATORS], and as specified herein. Activation of any smoke detector in an elevator shaft, machine room, or lobby (except at designated recall level) must cause all elevators associated with that shaft, machine room, or lobby to return nonstop to the designated level. Activation of a smoke detector in the lobby or machine room at the designated level must cause all elevators associated with that lobby to return nonstop to the assigned alternate level. Activation of a detector in an elevator shaft, machine room, or lobby must also cause illumination of elevator cab warning signal (fire hat) and complete operation of fire alarm system as specified in paragraph titled "Functions and Operating Features".

1.7 TECHNICAL DATA AND SITE-SPECIFIC SOFTWARE

Technical data and site-specific software (meaning technical data that relates to computer software) that are specifically identified in this project, and may be required in other specifications, must be delivered, strictly in accordance with the CONTRACT CLAUSES. The fire alarm system manufacturer must submit written confirmation of this contract provision as "Fire Alarm System Site-Specific Software Acknowledgement". Identify data delivered by reference to the specification paragraph against which it is
furnished. Data to be submitted must include complete system, equipment, 
and software descriptions. Descriptions must show how the equipment will 
operate as a system to meet the performance requirements of this contract. 
The site-specific software data package must also include the following:

a. Items identified in NFPA 72, titled "Site-Specific Software".

b. Identification of programmable portions of the system equipment and 
capabilities.

c. Description of system revision and expansion capabilities and methods 
of implementation detailing both equipment and software requirements.

d. Provision of operational software data on all modes of programmable 
portions for fire alarm and mass notification.

e. Description of Fire Alarm and Mass Notification Control Unit equipment 
operation.

f. Description of auxiliary and remote equipment operations.

g. Library of application software.

h. Operation and maintenance manuals.

[1.8 EXISTING EQUIPMENT

************************************************************************************

NOTE: If an addition to an existing fire alarm/mass 
novation system is required, the contract 
drawings or this section must include the make, 
model number, and other pertinent information of 
existing components that are to operate with the new 
equipment. Since new interfaces will have to be 
compatible with the existing system or to the 
central fire alarm reporting system, it may be 
necessary to edit major items out of this 
specification. If a new FMCU is required, it has to 
be compatible with the existing central fire alarm 
reporting system. When an existing system is to be 
expanded, show the following information on the 
contract drawings:

1. Manufacturer and model of existing control unit.

2. Number of existing initiating circuits (zones), 
notification appliance circuits, and control 
circuits served by the control unit.

3. Number of existing alarm notification appliances 
on the system.

4. Total calculated current draw of all devices 
served by each existing standby battery under both 
supervisory (standby) and alarm conditions, 
including NAC/extender control units and subcontrol 
units.

5. Ampere-hour rating and type of each existing
a. Equipment and devices must be compatible and operable with the existing fire alarm/mass notification system and must not impair reliability or operational functions of existing supervising station fire alarm system. The proprietary type supervising station (PSS) is located in Building [____]. The supervising equipment is existing and consists of the following brands and models: [supervising station control unit [____].][____][signal reporting components [____]], [annunciator [____]][____].

b. Equipment and devices must be compatible and operable with the existing building fire alarm/mass notification system. Equipment must not impair reliability or operational functions of the existing system. The existing building system control unit is [____].

c. Equipment and devices must be compatible and operable with the existing installation-wide mass notification system and must not impair reliability or operational functions of the existing system. The installation-wide mass notification system utilizes [____] transceivers.

1.9 QUALITY ASSURANCE

1.9.1 Submittal Documents

1.9.1.1 Preconstruction Submittals

Within 36 days of contract award but not less than [14 days][____] prior to commencing any work on site, the Contractor must submit the following for review and approval. SD-02, SD-03 and SD-05 submittals received prior to the review and approval of the qualifications of the fire alarm subcontractor and QFPE must be returned disapproved without review. All resultant delays must be the sole responsibility of the Contractor.

1.9.1.2 Shop Drawings

Shop drawings must not be smaller than [ISO A1][ANSI D][the Contract Drawings]. Drawings must comply with the requirements of NFPA 72 and NFPA 170. Minimum scale for floor plans must be 1/8"=1'.

1.9.1.3 Nameplates

Nameplate illustrations and data to obtain approval by the Contracting Officer before installation.

1.9.1.4 Wiring Diagrams

[____] copies of point-to-point wiring diagrams showing the points of connection and terminals used for electrical field connections in the system, including interconnections between the equipment or systems that are supervised or controlled by the system. Diagrams must show connections from field devices to the FMCU and remote FMCU, initiating circuits, switches, relays and terminals, including pathway diagrams between the control unit and shared communications equipment within the protected premises. Point-to-point wiring diagrams must be job specific and must not indicate connections or circuits not being utilized. Provide complete riser diagrams indicating the wiring sequence of all devices and their
connections to the control equipment. Include a color-code schedule for the wiring.

1.9.1.5 System Layout

[_____] copies of plan view drawing showing device locations, terminal cabinet locations, junction boxes, other related equipment, conduit routing, conduit sizes, wire counts, conduit fill calculations, wire color-coding, circuit identification in each conduit, and circuit layouts for all floors. Indicate candela rating of each visual notification appliance. Indicate the wattage of each speaker. Clearly identify the locations of isolation modules. Indicate the addresses of all devices, modules, relays, and similar. Show/identify all acoustically similar spaces. Indicate if the environment for the FMCU is within its environmental listing (e.g. temperature/humidity).

Provide a complete description of the system operation in matrix format similar to the "Typical Input/Output Matrix" included in the Annex of NFPA 72.

[For air sampling smoke detection systems, provide floor plan layouts indicating location of fire alarm control unit, air sampling piping (lengths of pipe) and sampling ports (sizes and locations). Floor plan must also indicate geographic monitor zone boundaries, location of display control unit, bar level annunciation panels if separate, and all other associated equipment that is required to provide a complete operational system.

1.9.1.6 Notification Appliances

Calculations and supporting data on each circuit to indicate that there is at least 25 percent spare capacity for notification appliances. Annotate data for each circuit on the drawings.

1.9.1.7 Initiating Devices

Calculations and supporting data on each circuit to indicate that there is at least [25][_____] percent spare capacity for initiating devices. Annotate data for each circuit on the drawings.

1.9.1.8 Amplifiers

Calculations and supporting data to indicate that amplifiers have sufficient capacity to simultaneously drive all notification speakers at tapped settings plus [25][_____] percent spare capacity. Annotate data for each circuit on the drawings.

1.9.1.9 Battery Power

Calculations and supporting data as required in paragraph Battery Power Calculations for alarm, alert, and supervisory power requirements. Calculations including ampere-hour requirements for each system component and each control unit component, and the battery recharging period, must be included on the drawings.

1.9.1.10 Voltage Drop Calculations

Voltage drop calculations for each notification circuit indicating that sufficient voltage is available for proper operation of the system and all
components, at a minimum rated voltage of the system operating on batteries. Include the calculations on the system layout drawings.

1.9.1.11 Product Data

[_____] copies of annotated descriptive data to show the specific model, type, and size of each item. Catalog cuts must also indicate the NRTL listing. The data must be highlighted to show model, size, and options that are intended for consideration. Data must be adequate to demonstrate compliance with all contract requirements. Product data for all equipment must be combined into a single submittal.

Provide an equipment list identifying the type, quantity, make, and model number of each piece of equipment to be provided under this submittal. The equipment list must include the type, quantity, make and model of spare equipment. Types and quantities of equipment submitted must coincide with the types and quantities of equipment used in the battery calculations and those shown on the shop drawings.

1.9.1.12 Air Sampling Smoke Detection System Calculations

Submit air sampling detection system design analysis calculations consisting of battery capacity, loading calculations, and fan speed and air flow/transport calculations. Include schematic diagrams showing pipe segments, pipe diameters, lengths of pipe, node numbers, and sample port diameters to verify the requirements are met.

1.9.1.13 Operation and Maintenance (O&M) Instructions

[Six][_____] copies of the Operation and Maintenance Instructions. The O&M Instructions must be prepared in a single volume or in multiple volumes, with each volume indexed, and may be submitted as a Technical Data Package. Manuals must be approved prior to training. The Interior Fire Alarm And Mass Notification System Operation and Maintenance Instructions must include the following:

a. "Manufacturer Data Package [five][____]" as specified in [Section 01 78 23 OPERATION AND MAINTENANCE DATA][____].

b. Operating manual outlining step-by-step procedures required for system startup, operation, and shutdown. The manual must include the manufacturer's name, model number, service manual, parts list, and preliminary equipment list complete with description of equipment and their basic operating features.

c. Maintenance manual listing routine maintenance procedures, possible breakdowns and repairs, and troubleshooting guide. The manuals must include conduit layout, equipment layout and simplified wiring, and control diagrams of the system as installed.

d. Complete procedures for system revision and expansion, detailing both equipment and software requirements.

e. Software submitted for this project on CD/DVD media utilized.

f. Printouts of configuration settings for all devices.

g. Routine maintenance checklist. The routine maintenance checklist must be arranged in a columnar format. The first column must list all
installed devices, the second column must state the maintenance activity or state no maintenance required, the third column must state the frequency of the maintenance activity, and the fourth column provided for additional comments or reference. All data (devices, testing frequencies, and similar) must comply with UFC 3-601-02.

h. A final Equipment List must be submitted with the Operating and Maintenance (O&M) manual.

1.9.1.14 As-Built Drawings

The drawings must show the system as installed, including deviations from both the project drawings and the approved shop drawings. These drawings must be submitted within two weeks after the final Government test of the system. At least one set of the as-built (marked-up) drawings must be provided at the time of, or prior to the final Government test.

1.9.2 Qualifications

**************************************************************************
NOTE: NICET (National Institute for Certification in Engineering Technologies) establishes the qualifications of an individual as an Engineering Technologist with verification of experience by having a current NICET certification.
**************************************************************************

1.9.2.1 Fire Alarm System Designer

The fire alarm system designer must be certified as a Level [III][IV] (minimum) Technician by National Institute for Certification in Engineering Technologies (NICET) in the Fire Alarm Systems subfield of Fire Protection Engineering Technology or meet the qualifications for a QFPE.

1.9.2.2 Supervisor

[A NICET Level [III][ or ][IV] fire alarm technician must supervise the installation of the fire alarm/mass notification system[, including the air sampling smoke detection system].] [A fire alarm technician with a minimum of eight years of experience must supervise the installation of the fire alarm/mass notification system.] The fire alarm technicians supervising the installation of equipment must be factory trained in the installation, adjustment, testing, and operation of the equipment specified herein and on the drawings.

1.9.2.3 Technician

Fire alarm technicians with a minimum of four years of experience must be utilized to install and terminate fire alarm/mass notification devices, cabinets and control units. The fire alarm technicians installing the equipment must be factory trained in the installation, adjustment, testing, and operation of the equipment specified herein and on the drawings[, and must be thoroughly experienced in the installation of air sampling detection systems].

1.9.2.4 Installer

[Fire alarm installer with a minimum of two years of experience utilized to assist in the installation of fire alarm/mass notification devices,
cabinets and control units]. A licensed electrician must be allowed to install wire, cable, conduit and backboxes for the fire alarm system/mass notification system. The fire alarm installer must be factory trained in the installation, adjustment, testing, and operation of the equipment specified herein and on the drawings.

1.9.2.5 Test Technician

Fire alarm technicians with a minimum of eight years of experience and NICET Level III or IV utilized in testing and certification of the installation of the fire alarm/mass notification devices, cabinets and control units. The fire alarm technicians testing the equipment must be factory trained in the installation, adjustment, testing, and operation of the equipment installed as part of this project.

1.9.2.6 Manufacturer

Components must be of current design and must be in regular and recurrent production at the time of installation. Provide design, materials, and devices for a protected premises fire alarm system, complete, conforming to NFPA 72, except as specified herein.

1.9.3 Regulatory Requirements

Equipment and material must be listed or approved. Listed or approved, as used in this section, means listed, labeled or approved by a Nationally Recognized Testing Laboratory (NRTL) such as UL Fire Prot Dir or FM APP GUIDE. The omission of these terms under the description of any item of equipment described must not be construed as waiving this requirement. All listings or approvals by testing laboratories must be from an existing ANSI or UL published standard. The recommended practices stated in the manufacturer's literature or documentation must be considered as mandatory requirements.

1.10 DELIVERY, STORAGE, AND HANDLING

Protect equipment delivered and placed in storage from the weather, humidity, and temperature variation, dirt and dust, and other contaminants.

1.11 MAINTENANCE

1.11.1 Spare Parts

Furnish the following spare parts in the manufacturers original unopened containers:

a. [Five] complete sets of system keys.

b. [Two] of each type of fuse required by the system.

d. [Two] of each type of detector installed.

e. [Two] of each type of detector base and head installed.

[g. One smoke detector manufacturer's test screen, card or magnet for each
  ten beam smoke detectors, or fraction thereof, installed in the system.

[h. Two air sampling smoke detection system filter assemblies.

] [i. Two] of each type of audible and visual alarm device installed.

] k. Two] of each type of addressable monitor module installed.

] l. Two] of each type of addressable control module installed.

] m. Two] low voltage, [one] [telephone][internet][ethernet],
  and [one] 120 VAC surge protective device.

] n. Two] spare reams of paper for the system printer, plus
  sufficient paper for testing.

] [o. Two] spare printer ribbons.

] 1.11.2 Special Tools

Software, connecting cables and proprietary equipment, necessary for the
maintenance, testing, and reprogramming of the equipment must be furnished
to the Contracting Officer, prior to the instruction of Government
employees.

PART 2 PRODUCTS

2.1 GENERAL PRODUCT REQUIREMENT

All fire alarm and mass notification equipment must be listed for use under
the applicable reference standards. Interfacing of UL 864 or similar
approved industry listing with Mass Notification equipment listed to UL 2572
must be done in a laboratory listed configuration, if the software
programming features cannot provide a listed interface control.

2.2 MATERIALS AND EQUIPMENT

2.2.1 Standard Products

Provide materials, equipment, and devices that have been tested by a
nationally recognized testing laboratory and listed for fire protection
service when so required by NFPA 72 or this specification. Select material
from one manufacturer, where possible, and not a combination of
manufacturers, for any particular classification of materials. Material
and equipment must be the standard products of a manufacturer regularly
engaged in the manufacture of the products for at least two] years
prior to bid opening.

2.2.2 Nameplates

Major components of equipment must have the manufacturer's name, address,
type or style, model or serial number, catalog number, date of
installation, installing Contractor's name and address, and the contract
number provided on a new name plate permanently affixed to the item or
equipment. Major components include, but are not limited to, the following:
a. FMCU

Nameplates must be etched metal or plastic, permanently attached by screws to control units or adjacent walls.

2.2.3 Keys

Keys and locks for equipment, control units and devices must be identical. [Master all keys and locks to a single key as required by the Installation Fire Department][______]. [Keys must be CAT [60][______].]

2.2.4 Instructions

Provide a typeset printed or typewritten instruction card mounted behind a Lexan plastic or glass cover in a stainless steel or aluminum frame. [Install the instructions on the interior of the FMCU.] [Install the frame in a conspicuous location observable from the FMCU.] The card must show those steps to be taken by an operator when a signal is received as well as the functional operation of the system under all conditions, normal, alarm, supervisory, and trouble. The instructions must also include procedures for operating live voice microphones. The instructions and their mounting location must be approved by the Contracting Officer before being posted.

2.3 FIRE ALARM AND MASS NOTIFICATION CONTROL UNIT

**************************************************************************
NOTE: The control unit must be located in an air conditioned space where the ambient temperature is maintained between 15 and 27 degrees C 60 and 80 degrees F.
**************************************************************************

Provide a complete fire alarm and mass notification control unit (FMCU) fully enclosed in a lockable steel cabinet as specified herein. Operations required for testing or for normal care, maintenance, and use of the system must be performed from the front of the enclosure. If more than a single unit is required at a location to form a complete control unit, the unit cabinets must match exactly.[ If more than a single unit is required, and is located in the lobby/entrance, notify the Contracting Officer's Designated Representative (COR), prior to installing the equipment.] The system must be capable of defining any module as an alarm module and report alarm trouble, loss of polling, or as a supervisory module, and reporting supervisory short, supervisory open or loss of polling such as waterflow switches, valve supervisory switches, fire pump monitoring, independent smoke detection systems, relays for output function actuation.

a. Each control unit must provide power, supervision, control, and logic for the entire system, utilizing solid state, modular components, internally mounted and arranged for easy access. Each control unit must be suitable for operation on a 120 volt, 60 hertz, normal building power supply. Provide each control unit with supervisory functions for power failure, internal component placement, and operation.

b. Visual indication of alarm, supervisory, or trouble initiation on the FMCU must be by liquid crystal display or similar means with a minimum of 80 characters. The mass notification control unit must have the capability of temporarily deactivate the fire alarm audible notification appliances while delivering voice messages.
c. Provide secure operator console for initiating recorded messages, strobes and displays; and for delivering live voice messages. Provide capacity for at least eight prerecorded messages. Provide the ability to automatically repeat prerecorded messages. Provide a secure microphone for delivering live messages. Provide adequate discrete outputs to temporarily deactivate fire alarm audible notification, initiate/synchronize strobes and initiate textual visual notification appliances. Provide a complete set of self-diagnostics for controller and appliance network. Provide local diagnostic information display and local diagnostic information and system event log file.

2.3.1 Cabinet

Install control unit components in cabinets large enough to accommodate all components and also to allow ample gutter space for interconnection of control units as well as field wiring. The cabinet must be a sturdy steel housing, complete with back box, hinged steel door with cylinder lock, and [surface][semi-recessed] mounting provisions. The enclosure must be identified by an engraved phenolic resin nameplate. Lettering on the nameplate must say "Fire Alarm and Mass Notification control unit" and must not be less than 25 mm 1-inch high. Provide prominent rigid plastic or metal identification plates for lamps, circuits, meters, fuses, and switches.

2.3.2 Silencing Switches

2.3.2.1 Alarm Silencing Switch

Provide an alarm silencing switch at the FMCU that must silence the audible and visual notification appliances. Subsequent activation of initiating devices must cause the notification appliances to re-activate.

2.3.2.2 Supervisory/Trouble Silencing Switch

Provide supervisory and trouble silencing switch(es) that must silence the audible trouble and supervisory signal(s), but not extinguish the visual indicator. This switch must be overridden upon activation of a subsequent supervisory or trouble condition. Audible trouble indication must resound automatically every 24 hours after the silencing feature has been operated if the supervisory or trouble condition still exists.

2.3.3 Non-Interfering

Power and supervise each circuit such that a signal from one device does not prevent the receipt of signals from any other device. Initiating devices must be manually reset by switch from the FMCU after the initiating device or devices have been restored to normal.

2.3.4 Audible Notification System

**************************************************************************
NOTE: Use the proper bracketed item depending upon whether the fire alarm system is to cause total evacuation upon an alarm.
**************************************************************************

The Audible Notification System must comply with the requirements of NFPA 72 for Emergency Voice/Alarm Communications System requirements, except as
specified herein. The system must be a one-way, multi-channel voice notification system incorporating user selectability of a minimum eight distinct sounds for tone signaling, and the incorporation of a voice module for delivery of recorded messages. Audible appliances must produce a three-pulse temporal pattern for three cycles followed by a voice message that is repeated until the control unit is reset or silenced. For carbon monoxide detector activation, audible appliances must produce a four-pulse temporal pattern for three cycles followed by a voice message that is repeated until the control unit is reset or silenced. Automatic messages must be broadcast through speakers throughout the building/facility but not in stairs or elevator cabs. A live voice message must override the automatic audible output through use of a microphone input at the control unit or the LOC.

a. When using the microphone, live messages must be broadcast [throughout a selected floor or floors, ] [selectable by zone, ] or all call. The system must be capable of operating all speakers at the same time. [The Audible Notification System must support Public Address (PA) paging for the facility.] This must be accomplished with the provision of a separate microphone with a head unit that interfaces with the FMCU. The public address paging function must not override any fire alarm or mass notification functions. The microphone must be [desktop] [hand-held] [_____] style. Hand-held microphones must be housed in a separate protective cabinet. The cabinet must be accessible without the use of a key. The location of the microphone(s) must be approved by the [_____] Designated Fire Protection Engineer (DFPE).) Activation of the public address microphone must not initiate activation of visual notification appliances or LED text displays.

b. The microprocessor must actively interrogate circuitry, field wiring, and digital coding necessary for the immediate and accurate rebroadcasting of the stored voice data into the appropriate amplifier input. Loss of operating power, supervisory power, or any other malfunction that could render the digitalized voice module inoperative must automatically cause the three-pulse temporal pattern to take over all functions assigned to the failed unit in the event an alarm is activated.

2.3.4.1 Outputs and Operational Modules

All outputs and operational modules must be fully supervised with on-board diagnostics and trouble reporting circuits. Provide form "C" contacts for system alarm and trouble conditions. Provide circuits for operation of auxiliary appliance during trouble conditions. During a Mass Notification event, the control unit must not generate nor cause any trouble alarms to be generated with the Fire Alarm system.

2.3.4.2 Mass Notification

**************************************************************************
NOTE: The specification writer must comply with the requirements of UFC 4-021-01 and must use messages approved for each specific installation since risks are different at each and every installation.

These message that follow are suggestions for use in the event that installation specific messages are not available.
**************************************************************************
a. The system must have the capability of utilizing an LOC with redundant controls of the FMCU. Notification Appliance Circuits (NAC) must be provided for the activation of strobe appliances. Audio output must be selectable for line level. A hand-held microphone must be provided and, upon activation, must take priority over any tone signal, recorded message or PA microphone operation in progress, while maintaining the strobe NAC circuit activation.

b. The Mass Notification functions must override the manual or automatic fire alarm notification, and public address (PA) functions. Other fire alarm functions including transmission of a signal(s) to the fire department must remain operational. When a mass notification announcement is disengaged and a fire alarm condition still exists, the audible and visual notification appliances must resume activation for alarm conditions. The fire alarm message must be of lower priority that all other messages (except any "test" messages) and must not override any other messages.

**************************************************************************
NOTE: Include ALL installation specific messages in this section.
**************************************************************************

[ c. Messages must be recorded professionally utilizing standard industry methods, in a professional [male][female] voice. Message and tone volumes must both be at the same decibel level. Messages recorded from the system microphone must not be accepted. A 1000 Hz tone (as required by NFPA 72) must precede messages and be similar to the following unless Installation or Facility specific messages are required:

(1) "May I have your attention please. May I have your attention please. [Insert installation specific message here.]") (Provide a [2][_____] second pause.) "May I have your attention please, (repeat the tones and message [on a continuous loop][_____] times)]."

(2) Carbon Monoxide: "May I have your attention please. May I have your attention please. Carbon monoxide has been detected in the building. Please walk to the nearest exit and leave the building." (Provide a [2][_____] second pause.) "May I have your attention please, (repeat the tones and message [on a continuous loop][_____] times])."

(3) Fire: "May I have your attention please. May I have your attention please. A fire emergency has been reported in the building. Please leave the building by the nearest exit[ or exit stairway].[ Do not use the elevators.]" (Provide a [2][_____] second pause.) "May I have your attention please, (repeat the tones and message on a continuous loop)."

(4) Test: "May I have your attention please. May I have your attention please. This is a test of the building mass notification system. Please continue your normal duties. This is only a test." (Provide a [2][_____] second pause.)

(5) All Clear: "May I have your attention please. May I have your attention please. An all clear has been issued, resume normal activities." (Provide a [2][_____] second pause.)
d. Auxiliary Input Module must be designed to be an outboard expansion module to either expand the number of optional LOC's, or allow a telephone interface.

[2.3.4.3] Installation-Wide Control

**************************************************************************
NOTE: Show on the contract drawings the manufacturer make and model number of any existing installation-wide control system to facilitate communications with the system being specified in this section.
**************************************************************************

If an installation-wide control system for mass notification exists on the Base, the autonomous control unit must communicate with the central control unit of the Installation-wide system. The autonomous control unit must receive commands/messages from the central control unit and provide status information.

[2.3.5] Memory

Provide each control unit with non-volatile memory and logic for all functions. The use of long life batteries, capacitors, or other age-dependent devices must not be considered as equal to non-volatile processors, PROMs, or EPROMs.

[2.3.6] Field Programmability

Provide control units and control units that are fully field programmable for both input and output of control, initiation, notification, supervisory, and trouble functions. The system program configuration must be menu driven. System changes must be password protected. Any proprietary equipment and proprietary software needed by qualified technicians to implement future changes to the fire alarm system must be provided as part of this contract.

[2.3.7] Input/Output Modifications

The FMCU must contain features that allow the bypassing of input devices from the system or the modification of system outputs. These control features must consist of a control unit mounted keypad[ and a keyboard]. Any bypass or modification to the system must indicate a trouble condition on the FMCU.

[2.3.8] Resetting

Provide the necessary controls to prevent the resetting of any alarm, supervisory, or trouble signal while the alarm, supervisory or trouble condition on the system still exists.

[2.3.9] Walk Test

The FMCU must have a walk test feature. When using this feature, operation of initiating devices must result in limited system outputs, so that the notification appliances operate for only a few seconds and the event is indicated in the history log[ and on the system printer], but no other outputs occur.
2.3.10 History Logging

The control unit must have the ability to store a minimum of 400 events in a log. These events must be stored in a battery-protected memory and must remain in the memory until the memory is downloaded or cleared manually. Resetting of the control unit must not clear the memory.

2.3.11 Manual Access

An operator at the control unit, having a proper access level, must have the capability to manually access the following information for each initiating device.

a. Primary status.

b. Device type.

c. Present average value.

d. Present sensitivity selected.

e. Detector range (normal, dirty).

2.3.12 Heat Detector Self-Test Routines

Automatic self-test routines must be performed on each detector that will functionally check detector sensitivity electronics and ensure the accuracy of the value being transmitted. Any detector that fails this test must indicate a trouble condition with the detector location at the control unit.

2.4 LOCAL OPERATING CONSOLES (LOC)

2.4.1 General

The LOC must consist of a remote microphone station incorporating a push-to-talk (PTT) hand-held microphone and system status indicators. The LOC must have the capability of being utilized to activate prerecorded messages. The unit must incorporate microphone override of any tone generation or recorded messages. The unit must be fully supervised from the FMCU. The housing for the LOC must not be lockable. The LOC must have public address capability with the provision of a separate microphone. The PA paging function must not override any alarm or notification functions. The PA microphone must be [desktop][hand-held][_____] style. Hand-held microphones must be housed in a separate protective cabinet. The cabinet must be accessible without the use of a key. The location of the microphone[s] must be approved by the [_____] Designated Fire Protection Engineer (DFPE). Activation of the PA microphone must not initiate activation of visual notification appliances or LED text displays. The PA paging function must not override any alarm or notification functions.

2.4.2 Multiple LOCs

When an installation has more than one LOC, the LOCs must be programmed to allow only one LOC to be available for paging or messaging at a time. Once one LOC becomes active, all other LOC's will have an indication that the system is busy (Amber Busy Light) and cannot be used at that time. This is to avoid two messages being given at the same time. It must be possible to override or lockout the LOC's from the FMCU.
2.5 AMPLIFIERS, PREAMPLIFIERS, TONE GENERATORS

Any amplifiers, preamplifiers, tone generators, digitalized voice generators, and other hardware necessary for a complete, operational, textual audible circuit conforming to NFPA 72 must be housed in a remote FMCU, terminal cabinet, or in the FMCU. Individual amplifiers must be 100 watts maximum.

2.5.1 Operation

The system must automatically operate and control all building speakers[ except those installed in the stairs][ and within elevator cabs].[ The speakers in the stairs[ and elevator cabs] must operate only when the microphone is used to deliver live messages.]

2.5.2 Construction

Amplifiers must utilize computer grade solid state components and must be provided with output protection devices sufficient to protect the amplifier against any transient up to 10 times the highest rated voltage in the system.

2.5.3 Inputs

Equip each system with separate inputs for the tone generator, digitalized voice driver and control unit mounted microphone [Public Address Paging Function]. Microphone inputs must be of the low impedance, balanced line type. Both microphone and tone generator input must be operational on any amplifier.

2.5.4 Tone Generator

The tone generator must produce a three-pulse temporal pattern and must be constantly repeated until interrupted by either the digitalized voice message, the microphone input, or the alarm silence mode as specified. The tone generator must be single channel with an automatic backup generator per channel such that failure of the primary tone generator causes the backup generator to automatically take over the functions of the failed unit and also causes transfer of the common trouble relay. The tone generator must be provided with securely attached labels to identify the component as a tone generator and to identify the specific tone it produces.

2.5.5 Protection Circuits

Each amplifier must be constantly supervised for any condition that could render the amplifier inoperable at its maximum output. Failure of any component must cause illumination of a visual "amplifier trouble" indicator on the control unit, appropriate logging of the condition in the history log[ and on the system printer], and other actions for trouble conditions as specified.

[2.6 VIDEO DISPLAY UNIT (VDU)

**************************************************************************
NOTE: Contact the DFPE to determine if a VDU is to be provided.
**************************************************************************

a. The VDU must be the secondary operator-to-system interface for data
retrieval, alarm annunciation, commands, and programming functions. The desk mounted VDU must consist of a LCD monitor and a keyboard. The VDU must have a touch screen, capable of displaying 25 lines of 80 characters each. Communications with the FMCU must be supervised. Faults must be recorded in the history log and on the printer. Power required must be 120 VAC, 60 Hz from the same source as the FMCU.

b. To eliminate confusion during an alarm situation, the screen must have dedicated areas for the following functions:

(1) Alarm and return to normal.
(2) Commands, reports, and programming.
(3) Time, day, and date.

c. Use full English language throughout to describe system activity and instructions. Full English language descriptors defining system points must be 100 percent field programmable by factory trained personnel, alterable and user definable to accurately describe building areas.

d. Alarms and other changes of status must be displayed in the screen area reserved for this information. Upon receipt of alarm, an audible alarm must sound and the condition and point type must flash until acknowledged by the operator. Return to normal must also be annunciated and must require operator acknowledgment. The following information must be provided in full English:

(1) Condition of device (alarm, trouble, or supervisory).
(2) Type of device (for example, manual pull, waterflow)
(3) Location of device plus numerical system address.

e. The system must have multiple levels of priority for displaying alarms to conform with UL 864. Priority levels must be as follows:

(1) Level 1 - Mass Notification Signals
(2) Level 2 - Fire Alarm Signals
(3) Level 3 - Carbon Monoxide Alarm Signals
(4) Level 4 - Supervisory Signals
(5) Level 5 - Trouble Signals

f. Provide the system with memory so that no alarm is lost. A highlighted message must advise the operator when unacknowledged alarms are in the system.

g. Multiple levels of access must be provided for operators and supervisors via user-defined passwords. Provide the following functions for each level:

(1) Operator level access functions:
   (a) Display system directory, definable by device.
(b) Display status of an individual device.

(c) Manual command (alarm device with an associated command must use the same system address for both functions).

(d) Report generation, definable by device, output on the VDU[ or printer], as desired by the operator.

(e) Activate building notification appliances.

(2) Supervisor level access functions:

(a) Reset time and date.

(b) Enable or disable event initiated programs[, printouts,] and initiators.

(c) Enable or disable individual devices and system components.

h. The above supervisor level functions must not require computer programming skills. Changes to system programs must be [recorded on the printer and ]maintained in the control unit as a trouble condition.

2.7 REMOTE ANNUNCIATOR

******************************************************************************

NOTE: Provide the annunciator at a location in accordance with NFPA 72. A suggested location should be near the door through which the first responders will enter the building as indicated in their pre-fire plan, typically the main entrance.

******************************************************************************

2.7.1 LCD Annunciator

Provide a [semi-recessed][flush] mounted annunciator that includes an LCD display. The display must indicate the device in trouble/alarm or any supervisory device. Display the device name, address[, and actual building location]. The remote annunciator must duplicate functions of the FMCU for message display, fire alarm, supervisory alarm, and trouble conditions, visual and audible notification, and system reset functions. Remote annunciator must require the use of a key for accessing the reset, control and other functions.

A building floor plan must be provided and mounted (behind Plexiglass or similar protective material) at the annunciator location. The floor plan must indicate all rooms by name and number including the locations of stairs and elevators. The floor plan must show all devices and their programmed address to facilitate identification of their physical location from the LCD display information.

2.7.2 Graphic Annunciator

******************************************************************************

NOTE: Graphic annunciators should be provided only when a large number of concealed devices are installed. Normally, exposed devices will be annunciated by zone only on the fire alarm control

SECTION 28 31 76 Page 36
unit zone annunciator and remote zone annunciator.
Edit accordingly. Locate graphic annunciator(s) at
or near building entrance to allow fire department
quick access to the annunciator.

Graphic annunciator must be of the [interior][weatherproof] type,
[flush][surface][pedestal]-mounted. Annunciator must be provided with the
[building][room] floor plan, drawn to scale, with alarm lamps mounted to
represent the location of [each concealed detector][each initiating
device]. Annunciator graphic must also show the locations of the
annunciator and control unit, and must have a "you are here" arrow showing
its location. Orient building floor plan on graphic to location of person
viewing the graphic (i.e., the direction the viewer is facing must be toward
the top of the graphic display). Provide a North arrow. [Principal rooms
and areas shown must be labeled with room numbers or titles.] Detectors
mounted above ceilings, [on ceilings, ] and beneath raised floors and
different types of initiating devices must have different symbols or lamps
of different colors for identification. Lamps must illuminate upon
activation of corresponding device and must remain illuminated until the
system is reset. Annunciator must have a lamp test switch.

2.7.2.1 Materials

Construct the graphic annunciator face plate of [smoked
Flexiglas][non-glare matte finish][anodized bronze][anodized aluminum].
The face plate must be backlit with LEDs. Control equipment and wiring
must be housed in a [recessed][semi-recessed][surface mounted] back box.
The exposed portions of the back box must be [chrome plated][anodized
bronze][anodized aluminum] without knockouts.

2.7.2.2 Programming

Where programming for the operation of the graphic annunciator is
accomplished by a separate software program other than the software for the
FMCU, the software program must not require reprogramming after loss of
power. The software must be reprogrammable in the field.

[2.7.3 Printer

**************************************************************************
NOTE: If the printer will be located in a SCIF or
similar area, specify "no stored memory".
**************************************************************************

a. Provide a system printer [with no stored memory] to record alarm,
supervisory, and trouble conditions without loss of any signal or
signals. Printout must be by circuit, device, and function as provided
in the FMCU. Printer must operate on a 120 VAC, 60 Hz power supply.

b. The printer must have at least 80 characters per line and have a 96
ASCII character set. The printer must have a
microprocessor-controlled, bi-directional, logic seeking head capable
of printing 120 characters per second utilizing a 9 by 7 dot matrix
print head. Printer must not contain internal software which is
essential for proper operation.

c. When the FMCU receives a signal, the alarm, supervisory, and trouble
condition must be printed. The printout must include the type of
signal, the circuit or device reporting, the date, and the time of the
occurrence. The printer must differentiate alarm signals from other printed indications. When the system is reset, this condition must also be printed including the same information concerning device, location, date, and time. Provide a means to automatically print a list of existing alarm, supervisory, and trouble conditions in the system. If a printer is off-line when an alarm is received, the system must have a buffer to retain the data and it must be printed when the printer is restored to service. The printer must have an indicator to alert the operator that the paper has run out.

2.8 MANUAL STATIONS

**************************************************************************
NOTE: Architectural Barriers Act (ABA) requires that manual alarm stations be mounted at a maximum of 1.1 m 44 inches above finished floor (AFF).
**************************************************************************

Provide metal or plastic, [semi-flush][flush][surface] mounted, [single][double]-action, addressable manual stations, that are not subject to operation by jarring or vibration. Stations must be equipped with screw terminals for each conductor. Stations that require the replacement of any portion of the device after activation are not permitted. Stations must be finished in red with molded raised lettering operating instructions of contrasting color. The use of a key must be required to reset the station.

2.9 SMOKE DETECTORS

**************************************************************************
NOTE: Provide smoke detectors only in spaces where they are specifically required by UFC 3-600-01, DESIGN: FIRE PROTECTION ENGINEERING FOR FACILITIES.
**************************************************************************

Smoke detectors provided in elevator machinery rooms are to be provided per requirements of UFC 3-600-01. Coordinate with Section 14 21 13 ELECTRIC TRACTION FREIGHT ELEVATORS, Section 14 21 23 ELECTRIC TRACTION PASSENGER ELEVATORS and/or Section 14 24 13 HYDRAULIC FREIGHT ELEVATORS, Section 14 24 23 HYDRAULIC PASSENGER ELEVATORS.

2.9.1 Spot Type Detectors

Provide addressable [photoelectric][ionization][laser] smoke detectors as follows:

a. Provide analog/addressable [photoelectric smoke detectors utilizing the photoelectric light scattering principle for operation in accordance with UL 268][smoke detectors that operate on the ionization principle and are actuated by the presence of visible or invisible products of combustion][laser smoke detectors utilizing laser diode and patented smoke sensing chamber, designed to amplify signals from smoke but diminish stray internal reflections and must, on command from the FMCU, send data to the control unit representing the analog level of smoke density]. Smoke detectors must be listed for use with the FMCU.

b. Provide self-restoring type detectors that do not require any readjustment after actuation at the FMCU to restore them to normal
operation. The detector must have a visual indicator to show actuation.

c. Vibration must have no effect on the detector's operation. Protect the
detection chamber with a fine mesh metallic screen that prevents the
entrance of insects or airborne materials. The screen must not inhibit
the movement of smoke particles into the chamber.

d. Provide twist lock bases [with sounder that produces a minimum of 90
dBA at 3 m 10 feet] with screw terminals for each conductor. The
detectors must maintain contact with their bases without the use of
springs.

e. The detector address must identify the particular unit, its location
within the system[,] and its sensitivity setting]. Detectors must be of
the low voltage type rated for use on a 24 VDC system.

f. Laser smoke detector must be listed for use with the FM CU. Detector
must be able to achieve sensitivities from 0.02 percent-per-foot to 2
percent-per-foot obscuration.

g. Laser smoke detector must provide point identification of the fire
location through addressability, must experience no delay in response
time due to smoke dilution or smoke transportation time, and must offer
complete supervision of wiring and detector.

][2.9.2 Projected Beam Smoke Detector

Detectors must consist of [combined transmitter and receiver unit]
[separate transmitter and receiver units]. The transmitter unit must emit
an infrared beam to the receiver unit [the use of a supplied reflector is
required for the combined unit]. When the signal at the receiver falls
below a preset threshold, the detector must initiate an alarm. The
receiver must contain an LED status indicator that illuminates when an
alarm condition exists. Long-term changes to the received signal caused by
environmental variations must be automatically compensated. Detectors must
incorporate features to assure that they are operational; a trouble signal
must be initiated if the beam is obstructed for more than 3 seconds, the
limits of the compensation circuit are reached, or the housing cover is
removed. Detectors must have multiple sensitivity settings in order to
meet UL listings for the different distances covered by the beam.

][2.9.3 Duct Smoke Detectors

**************************************************************************
NOTE: The requirements for Duct Detectors will be
coordinated with the HVAC requirements and Section
23 09 00 INSTRUMENTATION AND CONTROL FOR HVAC. All
required duct detectors will be shown on the
contract drawings.
**************************************************************************

Duct-mounted addressable photoelectric smoke detectors must consist of a
smoke detector, as specified in paragraph Spot Type Detectors, mounted in a
special housing fitted with duct sampling tubes. Detector circuitry must
be mounted in a metallic or plastic enclosure exterior to the duct.[ It is
not permitted to cut the duct insulation to install the duct detector
directly on the duct.] Detectors must be listed for operation over the
complete range of air velocities, temperature and humidity expected at the
detector when the air-handling system is operating. Detectors must be
powered from the FMCU.

a. Sampling tubes must run the full width of the duct. The duct detector package must conform to the requirements of NFPA 90A, UL 268A, and must be listed for use in air-handling systems. The control functions, operation, reset, and bypass must be controlled from the FMCU.

b. Lights to indicate the operation and alarm condition must be visible and accessible with the unit installed and the cover in place. Remote indicators must be provided where required by NFPA 72. Remote indicators as well as the affected fan units must be properly identified in etched plastic placards.

c. Detectors must provide for control of auxiliary contacts that provide control, interlock, and shutdown functions specified in Section 23 09 00 to INSTRUMENTATION AND CONTROL FOR HVAC. Auxiliary contacts provide for this function must be located within 1 m 3 feet of the controlled circuit or appliance. The auxiliary contacts must be supplied by the fire alarm system manufacturer to ensure complete system compatibility.

[2.10 AIR SAMPLING SMOKE DETECTION SYSTEM]

The [addressable] air sampling smoke system must consist of a detector assembly housing an integral aspiration fan, filter, laser-based detection chamber and control, output and supervision circuitry. [Each sampling point must be capable of being independently addressable.] The system must consist of a piping or tubing distribution network that runs from the detector assembly(s) to the protected area(s) and is supported by air sampling smoke detection system calculations from a computer-based design modeling tool. The system must include configurable alarm and trouble relay outputs for interface to other systems where required.

a. System must be complete in all ways. It must include all engineering, and electrical installation, all detection and control equipment, auxiliary devices and controls, alarm interface, functional checkout and testing, training and all other operations necessary for a functional system.

b. System base detectors and modules must each accommodate up to [40 addressable][_____] microbore sampling tubes where each tube has a sampling point at the end. Additional modules may be used to provide up to [20 addressable][_____] sampling holes per system.

c. Program alarm thresholds to the following values unless the results of the pre-Government system tests indicate a clear need to change them. In the event that such a need is indicated, notify the Contracting Officer and provide complete documentation concerning the need to deviate from these values. Include within the deviation documentation request, information that complies with the paragraph entitled "Sensitivity Verification Test". Ensure initial threshold levels are approved prior to the Government test.

(1) Alarm Level 1: set ALERT at [_____] [0.0250] percent obscuration/foot

(2) Alarm Level 2: set PRE-ALARM at [_____] [0.0500] percent obscuration/foot

(3) Alarm Level 3: set FIRE 1 at [_____] [0.1000] percent
(4) Alarm Level 4: set FIRE 2 at [_____] [0.2000] percent obscuration/foot

d. All air sampling smoke detection devices and associated components must be new, standard products or the manufacturer's latest design and suitable to perform the functions intended.

e. The laser detection chamber must be of the mass light scattering type and capable of detecting a wide range of smoke particle types of varying size. A particle counting method must be employed for the purposes of:

(1) Preventing large particles from affecting the true smoke reading.

(2) Monitoring contamination of the filter (for example, dust and dirt) to automatically notify when maintenance is required. The particle counting method must not be used for the purpose of smoke density measurement.

f. Detector(s) must be self-monitoring for filter contamination and provide indication through system fault when replacement is necessary. Detectors which allow automatic reset of filter status upon removal and re-insertion are not permitted.

g. Detector(s) must contain relays for alarm and fault conditions. The relays must be software programmable to the required functions.

h. Detector(s) must permit configuration by programmers that are either integral to the system, portable or PC based.

i. Detector(s) must allow programming of:

(1) Smoke threshold alarm levels; ALERT, PRE-ALARM, FIRE 1 and FIRE 2.

(2) Time delays. Ensure the display control unit contains individual adjustable alarm time delay features for each of the alarm threshold levels. Provide an adjustment range between 0 and 60 seconds. Program the alarm threshold time delays to 30 seconds for alarm levels 1 and 2, and 15 seconds for alarm levels 3 and 4.

(3) Faults, including airflow, detector, power, filter and network, as well as an indication of the urgency of the fault.

(4) Configuration of relay outputs for remote indication of alarm and fault conditions.

(5) General purpose input functionality.

2.11 HEAT DETECTORS

**************************************************************************
NOTE: Heat detectors provided in elevator machinery rooms are strictly for the warning sign in the elevator cab and must not alarm the FMCU. Coordinate with Section 14 21 13 ELECTRIC TRACTION FREIGHT ELEVATORS, Section 14 21 23 ELECTRIC TRACTION PASSENGER ELEVATORS and/or Section 14 24 13.
2.11.1 Heat Detectors

Heat detectors must be analog/addressable and designed for detection of fire by [fixed temperature][combination fixed temperature and rate-of-rise principle][rate-compensating principle] in accordance with UL 521. The alarm condition must be determined by comparing detector value with the stored values. Detectors located in areas subject to moisture, exterior atmospheric conditions, or hazardous locations [as defined by NFPA 70][as indicated], must be types approved for such locations.

2.11.1.1 Combination Fixed-Temperature and Rate-of-Rise Detectors

Detectors must be [surface][semi-flush] mounted in the [vertical][horizontal] orientation and supported independently of wiring connections. Detectors must operate at [57.2][90] degrees C[135][194] degrees F. Detector must feature rate compensation. [Detectors rated to operate at 57.2 degrees C135 degrees F must not respond to momentary temperature fluctuations less than 16.7 degrees C30 degrees F per minute between 16 and 38 degrees C60 and 100 degrees F]. [Detectors rated to operate at 90 degrees C194 degrees F must not respond to momentary temperature fluctuations less than 27.8 degrees C50 degrees F per minute between 16 and 66 degrees C60 and 150 degrees F.][The detector assembly must be [weatherproof][and ][explosionproof].]

2.11.1.2 Rate Compensating Detectors

Detector backbox must be [surface][flush] mounted in the [vertical][horizontal] orientation and supported independently of wiring connections. Detectors must be self-restoring and hermetically sealed.[The detector assembly must be [weatherproof][and ][explosionproof].]

2.11.1.3 Line-Type Fixed Temperature Detectors

 Provide [thermostatic][or ][thermistor] line-type heat detection cable [with weather-resistant outer covering] where indicated. Cable must be nominally rated for a temperature of [68][88][138] degrees C[155][190][280] degrees F and must operate on fixed temperature principle only.

2.11.1.4 Fixed Temperature Detectors

Detectors must be [surface][semi-flush] mounted in the [vertical][horizontal] orientation and supported independently of wiring connections. Detectors must be self-restoring. The detectors must have a specific temperature setting [of [57.2][_____] degrees C[135][_____] degrees F][as shown].[The detector assembly must be [weatherproof][and ][explosionproof].]
2.12 FLAME DETECTORS

NOTE: Modify these paragraphs as necessary to indicate that detectors placed in an explosive environment will be approved for use in the appropriate class, division, and group environment as defined in NFPA 70 and as shown on drawings.

Detectors must be sensitive to the micron range best suited for their intended use. Detectors must operate over electrically supervised wiring circuits and the loss of power to the detector must result in a trouble signal. A self-test feature must be provided for each detector to be individually tested.

2.12.1 Infrared (IR) Single Frequency Flame Detector

NOTE: The single frequency IR flame detector has the advantage of a fast response and is moderately sensitive. Its disadvantages are being affected by temperature extremes and being subject to false alarms from a myriad of IR sources.

The detector must be sensitive in the range of [_____] to [_____] micrometers only.

2.12.2 Infrared (IR) Multi Frequency Flame Detector

NOTE: The IR multi frequency flame detector has the advantages of a moderately fast response, moderate sensitivity, and a lower false alarm rate. Its disadvantage is being affected by temperature extremes.

The IR detector must consist of three or more IR sensors, each selected for a different IR frequency. The primary sensor must be sensitive in the range of [_____] to [_____] micrometers only. Secondary sensors are tuned to different IR wavelengths to null out the effect of black body radiation to the primary sensor.

2.12.3 Ultraviolet (UV) Flame Detectors

NOTE: Ultraviolet (UV) flame detectors can be set to respond accurately to UV wavelength light produced by flame from both indoors and outdoors. UV flame detectors operate on the Geiger-Muller principle. These gas-filled vacuum tubes respond in the UV portion of the spectrum but can ignore UV radiation from the sun because the upper response range of the detector falls below the range of UV radiation that reaches the earth.

Solid-state UV detectors are available, but their...
spectral response extends into the sun's UV range and are not recommended for external use.

UV detectors have an 80 to 90 degree cone of vision. The UV detector has a fast response time and usually is not affected by rain, wind, snow, high humidity, or temperature and pressure extremes. UV units will produce false alarms if they are exposed to arc welding or X-ray and gamma radiation. They can also be blinded by oil film or smoke. UV flame detectors that are used in dirty and dusty environments should be equipped with automatic self-test and self-cleaning devices. The cleaning device uses a stream of clean air across the lens surface to minimize the build-up of contaminants.

UV flame detector must be of the narrow band response type which operates on radiated ultraviolet energy and must be sensitive in the range of [_____] to [_____] micrometers only. The cone of vision must be 80 degrees or greater. Each detector must be completely insensitive to light sources in the visible frequency range.

[2.12.4  Combination UV/IR Flame Detector

NOTE: Combination UV/IR flame detectors have been used both inside and outside to detect fires, but are slower to react than individual units.

The UV/IR detector must provide discrimination against false alarms by requiring both UV and IR flame detection before an alarm is sent. The UV sensor must be sensitive in the range of 0.185 to 0.265 micrometers only. The IR sensor must be sensitive in the range of [_____] to [_____] micrometers only. Detectors must be completely insensitive to light sources in the visible frequency range.

][2.13  MULTI-CRITERIA DETECTORS

The designer must select the sensor required to initiate a fire alarm condition.

Multi-criteria detectors must contain [fixed temperature [_____] degrees C F heat sensor], [rate-of-rise heat sensor], [photoelectric smoke detector], [_____] elements in a single housing.

][2.14  CARBON MONOXIDE DETECTOR

Analog/addressable carbon monoxide (CO) detectors must be listed to UL 2075 and set to respond to the sensitivity limits of UL 2034. Carbon monoxide detectors must be listed for use with fire alarm control units. Detectors must be [surface] [semi-flush] mounted in the [vertical][horizontal] orientation and supported independently of wiring connections. Detectors must be self-restoring. For FMCU with no listed compatible addressable CO detectors, provide listed 4-wire detectors.[ Do not provide CO detectors
with local alarms.] Detector must be provided with an LED status indicator.

a. Where 4-wire CO detectors are necessary, each 4-wire CO detector must be individually monitored via addressable interface modules for alarm and off normal/trouble conditions (including loss of power to the individual detector). Power circuits for 4-wire CO detectors must be dedicated to powering the CO detectors only. Battery powered and 120 VAC powered detectors are prohibited.

b. Wiring connections must be made by means of screw terminals and detectors must be equipped with trouble relays. Detectors must be able to mount a single-gang electrical box.

c. A trouble condition at an individual CO detector must not affect any other CO detectors. CO detectors must be powered by the FMCU.

d. Detectors must be provided with a means to test CO gas entry into the CO sensing cell.

2.15 ADDRESSABLE INTERFACE DEVICES

The initiating device being monitored must be configured as a [Class "A"] [Class "B"] initiating device circuits. The module must be listed as compatible with the control unit. The module must provide address setting means compatible with the control unit's SLC supervision and store an internal identifying code. Monitor module must contain an integral LED that flashes each time the monitor module is polled and is visible through the device cover plate. Pull stations with a monitor module in a common backbox are not required to have an LED. [Existing fire alarm system initiating device circuits must be connected to a single module to supervise the circuit.] Modules must be listed for the environmental conditions in which they will be installed.

2.16 ADDRESSABLE CONTROL MODULES

The control module must be capable of operating as a relay (dry contact form C) for interfacing the control unit with other systems, and to control door holders or initiate elevator fire service. The module must be listed as compatible with the control unit. The indicating device or the external load being controlled must be configured as [Class B] [Class A] notification appliance circuits. The system must be capable of supervising, audible, visual and dry contact circuits. The control module must have both an input and output address. The supervision must detect a short on the supervised circuit and must prevent power from being applied to the circuit. The control module must provide address setting means compatible with the control unit's SLC supervision and store an internal identifying code. The control module must contain an integral LED that flashes each time the control module is polled and is visible through the device cover plate. Control Modules must be listed for the environmental conditions in which they will be installed.

2.17 ISOLATION MODULES

a. Provide isolation modules to subdivide each signaling line circuit [into groups of not more than [20 addressable devices][_____]][each floor][in accordance with NFPA 72] between adjacent isolation modules.

b. Isolation modules must provide short circuit isolation for signaling line circuit wiring.
c. Power and communications must be supplied by the SLC and must report faults to the FMCU.

d. After the wiring fault is repaired, the fault isolation modules must test the lines and automatically restore the connection.

2.18 NOTIFICATION APPLIANCES

2.18.1 Audible Notification Appliances

**************************************************************************
NOTE: The designer must layout speakers to achieve both the required dBA levels required by NFPA 72 and also the required intelligibility required. See 3.7 for testing for intelligibility requirements that must be incorporated into the design.

**************************************************************************

Audible appliances must conform to the applicable requirements of UL 464. Appliances must be connected into notification appliance circuits. Surface mounted audible appliances must be painted [red][white][______]. Recessed audible appliances must be installed with a grill that is painted [red][white][______][with a factory finish to match the surface to which it is mounted].

2.18.1.1 Speakers

a. Speakers must conform to the applicable requirements of UL 1480. Speakers must have six different sound output levels and operate with audio line input levels of 70.7 VRMs and 25 VRMs, by means of selectable tap settings. Interior speaker tap settings must include taps of 1/4, 1/2, 1, and 2 watt, at a minimum. Exterior speakers must also be multi-tapped with no more than 15 watt maximum setting. Speakers must incorporate a high efficiency speaker for maximum output at minimum power across a frequency range of 400 Hz to 4,000 Hz, and must have a sealed back construction. Speakers must be capable of installation on standard 100 mm 4-inch square electrical boxes. Where speakers and strobes are provided in the same location, they may be combined into a single [wall mounted] unit. All inputs must be polarized for compatibility with standard reverse polarity supervision of circuit wiring via the FMCU.

b. Provide speaker mounting plates constructed of cold rolled steel having a minimum thickness of 1.519 mm 16 gage or molded high impact plastic and equipped with mounting holes and other openings as needed for a complete installation. Fabrication marks and holes must be ground and finished to provide a smooth and neat appearance for each plate. Each plate must be primed and painted.

c. Speakers must utilize screw terminals for termination of all field wiring.

2.18.2 Visual Notification Appliances

**************************************************************************
NOTE:
1. ABA requires that Visual Notification Appliances be provided in buildings and facilities in each of the following areas: restrooms, and any general usage area (e.g., meeting rooms), hallways, lobbies, and any other area for common use and other areas stated at www.access-board.gov. The Visual Notification Appliance must be mounted as required by ABA that directs compliance with NFPA 72. In addition, alarms in guest rooms required to provide communication features must comply with sections 18.5.5.7 of NFPA 72. Shop drawings must indicate location, dimensions, content, details, and other required information to indicate extent of complying with ABA requirements.

2. Currently NFPA 72 requires "clear color" strobes for Fire Alarm Notification. NFPA 72 requires the strobe must be marked "Fire" to clear identify the function.

Visual notification appliances must conform to the applicable requirements of UL 1638, UL 1971 and conform to the Architectural Barriers Act (ABA). Visual Notification Appliances must have clear high intensity optic lens, xenon flash tubes, or light emitting diode (LED) and be marked "Alert" in letters of contrasting color. The light pattern must be dispersed so that it is visible above and below the strobe and from a 90 degree angle on both sides of the strobe. Strobe flash rate must be 1 flash per second and a minimum of [15][30][75][_____] candela based on the UL 1971 test. Strobe must be [surface][semi-flush] mounted.

2.18.3 Textual Display Signs

NOTE: Provide remote LED Text display in locations where Hearing Impaired personnel might read instructions on the emergency. For Navy projects, the Text displays will be located over stairwell doors and major egress doors at the level of discharge.

Textual display signs must be [LED][LCD flat panel][LED scrolling] and must not exceed 400 mm long by 150 mm high by 75 mm deep 16 inches long by 6 inches high by 3 inches deep with a height necessary to meet the requirements of NFPA 72. The text display must spell out the word "EVACUATE" or "ANNOUNCEMENT" [and the remainder of the emergency instructions ]as appropriate. The design of text display must be such that it cannot be read when not illuminated.

LCD or LED scrolling text displays must meet the following requirements at a minimum:

a. Two lines of information for high priority messaging.

b. Minimum of 20 characters per line (40 total) displayed.

c. Text must be no less than height requirements and color/contrast requirements of NFPA 72.
d. 32K character memory.

e. Display must be wall or ceiling mounted.

f. Mounting brackets for a convenient wall/cubicle mount.

[g. During non-emergency periods, display date and time.]

h. The system must interface with the textual display sign control panel to activate the proper message.]

2.19 ELECTRIC POWER

2.19.1 Primary Power

Power must be [120][_____] VAC [50][60] Hz service for the FMCU from the AC service to the building in accordance with NFPA 72.

2.20 SECONDARY POWER SUPPLY

Provide for system operation in the event of primary power source failure. Transfer from normal to auxiliary (secondary) power or restoration from auxiliary to normal power must be automatic and must not cause transmission of a false alarm.

2.20.1 Batteries

Provide sealed, maintenance-free, [sealed lead acid][lead-calcium][gel cell] batteries as the source for emergency power to the FMCU. Batteries must contain suspended electrolyte. The battery system must be maintained in a fully charged condition by means of a solid state battery charger. Provide an automatic transfer switch to transfer the load to the batteries in the event of the failure of primary power.

2.20.1.1 Capacity

Battery size must be the greater of the following two capacities. This capacity applies to every control unit associated with this system, including supplemental notification appliance circuit panels, auxiliary power supply panels, fire alarm transmitters, and Base-wide mass notification transceivers. When determining the required capacity under alarm condition, visual notification appliances must include both textual and non-textual type appliances.

a. Sufficient capacity to operate the fire alarm system under supervisory and trouble conditions, including audible trouble signal devices for 48 hours and audible and visual signal devices under alarm conditions for an additional 15 minutes.

b. Sufficient capacity to operate the mass notification for 60 minutes after loss of AC power.

2.20.1.2 Battery Power Calculations

a. Verify that battery capacity exceeds supervisory and alarm power requirements for the criteria noted in the paragraph "Capacity" above.

(1) Substantiate the battery calculations for alarm and supervisory power requirements. Include ampere-hour requirements for each
system component and each control unit component, and compliance with UL 864.

(2) Provide complete battery calculations for both the alarm and supervisory power requirements. Submit ampere-hour requirements for each system component with the calculations.

(3) Provide voltage drop calculations to indicate that sufficient voltage is available for proper operation of the system and all components. Calculations must be performed using the minimum rated voltage of each component.

b. For battery calculations assume a starting voltage of 24 VDC for starting the calculations to size the batteries. Calculate the required Amp-Hours for the specified standby time, and then calculate the required Amp-Hours for the specified alarm time. Using 20.4 VDC as starting voltage, perform a voltage drop calculation for circuits containing device and/or appliances remote from the power sources.

2.20.2 Battery Chargers

Provide a solid state, fully automatic, variable charging rate battery charger. The charger must be capable of providing 120 percent of the connected system load and must maintain the batteries at full charge. In the event the batteries are fully discharged (20.4 Volts dc), the charger must recharge the batteries back to 95 percent of full charge within 48 hours after a single discharge cycle as described in paragraph CAPACITY above. Provide pilot light to indicate when batteries are manually placed on a high rate of charge as part of the unit assembly if a high rate switch is provided.

2.21 SURGE PROTECTIVE DEVICES

Surge protective devices must be provided to suppress all voltage transients which might damage fire alarm control unit components. Systems having circuits located outdoors, communications equipment must be protected against surges induced on any signaling line circuit. Cables and conductors, that serve as communications links, must have surge protection circuits installed at each end. The surge protective device must wire in series to the power supply of the protected equipment with screw terminations. Line voltage surge arrester must be installed directly adjacent to the power panel where the FMCU breaker is located.

a. Surge protective devices for nominal 120 VAC must be UL 1449 listed with a maximum 500 volt suppression level and have a maximum response time of 5 nanoseconds. The surge protective device must also meet IEEE C62.41.1 and IEEE C62.41.2 category B tests for surge capacity. The surge protective device must feature multi-stage construction and be provided with a long-life indicator lamp (either light emitting diode or neon) which extinguishes upon failure of protected components. Any unit fusing must be externally accessible.

b. Surge protective devices for nominal 24 VAC, fire alarm telephone dialer, or ethernet connection must be UL 497B listed, meet IEEE C62.41.1 and have a maximum response time of 1-nanosecond. The surge protective device must feature multi-stage construction and be self-resetting. The surge protective device must be a base and plug style. The base assembly must have screw terminals for fire alarm wiring. The base assembly must accept "plug-in" surge protective
module.

c. All surge protective devices (SPD) must be the standard product of a single manufacturer and be equal or better than the following:

(1) For 120 VAC nominal line voltage: UL 1449 and UL 1283 listed, series connected 120 VAC, 20A rated, surge protective device in a NEMA 4x enclosure. Minimum 50,000 amp surge current rating with EMI/RFI filtering and a dry contact circuit for remote monitoring of surge protection status.

(2) For 24-volt nominal line voltage: UL 497B listed, series connected low voltage, 24-volt, 5A rated, loop circuit protector, base and replaceable module.

(3) For alarm telephone dialers: UL 497A listed, series connected, 130-volt, 150 mA rated with self-resetting fuse, dialer circuit protector with modular plug and play.

(4) For IP-DACTS: UL 497B listed, series connected, 6.4-volt, 1.5A rated with 20 kA/pair surge current, data network protector with modular plug and play.

2.22 WIRING

Provide wiring materials under this section as specified in Section 26 20 00 INTERIOR DISTRIBUTION SYSTEM with the additions and modifications specified herein.

2.22.1 Alarm Wiring

IDC and SLC wiring must be [fiber optic][ or ][solid copper] cable in accordance with the manufacturers requirements. Copper signaling line circuits and initiating device circuit field wiring must be No. [14][16][18][_____] AWG size conductors at a minimum. Visual notification appliance circuit conductors, that contain audible alarm appliances, must be copper No. 14 AWG size conductors at a minimum. Speaker circuits must be copper No. [16][_____] AWG size twisted and shielded conductors at a minimum. Wiring for textual notification appliance circuits must be in accordance with manufacturer's requirements but must be supervised by the FMCU.] Wire size must be sufficient to prevent voltage drop problems. Circuits operating at 24 VDC must not operate at less than the listed voltages for the detectors and/or appliances. Power wiring, operating at 120 VAC minimum, must be a minimum No. 12 AWG solid copper having similar insulation. Acceptable power-limited cables are FPL, FPLR or FPLP as appropriate with red colored covering. Nonpower-limited cables must comply with NFPA 70.

2.23 INTERFACE TO THE BASE-WIDE MASS NOTIFICATION NETWORK

******************************************************************************
NOTE: Provide as required for connection to a remote Central Control/Monitoring Mass Notification System Command Center.
******************************************************************************

[2.23.1 Fiber Optic

The fiber optic transceiver must be fully compatible with EIA standards for
RS-232, RS-422 and RS-485 at data rates from 0 (DC) to 2.1 mbps (200 kbps for RS-232) in the low speed mode or from 10 kbps to 10 mbps in the high-speed mode. The fiber optic transceiver must be capable of simplex or full duplex asynchronous transmissions in both point-to-point systems and drop-and-repeat data networks. The fiber optic transceiver must be user configurable for the protocol, speed and mode of operation required. The fiber optic transceiver must be supplied with [ST][ or ][FCPC] type optical connectors. Cabling: as specified in Section 27 10 00 BUILDING TELECOMMUNICATIONS CABLELING SYSTEM.}

]2.23.2 Radio

**************************************************************************

Note: Receiving a new radio frequency assignment often takes a relatively long period of time. Be sure to request the frequency assignment early in the design process.

**************************************************************************

The mass notification transceiver must be bi-direction and meet all the requirements of paragraph, RADIO TRANSMITTER AND INTERFACE PANELS as specified in this specification section. The transceiver utilized in the mass notification system must be capable of the following:

a. Communication with the central control/monitoring system to provide supervision of communication link and status changes are reported by automatic and manual poll/reply/acknowledge routines.

b. All monitored points/status changes are transmitted immediately and at programmed intervals until acknowledged by the central control/monitoring system.

c. Each transceiver must transmits a unique identity code as part of all messages; the code is set by the user at the transceiver.

]2.23.3 Telephone

A modem must be provided for communication with the central control/monitoring system. The modem must be 56k, compatible with data mode V.90, utilizing Hayes compatible command codes. The modem must be capable of auto dialing a preset number based on preprogrammed events. The modem must auto answer and provide a secure password protection system. Cabling: as specified in Section 27 10 00 BUILDING TELECOMMUNICATIONS CABLELING SYSTEM.

]2.23.4 Secure Radio System

**************************************************************************

Note: Receiving a new radio frequency assignment often takes a relatively long period of time. Be sure to request the frequency assignment early in the design process.

**************************************************************************

2.23.4.1 Communications Network

The communications network provides two-way signals between central control
units and autonomous control units (in individual building systems), and should include redundant (primary and backup) communication links. The system must incorporate technology to prevent easy interruption of the radio traffic for MNS alerting.

2.23.4.2 Radio Frequency Communications

Use of radio frequency-type communications systems must comply with National Telecommunications and Information Administration (NTIA) requirements. The systems must be designed to minimize the potential for interference, jamming, eavesdropping, and spoofing.

2.23.4.3 Licensed Radio Frequency Systems

An approved DD Form 1494 for the system is required prior to operation.

2.24 AUTOMATIC FIRE ALARM TRANSMITTERS

**************************************************************************
NOTE: State the make and model number of existing proprietary supervising station receiving equipment. The choice of code transmitter, or radio transmitter depends upon the type of existing fire reporting system at the activity. Determine the type of activity reporting system (e.g., positive non interfering or shunt). In most cases a local energy-tripping device will be required. The facility Fire Dept. or Engineering office should be contacted to determine the type and amount of data to be supervised (monitored), e.g., -type: separate or common transmission of alarm, supervisory, and trouble type signals; -amount: all points, all zones, or the combined premises. Verify that existing monitoring equipment has sufficient capacity to support the additional premises or that it can be expanded as necessary to accommodate the new fire alarm system. Identify existing components.
**************************************************************************

[2.24.1 Radio Transmitter and Interface Panels]

Transmitters must be compatible with proprietary supervising station receiving equipment. Each radio alarm transmitter must be the manufacturer's recognized commercial product, completely assembled, wired, factory tested, and delivered ready for installation and operation. Transmitters must be provided in accordance with applicable portions of NFPA 72, Federal Communications Commission (FCC) 47 CFR 90 and Federal Communications Commission (FCC) 47 CFR 15. Transmitter electronics module must be contained within the physical housing as an integral, removable assembly. The proprietary supervising station receiving equipment is [_____] and the transmitter must be fully compatible with this equipment. At the contractors option, and if listed, the transmitter may be housed in the same control unit as the FMCU. The transmitter must be narrowband radio, with FCC certification for narrowband operation and meets the requirements of the NTIA (National Telecommunications and Information Administration) Manual of Regulations and Procedures for Federal Frequency Management.
2.24.1.1 Operation

Operate each transmitter from 120-volt ac power. In the event of 120-volt ac power loss, the transmitter must automatically switch to battery operation. Switchover must be accomplished with no interruption of protective service, and must automatically transmit a trouble message. Upon restoration of ac power, transfer back to normal ac power supply must also be automatic.

2.24.1.2 Battery Power

Transmitter standby battery capacity must provide sufficient power to operate the transmitter in a normal standby status for a minimum of 72 hours and be capable of transmitting alarms during that period.

2.24.1.3 Transmitter Housing

Use NEMA Type 1 for housing. The housing must contain a lock that is keyed [identical to the fire alarm system for the building][identical to radio alarm transmitter housings on the Installation]. Radio alarm transmitter housing must be factory painted with a suitable priming coat and not less than two coats of a hard, durable weatherproof enamel.

2.24.1.4 Antenna

Antenna must be [omnidirectional, coaxial, halfwave dipole antennas][_____] for radio alarm transmitters with a driving point impedance to match transmitter output. The antenna and antenna mounts must be corrosion resistant and designed to withstand wind velocities of 161 km/hour 100 mph. Do not mount antennas to any portion of the building roofing system. Protect the antenna from physical damage.

2.24.2 Digital Alarm Communicator Transmitter (DACT)

Provide DACT that is compatible with the existing supervising station fire alarm system. Transmitter must have a means to transmit alarm, supervisory, and trouble conditions via a single transmitter. Transmitter must have a source of power for operation that conforms to NFPA 72. Transmitter must be capable of initiating a test signal daily at any selected time. Transmitter must be arranged to seize telephone circuits in accordance with NFPA 72.

2.24.3 Signals to Be Transmitted to the Base Receiving Station

**************************************************************************
NOTE: The following paragraph is applicable only to existing installations for connections to an auxiliary (public) alarm system. Edit this for the installation specific criteria.
**************************************************************************

The following signals must be sent to the base receiving station:

[ a. Sprinkler waterflow

][b. Manual pull stations

][c. Smoke detectors
[d. Duct smoke detectors
[e. Sleeping room smoke detectors
[f. Carbon monoxide detectors
[g. Heat detectors
[h. Fire extinguishing system
[i. Sprinkler valve supervision
[j. Fire pump running
[k. Fire pump supervision
[l. Water supply level and temperature
[m. Combustion engine drive fire pump running
  (1) Selector switch in position than automatic
  (2) Engine over-speed
  (3) Low fuel
  (4) Low battery
  (5) Engine trouble (for example, low oil, over temp)

2.25 SYSTEM MONITORING

2.25.1 Valves

Each valve affecting the proper operation of a fire protection system, including automatic sprinkler control valves, standpipe control valves, sprinkler service entrance valve, valves at fire pumps, isolating valves for pressure type waterflow or supervision switches, and valves at backflow preventers, whether supplied under this contract or existing, must be electrically monitored to ensure its proper position. Provide each tamper switch with a separate address, unless they are within the same room, then a maximum of five can use the same address.

2.25.2 High/Low [Air][Nitrogen] Supervisory Switches

Provide monitoring of high and low supervisory [air][nitrogen] for [dry pipe][ and][ preaction] systems. Each air supervisory switch must have a separate address. Switches must be listed extinguishing system attachments. The device must contain double pole, double throw contacts. Operation of the switch must cause a supervisory signal to be transmitted to the FMCU when [air][nitrogen] pressure in the system monitored sprinkler system increases more than 34.5 kPa (5 psi) above the normal system pressure or drops halfway from the normal pressure to the tripping point.

2.25.3 Room Low Temperature Supervisory Switch

Provide [monitoring of the ]listed supervisory air temperature switch for the [fire pump][sprinkler riser] room[s]. Switch must cause a supervisory signal to be transmitted to the FMCU whenever the temperature in the room
drops to below 4.4 degrees C/40 degrees F. Device must reset when temperature rises above 4.4 degrees C/40 degrees F.

][2.25.4 Electromagnetic Door Holders

Electromagnetic holding devices must operate on [120 VAC][24 VDC], and require not more than [3][_____] watts of power to develop 6.9 kPa/25 psi of holding force. Under normal conditions, the magnets must attract and hold the doors open. Operation must be fail safe with no moving parts. Electromagnetic door hold-open devices must not be required to be held open during building power failure. The device must be listed based on UL 228 tests.

][2.26 ENVIRONMENTAL ENCLOSURES OR GUARDS

Environmental enclosures must be provided to permit fire alarm/mass notification components to be used in areas that exceed the environmental limits of the listing. The enclosure must be listed for the device or appliance as either a manufactured part number or as a listed compatible accessory for the component is currently listed. Guards required to deter mechanical damage must be either a listed manufactured part or a listed accessory for the category of the initiating device or notification appliance.

][2.27 FIREFIGHTER TELEPHONE COMMUNICATION SYSTEM

 **************************************************************************
 NOTE: Provide a master control station at the FMCU with remote telephone stations in each stair at each floor landing, in each elevator lobby on each floor, and in elevator cabs. In addition, provide them at specific locations containing essential fire protection equipment, such as the fire pump room and outside the emergency generator room.

 NOTE: In lieu of firefighter telephones radio repeater equipment compatible with responding fire department may be used if approved by the responding fire department.
 **************************************************************************

 2.27.1 General

 Provide a firefighter telephone communication system with complete, common talk, closed circuits. The system must include, but not be limited to, a master control station mounted in the fire alarm control unit, a power supply and standby battery system, and remote telephone stations.

 2.27.2 Features

 The system must include the following features:

 a. A master control station which must provide power, supervision, and control for wiring, components, and circuits. The act of lifting any remote telephone hand set from its cradle must cause both a visual and audible signal to annunciate at the master control station. Removing the hand set at the master control station and depressing a button at the remote telephone hand set must cause the automatic silencing of the audible signal.
b. Communication between the master control station hand set and any/or all remote hand sets must require the depressing of a push-to-talk switch located on any/all remote hand sets. During the time that the master control hand set is removed from its cradle it must be possible to communicate between five remote hand sets and the master control station.

c. Hand sets must be able to monitor any conversation in progress and join the conversation by pressing the push-to-talk button. It must not be possible to communicate between two or more remote hand sets with the master control station hand set in its cradle.

d. The master control station hand set must be red in color and equipped with a 1.5 m5-foot long strain-relieved coiled cord.

e. The master control station must monitor wire and connections for any opens, shorts, or grounds which would render the system inoperable or unintelligible.

f. The master control station must be equipped with a silencing switch and ring-back feature such that any audible trouble signal can be silenced and must be so indicated by the lighting of an amber LED. Once any trouble condition has been corrected, the amber LED must be extinguished.

g. The master control station must be equipped with a separate, LED annunciated switch for each telephone circuit. In addition, LEDs must provide for the annunciation of operating and supervisory power.

h. The loss of operating or supervisory power must cause an audible and visual indication at the master control station and must also cause the fire alarm trouble signal to sound on the FMCU.

i. Switches, LEDs, and controls must be fully labeled.

2.27.3 Handsets

Handsets must have the following features:

a. Provide [surface][flush] mounted remote telephone stations.

b. Each station must be equipped with a hinged door that is magnetically locked.

c. Each hand set must be permanently wired in place with a coiled cord.

d. Each hand set must be red high-impact cycolac and must be equipped with a push-to-talk switch which, when operated, must signal the master control station and a switch-equipped, storage cradle.

e. Provide operating and supervising power from the same supply circuit(s) utilized for the FMCU.

]PART 3 EXECUTION

3.1 VERIFYING ACTUAL FIELD CONDITIONS

Before commencing work, examine all adjoining work on which the
contractor's work is in any way dependent for perfect workmanship according to the intent of this specification section, and report to the Contracting Officer's Representative any condition which prevents performance of first class work. No "waiver of responsibility" for incomplete, inadequate or defective adjoining work will be considered unless notice has been filed before submittal of a proposal.

3.2 INSTALLATION

3.2.1 Fire Alarm and Mass Notification Control Unit (FMCU)

Locate the FMCU [where indicated on the drawings]. [Recess][Semi-recess][Surface mount] the enclosure with the top of the cabinet 2 m 6 feet above the finished floor or center the cabinet at [1.5][_____] m [5][_____] feet, whichever is lower. Conductor terminations must be labeled and a drawing containing conductors, their labels, their circuits, and their interconnection must be permanently mounted in the FMCU. Locate the document storage cabinet adjacent to the FMCU unless the Contracting Officer directs otherwise.

3.2.2 Battery Cabinets

When batteries will not fit in the FMCU, locate battery cabinets below or adjacent to the FMCU. Battery cabinets must be installed at an accessible location when standing at floor level. Battery cabinets must not be installed lower than 300 mm 12 inches above finished floor, measured to the bottom of the cabinet, nor higher than 900 mm 36 inches above the floor, measured to the top of the cabinet. Installing batteries above drop ceilings or in inaccessible locations is prohibited. Battery cabinets must be large enough to accommodate batteries and also to allow ample gutter space for interconnection of control units as well as field wiring. The cabinet must be provided in a sturdy steel housing, complete with back box, hinged steel door with cylinder lock, and surface mounting provisions. The cabinet must be identified by an engraved phenolic resin nameplate. Lettering on the nameplate must indicate the control unit(s) the batteries power and must not be less than 25 mm 1-inch high.

3.2.3 Manual Stations

Locate manual stations as required by NFPA 72 [and as indicated on the drawings]. Mount stations so they are located no farther than [1.5][_____] m [5][_____] feet from the exit door they serve, measured horizontally. Manual stations must be mounted at [1067][1117][_____] mm [42][44][_____] inches measured to the operating handle.

3.2.4 Notification Appliances

**************************************************************************
NOTE: Locate strobes wall mounted in corridors no more than 4.5 m 15 feet from the end of a corridor with 30 m 100 feet maximum distance between strobes. Where there is an obstruction to the viewing path in the corridors, such as a cross-corridor door or ceiling elevation change, consider the obstruction as defining a new corridor. Provide ceiling mounted strobes in rooms accessible to the public, such as conference rooms, restrooms, courtrooms, cafeterias, and auditoriums in accordance with NFPA 72. In Child Development
Centers only chimes must be used as the pre-alert tone prior to voice messages.

**************************************************************************

a. Locate notification appliance devices[ as required by NFPA 72][ where indicated][ and to meet the intelligibility requirements]. Where two or more visual notification appliances are located in the same room or corridor or field of view, provide synchronized operation. Devices must use screw terminals for all field wiring.[ Audible and visual notification appliances mounted in acoustical ceiling tiles must be centered in the tiles plus or minus 50 mm 2 inches.]

b. Audible and visual notification appliances mounted on the exterior of the building, within unconditioned spaces, or in the vicinity of showers must be listed weatherproof appliances installed on weatherproof backboxes.

c. Speakers must not be located in close proximity to the FMCU or LOC so as to cause feedback when the microphone is in use.

3.2.5 Smoke and Heat Detectors

Locate detectors[ as required by NFPA 72 and their listing][ as indicated on the drawings] on a 100 mm 4-inch mounting box. Install heat detectors not less than 100 mm 4 inches from a side wall to the near edge. Heat detectors located on the wall must have the top of the detector at least 100 mm 4 inches below the ceiling, but not more than 300 mm 12 inches below the ceiling. Smoke detectors are permitted to be on the wall no lower than 300 mm 12 inches from the ceiling with no minimum distance from the ceiling.[ In raised floor spaces, install the smoke detectors to protect[ 21 square meters 225 square feet per detector][____].] Install smoke detectors no closer than 1 m 3 feet from air handling supply diffusers. Detectors installed in acoustical ceiling tiles must be centered in the tiles plus or minus 50 mm 2 inches.

3.2.6 Carbon Monoxide Detectors

Locate detectors[ as required by NFPA 72 and their listings][ as indicated on the drawings] on a 100-mm4-inch mounting box.[ Carbon monoxide detectors must be installed separate from smoke and/or heat detectors.]

[3.2.7 Air Sampling Smoke Detector

Locate air sampling smoke detectors in accordance with the manufacturer's instructions. Air sampling smoke detectors must be installed as follows:

a. Air Sampling Smoke Detector Assembly:

(1) Detector assembly must be mounted to a wall at a height between 48 to 60 inches1200 mm to 1800 mm to top of detector measured above the finished floor.

(2) Mounting must be in a fully accessible and visible location.

(3) Mounting or attachment to site equipment, cable trays, movable walls, other equipment or equipment supports is not permitted.

(4) Piping network insertion into the detector inlet must not be glued.
(5) Air sampling smoke detector assembly must be installed in accordance with this specification section and the manufacturer's installation and instruction manuals.

(6) Flexible tubing for termination of the sampling pipe network into detector inlet is not permitted unless allowed by its listing.

(7) Provide red background with white lettering labels that are plastic or phenolic type with a minimum of 0.25-inch\(6.4\) mm block lettering to indicate detector and zone. For example: "AIR SAMPLING SOME DETECTOR No. 1-1 No. 5".

(8) Provide a typeset printed or typewritten instruction card mounted behind a Lexan plastic or glass cover in a stainless steel or aluminum frame. Install the frame in a conspicuous location observable from the ASD panel. The card must show those steps to be taken by an operator when a signal is received as well as the functional operation of the system under all conditions, normal, alarm, supervisory, and trouble. The instructions must be approved by the Contracting Officer before being posted.

b. Pipe and Sampling Tube Mounting:

(1) The pipe and sampling tubing detection network must be mounted as per the design and manufacturer's specification. The hardware used for mounting will depend upon the design and site requirements.

(2) To minimize flexing, pipes must be secured every 1.5 m\(5\) feet.

(3) Pipes must be suspended between 25 mm and 100 mm\(1\) and 4 inches below the ceiling. In areas with a suspended ceiling, the pipe network must be installed above the ceiling utilizing the manufacturer's capillary sample port supported by the ceiling.

(4) The sampling tubes must be of the same length or use the manufacturer's guidelines to run tubes of the required lengths.

(5) When installing a pipe network in areas subject to high temperature fluctuations allow for the contraction and expansion of pipes.

(6) Where expansion or contraction of pipes is likely either after installation or on a continuous basis, do not place pipe clips adjacent to couplings and socket unions as these may interfere with the movement of the pipe.

(7) No bends are permitted within the first 450 mm\(18\) inches from the detector inlet.

(8) The routing of the piping and sample tube network must be coordinated with potential obstructions, including cable trays, grounding bars, and HVAC ductwork.

(9) All changes in direction must be made with standard elbows or tees.

(10) All joints must be air-tight and made by using solvent cement, except at the entry to the detector assembly. Refer to ASTM F402.
(11) All pipes must be supported by mechanical hangers attached to the structure of the building. Not more than 300 mm1-foot of pipe must extend beyond the last hanger of each sampling pipe. The final installation must result in no noticeable deflection in the piping network.

(12) Attachment of air sampling pipes to cable trays, "gray iron", and telecommunications equipment is prohibited.

(13) Clearly label pipe network to distinguish the pipe from other facility pipe work or protective cabling enclosures. For example: "SMOKE DETECTION SAMPLING TUBE - DO NOT DISTURB". In open rooms and exposed areas, provide labels at no greater than 6.1-m20-foot intervals. Provide labels every 3 m10 feet where piping is installed above suspended ceilings and every 609 mm2 feet, centered in the floor panels, where piping is installed within the raised floor cavity.

(14) Placement of the sampling tube must take into consideration appropriate sampling point locations and spacing.

c. Air Sampling Points:

(1) Open area ceiling sampling points must be oriented downward and must be within 25 mm to 100 mm1 to 4 inches below the underside of the ceiling above where the ceiling is smooth.

(2) Label all air sampling points with a round red label, each with a center hole to match the diameter of the drilled sampling point. For example: "AIR SAMPLING POINT DIA 3.2 MM0.125 INCHES". Indicate fractional dimensions in decimal format with a minimum of three decimal places.

][3.2.8 Graphic Annunciator

Locate the graphic annunciator as shown on the drawings. Mount the annunciator, with the top 1830 mm6 feet above the finished floor or center the annunciator at [1525][_____] mm [5][_____] feet, whichever is lower.

][3.2.9 LCD REMOTE Annunciator

Locate the LCD annunciator as shown on the drawings. Mount the annunciator, with the top 2 m6 feet above the finished floor or center the annunciator at [1.5][_____] m [5][_____] feet, whichever is lower.

][3.2.10 Electromagnetic Door Holder Release

Doors must be held open at a minimum of 90 degrees so as not to impede egress from the space. Mount the armature portion on the door and have an adjusting screw for seating the angle of the contact plate. Wall-mount the electromagnetic release, with a total horizontal projection not exceeding 100 mm4 inches. Ensure all doors release to close upon first stage (pre-discharge) alarm. Electrical supervision of wiring external of control unit for magnetic door holding circuits is not required.

][3.2.11 Firefighter Telephones

Mount telephone[ hand sets][ jacks] on the wall in each stair at each floor landing, in each emergency generator room, in each fire pump room, in each
elevator machine room, in each elevator lobby, and in each elevator cab 1200 mm 4 feet above the finished floor.

3.2.12 Local Operating Console (LOC)

Locate the LOC(s) as required by NFPA 72 and as indicated. Mount the console so that the top message button and microphone is no higher than 1200 mm 4 feet above the floor and the bottom (lowest) message button and microphone is at least 1-meter 3 feet above the finished floor.

3.2.13 Ceiling Bridges

Provide ceiling bridges for ceiling-mounted appliances. Ceiling bridges must be as recommended/required by the manufacturer of the ceiling-mounted notification appliance.

3.3 SYSTEM FIELD WIRING

3.3.1 Wiring within Cabinets, Enclosures, and Boxes

Provide wiring installed in a neat and workmanlike manner and installed parallel with or at right angles to the sides and back of any box, enclosure, or cabinet. Conductors that are terminated, spliced, or otherwise interrupted in any enclosure, cabinet, mounting, or junction box must be connected to screw-type terminal blocks. Mark each terminal in accordance with the wiring diagrams of the system. The use of wire nuts or similar devices is prohibited. Wiring to conform with NFPA 70.

Indicate the following in the wiring diagrams:

a. Point-to-point wiring diagrams showing the points of connection and terminals used for electrical field connections in the system, including interconnections between the equipment or systems that are supervised or controlled by the system. Diagrams must show connections from field devices to the FMCU and remote fire alarm/mass notification control units, initiating circuits, switches, relays and terminals.

b. Complete riser diagrams indicating the wiring sequence of devices and their connections to the control equipment. Include a color code schedule for the wiring. Include floor plans showing the locations of devices and equipment.

3.3.2 Terminal Cabinets

**************************************************************************
NOTE: Provide terminal cabinets on each floor where the fire alarm system supply riser is located and where the fire alarm return riser is located.
**************************************************************************

Provide a terminal cabinet at the base of any circuit riser, on each floor at each riser, and where indicated on the drawings. Terminal size must be appropriate for the size of the wiring to be connected. Conductor terminations must be labeled and a drawing containing conductors, their labels, their circuits, and their interconnection must be permanently mounted in the terminal cabinet. Minimum size is 200 mm by 200 mm 8 inches by 8 inches. Only screw-type terminals are permitted. Provide an identification label, that displays "FIRE ALARM TERMINAL CABINET" with 50 mm 2-inch lettering, on the front of the terminal cabinet.
3.3.3 Alarm Wiring

**************************************************************************
NOTE: Do not penetrate SCIF perimeters with copper signal line circuits. SCIF penetrations should be either fiber optic cable or IDC. IDC circuits penetrating the SCIF must be filtered.
**************************************************************************

a. Voltages must not be mixed in any junction box, housing or device, except those containing power supplies and control relays.

b. Utilize shielded wiring where recommended by the manufacturer. For shielded wiring, ground the shield at only one point, in or adjacent to the FMCU.

c. [Pigtail or T-tap connections to signal line circuits, initiating device circuits, supervisory alarm circuits, and notification appliance circuits are prohibited.][ T-tapping using screw terminal blocks is allowed for Class "B" signaling line circuits.]

d. Color coding is required for circuits and must be maintained throughout the circuit. Conductors used for the same functions must be similarly color coded. Conform wiring to NFPA 70.

e. Pull all conductors splice free. The use of wire nuts, crimped connectors, or twisting of conductors is prohibited. Where splices are unavoidable, the location of the junction box or pull box where they occur must be identified on the as-built drawings. The number and location of splices must be subject to approval by the [_____] Designated Fire Protection Engineer (DFPE).

3.3.4 Back Boxes and Conduit

In addition to the requirements of Section 26 20 00 INTERIOR DISTRIBUTION SYSTEM, provide all wiring in rigid metal conduit or intermediate metal conduit unless specifically indicated otherwise. Minimum conduit size must be 19 mm3/4-inch in diameter. Do not use electrical non-metallic tubing (ENT) or flexible non-metallic tubing and associated fittings.

a. Galvanized rigid steel (GRS) conduit must be utilized where exposed to weather, where subject to physical damage, and where exposed on exterior of buildings. Intermediate metal conduit (IMC) may be used in lieu of GRS as allowed by NFPA 70.

b. Electrical metallic tubing (EMT) is permitted above suspended ceilings or exposed where not subject to physical damage. Do not use EMT underground, encased in concrete, mortar, or grout, in hazardous locations, where exposed to physical damage, outdoors or in fire pump rooms. Use die-cast compression connectors.

c. For rigid metallic conduit (RMC), only threaded type fitting are permitted for wet or damp locations.

d. Flexible metal conduit is permitted for initiating device circuits [_____]6 feet in length or less. Flexible metal conduit is prohibited for notification appliance circuits and signaling line circuits. Use liquid tight flexible metal conduit in damp and wet locations.
e. Schedule 40 (minimum) polyvinyl chloride (PVC) is permitted where conduit is routed underground or underground below floor slabs. Convert non-metallic conduit, other than PVC Schedule 40 or 80, to plastic-coated rigid, or IMC, steel conduit before turning up through floor slab.

f. Exterior wall penetrations must be weathertight. Conduit must be sealed to prevent the infiltration of moisture.

[g. For Class "A" or "X" circuits with conductor lengths of 10 feet3 meters or less, the conductors must be permitted to be installed in the same raceway in accordance with NFPA 72.

3.3.5 Conductor Terminations

Labeling of conductors at terminal blocks in terminal cabinets, FMCU[, and remote FMCU] and the LOC must be provided at each conductor connection. Each conductor or cable must have a shrink-wrap label to provide a unique and specific designation. Each terminal cabinet, FMCU, and remote FMCU must contain a laminated drawing that indicates each conductor, its label, circuit, and terminal. The laminated drawing must be neat, using 12 point lettering minimum size, and mounted within each cabinet, control unit, or unit so that it does not interfere with the wiring or terminals. Maintain existing color code scheme where connecting to existing equipment.

3.4 DISCONNECTION AND REMOVAL OF EXISTING SYSTEM

***********************************************************************************************
NOTE: Contact the Contracting Officer, Base Fire Prevention Office, and/or Base Maintenance Personnel to determine what action is appropriate for the salvaging of existing fire alarm equipment.
***********************************************************************************************

Maintain existing fire alarm/mass notification equipment fully operational until the new equipment has been tested and accepted by the Contracting Officer. As new equipment is installed, label it "NOT IN SERVICE" until the new equipment is accepted. Once the new system is completed, tested, and accepted by the Government, it must be placed in service and connected to the supervising station. Remove tags from new equipment and tag the existing equipment "NOT IN SERVICE" until removed from the building.

a. After acceptance of the new system by the Contracting Officer, remove existing equipment not connected to the new system, remove unused exposed conduit, and restore damaged surfaces. Remove the material from the site and dispose.

b. Disconnect and remove the existing fire alarm/mass notification and smoke detection systems where indicated and elsewhere in the specification.

c. Control units and fire alarm devices and appliances disconnected and removed must be turned over to the Contracting Officer.

d. Properly dispose of fire alarm outlet and junction boxes, wiring, conduit, supports, and other such items.
3.5 CONNECTION OF NEW SYSTEM

The following new system connections must be made during the last phase of construction, at the beginning of the pre-Government tests. New system connections must include:

a. Connection of new relays to existing magnetic door hold-open devices.

b. Connection of new elevator recall relays to existing wiring and conduit.

c. Connection of new system transmitter to existing installation fire reporting system.

Once these connections are made, system must be left energized. Report immediately to the Contracting Officer, coordination and field problems resulting from the connection of the above components.

3.6 FIRESTOPPING

Provide firestopping for holes at conduit penetrations through floor slabs, fire-rated walls, partitions with fire-rated doors, corridor walls, and vertical service shafts in accordance with Section 07 84 00 FIRESTOPPING.

3.7 PAINTING

a. In unfinished areas (including areas above drop ceilings), paint all exposed electrical conduit (serving fire alarm equipment), fire alarm conduit, surface metal raceway, junction boxes and covers red. In lieu of painting conduit, the contractor may utilize red conduit with a factory applied finish.

b. In finished areas, paint exposed electrical conduit (serving fire alarm equipment), fire alarm conduit, surface metal raceways, junction boxes, and electrical boxes to match adjacent finishes. The inside cover of the junction box must be identified as "Fire Alarm" and the conduit must have painted red bands 19 mm/3/4-inch wide at 3-meter/10-foot centers and at each side of a floor, wall, or ceiling penetration.

c. Painting must comply with Section 09 90 00 PAINTS AND COATINGS.

3.8 FIELD QUALITY CONTROL

**************************************************************************
NOTE: Listed tests are minimum required. Coordinate with the local Authority Having Jurisdiction (AHJ) for minimum requirements in excess of the NFPA 72 minimums or those recommend below. If additional tests are required, such tests must be added to the list.
**************************************************************************

3.8.1 Test Procedures

Submit detailed test procedures, prepared and signed by the NICET Level [III] or [IV] Fire Alarm Technician, and the representative of the installing company, [and reviewed by the QFPE] [60] days prior to performing system tests. Detailed test procedures must list all components of the installed system such as initiating devices and circuits, notification appliances and circuits, signaling line devices and circuits,
control devices/equipment, batteries, transmitting and receiving equipment, power sources/supply, annunciators, special hazard equipment, emergency communication equipment, interface equipment, and surge protective devices. Test procedures must include sequence of testing, time estimate for each test, and sample test data forms. The test data forms must be in a check-off format (pass/fail with space to add applicable test data; similar to the forms in NFPA 72 and NFPA 4.) The test procedures and accompanying test data forms must be used for the pre-Government testing and the Government testing. The test data forms must record the test results and must:

a. Identify the NFPA Class of all Initiating Device Circuits (IDC), and Notification Appliance Circuits (NAC), Voice Notification System Circuits (NAC Audio), and Signaling Line Circuits (SLC).

b. Identify each test required by NFPA 72 Test Methods and required test herein to be performed on each component, and describe how these tests must be performed.

c. Identify each component and circuit as to type, location within the facility, and unique identity within the installed system. Provide necessary floor plan sheets showing each component location, test location, and alphanumeric identity.

d. Identify all test equipment and personnel required to perform each test (including equipment necessary for smoke detector testing. The use of magnets is not permitted.

e. Provide space to identify the date and time of each test. Provide space to identify the names and signatures of the individuals conducting and witnessing each test.

3.8.2 Pre-Government Testing

3.8.2.1 Verification of Compliant Installation

Conduct inspections and tests to ensure that devices and circuits are functioning properly. Tests must meet the requirements of paragraph entitled "Minimum System Tests" as required by NFPA 72. The contractor and an authorized representative from each supplier of equipment must be in attendance at the pre-Government testing to make necessary adjustments. After inspection and testing is complete, provide a signed Verification of Compliant Installation letter by the QFPE that the installation is complete, compliant with the specification and fully operable. The letter must include the names and titles of the witnesses to the pre-Government tests. Provide all completion documentation as required by NFPA 72 including all referenced annex sections and the test reports noted below.

a. NFPA 72 Record of Completion.

b. NFPA 72 Record of Inspection and Testing.

d. Audibility test results with marked-up test floor plans.

e. Intelligibility test results with marked-up floor plans.
f. Documentation that all tests identified in the paragraph "Minimum System Tests" are complete.

3.8.2.2 Request for Government Final Test

When the verification of compliant installation has been completed, submit a formal request for Government final test to the [_____][Designated Fire Protection Engineer (DFPE)][Contracting Officer's Representative (COR)]. Government final testing will not be scheduled until the DFPE has received copies of the request for Government final testing and Verification of Compliant Installation letter with all required reports. Government final testing will not be performed until after the connections to the installation-wide fire reporting system[ and the installation-wide mass notification system have] been completed and tested to confirm communications are fully functional. Submit request for test at least [15][_____] calendar days prior to the requested test date.

3.8.3 Correction of Deficiencies

If equipment was found to be defective or non-compliant with contract requirements, perform corrective actions and repeat the tests. Tests must be conducted and repeated if necessary until the system has been demonstrated to comply with all contract requirements.

3.8.4 Government Final Tests

The tests must be performed in accordance with the approved test procedures in the presence of the DFPE. Furnish instruments and personnel required for the tests. The following must be provided at the job site for Government Final Testing:

a. The manufacturer's technical representative.

b. The contractor's Qualified Fire Protection Engineer (QFPE).

c. Marked-up red line drawings of the system as actually installed.

d. Loop resistance test results.

e. Complete program printout including input/output addresses.

f. Copy of pre-Government Test Certificate, test procedures and completed test data forms.

g. Audibility test results with marked-up floor plans.

h. Intelligibility test results with marked-up floor plans.

Government Final Tests will be witnessed by the [_____], [Designated Fire Protection Engineer][Contracting Officer's Representative (COR)][, Qualified Fire Protection Engineer (QFPE)]. At this time, any and all required tests noted in the paragraph "Minimum System Tests" must be repeated at their discretion.

3.9 MINIMUM SYSTEM TESTS

3.9.1 System Tests

Test the system in accordance with the procedures outlined in NFPA 72. The
required tests are as follows:

a. Loop Resistance Tests: Measure and record the resistance of each circuit with each pair of conductors in the circuit short-circuited at the farthest point from the circuit origin. The tests must be witnessed by the Contracting Officer and test results recorded for use at the final Government test.

b. Verify the absence of unwanted voltages between circuit conductors and ground. The tests must be accomplished at the pre-Government test with results available at the final system test.

c. Verify that the control unit is in the normal condition as detailed in the manufacturer's O&M manual.

d. Test each initiating device and notification appliance and circuit for proper operation and response at the control unit. Smoke detectors must be tested in accordance with manufacturer's recommended calibrated test method. Use of magnets is prohibited. Testing of duct smoke detectors must comply with the requirements of NFPA 72 except disconnect at least 20 percent of devices. If there is a failure at these devices, then supervision must be tested at each device.

e. Carbon Monoxide Detector Tests: Carbon monoxide detectors must be tested in accordance with NFPA 72 and the manufacturer's recommended calibrated test method.

f. Test the system for specified functions in accordance with the contract drawings and specifications and the manufacturer's O&M manual.

g. Test both primary power and secondary power. Verify, by test, the secondary power system is capable of operating the system for the time period and in the manner specified.

h. Determine that the system is operable under trouble conditions as specified.

i. Visually inspect wiring.

j. Test the battery charger and batteries.

k. Verify that software control and data files have been entered or programmed into the FMCU. Hard copy records of the software must be provided to the Contracting Officer.

l. Verify that red-line drawings are accurate.

m. Measure the current in circuits to ensure there is the calculated spare capacity for the circuits.

n. Measure voltage readings for circuits to ensure that voltage drop is not excessive.

o. Disconnect the verification feature for smoke detectors during tests to minimize the amount of smoke needed to activate the sensor. Testing of smoke detectors must be conducted using real smoke or the use of canned smoke which is permitted.

p. Measure the voltage drop at the most remote appliance (based on wire
length) on each notification appliance circuit.

q. Verify the documentation cabinet is installed and contains all as-built shop drawings, product data sheets, design calculations, site-specific software data package, and all documentation required by paragraph titled "Test Reports".

3.9.2 Audibility Tests

Sound pressure levels from audible notification appliances must be a minimum of 15 dBa over ambient with a maximum of 110 dBa in any occupiable area. The provisions for audible notification (audibility and intelligibility) must be met with doors, fire shutters, movable partitions, and similar devices closed.

3.9.3 Intelligibility Tests

**************************************************************************
NOTE: Occasionally, large DoD buildings are designed to provide cavernous-type open areas to meet unique operational requirements. Such areas are typically designed with hard wall and ceiling surfaces (such as metal or concrete) without acoustical treatments, and this has been found to cause excessive sound reflections that prevent obtaining the normal, minimum required CIS value. In such facilities, the cavernous-type open area is permitted to have locations with a CIS value lower than the normal, minimum required CIS value when the following conditions are met:

The requirement for a deviation from the normal, minimum CIS criteria identified in the design phase.

Justification for the deviation from the normal, minimum CIS criteria is provided to the approving authority (i.e., the AHJ for the Navy and Marine Corps; the DoD installation in conjunction with the contracting officer for the Army and Air Force). The justification must address all factors relevant to the request for deviation from normal, minimum CIS criteria, including, but not limited to: the operational requirements that restrict the installation of acoustical wall and ceiling treatments; the potential use of special speaker technologies such as directional speakers or stacked speaker systems; and, the availability of physically larger or higher-fidelity speakers even though such speakers might not be listed for fire alarm use.

Note: Deviation from normal, minimum CIS criteria should not be requested for the design of normal, large, open areas that are typically found in permanent DoD buildings, such as dining halls, theaters, and gymnasiums. The potential for deviation from normal criteria is intended to address the rare exception to normal criteria that is sometimes needed for DoD buildings with unique operational requirements.
Building occupants located in the large, cavernous area can adequately understand the message content in the voice signal being broadcast. Whether the voice message is adequately understood must be determined by the approving authority (i.e., the AHJ for the Navy and Marine Corps; the DoD installation in conjunction with the contracting officer for the Army and Air Force).

The CIS value is not less than 0.6 at any location within the large, cavernous area.

The building occupants in the large, cavernous area must walk no more than 30 m (98 feet) to find another location within the large, cavernous area having at least the normal, minimum required CIS value. Note: An STI score of 0.5 is considered equivalent to a CIS score of 0.7. An STI value of 0.7 is considered equivalent to a CIS value of 0.8.

All readings for Sound Pressure Level (SPL) and Intelligibility score must be recorded on the installation drawings next to the speaker symbol. The readings must then be added on the "as-Built" drawings to be submitted at the conclusion of the Final Government test.

Intelligibility testing of the System must be accomplished in accordance with NFPA 72 for Voice Evacuation Systems, and ASA S3.2. Following are the specific requirements for intelligibility tests:

a. Intelligibility Requirements: Verify intelligibility by measurement after installation.

NOTE: The minimum required value for Navy and Marine Corps is 0.7 CIS. The minimum required value for Army and Air Force is 0.8 CIS, although rounding is permitted such that a value of 0.75 may be rounded to 0.8.

b. Ensure that a CIS value greater than the required minimum value is provided in each area where building occupants typically could be found. The minimum required value for CIS is [.7][.8]. Rounding of values is permitted.

NOTE: Edit the following paragraph as required for each specific project.

c. Areas of the building provided with hard wall and ceiling surfaces (such as metal or concrete) that are found to cause excessive sound reflections may be permitted to have a CIS score less than the minimum required value if approved by the DFPE, and if building occupants in these areas can determine that a voice signal is being broadcast and
they must walk no more than 10 m 33 feet to find a location with at least the minimum required CIS value within the same area.

**************************************************************************
NOTE: Edit the following paragraph as required for each specific project.
**************************************************************************

d. Areas of the building where occupants are not expected to be normally present are permitted to have a CIS score less than the minimum required value if personnel can determine that a voice signal is being broadcast and they must walk no more than 15 m 50 feet to a location with at least the minimum required CIS value within the same area.

e. Take measurements near the head level applicable for most personnel in the space under normal conditions (e.g., standing, sitting, sleeping, as appropriate).

f. The distance the occupant must walk to the location meeting the minimum required CIS value must be measured on the floor or other walking surface as follows:

(1) Along the centerline of the natural path of travel, starting from any point subject to occupancy with less than the minimum required CIS value.

(2) Curving around any corners or obstructions, with a 300 mm 12 inches clearance there from.

(3) Terminating directly below the location where the minimum required CIS value has been obtained.

Use commercially available test instrumentation to measure intelligibility as specified by NFPA 72 as applicable. Use the mean value of at least three readings to compute the intelligibility score at each test location.

3.10 SYSTEM ACCEPTANCE

Following acceptance of the system, as-built drawings and O&M manuals must be delivered to the Contracting Officer for review and acceptance. The drawings must show the system as installed, including deviations from both the project drawings and the approved shop drawings. These drawings must be submitted within two weeks after the final Government test of the system. At least one set of as-built (marked-up) drawings must be provided at the time of, or prior to the Final Government Test.

a. [ The drawings must be prepared electronically and sized no less than the contract drawings.][ Furnish one set of CDs or DVDs containing software back-up and CAD based drawings in latest version of [MicroStation] [AutoCAD, ]DXF and portable document formats of as-built drawings and schematics.]

b. Include complete wiring diagrams showing connections between devices and equipment, both factory and field wired.

c. Include a riser diagram and drawings showing the as-built location of devices and equipment.

d. Provide Operation and Maintenance (O&M) Instructions.
[In existing buildings, the transfer of devices from the existing system to the new system and the permission to begin demolition of the old fire alarm system will not be permitted until the as-built drawings and O&M manuals are received.]

3.11 INSTRUCTION OF GOVERNMENT EMPLOYEES

3.11.1 Instructor

Provide the services of an instructor, who has received specific training from the manufacturer for the training of other persons regarding the operation, inspection, testing, and maintenance of the system provided. The instructor must train the Government employees designated by the Contracting Officer, in the care, adjustment, maintenance, and operation of the fire alarm system. The instructor must be thoroughly familiar with all parts of this installation. The instructor must be trained in operating theory as well as in practical O&M work. Submit the instructors information and qualifications including the training history.

3.11.2 Required Instruction Time

Provide [8][16][_____] hours of instruction after final acceptance of the system. The instruction must be given during regular working hours on such dates and times selected by the Contracting Officer. The instruction may be divided into two or more periods at the discretion of the Contracting Officer. The training must allow for rescheduling for unforeseen maintenance and/or fire department responses.

3.11.2.1 Technical Training

Equipment manufacturer or a factory representative must provide [1][3][_____] days of on site and 5 days of technical training to the Government at the manufacturing facility. Training must allow for classroom instruction as well as individual hands on programming, troubleshooting and diagnostics exercises. Factory training must occur within [6][12][_____] months of system acceptance.

3.11.3 Technical Training Manual

Provide, in manual format, lesson plans, operating instructions, maintenance procedures, and training data for the training courses. The operations training must familiarize designated government personnel with proper operation of the installed system. The maintenance training course must provide the designated government personnel adequate knowledge required to diagnose, repair, maintain, and expand functions inherent to the system.

3.12 EXTRA MATERIALS

3.12.1 Repair Service/Replacement Parts

Repair services and replacement parts for the system must be available for a period of 10 years after the date of final acceptance of this work by the Contracting Officer. During the warranty period, the service technician must be on-site within 24 hours after notification. All repairs must be completed within 24 hours of arrival on-site.

During the warranty period, the installing fire alarm contractor is
responsible for conducting all required testing and maintenance in accordance with the requirements and recommended practices of NFPA 72 and the system manufacturer[s]. Installing fire alarm contractor is NOT responsible for any damage resulting from abuse, misuse, or neglect of equipment by the end user.

3.12.2  Spare Parts

Spare parts furnished must be directly interchangeable with the corresponding components of the installed system[s]. Spare parts must be suitably packaged and identified by nameplate, tagging, or stamping. Spare parts must be delivered to the Contracting Officer at the time of the Government testing and must be accompanied by an inventory list.

3.12.3  Document Storage Cabinet

Upon completion of the project, but prior to project close-out, place in the document storage cabinet copies of the following record documentation:

a.  As-built shop drawings
b.  Product data sheets
c.  Design calculations
d.  Site-specific software data package
e.  All documentation required by SD-06.

--- End of Section Table of Contents ---
NOTE: This guide specification covers the requirements for earthwork activities for buildings, utilities, roadways, railroads, and airfields.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1 GENERAL

NOTE: Consult with an engineer while editing this section to determine specific requirements for each job.

The following information will be indicated on the project drawings:

1. Surface elevations, existing and new;

2. Location of underground obstructions and existing utilities;

3. Location and record of soil borings and test
pits. Include ground water observations and topsoil thickness encountered in boring, soil classifications, and properties such as moisture content and Atterberg limit determinations;

4. Location of borrow and disposal area if located on Government property;

5. Clearing stripping and grubbing limits, if different from clearing limits;

6. Areas to be seeded;

7. Hydrological data where available;

8. Shoring and sheeting required (trench protection is specified in Corps of Engineers Manual EM 385-1-1); and

9. Pipe trench excavation details;

10. Location and limits of hard material (obstructions or bedrock);

11. Details of special construction such as under railroad and highways right-of-way requirements for jacking and boring;

12. Details of sewage absorption trenches, absorption pits, and subsurface drains.

1.2 DEFINITIONS

**************************************************************************
NOTE: Delete definitions that will not be used in the specification text or shown on the drawings for a specific project.

All materials called out in the project plan set must be defined in this section.

This list is not exhaustive, therefore will need to be tailored for each project.
**************************************************************************

1.2.1 Structural Fill

Soil material placed to support buildings, walls, pads, and other similar facilities.

1.2.2 Embankment Fill

Soil material placed to construct embankment.

1.2.3 Porous Fill

Free-draining material placed for subsurface drainage, as a capillary break, or another specific purpose.

1.2.4 Topsoil

Surface layer of primarily organic soil capable of supporting vegetation growth.

1.2.5 Utility Bedding Material

Fill placed to directly support pipes, conduits, cables, and appurtenant structures. Bedding may also be used to provide a cushion between
utilities and bedrock, obstacles, obstructions and other unyielding materials.

1.2.6 Flowable Fill

Fill placed in a plastic or liquid form that flows to near its final placement location with limited assistance and subsequently cures or solidifies to provide a stable or impermeable barrier.

1.2.7 Satisfactory Materials

**************************************************************************

NOTE: Satisfactory material will be defined in accordance with locally available materials, design slopes, etc., and suitable classes, based on the geotechnical report, will be listed in the project specification in accordance with the Unified Soil Classification System, ASTM D2487. Maximum rock size will be determined based on how thick the fill is and how it is going to be accomplished. As a rule of thumb, it should be no larger than 1/2 the allowable lift thickness. Clay material should be checked for expansive characteristics and this section should be edited accordingly.

**************************************************************************

Satisfactory materials for fill, backfill, and/or any in-situ soils to remain in place comprise any materials classified by ASTM D2487 as [GW], [GP], [GM], [GP-GM], [GW-GM], [GC], [GP-GC], [GM-GC], [SW], [SP], [SM], [SW-SM], [SC], [SW-SC], [SP-SM], [SP-SC], [CL], [ML], [CL-ML], [CH], [MH]. Maximum particle size to be no greater than [one-half of the allowable lift thickness] [_____] mm inches in any dimension.

1.2.8 Unsatisfactory Materials

**************************************************************************

NOTE: Unsatisfactory material will be defined in accordance with locally available materials, design slopes, etc., and unsuitable classes will be listed in the project specifications in accordance with ASTM D2487. This paragraph should be edited to delete inapplicable materials. Paragraphs UNSATISFACTORY MATERIALS and COHESIONLESS MATERIALS should only be utilized where are very limited variety of materials are to be used or where project soil parameter requirements are not necessary.

**************************************************************************

Materials which do not comply with the requirements for satisfactory materials are unsatisfactory. Unsatisfactory materials also include man-made fills; trash; refuse; backfills from previous construction; roots and other organic matter or frozen material. Notify the Contracting Officer when encountering any contaminated materials.

1.2.9 Cohesionless Materials

**************************************************************************

NOTE: When classification will be necessary during construction, determination of grain size for
classification will be specified to be made in conformance with ASTM C117, ASTM C136/C136M, and ASTM D1140. This paragraph should only be used where soil materials can be categorized as either cohesionless or cohesive without any other limiting parameters.

Cohesionless materials include materials classified in ASTM D2487 as GW, GP, SW, and SP. Materials classified as GM and SM will be identified as cohesionless only when the fines are nonplastic. Perform testing, required for classifying materials, in accordance with ASTM D4318, ASTM C117, ASTM C136/C136M and ASTM D1140.

1.2.10 Cohesive Materials

Cohesive materials include materials classified as GC, SC, ML, CL, MH, and CH. Materials classified as GM and SM will be identified as cohesive only when the fines are plastic. Perform testing, required for classifying materials, in accordance with ASTM D4318, ASTM C117, ASTM C136/C136M and ASTM D1140.

1.2.11 Hard/Unyielding Materials

Hard/Unyielding materials comprise weathered rock, dense consolidated deposits, or conglomerate materials which are not included in the definition of "rock" with stones greater than ____ mm inch in any dimension or as defined by the pipe manufacturer, whichever is smaller. These materials usually require the use of heavy excavation equipment, ripper teeth, or jack hammers for removal.

1.2.12 Unstable Material

Unstable materials are too weak to adequately support the utility pipe, conduit, equipment, or appurtenant structure. Satisfactory material may become unstable due to ineffective drainage, dewatering, becoming frozen, excessive loading.

1.2.13 Expansive Soils

NOTE: Additional laboratory testing and analysis
might be needed to better define site specific expansive soils. If expansive soils are anticipated at the construction site, this specification should be edited to ensure proper construction techniques are undertaken per UFC 3-220-01.

Expansive soils are defined as soils that have an expansion index greater than 20 when tested in accordance with ASTM D4829.

1.2.14 Rock

Solid homogeneous interlocking crystalline material with firmly cemented, laminated, or foliated masses or conglomerate deposits, neither of which can be removed without systematic drilling and blasting, drilling and the use of expansion jacks or feather wedges, or the use of backhoe-mounted pneumatic hole punchers or rock breakers; also large boulders, buried masonry, or concrete other than pavement exceeding $0.375$ cubic yard in volume. Removal of hard material will not be considered rock excavation because of intermittent drilling and blasting that is performed merely to increase production.

1.2.15 Capillary Water Barrier

A layer of clean, poorly graded crushed rock, stone, or natural sand or gravel having a high porosity which is placed beneath a building slab with or without a vapor barrier to cut off the capillary flow of pore water to the area immediately below a slab.

1.2.16 Degree of Compaction (Proctor)

NOTE: ASTM D1557 will be used for maximum density determinations, unless soil borings indicate a gradation that may include coarse material where more than 30 percent is retained on the 19 mm 3/4 inch sieve; in that case, the Contractor will be required to use AASHTO T 180, Method D and corrected with AASHTO T-180-21 Annex A for the maximum density determinations. The designer should determine if AASHTO T 180 is appropriate for the existing soil gradation. If maximum density cannot be determined by either method, the specification may need to require a test section and the COR to determine the number of compaction coverages and equipment type.

Degree of compaction required, except as noted in the second sentence, is expressed as a percentage of the maximum density obtained by the test procedure presented in [ASTM D1557] abbreviated as a percent of laboratory maximum density. Since ASTM D1557 applies only to soils that have 30 percent or less by weight of their particles retained on the 19.0 mm 3/4 inch sieve, express the degree of compaction for material having more than 30 percent by weight of their particles retained on the 19.0 mm 3/4 inch sieve as a percentage of the maximum density in accordance with AASHTO T 180-21 paragraph 1.5, Note 1.
1.2.17 Degree of Compaction (Relative Density)

Degree of compaction required for soils with less than 5 percent passing the No. 200 sieve, is expressed as a relative percentage of the maximum index density/dry unit weight and minimum index density/dry unit weight, obtained by the test procedures in accordance with ASTM D4253 and ASTM D4254, respectively, abbreviated as a percent of laboratory relative density.

1.2.18 Overhaul

**************************************************************************
NOTE: This paragraph is to be deleted when the earthwork is to be paid for under a lump sum contract. The blank will be filled with the appropriate number of stations.
**************************************************************************

Overhaul is the authorized transportation of satisfactory excavation or borrow materials in excess of the free-haul limit of [_____] stations. Overhaul is the product of the quantity of materials hauled beyond the free-haul limit, and the distance such materials are hauled beyond the free-haul limit, expressed in station meters yards.

1.2.19 Borrow

Soil brought to the project site from an external location for the purposes of project construction.

1.2.20 Subgrade

Earth materials directly below foundations and directly below granular base materials in building slab and pavement areas including shoulders.

1.3 SUBSURFACE DATA

Subsurface soil boring logs are shown [in project plans] [in an Attachment to these specifications] [______]. These data represent available subsurface information; however, variations may exist between boring locations.

1.4 CRITERIA FOR BIDDING

**************************************************************************
NOTE: For most projects, the scope of earthwork can accurately be determined. However, if earthwork is approximately known, a unit price for earth work should be provided in the Bid Schedule.
**************************************************************************

Measurement and Payment should be addressed with Section 01 20 00 PRICE AND PAYMENT PROCEDURES.

Unit-price items are multiplied by the approximated and stated quantity giving a sum that is then added to the price for the rest of the work. The result is a lump sum bid with automatic provision for payment or credit due to variations in earthwork within 15 percent of that shown and bid upon.

Variations exceeding 15 percent of that shown and
bid upon will become the subject of negotiations in accordance with FAR 52.211-18 Variation in Estimated Quantity.

Base bids on the following criteria:

a. Surface elevations are as indicated.

b. Pipes or other artificial obstructions, except those indicated, will not be encountered.

c. [Ground water elevations indicated by the boring log were those existing at the time subsurface investigations were made and do not necessarily represent ground water elevation at the time of construction.][ Ground water elevation is [_____] meters feet below existing surface elevation.]

d. Ground water elevation is [_____] meters feet below existing surface elevation.

e. Material character is indicated by the boring logs.

NOTE: Choose the following option if no boring information is available, or if the boring information is insufficient to permit a bidder to develop an accurate estimate of hard material or rock to be encountered. If hard material or rock is to be encountered, the following option should be modified to include a percent figure or an approximate depth at which hard material or rock will be encountered.

f. Hard materials[ and rock] [will not] [will] be encountered[ in [_____] percent of the excavations][ at [_____] meters feet below existing surface elevations].

1.5 SUBMITTALS

NOTE: Review Submittal Description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G". Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the
Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.

**************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

1.6 QUALITY CONTROL

1.6.1 Geotechnical Engineer

Provide a Professional Geotechnical Engineer to provide inspection of excavations and soil/groundwater conditions throughout construction. The Geotechnical Engineer is responsible for performing pre-construction and periodic site visits throughout construction to assess site conditions. The Geotechnical Engineer is responsible for preparing and updating the Excavation and Trenching Plan and Dewatering Work Plan as construction progresses to reflect changing conditions and submit an updated plan if necessary. Submit a monthly Geotechnical Evaluation report, informing the Contractor and Contracting Officer of the status of the plan and an accounting of the Contractor's adherence to the plan addressing any present or potential problems. The Contractor is responsible for arranging meetings with the Geotechnical Engineer and Contracting Officer throughout the contract duration.

1.6.2 Qualified Technician

Provide a Qualified Technician to inspect, monitor, sample, and performing field testing. The technician qualifications need to be one of the following: a current National Institute for Certification in Engineering Technologies (NICET) Level II minimum certification in Construction Materials Testing Soils; a Geologist-in-Training with minimum one-year experience; an Engineer-in-Training with minimum one-year experience; a Registered Geologist; or a Professional Engineer.

1.6.3 Lab Validation

Perform testing by a Corps validated commercial testing laboratory or Contractor established testing laboratory meeting the requirements of Section 01 45 00 (or similar number) entitled QUALITY CONTROL and approved by the Contracting Officer. Submit testing laboratory validation for the testing to be performed. Do not permit work requiring testing until testing facilities have been inspected, Corps validated and approved by the Contracting Officer.

1.6.4 Preconstruction Meeting

Conduct a preconstruction meeting at the jobsite at least five business days prior to the start of earthwork operations on the project. The preconstruction meeting is to be arranged by the Contractor and is to follow the written agenda submitted prior to the meeting. The purpose of this meeting is to review the requirements of this specification and the associated plans. The following individuals must be in attendance at this meeting.
meeting: Contractor's Project Manager and Project Superintendent, earthwork subcontractor's Project Manager and Site Foreman, Contractor's Geotechnical Engineer and Testing Agency, Government Geotechnical Engineer and Civil Engineer, and Government Construction Manager and Engineering Technician.

The minutes of this meeting are to be recorded by the Contractor and published via email within 48 hours to all attendees. The minutes must be re-published within 48 hours via email pending any subsequent comments from the attendees.

PART 2 PRODUCTS

**************************************************************************
NOTE: All PRODUCTS included must have an associated definition in PART 1.
**************************************************************************

2.1 SOIL MATERIALS

**************************************************************************
NOTE: All SOIL MATERIALS included must have an associated definition in PART 1. Soil materials as described in this subpart should be called out where applicable on project plan sets. Soil materials should expand upon definition to include required classifications and parameters.

For example, the following is a list of material properties/criteria that could be considered for specific soil materials such as Embankment Fill:

a. Liquid limit less than [_____];
b. Plasticity index [greater than] [less than] [_____];
c. Hydraulic conductivity (ASTM D5084) to be [less than] [greater than] or equal to [_____]; and
d. Grain size analysis resulting in greater than [_____] percent of material [passing] [retained on] the [_____] sieve.
**************************************************************************

2.1.1 Structural Fill

Materials classified as [GW], [GP],[GM], [GC], [GW-GM], [GW-GC], [GP-GM], [GP-GC], [GC-GM], [SW], [SP], [SM], [SW-SM], [SC], [SW-SC], [SP-SM], [SP-SC], [CL], or [CH] in accordance with ASTM D2487. Select material type appropriate for the intended purpose.

2.1.2 Embankment Fill

Materials classified as [GW], [GP],[GM], [GC], [GW-GM], [GW-GC], [GP-GM], [GP-GC], [GC-GM], [SW], [SP], [SM], [SW-SM], [SC], [SW-SC], [SP-SM], [SP-SC], [CL], or [CH] in accordance with ASTM D2487. Select material type appropriate for the intended purpose.

2.1.3 Porous Fill

Materials containing less than 5 percent passing the No. 200 sieve.
Provide the gradation as appropriate for the intended purpose.

2.1.4 Topsoil

**************************************************************************
NOTE: Additional requirements such as pH value and necessary soil conditioning, according to applicable provisions of Sections 32 92 19 SEEDING through 32 92 26 SPRIGGING, should be inserted in this paragraph. The depth of the topsoil should be given in the text of the specification, preferably in this paragraph.
**************************************************************************

Material suitable for topsoil obtained from [offsite areas] [excavations] [areas indicated on the drawings] is defined as: Natural, friable soil representative of productive, well-drained soils in the area, free of subsoil, stumps, rocks larger than 25 mm one inch diameter, brush, weeds, toxic substances, and other material detrimental to plant growth. [Amend topsoil pH range to obtain a pH of [5.5 to 7] [_____].] [Topsoil material will be in accordance with ASTM D5268.]

2.1.5 Capillary Water Barrier

Conform to ASTM C33/C33M for fine aggregate grading with a maximum of 3 percent by weight passing ASTM D1140, 75 micrometers No. 200 sieve, [or] [37.5 mm 1-1/2 inch and no more than 2 percent by weight passing the 4.75 mm No. 4 size sieve] [or coarse aggregate Size 57, 67, or 77].

2.1.6 Utility Bedding Material

Except as specified otherwise in the individual piping section, provide bedding for buried piping in accordance with [AWWA C600] [ASTM D2321]. Install bedding for plastic piping to spring line of pipe. [Provide geotextile fabric below bedding layer where indicated.] Utility bedding material may include the following:

2.1.6.1 Class I

Angular, 6 to 40 mm 0.25 to 1.5 inch, graded stone, including a number of fill materials that have regional significance such as coral, slag, cinders, crushed stone, and crushed shells.

2.1.6.2 Class II

Coarse sands and gravels with maximum particle size of 40 mm 1.5 inch, including various graded sands and gravels containing small percentages of fines, generally granular and noncohesive, either wet or dry. Soil Types GW, GP, SW, and SP are included in this class as specified in ASTM D2487.

2.1.6.3 Sand

Clean, coarse-grained sand classified as [_____], [gradation [_____]] of the [DOT] [State Standard] or [SW] [or] [SP] by ASTM D2487 for [bedding] [and] [backfill] [as indicated]].

2.1.6.4 Gravel and Crushed Stone

Clean, coarsely graded natural gravel, crushed stone or a combination
thereof identified as [____], [gradation [____] of the [DOT] [State Standard]] or having a classification of [GW] [GP] in accordance with ASTM D2487 for [bedding] [and] [backfill] [as indicated]. [Do not exceed maximum particle size of [75] [_____] mm [3] [_____] inches.]

2.2 FLOWABLE FILL

Design and submit flowable fill mix design to consist of Portland cement, fly ash, and/or slag cement and fine aggregate. Include the dry weights of cementitious material(s); quality and gradation of aggregates in the saturated surface-dry weights along with gradation tests; quantities, types, and names of admixtures; and quantity of water per cubic yard. The [minimum] [maximum] unconfined compressive strength to be [____] [psi] [psf] at [____] days in accordance with ASTM D4832. The aggregates in accordance with ASTM C33/C33M Fine Aggregates. Air-entrain fill in accordance with ASTM C260/C260M. The air content to be between [8 and 15 percent] in accordance with ASTM D6023. The flow to be between [17 to 25 mm] [8 and 12 inches] [_____] in accordance with ASTM D6103/D6103M. Portland cement to be Type I or II in accordance with ASTM C150/C150M. Fly ash to be Class C in accordance with ASTM C618. Provide slag cement in Grade 100 or 120 in accordance with ASTM C989/C989M.

2.3 BURIED WARNING AND IDENTIFICATION MARKERS

**************************************************************************
NOTE: Delete paragraph if tape is not required in the project. The use of a plastic warning tape for identification is mandatory for buried hazardous utilities such as electrical conduit, gas lines, fuel lines, high pressure nitrogen, high pressure water and steam lines, domestic sewage force mains, industrial waste force mains and industrial sewers carrying hazardous, explosive, or toxic waste. Coordinate color codes with other specification sections and conform, if possible, to local practice for identifying buried utilities.
**************************************************************************

Provide [polyethylene plastic] [and] [metallic core or metallic-faced, acid- and alkali-resistant, polyethylene plastic] warning tape manufactured specifically for warning and identification of buried utility lines. Provide tape on rolls, 75 mm 3 inches minimum width, color coded as specified below for the intended utility with warning and identification imprinted in bold black letters continuously over the entire tape length. Warning and identification to read, "CAUTION, BURIED (intended service) LINE BELOW" or similar wording. Provide permanent color and printing, unaffected by moisture or soil.

2.3.1 Warning Tape for Metallic Piping

Provide acid and alkali-resistant polyethylene plastic tape conforming to the width, color, and printing requirements specified above, with a minimum thickness of 0.08 mm 0.003 inch and a minimum strength of 10.3 MPa 1500 psi lengthwise, and 8.6 MPa 1250 psi crosswise, with a maximum 350 percent elongation.

2.3.2 Detectable Warning Tape for Non-Metallic Piping

Provide polyethylene plastic tape conforming to the width, color, and printing requirements specified above, with a minimum thickness of 0.10 mm 0.004 inch, and a minimum strength of 10.3 MPa 1500 psi lengthwise and 8.6 MPa 1250 psi crosswise. Manufacture tape with integral wires, foil backing, or other means of enabling detection by a metal detector when tape is buried up to 920 mm 3 feet deep. Encase metallic element of the tape in a protective jacket or provide with other means of corrosion protection.

2.3.3 Detection Wire for Non-Metallic Piping

Insulate a single strand, solid copper detection wire with a minimum of 12 AWG.

2.4 MATERIAL FOR RIP-RAP

**************************************************************************
NOTE: Make sure there is no duplication of rip-rap requirements between this and other specification sections. In this paragraph refer to standard specifications for rip-rap if local specifications are satisfactory and available. Delete this paragraph or subparagraphs not required in the project. Large scale marine applications should utilize Division 35 of the UFGS.
**************************************************************************

Provide [bedding material] [grout] [filter fabric] and rock conforming to [these requirements] [DOT] [_____ State Standard] for construction indicated.

2.4.1 Bedding Material

Provide bedding material consisting of sand, gravel, or crushed rock, well graded, [or poorly graded] with a maximum particle size of 50 mm 2 inches. Compose material of tough, durable particles. Allow fines passing the 75 micrometers No. 200 standard sieve with a plasticity index less than [6] [____].
2.4.2 Grout

Provide durable grout composed of cement, water, an air-entraining admixture, and sand mixed in proportions of one-part Portland cement to [two] [_____] parts of sand, sufficient water to produce a workable mixture, and an amount of admixture which will entrain sufficient air, as determined by the Contracting Officer. Mix grout in a concrete mixer. Allow a sufficient mixing time to produce a mixture having a consistency permitting gravity flow into the interstices of the riprap with limited spading and brooming.

2.4.3 Rock

**************************************************************************

NOTE: Adjust weights in brackets to fit application. Take local practice into consideration.
**************************************************************************

Provide rock fragments which ensure permanence in the structure and the environment in which it is to be used. Use rock fragments free from cracks, seams, and other defects that would increase the risk of deterioration from natural causes. Provide fragments sized such that no individual fragment exceeds a weight of [68] [_____] kg [150] [_____] pounds and that no more than 10 percent of the mixture, by weight, consists of fragments weighing 0.91 kg 2 pounds or less each. Provide rock with a minimum specific gravity of [2.50] [_____]. Do not permit the inclusion of more than trace [1 percent] [_____] quantities of dirt, sand, clay and rock fines.

2.5 BORROW

Provide borrow materials from sources located [within] [and/or] [outside of Government] property meeting the requirements of paragraph [STRUCTURAL FILL] [EMBANKMENT FILL] [TOPSOIL].

2.6 GEOTEXTILE

**************************************************************************

NOTE: FILTER FABRIC should only be included for relatively small projects that have a scope limited such that a separate section is not warranted.
**************************************************************************

Provide a pervious sheet of polyester, nylon, glass or polypropylene ultraviolet resistant filaments woven, spun bonded, fused, or otherwise manufactured into a non-raveling fabric with uniform thickness and strength. Fabric must have manufacturer certified minimum average roll properties that conform with [______]. Submit a sample and material product data for all Geotextiles utilized.

PART 3 EXECUTION

3.1 PROTECTION

**************************************************************************

NOTE: Include this paragraph when scope of work requires excavations which are greater than 1.5 m 5 feet or where it is known that in-situ soils lack the stability to hold near vertical faces. Where
sufficient room is available, the Contractor may slope back trench walls rather than having to use a shoring system. However, the Contractor should not be given the opportunity to slope the faces of excavations in lieu of providing shoring unless all the following conditions are met:

The excavation is less than 6 m 20 feet in depth.

There are no adjacent structures, roads, or pavements that will affect the excavation.

No equipment, stored material, or overlying material will affect the excavation.

Vibration from equipment, traffic, or blasting will not affect the excavation.

There will be no ground water problems.

Surcharges will not affect the excavation.

Operational considerations permit laying back the slopes of the excavation.

In conditions requiring engineering expertise to assess or design, include requirement for Geotechnical Engineer in paragraph QUALITY CONTROL.

Perform all work specified in accordance with applicable requirements of the Corps of Engineers publication EM 385-1-1 Safety and Health Requirements Manual.[ Provide a Geotechnical Engineer to monitor construction activities and to prepare necessary work plans and reports; see paragraph QUALITY CONTROL.]

Use equipment of type and size appropriate for the site conditions (soil character and moisture content). Maintenance of exposed subgrades and fills is the responsibility of the Contractor. The Contractor is required to prevent damage by ineffective drainage, dewatering, and heavy loads and equipment by implementing precautionary measures. Repair or replace any defects or damage.

3.1.1 Underground Utilities

Location of the existing utilities indicated is approximate. Physically verify the location and elevation of the existing utilities indicated prior to starting construction. The Contractor is responsible for protecting utilities from damage during construction.

3.1.2 Drainage and Dewatering

NOTE: Sentence can be used instead of paragraphs DRAINAGE and DEWATERING for minor, low consequence situations related to impacts from surface or groundwater.

**************************************************************************
Perform all work specified in accordance with applicable requirements of the Corps of Engineers publication EM 385-1-1 Safety and Health Requirements Manual.[ Provide a Geotechnical Engineer to monitor construction activities and to prepare necessary work plans and reports; see paragraph QUALITY CONTROL.]

Use equipment of type and size appropriate for the site conditions (soil character and moisture content). Maintenance of exposed subgrades and fills is the responsibility of the Contractor. The Contractor is required to prevent damage by ineffective drainage, dewatering, and heavy loads and equipment by implementing precautionary measures. Repair or replace any defects or damage.

3.1.1 Underground Utilities

Location of the existing utilities indicated is approximate. Physically verify the location and elevation of the existing utilities indicated prior to starting construction. The Contractor is responsible for protecting utilities from damage during construction.

3.1.2 Drainage and Dewatering

**************************************************************************
Perform all work specified in accordance with applicable requirements of the Corps of Engineers publication EM 385-1-1 Safety and Health Requirements Manual.[ Provide a Geotechnical Engineer to monitor construction activities and to prepare necessary work plans and reports; see paragraph QUALITY CONTROL.]

Use equipment of type and size appropriate for the site conditions (soil character and moisture content). Maintenance of exposed subgrades and fills is the responsibility of the Contractor. The Contractor is required to prevent damage by ineffective drainage, dewatering, and heavy loads and equipment by implementing precautionary measures. Repair or replace any defects or damage.

3.1.1 Underground Utilities

Location of the existing utilities indicated is approximate. Physically verify the location and elevation of the existing utilities indicated prior to starting construction. The Contractor is responsible for protecting utilities from damage during construction.

3.1.2 Drainage and Dewatering

**************************************************************************
Perform all work specified in accordance with applicable requirements of the Corps of Engineers publication EM 385-1-1 Safety and Health Requirements Manual.[ Provide a Geotechnical Engineer to monitor construction activities and to prepare necessary work plans and reports; see paragraph QUALITY CONTROL.]

Use equipment of type and size appropriate for the site conditions (soil character and moisture content). Maintenance of exposed subgrades and fills is the responsibility of the Contractor. The Contractor is required to prevent damage by ineffective drainage, dewatering, and heavy loads and equipment by implementing precautionary measures. Repair or replace any defects or damage.

3.1.1 Underground Utilities

Location of the existing utilities indicated is approximate. Physically verify the location and elevation of the existing utilities indicated prior to starting construction. The Contractor is responsible for protecting utilities from damage during construction.

3.1.2 Drainage and Dewatering

**************************************************************************
Provide for the collection and disposal of surface and subsurface water encountered during construction.

3.1.2.1 Drainage

Provide for the collection and disposal of surface and subsurface water encountered during construction. Construct storm drainage features (ponds/basins) at the earliest stages of site development, and throughout construction grade the construction area to provide positive surface water runoff away from the construction activity [and][or] provide temporary ditches, swales, and other drainage features and equipment as required to keep soils from becoming unstable, prevent erosion, or undermining of foundations. Remove unstable material from working platforms for equipment operation and soil support for subsequent construction features and provide new material as specified herein. It is the responsibility of the Contractor to assess the site conditions to employ necessary measures to permit construction to proceed.

3.1.2.2 Dewatering

******************************************************************************
NOTE: UFC 3-220-01 only requires 300 mm 12 inches for temporary dewatering during construction.
******************************************************************************

Control groundwater flowing toward or into excavations to prevent sloughing of excavation slopes and walls, boils, uplift and heave in the excavation and to eliminate interference with orderly progress of construction. French drains, sumps, ditches or trenches are not allowed within one meter 3 feet of the foundation of any structure, except with specific written approval, and after specific contractual provisions for restoration of the foundation area have been made. Perform control measures by the time the excavation reaches the water level in order to maintain the integrity of the in-situ material. While the excavation is open, maintain the water level continuously, at least [_____] meters feet below the working level.[ Submit a Dewatering Work Plan outlining procedures for accomplishing dewatering work.][ Operate dewatering system continuously until construction work below existing water levels is complete. Measure and record performance of dewatering system at same time each day by use of observation wells or piezometers installed in conjunction with the dewatering system. Submit dewatering performance records weekly.]

3.1.3 Shoring and Sheeting

Submit an Excavation and Trenching Plan to stabilize features, prevent undermining or unintended horizontal and vertical movement of adjacent structures, and prevent slippage or movement in banks or slopes adjacent to the excavation. Submit drawings and calculations, certified by a registered professional engineer, describing the methods for shoring and sheeting of excavations. Drawings to include material sizes and types, arrangement of members, and the sequence and method of installation and removal. Calculations are to include data and references used.

3.1.4 Protection of Graded Surfaces

Protect newly backfilled, graded, and topsoiled areas from traffic, erosion, and settlements that may occur. Repair or reestablish damaged grades, elevations, or slopes.
3.2 BORROW

**NOTE:** Where a substantial quantity of borrow excavation is anticipated, the drawings and specifications will indicate the location or locations within the project site, and the conditions under which borrow may be obtained.

Select borrow material to meet the requirements and conditions of the fill or embankment for which it is to be used. Obtain borrow material from [the borrow areas shown] [within the limits of the project site, selected by the Contractor] [from approved private sources].[ Submit a Borrow Plan that includes materials to be excavated, stockpile locations, proposed slopes, drainage, and closure.] Unless otherwise provided in the contract, the Contractor is responsible for obtaining the right to procure material, pay royalties and other charges involved, and bear the expense of developing the sources, including rights-of-way for hauling from the owners. Unless specifically provided, do not obtain borrow within the limits of the project site without prior written approval.

3.2.1 Government Furnished Borrow Area(s)

**NOTE:** Verify materials from Government furnished borrow are suitable for intended use. Alternatively, indicate that Contractor needs to determine suitability. Provide available information on material properties. Include in paragraph any Installation or Government requirements, conditions, and restrictions.

Utilize this paragraph where borrow site for the project will be furnished by the Government. Delete and utilize paragraph CONTRACTOR FURNISHED BORROW AREA(S) where borrow is furnished by the Contractor. In the event that a combination of multiple borrow sites is required for the project, maintain both paragraphs.

Obtain approved borrow materials from [______]. The rights-of-way and earth materials for constructing the work have been furnished, without cost, to the Contractor at locations as [specified] [shown]. Submit a Borrow Plan to the Government of intention to use the specified Government-furnished borrow areas.

3.2.1.1 Stripping and Stockpiling Operations in Borrow Area

Strip in accordance with paragraph STRIPPING. Strip at least 1.5 meters 5 feet beyond the limits of the borrow excavation and any stockpiles of fill and embankment materials.

Stockpile materials within the borrow area work limits such that the stockpiles does not interfere with borrow operations. Stockpile borrow material awaiting transport in approved segregated piles. Maintain a minimum of 10 meters 30 feet between all stockpile toes and the top of the borrow cut.
3.2.1.2 Drainage of Borrow Excavations

Provide adequate drainage of borrow area. Ensure that borrow operations result in minimum detrimental effects on natural environmental conditions.

3.2.1.3 Borrow Area Closure

Complete borrow areas final grading, so that slopes are not steeper than [_____] vertical on [_____] horizontal, except as otherwise indicated. Avoid abrupt changes in grade. Distribute stripped material and stockpiles of unstable materials over the disturbed borrow area, as directed. Final grade the borrow area to drain.

3.2.2 Contractor Furnished Borrow Area(s)

**************************************************************************
NOTE: Utilize this paragraph where borrow site for project will be furnished by the Contractor. Delete and utilize paragraph GOVERNMENT FURNISHED BORROW AREA(S) where borrow is furnished by the Government. In the event that a multiple borrow sites are required for the project, maintain both paragraphs.
**************************************************************************

Obtain approved borrow materials from approved offsite sources. If a borrow source is selected that is not a commercial entity from which soil material is directly purchased, submit a Borrow Plan that includes the borrow source location, geotechnical test results showing the fill material meets the Contract requirements, environmental test results in accordance with paragraph ENVIRONMENTAL REQUIREMENTS FOR OFF-SITE SOIL, and any Federal, State, and local permits required for excavation and reclamation of the borrow area.

3.2.3 Environmental Requirements for Off-Site Soil

**************************************************************************
NOTE: Check with regional and local authorities as well as the facility/installation manager to determine actual requirements of bracketed items; values shown come from the Commonwealth of Virginia. Remove this paragraph if not required by the project.
**************************************************************************

Generally, Government Furnished Borrow Area(s) should be tested before contract award.

**************************************************************************
Test offsite soils brought in for use as backfill for Total Petroleum Hydrocarbons (TPH), Benzene, Toluene, Ethyl Benzene, and Xylene (BTEX) and full Toxicity Characteristic Leaching Procedure (TCLP) including ignitability, corrosivity and reactivity. Backfill may not contain concentrations above [appropriate State and EPA criteria, and for hazardous waste characteristics] [10] [_____] parts per million (ppm) of total petroleum hydrocarbons (TPH) and [10] [_____] ppm of the sum of Benzene, Toluene, Ethyl Benzene, and Xylene (BTEX) and pass the TCLP test. Determine TPH concentrations by using EPA 600/4-79/020 Method 418.1. Determine BTEX concentrations by using EPA SW-846.3-3 Method.

SECTION 31 00 00 Page 24
5030/8020/8260B. Perform TCLP in accordance with EPA SW-846.3-3 Method 1311. Perform hazardous waste characteristic tests for ignitability, corrosivity, and reactivity in accordance with accepted standard methods. Perform PCB testing in accordance with accepted standard methods for sampling and analysis of bulk solid samples. Provide borrow site testing for petroleum hydrocarbons and BTEX from a grab sample of material from the area most likely to be contaminated at the borrow site (as indicated by visual or olfactory evidence), with at least one test from each borrow site. Provide borrow site testing for hazardous waste characteristics (TPH, BTEX and TCLP) from a composite sample of material, collected in accordance with standard soil sampling techniques. Do not bring borrow material to project site until Borrow Plan containing environmental test results has been received and approved by the Contracting Officer.

3.3 SURFACE PREPARATION

3.3.1 Clearing and Grubbing

Clear and grub as specified in Section 31 11 00 CLEARING AND GRUBBING.

Remove trees, stumps, logs, shrubs, brush and vegetation and other items that would interfere with construction operations. Remove stumps entirely. Grub out matted roots and roots over 75 mm 3 inches in diameter to at least 500 mm 18 inches below existing surface.

3.3.2 Stripping

**************************************************************************
NOTE: Topsoil will be separately excavated, stored, and used for surface finish in preparation for seeding, sodding, or other planting, only where topsoil is definitely superior for grass and plant growth as compared with the remainder of the excavated material. Surface soil that is a heavy clay, predominantly sandy, or is lean in grass- and plant-growth qualities, will not be saved. The hauling, spreading, smoothing, and maintenance of the topsoil in preparation for the seeding and planting operations are generally considered under a separate section, and therefore are not considered in this specification. The blank will be filled with the appropriate depth dimension.
**************************************************************************

Strip site where indicated on the plans. Strip existing surface materials to a depth of [100] [_____] mm [4] [_____] inches below the existing ground surface in areas designated as Clear and Grub on the plans. Strip existing surficial soils to a depth of [_____] mm inches in all other areas. Strip in all areas within the planned limits of disturbance. All stripped materials not suitable for reuse as topsoil will be wasted in specified disposal area. Screen all stripped soils to remove roots and organic materials prior disposal.

Strip suitable soil from the site where excavation or grading is indicated and stockpile separately from other excavated material. Protect topsoil and keep in segregated piles until needed.
3.3.3 Proof Rolling

**************************************************************************
NOTE: Specify proof rolling when the quality of the existing subgrade is questionable. Proof rolling can be used to verify that material in question is acceptable for constructing a project feature (no bid quantity required, location shown or specified) or to locate suspected areas where material is not acceptable for project features (indicate a bid quantity to be removed). Remove this paragraph if not required in the project.
**************************************************************************

Perform proof rolling on exposed subgrade that is unfrozen and free of surface water (wet conditions resulting from rainfall). Notify the Contracting Officer a minimum of three days prior to proof rolling. Perform proof rolling in the presence of the Contracting Officer.

After stripping, excavating, and rough grading to the planned elevation, proof roll the existing subgrade of all building, pavement and embankment locations with six passes of a [loaded tandem axle dump truck] [15 ton, pneumatic-tired or smooth drum roller]. Operate the [roller] [truck] in a systematic manner to ensure the number of passes over all areas, and at speeds between 4 to 5.5 km per hour 2.5 to 3.5 miles per hour. Subgrade materials that exhibit excessive deflection and/or rutting during proof rolling need to be scarified, aerated, and re-compacted to specified density at [plus or minus] % of optimum moisture content prior to being considered for remedial action by the Contracting Officer. When proof rolling under buildings, the building subgrade is considered to extend 1.5 meters 5 feet beyond the building lines, and make one-half of the passes with the roller in a direction perpendicular to the other passes.

3.3.4 Stockpiling Operations

**************************************************************************
NOTE: When spoil areas or borrow areas are within the limits of Government-controlled land, additional requirements based on the following, and as appropriate for the project, will be included in the contract document. Locations of areas will be indicated, or the approximate distances from the project site will be specified. Generally, unburned vegetative material and surplus excavated material will be disposed of in inconspicuous spoil areas where no future construction is planned. If economically justifiable, surplus suitable excavated material may be stockpiled or may be disposed of in areas where future construction is planned and where fill will be required. Spoil materials will be so placed and the worked portions of spoil areas and borrow areas will be so graded and shaped as to minimize soil erosion, siltation of drainage channels, and damage to existing vegetation.
**************************************************************************

Place and grade stockpiles of satisfactory [and unsatisfactory] [and wasted materials] as specified. Keep stockpiles in a neat and well drained condition, giving due consideration to drainage at all times. Clear, grub,
and seal by rubber-tired equipment, the ground surface at stockpile locations; separately stockpile excavated satisfactory and unsatisfactory materials. Protect stockpiles of satisfactory materials from contamination which may destroy the quality and fitness of the stockpiled material. Do not create stockpiles that could obstruct the flow of any stream, endanger a partly finished structure, impair the efficiency or appearance of any structure, or be detrimental to the completed work in any way. If the Contractor fails to protect the stockpiles, and any material becomes unsatisfactory, remove and replace such material with satisfactory material from approved sources.

3.4 EXCAVATION

Excavate to contours, elevation, and dimensions indicated. Excavate soil disturbed or weakened by Contractor's operations, and soils softened or made unstable for subsequent construction due to exposure to weather. Use material removed from excavations meeting the specified requirements in the construction of fills, embankments, subgrades, shoulders, bedding (as backfill), and for similar purposes to minimize surplus material and to minimize additional material to brought on site. Do not excavate below indicated depths except to remove unstable material as determined by the [Government] [Geotechnical Engineer] and confirmed by the Contracting Officer. Remove and replace excavations below the grades shown with appropriate materials as directed by the Contracting Officer.

If at any time during excavation, including excavation from borrow areas, the Contractor encounters material that may be classified as rock or as hard/unyielding material, uncover such material, and notify the Contracting Officer. Do not proceed with the excavation of this material until the Contracting Officer has classified the materials as common excavation or rock excavation. Failure on the part of the Contractor to uncover such material, notify the Contracting Officer, and allow sufficient time for classification and delineation of the undisturbed surface of such material will cause the forfeiture of the Contractor's right of claim to any classification or volume of material to be paid for other than that allowed by the Contracting Officer for the areas of work in which such deposits occur.

3.4.1 Ditches, Gutters, and Channel Changes

Finish excavation of ditches, gutters, and channel changes by cutting accurately to the cross sections, grades, and elevations shown. Do not excavate below grades shown. Backfill excessive excavation as directed by the Contracting Officer, with satisfactory, compacted, material or with suitable stone or cobble to grades shown. Dispose excavated material as shown or as directed. Do not allow material to be deposited within one meter 4 feet from edge of a ditch. Maintain excavations free from detrimental quantities of leaves, brush, sticks, trash, and other debris until final acceptance of the work.

3.4.2 Trench Excavation Requirements

*********************************************************************************************************************
NOTE: The width of the trench below the top of the pipe will depend on the type of pipe used and soil conditions. The pipe manufacturer's installation manual should provide this information, and if so, it will be followed. In general, the width of trench will be 300 mm to 600 mm 12 inches to 24
Excavate the trench as recommended by the manufacturer of the pipe to be installed. Slope trench walls below the top of the pipe, or make vertical, and of such width as recommended by the manufacturer. Provide vertical trench walls where no manufacturer installation instructions are available. Do not exceed the trench width of 600 mm 24 inches below the top pipe plus pipe outside diameter (O.D.) for pipes of less than 600 mm 24 inches inside diameter, and do not exceed 900 mm 36 inches plus pipe outside diameter for pipe sizes larger than 600 mm 24 inches inside diameter. Where recommended trench widths are exceeded, provide redesign, stronger pipe, or special installation procedures. The Contractor is responsible for the cost of redesign, stronger pipe, or special installation procedures without any additional cost to the Government.

3.4.2.1 Bottom Preparation

NOTE: Stones 75 mm 3 inches or greater should be removed. However, pipe manufacturer's criteria, if any, should be used.

Grade the bottoms of trenches accurately to provide uniform bearing and support for the bottom quadrant of each section of the pipe. Excavate bell holes to the necessary size at each joint or coupling to eliminate point bearing. Remove stones of [_____] mm inch or greater in any dimension, or as recommended by the pipe manufacturer, whichever is smaller, to avoid point bearing.

3.4.2.2 Removal of Unyielding Material

NOTE: Minimum of 100 mm 4 inches should be removed to produce a suitable cushion for the pipe.

Where [overdepth is not indicated and ]unyielding material is encountered in the bottom of the trench, notify the Contracting Officer. Following approval, remove such material [_____] mm inch below the required grade and replaced with suitable materials as provided in paragraph FILLING AND COMPACTION.

3.4.2.3 Removal of Unstable Material

Where unstable material is encountered in the bottom of the trench, remove such material to the depth directed and replace it to the proper grade with suitable material as provided in paragraph FILLING AND COMPACTION. When removal of unstable material is required due to the Contractor's fault or neglect in performing the work, the Contractor is responsible for excavating the resulting material and replacing it without additional cost to the Government.
3.4.2.4 Excavation for Appurtenances

Provide excavation for manholes, catch-basins, inlets, or similar structures [sufficient to leave at least 300 mm 12 inches clear between the outer structure surfaces and the face of the excavation or support members.] [of sufficient size to permit the placement and removal of forms for the full length and width of structure footings and foundations as shown.]

3.4.2.5 Gas Distribution

Excavate trenches to a depth that will provide a minimum 450 mm 18 inches of cover in rock excavation and a minimum 600 mm 24 inches of cover in other excavation.

3.4.2.6 Water Lines

**************************************************************************
NOTE: Minimum depth of cover will be that required for frost penetration in the region and for safe operation of the utility. For fire protection yard mains, reference is made to NFPA 24 for recommended depth of cover.
**************************************************************************

Excavate trenches to a depth that provides a minimum cover of [_____] meters feet from the existing ground surface, or from the indicated finished grade, whichever is lower, to the top of the pipe.[ For fire protection yard mains or piping, an additional [_____] mm inch of cover is required.]

3.4.3 Jacking, Boring, and Tunneling

**************************************************************************
NOTE: Generally, Section 33 05 23 TRENCHLESS UTILITY INSTALLATION should be used instead. This section should only be considered for minor, low risk, and relatively simple situations.
**************************************************************************

In situations where utility lines must be installed more than 5 to 7 meters 15 to 20 feet below ground surface, through embankments, under minor roads or parking areas, or where surface conditions make it difficult or impractical to excavate open trenches, utility lines may be installed by jacking, boring, or tunneling as a Contractor option. Where operational requirements preclude installation by trenching, the use of jacking, boring, or tunneling should be specified as mandatory alternatives. This requirement will normally exist where utilities must cross railroads, highways, primary access roads and airfield pavements. Pipe and conduit smaller than 900 mm 36 inches in diameter will normally be installed in smooth steel pipe casing. Designing engineers must coordinate with installation facility engineers to identify and validate utility crossings where jacking, boring, or tunneling will be specified as mandatory.

Where the above conditions/requirements are not
present, and where the existing subsurface conditions would prove difficult and costly to bore/tunnel (e.g., large boulders/cobbles or shallow rock), delete this paragraph in its entirety.

Unless otherwise indicated, provide excavation by open cut except those sections requested and if, in the opinion of the Contracting Officer, can be safely and properly installed and backfill. Provide a Jacking, Boring, and Tunneling Plan, signed and sealed by a licensed Professional Engineer that includes a work site layout, methods and procedures, equipment, alignment control, monitoring, and contingency for responding to unplanned movements.

3.4.3.1 Pipeline Casing

Provide new smooth wall steel pipeline casing under [new] [existing] [railroad] [and] [pavement] [in a trench] [by the boring and jacking method of installation]. Provide each new pipeline casing, where indicated and to the lengths and dimensions shown, complete and suitable for use with the new piped utility as indicated. [Install pipeline casing by dry boring and jacking method as follows:]

3.4.3.2 Bore Holes

Mechanically bore holes and case through the soil with a cutting head on a continuous auger mounted inside the casing pipe. Weld lengths of pipe together in accordance with AWS D1.1/D1.1M. Do not use water or other fluids in connection with the boring operation.

3.4.3.3 Cleaning

Clean inside of the pipeline casing of dirt, weld splatters, and other foreign matter which would interfere with insertion of the piped utilities by attaching a pipe cleaning plug to the boring rig and passing it through the pipe.

3.4.3.4 End Seals

After installation of piped utilities in pipeline casing, provide watertight end seals at each end of pipeline casing between pipeline casing and piping utilities. Provide watertight [end seals as indicated.][segmented elastomeric end seals.]

3.4.4 Underground Utilities

[Perform work adjacent to utilities [as indicated] [in accordance with procedures outlined by utility owner].] [Excavation made with power-driven equipment is not permitted within [600] [_____] mm [2] [_____] feet of known utility or subsurface construction. For work immediately adjacent to or for excavations exposing a utility or other buried obstruction, excavate by hand. Start hand excavation on each side of the indicated obstruction.
and continue until the obstruction is uncovered or until clearance for the new grade is assured. Support uncovered lines or other existing work affected by the contract excavation until approval for backfill is granted by the Contracting Officer.] Report damage to utility lines or subsurface construction immediately to the Contracting Officer.

3.4.5 Structural Excavation

**************************************************************************
NOTE: For projects requiring over-excavation and replacement of near-surface materials below building and/or pavement areas, retain and edit the bracketed text.
**************************************************************************

[Following general excavation and rough grading activities, excavate the entire building footprint area and at least 1.5 meters 5 feet beyond, to the deeper of [1200] [_____] mm [4] [_____] feet below existing grade or [600] [_____] mm [2] [_____] feet below bottom of footings. Scarify the exposed surface to a depth of [150 to 200 mm] [6 to 8 inches], moisture-condition, and compact to at least 95 percent of laboratory maximum density.][ Do not excavate to final grade until just before concrete is to be placed. Roughen level surfaces. Cut sloped surfaces as indicated into rough steps or benches to provide a satisfactory bond for compacting materials.][ For new pavement areas including exterior concrete pads, over-excavate to a minimum of 300 mm 12 inches below bottom of new pavement/pad base course, scarify, moisture-condition, and compact to at least 95 percent.]

Make excavations to the lines, grades, and elevations shown, or as directed. Provide trenches and foundation pits of sufficient size to permit the placement and removal of forms for the full length and width of structure footings and foundations as shown. Clean rock or other hard foundation material of loose debris and cut to a firm, level, stepped, or serrated surface. Remove loose disintegrated rock and thin strata. Concrete placement is not allowed until footing subgrades have been inspected and approved by the Contracting Officer.

3.4.6 Pile Cap Excavation

[Stop the excavation at an elevation 150 to 300 mm 6 to 12 inches above the bottom of the footing before driving piles. After pile driving has been completed, complete the remainder of the excavation to the elevations shown.] [Excavate to bottom of pile cap prior to placing or driving piles, unless authorized otherwise by the Contracting Officer.] After the pile driving has been completed, remove loose and displaced material and complete excavation, leaving a smooth, solid, undisturbed surface to receive the concrete or masonry. Backfill and compact over-excavations and changes in grade due to pile driving operations to 95 percent of [ASTM D698] [ASTM D1557] maximum density.

3.4.7 Rock Excavation and Blasting

Excavate rock encountered in the cut section to a depth of 150 mm 6 inches below finished grade and replace with [satisfactory material] [____].[ Submit a Rock Excavation Plan, prepared and sealed by a registered professional engineer.][ Perform blasting in accordance with EM 385-1-1 and in conformance with Federal, State, and local safety regulations.
Submit notice 15 days prior to starting work. Submit a Blasting Plan, prepared and sealed by a registered professional engineer that includes calculations for overpressure and debris hazard. Provide blasting mats and use the non-electric blasting caps. Obtain written approval prior to performing any blasting and notify the Contracting Officer 24 hours prior to blasting. Include provisions for storing, handling and transporting explosives as well as for the blasting operations in the plan. The Contractor is responsible for damage caused by blasting operations. [Blasting will not be permitted.]

3.5 SUBGRADE PREPARATION

3.5.1 General Requirements

**************************************************************************
NOTE: Moisture content limits for compaction should be included in these paragraphs when necessary for obtaining strength and stability in embankments and fill, for controlling movement of expansive soils and when, in the opinion of the project geotechnical engineer, moisture control is required for the soils being used.
**************************************************************************

Shape subgrade to line, grade, and cross section as indicated. Remove unsatisfactory and unstable material in surfaces to receive fill or in excavated areas, [as determined by proof rolling, ]and replaced with [satisfactory materials] [structural fill] [_____]. Do not place material on surfaces that are muddy, frozen, contain frost, or otherwise containing unstable material. Scarify the surface to a depth of 100 mm 4 inches prior to placing fill. Step or bench sloped surfaces steeper than 1 vertical to 4 horizontal prior to scarifying. Place 100 mm 4 inches of loose fill and blend with scarified material. When subgrade is part fill and part excavation or natural ground, scarify to a depth of 200 mm 8 inches.

3.5.2 Subgrade for Structures, Spread Footings, and Concrete Slabs

Do not excavate below depth shown for structures, spread footings, and concrete slabs. If over excavation occurs, [notify the Contracting Officer and remove, replace, and compact as directed.] [compact disturbed material to [95] [_____] percent of [ASTM D698] [ASTM D1557].] After final rolling, the surface of the subgrade for buildings and pavements must not show deviations greater than 15 mm 0.05 foot when tested with a 4 meter 12-foot straightedge applied both parallel and at right angles to the centerline of the area.

3.5.3 Subgrade for Railroads

Compact subgrade for railroads to at least 90 percent laboratory maximum density for cohesive materials or 95 percent laboratory maximum density for cohesionless materials.

3.5.4 Subgrade for Pavements

Compact top 300 mm 12 inches of subgrade for pavements to at least 95 percent of [ASTM D698] [ASTM D1557]. After final rolling, the surface of the subgrade for buildings and pavements must not show deviations greater than 15 mm 0.05 foot when tested with a 4 meter 12-foot straightedge applied both parallel and at right angles to the centerline of the area.
3.5.5 Subgrade for Shoulders

Compact the upper [150] [_____] mm [6] [_____] inches of subgrade for shoulders to at least [95] [_____] percent of [ASTM D698] [ASTM D1557] for the [depth below the surface of shoulder shown] [full depth of the shoulder].

3.5.6 Subgrade for Airfield Pavements

******************************************************************************
NOTE: Refer to UFC 3-260-02 for specific requirements for compaction of Airfield Pavement subgrade and modify paragraph as necessary.
******************************************************************************

Compact top [_____] mm inches of subgrade, to [95] [_____] percent of ASTM D1557. After final rolling, the surface of the subgrade for buildings and pavements must not show deviations greater than 15 mm 0.05 foot when tested with a 4 meter 12-foot straightedge applied both parallel and at right angles to the centerline of the area.

3.5.7 Subgrade Filter Fabric

Place filter fabric as indicated directly on prepared subgrade free of vegetation, stumps, rocks larger than 50 mm 2 inch diameter and other debris which may puncture or otherwise damage the fabric. Repair damaged fabric by placing an additional layer of fabric to cover the damaged area a minimum of one meter 3 feet overlap in all directions. Overlap fabric at joints a minimum of one meter 3 feet. Obtain approval of filter fabric installation before placing fill or backfill. Place fill or backfill on fabric in the direction of overlaps and compact as specified herein. Follow manufacturer's recommended installation procedures.

3.6 FILLING AND COMPACTION

******************************************************************************
It is imperative to specify a high degree of compaction in fills under structures to minimize settlement and to ensure stability of a structure. In addition to the criteria set forth in UFC 3-220-01, the following factors will be considered in establishing the specific requirements:

a. The sensitivity of the structure to total and differential settlement as related to the structural design. This is particularly true of structures to be founded partly on fill and partly on natural ground.

b. The ability of normal compaction equipment to produce the desired densities in existing or locally available materials within a reasonable range of molding moisture content. If considered essential, special equipment will be specified.

c. The compaction requirements for clean, cohesionless, granular materials will be generally higher than those for cohesive materials because
cohesionless materials readily consolidate when subjected to vibration. For structures with critical stability requirements and settlement limitations, the minimum density requirements may be altered. If only a cohesionless soil or only a cohesive soil is used, the inapplicable values will be deleted.

d. The exception to required high degree of compaction in fills and backfills is in expansive soils (see UFC 3-220-01). Where it is necessary to use materials having swelling characteristics, usually CL or CH classifications, the specified degree of compaction will be related to laboratory test results for swelling under a considerable range of molding moisture and compactive effort. In swelling soils, it is important to specify a density and molding moisture range that will enable the soil to stay stable, striking a reasonable balance between potential swell and excessive settlement under load, even at the expense of accepting a reduced bearing capacity. A maximum permissible density should be established to minimize swelling. If possible, soils with swelling characteristics will be classified as unsatisfactory material, particularly under critical stability structures.

e. ASTM D1557 is satisfactory for establishing moisture density characteristics of a material in most cases. However, other modifications may be necessary as discussed in this ASTM and under soil tests in DM 21.3/UFC 3-260-02. The procedures and precautions in the subgrade compaction paragraphs of DM 21.3/UFC 3-260-02, will be considered in establishing minimum density requirements for a particular project.

Modifications will be made to meet the backfill requirements for deep-seated or subsurface structures as discussed in UFC 3-220-04FA.

Prepare ground surface on which backfill is to be placed and provide compaction requirements for backfill materials in conformance with the applicable portions of paragraphs for SUBGRADE PREPARATION. Do not place material on surfaces that are muddy, frozen, or contain frost. Finish compaction by sheepfoot rollers, pneumatic-tired rollers, steel-wheeled rollers, or other approved equipment well suited to the soil being compacted. Moisten material as necessary [to plus or minus [_____] percent of optimum moisture] [to provide the moisture content that will readily facilitate obtaining the specified compaction with the equipment used]. Fill and backfill to contours, elevations, and dimensions indicated. Compact and test each lift before placing overlaying lift.

3.6.1 Trench Backfill

NOTE: Most pressure tests require backfilling to at least 600 mm 2 feet over the pipe with the joints
and couplings left open for inspection.

**************************************************************************

Backfill trenches to the grade shown. [Backfill the trench to [_____] meters feet above the top of pipe prior to performing the required pressure tests. Leave the joints and couplings uncovered during the pressure test.] [Do not backfill the trench until all specified tests are performed.]

3.6.1.1 Replacement of Unyielding Material

Replace unyielding material removed from the bottom of the trench with satisfactory material or initial backfill material.

3.6.1.2 Replacement of Unstable Material

Replace unstable material removed from the bottom of the trench or excavation with satisfactory material placed in layers not exceeding 150 mm 6 inches loose thickness.

3.6.1.3 Bedding and Initial Backfill

**************************************************************************

NOTE: Bedding is provided to level out any irregularities in the foundation and to assure uniform support along the barrel of each pipe section. Bedding is also constructed to distribute the load bearing reaction, due to the weight of the backfill material, around the lower portion of the pipe. If the pipe or conduit is placed directly on a flat or shaped foundation, delete "bedding" from the title and from any reference in the paragraph. If bedding will be specified, determine type and thickness and show on the plans. Specify compaction to 95 percent maximum density for cohesionless soils, and 90 percent maximum density for cohesive soils.

Any locally available fine aggregate for concrete or asphalt mixtures will qualify as sand and may be specified by local gradation and specification number in lieu of "SW" or "SP." Drawings (details) should clearly show where sand backfill or bedding is required.

Locally available coarse aggregate for concrete will suffice and may be specified by local gradation and specification number in lieu of "GW" or "GP." Maximum size of aggregate should not be more than 25 mm per 300 mm one inch per foot of pipe diameter or 75 mm 3 inches maximum. Refer to pipe manufacturer's criteria for more stringent requirements, if any, on aggregate size and gradation. On drawings (details), clearly show where gravel backfill or bedding is required.

**************************************************************************

[Provide bedding of the type and thickness shown. ]Place initial backfill material and compact it with approved tampers to a height of at least 300 mm one foot above the utility pipe or conduit. Bring up the backfill evenly
on both sides of the pipe for the full length of the pipe. Take care to ensure thorough compaction of the fill under the haunches of the pipe. Except where shown or when specified otherwise in the individual piping section, provide bedding for buried piping in accordance with PART 2 paragraph UTILITY BEDDING MATERIAL. Compact backfill to top of pipe to [95 percent of ASTM D698 maximum density] [85 percent of ASTM D1557]. Provide plastic piping with bedding to spring line of pipe.

3.6.1.4 Final Backfill

Do not begin backfill until construction below finish grade has been approved, underground utilities systems have been inspected, tested and approved, forms removed, and the excavation cleaned of trash and debris. Bring backfill to indicated finish grade. Where pipe is coated or wrapped for protection against corrosion, the backfill material up to an elevation 600 mm 2 feet above sewer lines and 300 mm one foot above other utility lines need to be free from stones larger than 25 mm one inch in any dimension. Heavy equipment for spreading and compacting backfill are not to be operated closer to foundation or retaining walls than a distance equal to the height of backfill above the top of footing; compact remaining area in layers not more than 100 mm 4 inches in compacted thickness with power-driven hand tampers suitable for the material being compacted. Place backfill carefully around pipes or tanks to avoid damage to coatings, wrappings, or tanks. Do not place backfill against foundation walls prior to 7 days after completion of the walls. As far as practicable, bring backfill up evenly on each side of the wall and sloped to drain away from the wall.

Fill the remainder of the trench, except for special materials for buildings[, railroads][, airfields] and pavements with satisfactory material. Place backfill material and compact as follows:

3.6.1.4.1 Buildings[, Railroads][, Airfields] and Pavements

Place backfill up to the required elevation as specified. Do not permit water flooding or jetting methods of compaction. Compact as specified for Structural Fill.

3.6.1.4.2 Turfed or Seeded Areas and Miscellaneous Areas

Deposit backfill in layers of a maximum of 300 mm 12 inches loose thickness, and compact it to 85 percent maximum density for cohesive soils and 90 percent maximum density for cohesionless soils.[ Allow water flooding or jetting methods of compaction for granular noncohesive backfill material. Do not allow water jetting to penetrate the initial backfill.][ Do not permit compaction by water flooding or jetting.] Apply this requirement to all other areas not specifically designated above.

3.6.1.5 Heat Distribution System

Free initial backfill material of stones larger than 6.3 mm 1/4 inch in any dimension.

3.6.1.6 Electrical Distribution System

Provide a minimum cover of 600 mm 24 inches from the finished grade to direct burial cable and conduit or duct line, unless otherwise indicated.
3.6.1.7  Sewage Absorption Trenches or Pits

**************************************************************************
NOTE: Delete these paragraphs when sewage absorption trenches or pits are not included in the project. Consult a geotechnical engineer and local standards in selecting bracketed information.
**************************************************************************

3.6.1.7.1 Porous Fill

Provide backfill consisting of porous fill material in the locations and thickness as shown on the drawings. No compaction is required.

3.6.1.7.2 Cover

**************************************************************************
NOTE: Select appropriate bracketed information to correspond to the design indicated on the drawings.
**************************************************************************

[Filter fabric ] [Concrete ] [Kraft paper conforming to CID A-A-203, Grade B, No. 2, 22.7 kg 50 pound weight ] [or a layer of straw at least 50 mm 2 inches thick ] as indicated.

3.6.1.8 Displacement of Features

**************************************************************************
NOTE: The trench should be backfilled to at least 600 mm 2 feet.
**************************************************************************

After other required tests have been performed and the trench backfill compacted to [[_____] meters feet above the top of the pipe] [the finished grade surface], inspect the pipe to determine whether unexpected or damaging displacement has occurred. Conduct walk-through inspection of pipe sizes larger than 1200 mm 48 inches. Inspect pipes smaller than 1200 mm 48 inches using remote methods using closed circuit television, sonar, or hybrid that can provide a 360-degree inspection of the pipe. Prepare and submit a pipe inspection report consisting of digital video or photos. If, in the judgment of the Contracting Officer, the interior of the pipe shows poor alignment or any other defects that would cause improper functioning of the system, replace or repair the defects as directed at no additional cost to the Government.

3.6.1.9 Buried Tape And Detection Wire

3.6.1.9.1 Buried Warning and Identification Tape

Provide buried utility lines with utility identification tape. Bury tape 300 mm 12 inches below finished grade; under pavements and slabs, bury tape 150 mm 6 inches below top of subgrade.

3.6.1.9.2 Buried Detection Wire

Bury detection wire directly above non-metallic piping at a distance not to exceed 300 mm 12 inches above the top of pipe. Extend the wire continuously and unbroken, from manhole to manhole. Terminate the ends of the wire inside the manholes at each end of the pipe, with a minimum of 0.9
meters 3 feet of wire, coiled, remaining accessible in each manhole. Furnish insulated wire over its entire length. Install wires at manholes between the top of the corbel and the frame, and extend up through the chimney seal between the frame and the chimney seal. For force mains, terminate the wire in the valve pit at the pump station end of the pipe.

### 3.6.2 Structural Fill Placement

Place fill and backfill beneath and adjacent to structures in successive horizontal layers of loose material not more than 200 mm 8 inches in depth, or in loose layers not more than 100 mm 4 inches in depth when using hand-operated compaction equipment. Do not place over wet or frozen materials. Compact to at least 90 percent of laboratory maximum density for cohesive materials or 95 percent of laboratory maximum density for cohesionless materials, except as otherwise specified. Perform compaction in such a manner as to prevent wedging action or eccentric loading upon or other damage to the structure. Moisture condition fill and backfill material to [a moisture content that will readily facilitate obtaining the specified compaction][ within range of plus 2 or minus 2 percent of optimum moisture content at the time of compaction].

### 3.6.3 Backfill for Appurtenances

**************************************************************************
NOTE: The number of days the concrete is allowed to cure before backfilling the structure will depend on the type of mix and the concrete strength requirements specified. Three days would be considered as a minimum. Seven days is more common.
**************************************************************************

After the manhole, catchbasin, inlet, or similar structure has been constructed[ and the concrete has been allowed to cure for [7][_____] days], place backfill in such a manner that the structure is not be damaged by the shock of falling earth. Deposit the backfill material, compact it as specified for final backfill, and bring up the backfill evenly on all sides of the structure to prevent eccentric loading and excessive stress.

### 3.6.4 Porous Fill Placement

Provide under floor and area-way slabs on a compacted subgrade. Place in a single lift and compact with a minimum of two passes of a hand-operated plate-type vibratory compactor.

### 3.6.5 Flowable Fill

Place fill in a manner to completely fill voids in the location indicated. Do not place when atmospheric temperatures are expected to be below one degree C 33 degrees F at any time during the 3 day period following placement.

### 3.6.6 Compaction

**************************************************************************
NOTE: In general for most projects, use ASTM D698 for compaction. Use ASTM D1557 for roads, airfields, and other heavily loaded areas or locations needing a greater density or compressive strength. Specify compaction in terms of one method
**************************************************************************
of compaction effort (ASTM D698 or ASTM D1557) for a contract, if possible. Use 90 percent of ASTM D698 or ASTM D1557 for general site compaction of cohesionless materials on Army projects and 85 percent for Navy projects. For airfield projects see UFC 3-260-02 for criteria and design guidelines.

3.6.6.1 General Site

Compact underneath areas designated for vegetation and areas outside the 1.5 meter 5 foot line of the paved area or structure to [85] [90] percent of [ASTM D698] [ASTM D1557].

3.6.6.2 Adjacent Areas

Compact areas within 1.5 meters 5 feet of structures to 95 percent of [ASTM D698] [ASTM D1557].

3.7 EMBANKMENTS

3.7.1 Earth Embankments

NOTE: Moisture content limits for compaction should be included in these paragraphs when necessary for obtaining strength and stability in embankments and fill, for controlling movement of expansive soils and when, in the opinion of the project geotechnical engineer, moisture control is required for the soils being used.

This paragraph should be omitted from projects where specialized earthwork controls not specified in EXCAVATION, SUBGRADE PREPARATION and FILLING AND COMPACTION.

Construct earth embankments from satisfactory materials free of organic or frozen material and rocks with any dimension greater than 75 mm 3 inches. Place the material in successive horizontal layers of loose material not more than 200 mm 8 inches in depth. Spread each layer uniformly on a soil surface that has been moistened or aerated as necessary and scarified or otherwise broken up so that the fill will bond with the surface on which it is placed. After spreading, plow, disk, or otherwise break up each layer; moisten or aerate as necessary; thoroughly mix; and compact to at least 90 percent laboratory maximum density for cohesive materials or 95 percent laboratory maximum density for cohesionless materials. Backfill and fill material are to be [within the range of minus 2 to plus 2 percent of optimum moisture] [to a moisture content that will readily facilitate obtaining the specified compaction].

Compaction requirements for the upper portion of earth embankments forming subgrade for pavements are identical with those requirements specified in paragraph SUBGRADE PREPARATION. Finish compaction by sheepfoot rollers, pneumatic-tired rollers, steel-wheeled rollers, vibratory compactors, or other approved equipment.
3.7.2 Rock Embankments

**NOTE:** The designer will determine the appropriate values for all blank spaces, except the last one, on the basis of recent experience on similar construction or of test results obtained from construction and testing of a test section. The specific method by which density will be determined in the laboratory and measured in the field will be described in the project specification. The total thickness of the pavement structure, including subbase, base, and pavement will be placed in the last blank space in this paragraph.

The first blank space applies to rock fill of small maximum dimension and maximum lift placement of 200 to 250 mm 8 to 10 inches. Coordinate maximum size with satisfactory material definition. If it is necessary to use larger rock and thicker lifts, the second expression in brackets is applicable. When thicker lifts are used, it may be necessary to specify a minimum number of passes of the compactor. Delete last sentence, unless the rock excavation is engineered to be used under pavements with sufficient fines to prevent consolidation of the embankment.

This paragraph should be omitted from projects where specialized earthwork controls not specified in EXCAVATION, SUBGRADE PREPARATION, and FILLING AND COMPACTION.

Construct rock embankments from material classified as rock excavation, as defined above, placed in successive horizontal layers of loose material not more than [_____] mm inch in depth. Do not use pieces of rock larger than [_____] mm inch in the greatest dimension. Spread each layer of material uniformly, completely saturate, and compact to a minimum density of [_____] kg/cubic meter pounds per cubic foot. Adequately bond each successive layer of material to the material on which it is placed. Finish compaction with vibratory compactors weighing at least [_____] metric tons tons, heavy rubber-tired rollers weighing at least [_____] metric tons tons, or steel-wheeled rollers weighing at least [_____] metric tons tons.[ Do not use rock excavation as fill material for the construction of pavements.][ In embankments on which pavements are to be constructed, do not use rock above a point [_____] mm inch below the surface of the pavement.]

3.8 RIP-RAP CONSTRUCTION

**NOTE:** Select information in brackets to best describe rip-rap construction. Provide detail or typical section through rip-rap on drawings as well as all dimensions necessary for estimating and construction. If DOT standard specifications are referenced for rip-rap construction, paragraphs PREPARATION through GROUTING may be deleted.
Construct rip-rap [on bedding material] [on filter fabric] [with grout] [in accordance with [DOT] [_____] State Standard, paragraph [_____]] in the areas indicated. Trim and dress indicated areas to conform to cross sections, lines and grades shown within a tolerance of 30 mm 0.1 foot.

3.8.1 Bedding Placement

Spread [filter fabric and] bedding material uniformly to a thickness of at least [75] [_____] mm [3] [_____] inches on prepared subgrade as indicated.[ Compaction of bedding is not required. Finish bedding to present even surface free from mounds and windrows.]

3.8.2 Stone Placement

Place rock for rip-rap on prepared bedding material to produce a well graded mass with the minimum practicable percentage of voids in conformance with lines and grades indicated. Distribute larger rock fragments, with dimensions extending the full depth of the rip-rap throughout the entire mass and eliminate "pockets" of small rock fragments. Rearrange individual pieces by mechanical equipment or by hand as necessary to obtain the distribution of fragment sizes specified above.[ For grouted rip-rap, hand-place surface rock with open joints to facilitate grouting and do not fill smaller spaces between surface rock with finer material. Provide at least one "weep hole" through grouted rip-rap for every 4.65 square meters 50 square feet of finished surface. Provide weep holes with columns of bedding material, 100 mm 4 inches in diameter, extending up to the rip-rap surface without grout.]

[3.8.3 Grouting

Prior to grouting, wet rip-rap surfaces. Grout rip-rap in successive longitudinal strips, approximately 3 meters 10 feet in width, commencing at the lowest strip and working up the slope. Distribute grout to place of final deposit and work into place between stones with brooms, spades, trowels, or vibrating equipment. Take precautions to prevent grout from penetrating bedding layer. Protect and cure surface for a minimum of 7 days.

]3.9 FINISHING/FINISH OPERATIONS

**************************************************************************

NOTE: Special smoothness tolerances are not required for subgrades for railroads; therefore, both sets of brackets will be removed when writing specifications for preparation of railroad subgrade only. When writing specifications for preparation of roadway and/or airfield pavement subgrade, the brackets will be removed from the applicable sentences and the smoothness tolerances showing permissible deviations in fractions of a millimeter inch and the length of straightedge in meters feet will be inserted in the blanks as appropriate.

**************************************************************************

During construction, keep embankments and excavations shaped and drained. Maintain ditches and drains along subgrade to drain effectively at all times. Do not disturb the finished subgrade by traffic or other operation. Protect and maintain the finished subgrade in a satisfactory
condition until ballast, subbase, base, or pavement is placed. Do not permit the storage or stockpiling of materials on finished subgrade. Do not lay subbase, base course, ballast, or pavement until the subgrade has been checked and approved, and in no case place subbase, base, surfacing, pavement, or ballast on a muddy, spongy, frozen or otherwise unstable subgrade.

Finish the surface of excavations, embankments, and subgrades to a smooth and compact surface in accordance with the lines, grades, and cross sections or elevations shown. Provide the degree of finish for graded areas within 30 mm 0.1 foot of the grades and elevations indicated except as indicated for subgrades specified in paragraph SUBGRADE PREPARATION. Finish gutters and ditches in a manner that will result in effective drainage. Finish the surface of areas to be turfed to a smoothness suitable for the application of turfing materials. Repair graded, topsoiled, or backfilled areas prior to acceptance of the work, and re-established grades to the required elevations and slopes.

3.9.1 Capillary Water Barrier

*******************************
NOTE: The compacted thickness and locations requiring a capillary water barrier must be indicated on the drawings. The thickness will not be less than 100 mm 4 inches. The paragraph will be deleted where site conditions make the barrier unnecessary.
*******************************

Place a capillary water barrier under concrete floor and area-way slabs grade directly on the subgrade and compact with a minimum of two passes of a hand-operated plate-type vibratory compactor.

3.9.2 Grading Around Structures

Construct areas within 1.5 meters 5 feet outside of each building and structure line true-to-grade, shape to drain, and maintain free of trash and debris until final inspection has been completed and the work has been accepted.

3.9.3 Shoulder Construction

**************************************************************************
NOTE: Shoulder construction will form a part of the work to be performed under this section of the specifications except when shoulder construction is specified under the subbase, base-course, wearing course, or pavement sections of the specifications and is designated in the contract to be performed and paid for under one of these sections.
**************************************************************************

Construct shoulders of [satisfactory material] [______]. Submit advanced notice on shoulder construction for rigid pavements. Construct shoulders immediately after adjacent paving is complete. In the case of rigid pavements, do not construct shoulders until permission of the Contracting Officer has been obtained. Compact the entire shoulder area to at least the percentage of maximum density as specified in paragraph SUBGRADE PREPARATION above, for specific ranges of depth below the surface of the
shoulder. Finish compaction by sheepsfoot rollers, pneumatic-tired rollers, steel-wheeled rollers, vibratory compactors, or other approved equipment. Finish shoulder construction in proper sequence in such a manner that adjacent ditches will be drained effectively and that no damage of any kind is done to the adjacent completed pavement. Align the completed shoulders true to grade and shaped to drain in conformity with the cross section shown.

3.9.4 Grading

Finish grades as indicated within 30 mm one-tenth of one foot. Grade areas to drain water away from structures. Maintain areas free of trash and debris. For existing grades that will remain but which were disturbed by Contractor's operations, grade as directed.

3.9.5 Topsoil and Seed

**************************************************************************
NOTE: Topsoil will be separated, excavated, stored, and used for surface finish in preparation for seeding, sodding, or other planting only where the topsoil is definitely superior for grass and other plant growth as compared to the balance of the excavated materials. Generally, topsoil will be spread after other operations have been completed. When topsoil spreading is covered under a separate section of the specifications, this paragraph will be deleted.
**************************************************************************

[ Provide as specified in Section 32 92 19 SEEDING [32 92 23 SODDING].]

On areas to receive topsoil, prepare the compacted subgrade soil to a 50 mm 2 inches depth for bonding of topsoil with subsoil. Spread topsoil evenly to a thickness of [_____] mm inch and grade to the elevations and slopes shown. Do not spread topsoil when frozen or excessively wet or dry. Keep topsoil separate from other excavated materials, brush, litter, objectionable weeds, roots, stones larger than 50 mm 2 inches in diameter, and other materials that would interfere with planting and maintenance operations. [Stockpile in locations indicated ] [Remove from the site ] any surplus of topsoil from excavations and gradings. Obtain material required for topsoil in excess of that produced by excavation within the grading limits from [offsite areas] [areas indicated].

3.10 DISPOSITION OF SURPLUS MATERIAL

**************************************************************************
NOTE: Coordinate with Installation POC for on-site disposition of materials. Ensure requirements are consistent with Environmental specification.
**************************************************************************

Remove from Government property all surplus or other soil material not required or not suitable for filling or backfilling, along with brush, refuse, stumps, roots, and timber. Properly disposed of in accordance with all applicable laws and regulations. Prepare plan for Disposition of Surplus Materials to include permissions document to dispose of nonsalable products.
NOTE: Modify Table 1 to identify each material type to be subject to quality control testing. List materials in paragraph DEFINITIONS. For each material type, list each test method and test frequency appropriate for required work. If numerous tests required for different materials, allowable to create separate tables for each material for clarity.

Density test frequency can vary from one test per 10 square meters 100 square feet for small areas up to one test per 900 square meters 10,000 square feet. The following table is to help establish test frequency for various situations:

<table>
<thead>
<tr>
<th>Material Type</th>
<th>Location of Material</th>
<th>Test Frequency</th>
</tr>
</thead>
<tbody>
<tr>
<td>Undisturbed native soil</td>
<td>Structures</td>
<td>Two random tests in building footings and two tests on subgrade within building line</td>
</tr>
<tr>
<td>Fills and backfills</td>
<td>Structures (adjacent to)</td>
<td>One test per structure per 200 sq m 2000 sq ft taken 300 mm 1 foot below finished grade</td>
</tr>
<tr>
<td>Subgrades</td>
<td>Site (except airfields)</td>
<td>One test per 250 sq m 2500 sq ft</td>
</tr>
<tr>
<td>Embankments or borrow</td>
<td>Any</td>
<td>One test per lift per 400 cubic m 500 cubic yds placed</td>
</tr>
<tr>
<td>Native soil subgrade other than structures and parking</td>
<td>Any</td>
<td>One test or one test per 900 sq m 10,000 sq ft whichever is greater</td>
</tr>
<tr>
<td>Borrow</td>
<td>Any</td>
<td>One test per lift per 400 cubic m 500 cubic yds placed</td>
</tr>
</tbody>
</table>

For projects having extensive amounts or a critical need for test data to verify design or other urgent needs, consider using Section 01 31 20 PROJECT TECHNICAL DATA MANAGEMENT AND VISUALIZATION and require Contractor to submit data to specified Data Management system in addition normal submission requirements.

Perform testing as indicated in Table 1. Submit Material Test Reports within [24 hours] [7 days] of tests being completed.[ In addition, submit test data in accordance with Section 01 31 20 PROJECT TECHNICAL DATA MANAGEMENT AND VISUALIZATION.]
<table>

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for furnishing, hauling, and placing the geotextile, complete, as specified and shown, and maintaining the geotextile until placement of the granular filter material, bedding material, and/or riprap cover is completed and accepted. This section was originally developed for USACE Civil Works projects.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1   GENERAL

NOTE: This guide specification is to facilitate the preparation and review of specifications for procurement and installation of woven and nonwoven geotextiles as filter material. It is based on field performance and the laboratory testing of a limited number of geotextiles. Geotextiles possess greatly varying engineering properties and physical characteristics. Such variations require the designer to decide which testing method and what
test criteria are necessary for each application. The apparent opening size (AOS), percent open area (POA), geotextile permeability (Kg), and strength test described in the specifications that follow are physical property tests. While it is acceptable to specify minimum thickness value where it governs performance, it is inappropriate to use thickness to identify a geotextile. Result of these tests are used to judge the acceptability of a geotextile for a particular use. Prospective geotextile suppliers should furnish these test results before their geotextile will be considered for use, or before contract specifications are adjusted to permit the use of geotextiles whose properties are outside the limits imposed by this guide. For severe soil conditions and/or for a project using a large amount of geotextiles, the specifications should require that the applicable tests be run during construction, either at a specific frequency or upon demand of the Contracting Officer. For projects requiring small amounts of geotextiles under normal soil conditions the physical properties of the geotextile supported by written authentication from an authorized representative of the manufacturers may be accepted.

The actual life of geotextiles is not known, and their use in inaccessible areas must be considered carefully. Therefore geotextiles should not be used as filter material in toe drains, buried collector system, relief wells, or within any portions of embankments. Caution is advised in using geotextiles on the upstream face of earth dams or to wrap permanent piezometers.

Geotextiles are basically inert materials for typical civil engineering applications. However certain applications may expose the geotextile to chemical or biological activities that could drastically influence the filtration properties of the geotextile. Specific site conditions should be reviewed, and if such conditions exist, testing and specifications should be written to overcome it.

Geotextile strength requirements vary with intended use and construction procedures. Experience has shown that when a heavier non-woven geotextile is used, the bedding material can often be reduced in thickness or be completely eliminated. TABLE I in SI ENGLISH UNITS (1) presents the most important geotextile strength properties. It should be noted that the strength requirements listed are only a guideline to the minimum values required for survivability. Specific applications may require additional testing.

Filter design criteria for geotextiles are based on the apparent opening size (AOS, which is designated as EOS in the previous guide specification), percent
open area (POA, for woven only), geotextile permeability (Kg), and an appropriate percent passing size of the soil. For piping analysis computations, AOS must be expressed as an equivalent U.S. standard sieve opening in millimeters. To assure adequate resistance to reduction in permeability over time (clogging) and sufficient long term flow through the soil/woven geotextile system, POA criteria, as expressed in the next note, can be used.

<table>
<thead>
<tr>

<td>515115</td>
</tr>
</tbody>
</table>

(1) Strength values are for the weaker principal direction.

The designer must specify geotextile properties which will allow retention of the soil being protected, permit sufficient flow through the textile, and prevent clogging. The designer should select the AOS, POA, and Kg, based on criteria in TABLE II. The AOS requirement should be specified as a range, to allow for manufacturing tolerance. It is preferable to specify a geotextile with opening as large as allowed by the design criteria. The smallest sieve opening size of the AOS range should not be smaller than the 0.125 mm sieve U.S. Standard sieve size No. 120.
### TABLE II GEOTEXTILE FILTER DESIGN CRITERIA

<table>
<thead>
<tr>
<th>PROTECTED SOIL (1) (PERCENT PASSING 75 µm NO. 200 SIEVE)</th>
<th>SOIL PIPING (2)</th>
<th>WOVEN</th>
<th>NON-WOVEN</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt; 5</td>
<td>$0.95/D_{85} &lt; 1$</td>
<td>POA 10 percent</td>
<td>Kg 5Ks</td>
</tr>
<tr>
<td>5 to 50</td>
<td>$0.95/D_{85} &lt; 1$</td>
<td>POA 4 percent</td>
<td>Kg 5Ks</td>
</tr>
<tr>
<td>50 to 85</td>
<td>$0.95/D_{85} &lt; 1$</td>
<td>POA 4 percent</td>
<td>Kg 5Ks</td>
</tr>
<tr>
<td></td>
<td>$0.95 &lt; 0.212$ mm No. 70 U.S. sieve)</td>
<td>Kg 5Ks</td>
<td></td>
</tr>
<tr>
<td></td>
<td>$0.95 &lt; 0.125$ No. 120 U.S. sieve)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

(1) Recent experiences have indicated that $0.95$ (i.e. AOS) increased with increasing relative density, $D_r$, and it is higher for uniform soil than well graded soil of similar density and average particle size.

(2) If the protected soil contains appreciable quantities of material retained on the 4.75 mm No. 4 U.S. sieve use only the soil passing the 4.75 mm No. 4 U.S. sieve in selecting the $0.95$ of the geotextile.

(3) Kg is the permeability of the geotextile and $K_s$ is the permeability of the protected soil.

Satisfactory geotextile performance is greatly dependent on the field preparation of the surface of the protected soil and the installation procedure.

The following information is related to TABLE 1. Geotextile calculations should be based on procedure from an accepted reference. Worst placement conditions should be considered since stresses generated during installation often exceed post construction stresses.

(1) The requirement of permittivity (as defined in ASTM D4491/D4491M) should be chosen in such a manner that the permeability of the geotextile should always be at least five times greater than the permeability of the adjacent soil during the life of the protected earth structure.

(2) The minimum seam strength listed in TABLE 1 is based on the tensile strength of the parent geotextile material. Seam strength can also be considered as not less than 90 percent of the unaged grab tensile strength of the geotextile in the applicable direction.

NOTE: TO DOWNLOAD UFGS GRAPHICS

Figure 2. Placement of geotextile on bank subject to streamflow action. Revetment materials have not yet been placed on the geotextile.

Figure 3. Geotextile on bank subject to wave attack showing placement of vertical-wall key trench at toe and top bank. Revetment materials have not yet been placed on geotextile.

Figure 4. Key trench design used when soil conditions do not permit construction of vertical walls.

The Designer must comply with the requirements of the following Regulatory Requirements:

U.S. DEPARTMENT OF INTERIOR, BUREAU OF RECLAMATION:

**************************************************************************

1.1 UNIT PRICES

**************************************************************************

NOTE: If Section 01 20 00 PRICE AND PAYMENT PROCEDURES is included in the project specifications, this paragraph title (UNIT PRICES) should be deleted from this section and the remaining appropriately edited subparagraphs below should be inserted into Section 01 20 00.

**************************************************************************

1.1.1 Payment

Payment will be made at the contract unit price and will constitute full compensation to the Contractor for providing all plant, labor, material, and equipment and performing all operations necessary for the complete and satisfactory installation of the geotextile. The following items are included in the contract unit price for Geotextiles and will not be counted a second time in the process of determining the extent of geotextile placed: Material and associated equipment and operation used in laps,
seams, or extra length; securing pins and associated material, equipment, and operations; and material and associated equipment and operations used to provide cushioning layer of sand or gravel or both to permit increase in allowable drop height of stone. No payment will be made for geotextiles replaced because of waste, contamination, damage, repair, or due to Contractor fault or negligence.

1.1.2 Measurement

Installed geotextiles will be measured for payment in place to the nearest [_____] square meter feet of protected area as delineated in the drawings.

1.1.3 Unit of Measure

Unit of measure: [_____] square meter feet.

1.2 REFERENCES

**************************************************************************
NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.
**************************************************************************

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

ASTM INTERNATIONAL (ASTM)

ASTM D4354 (2012; R 2020) Sampling of Geosynthetics for Testing

ASTM D4355/D4355M (2014) Deterioration of Geotextiles from Exposure to Light, Moisture and Heat in a Xenon-Arc Type Apparatus

Tearing Strength of Geotextiles

ASTM D4632/D4632M (2015a) Grab Breaking Load and Elongation of Geotextiles

ASTM D4884/D4884M (2014a) Strength of Sewn or Thermally Bonded Seams of Geotextiles

U.S. ARMY CORPS OF ENGINEERS (USACE)

1.3 SUBMITTALS

**************************************************************************
NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL
PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-04 Samples
Geotextiles

Minimum of [_____] [60] days prior to the beginning of installation of the same textile

SD-06 Test Reports
Geotextiles
Site Verification

SD-07 Certificates
Geotextiles
Needle Punched Geotextile

1.4   DELIVERY, STORAGE, AND HANDLING

Deliver only approved geotextile [rolls][, panels] [_____] to the project site. Label, ship, store, and handle all geotextile in accordance with ASTM D4873/D4873M. Do not use hooks, tongs, or other sharp instruments for handling geotextile.

PART 2   PRODUCTS

2.1   MATERIALS

2.1.1   General

**************************************************************************
NOTE: Nonwoven geotextiles are suitable for filtering fine-grained soils whereas woven or nonwoven are suitable for well graded granular soils.
**************************************************************************

Provide geotextile that is a [woven][non-woven] pervious sheet of plastic yarn as defined by ASTM D123 matching or exceeding the minimum average roll values listed in TABLE 1. Strength values indicated in the table are for the weaker principal direction.

<table>
<thead>
<tr>
<th>TABLE 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>MINIMUM PHYSICAL REQUIREMENTS FOR DRAINAGE GEOTEXTILE</td>
</tr>
</tbody>
</table>
2.1.2 Geotextile Fiber

Use fibers consisting of a long-chain synthetic polymer composed of at least 85 percent by weight of polyolefins, polyesters, or polyamides. Add stabilizers and/or inhibitors to the base polymer, if necessary to make the filaments resistant to deterioration caused by ultraviolet light and heat exposure. Do not add reclaimed or recycled fibers or polymer to the formulation. Form geotextile into a network such that the filaments or yarns retain dimensional stability relative to each other, including the edges. Finish the edges of the geotextile to prevent the outer fiber from pulling away from the geotextile.

2.1.3 Seams

NOTE: Most geotextiles are manufactured in widths of 1.8 to 5.5 m 6 to 18 feet, but to reduce the number of overlaps, wider sections may be produced by attaching narrow sections together. Pre-assembled sections of 11-m 36-foot widths or more are preferred to keep the number of overlaps to a minimum.

Sew the seams of the geotextile with thread of a material meeting the chemical requirements given above for geotextile yarn or bond the seams by cementing or by heat. Attach the sheets of geotextile at the factory or another approved location, if necessary, to form sections not less than [_____] meter [_____] feet wide. Test seams in accordance with method ASTM D4884/D4884M. Seam strength less than 90 percent of the required grab tensile strength of the unaged geotextile in any principal direction is not permitted.

2.1.4 Securing Pins

NOTE: The use of security pins should be restricted as much as possible since holes in geotextile allow
 Secure the geotextile to the embankment or foundation soil by pins to prevent movement prior to placement of revetment materials. Other appropriate means to prevent movement such as staples, sand bags, and stone could also be used. Insert securing pins through both strips of overlapped geotextile along the line passing through midpoints of the overlap. Remove securing pins as placement of revetment materials are placed to prevent tearing of geotextile or enlarging holes. Maximum spacing between securing pins depends on the steepness of the embankment slope. Provide maximum pins spacing equal to or less than the values listed in TABLE 2. When windy conditions prevail at the construction site, increase the number of pins upon the demand of the Contracting Officer. Anchor terminal ends of the geotextile with key trench or apron at crest, toe of the slope and upstream and downstream limits of installation.

</table>

2.2 INSPECTIONS, VERIFICATIONS, AND TESTING

2.2.1 Manufacturing and Sampling

Provide geotextiles and factory seams meeting the requirements specified in TABLE 1.

2.2.1.1 Conformance Testing

Perform conformance testing in accordance with the manufacturers approved quality control manual. Submit manufacturer's quality control conformance test results.

2.2.1.2 Factory Sampling

Randomly sample geotextiles in accordance with ASTM D4354 (Procedure Method A). Sample factory seams at the frequency specified in ASTM D4884/D4884M. Provide all samples from the same production lot as will be supplied for the contract, of the full manufactured width of the geotextile by at least 3 m 10 feet long, except that samples for seam strength may be a full width sample folded over and the edges stitched for a length of at least 1.5 m 5 feet. Identify samples submitted for testing by manufacturers lot designation.

2.2.1.3 Needle Punched Geotextile

For needle punched geotextile, provide manufacturer certification that the geotextile has been inspected using permanent on-line metal detectors and does not contain any needles.
2.2.1.4 Manufacturer Certification

[Upon delivery of the geotextile, submit duplicate copies of the written certificate of compliance signed by a legally authorized official of the manufacturer. State that the geotextile shipped to the site meets the chemical requirements and exceeds the minimum average roll value listed in TABLE 1.] [All brands of geotextile and all seams to be used will be accepted on the basis of mill certificates or affidavits. Submit duplicate copies of the mill certificate or affidavit signed by a legally authorized official from the company manufacturing the geotextile. Attest that the geotextile meets the chemical, physical and manufacturing requirements stated in this specification.]

2.2.2 Site Verification and Testing

**************************************************************************

NOTE: The need for, and amount of, site verification testing should be based on the severity of site conditions and the amount of textile being placed.
**************************************************************************

Collect samples at approved locations upon delivery to the site [at the request of the Contracting Officer][in accordance with ASTM D4354 (Procedure Method B)][at a frequency of once per 9290 square meters 100,000 square feet]. Test samples to verify that the geotextile meets the requirements specified in TABLE 1. Identify samples by manufacturers name, type of geotextile, lot number, roll number, and machine direction. Perform testing at an approved laboratory. Submit test results from the lot under review for approval prior to deployment of that lot of geotextile. Immediately rewrap rolls which are sampled in their protective covering.

PART 3 EXECUTION

3.1 SURFACE PREPARATION

Prepare surface, on which the geotextile will be placed, to a relatively smooth surface condition in accordance with the applicable portion of this specification and must be free from obstruction, debris, depressions, erosion feature, or vegetation. Remove any irregularities so as to ensure continuous, intimate contact of the geotextile with all the surface. Remove loose material, soft or low density pockets of material; grade erosion features such as rills and gullies out of the surface before geotextile placement.

3.2 INSTALLATION OF THE GEOTEXTILE

**************************************************************************

NOTE: This paragraph describes installation in an open area and on generally planar surfaces. For installation of geotextiles in drainage systems or about collector pipes, additional specification requirements may need to be added. The use of geotextiles to wrap collector pipes should be avoided whenever possible.

Minimum overlaps should be specified at 300 to 450 mm
12 to 18 inches depending on the specified orientation of the overlap to the direction of wave attack, velocity, or seepage. For under-water placement, minimum overlap should be 900 mm 3 feet.

Geotextiles will bridge small surface features in the slope and allow erosion to occur beneath the geotextile. Surface drainage should be directed away from the top of slope to prevent erosion under the geotextile. Surface flow should be brought downslope at controlled points such as lined ditches.

3.2.1 General

Place the geotextile in the manner and at the locations shown. At the time of installation, reject the geotextile if it has defects, rips, holes, flaws, deterioration or damage incurred during manufacture, transportation or storage.

3.2.2 Placement

NOTE: The placement of the geotextile relative to this paragraph may follow the following general procedures. (FIGURES referenced in this note are available on-line, see the note above).

(1) For current acting parallel to the bank the geotextile will be placed with the long dimension parallel to the current (Fig. 1a). Geotextile placement must be started from the bottom up with upper strips overlapping lower strips, and the upstream strips must overlap the downstream strips. The overlaps at the end of strips will be staggered at least 1.5 m 5 feet. Revetment and geotextile materials should be extended at least below the mean low water to minimize erosion at the toe (Fig. 2). If construction schedule permits, a period of low streamflow should be selected for the geotextile installation.

(2) When revetment material and geotextile filter are selected to protect against wave attack, the geotextile strips must be placed vertical to the slope of the bank with the upper strips overlapping the lower strips (Fig. 1b). The geotextile must be keyed at the toe to prevent uplift or undermining (Fig. 3). The key trench should be located below the mean low water to prevent erosion of the soil adjacent to the trench. When it is not possible to maintain vertical trench walls, the geotextile must be keyed to an excavated trench with stable slopes (Fig. 4). A key at the top of the bank will be installed where there is an overbank drainage problem.

Allowing the geotextile to drape or be free of high tensile stress during placement will require larger
quantities of geotextiles than the actual slope length.

Place the geotextile with the long dimension [parallel] [perpendicular] to the [centerline of the channel][shoreline][trench] and laid smooth and free of tension, stress, folds, wrinkles, or creases. Place the strips to provide a minimum width of [_____] mm inches of overlap for each joint. The placement procedure requires that the length of the geotextile be approximately [_____] percent greater than the slope length. Adjust the actual length of the geotextile used based on initial installation experience. Temporary pinning of the geotextile to help hold it in place until the [bedding layer][riprap] is placed will be allowed. Remove the temporary pins as the [bedding][granular material][riprap] is placed to relieve high tensile stress which may occur during placement of material on the geotextile. Design protection of riprap in compliance with EM 1110-2-1601. Perform trimming in such a manner that the geotextile is not damaged in any way.

3.3 PROTECTION

NOTE: All geotextiles can be damaged if stone is dropped on it from a height greater than 900 mm 3 feet. Some geotextiles can be damaged with lesser drop heights. When stone is heavy and angular it may cause punctures in the geotextile even if dropped from a height of 300 mm 1 foot. Tension in the geotextile must be minimized to prevent puncture.

Protect the geotextile at all times during construction from contamination by surface runoff; remove any geotextile so contaminated and replaced with uncontaminated geotextile. Replace any geotextile damaged during its installation or during placement of [granular filter materials][bedding materials][riprap] at no cost to the Government. Schedule the work so that the covering of the geotextile with a layer of the specified material is accomplished within [_____][7] calendar days after placement of the geotextile. Failure to comply will require replacement of geotextile. Protect the geotextile from damage prior to and during the placement of riprap or other materials. This may be accomplished by limiting the height of drop to less than 300 mm 1 foot, by placing a cushioning layer of sand or gravel on top of the geotextile before placing the material, or other methods deemed necessary. Care should be taken to ensure that the utilized cushioning materials will not impede the flow of water. Before placement of riprap or other materials, demonstrate that the placement technique will not cause damage to the geotextile. Do not allow equipment on the unprotected geotextile.

3.4 PLACEMENT OF CUSHIONING MATERIAL

Perform placing of cushioning material in a manner to ensure intimate contact of the geotextile with the prepared surface and with the cushioning material. Do not damage the geotextile, including tear, puncture, or abrasion, during placement. On sloping surfaces place the cushioning material from the bottom of the slopes upward. During placement, the height of the drop of riprap material greater than 300 mm 12 inches is not permitted. Uncover any geotextile damaged beneath the cushioning material, as necessary, and replaced at no cost to the Government.
3.5 OVERLAPPING AND SEAMING

3.5.1 Overlapping

**************************************************************************
NOTE: In general, overlapping is sufficient where the primary purpose is to hold the material in place during installation. However, where the design requires the geotextile to resist tensile stresses, seams should be sewn. A 300-mm 12-inch overlap specified in this section is considered minimum for all cases. The Contractor has the option of field sewing instead of overlapping.
**************************************************************************

The overlap of geotextile [rolls] [panels] [_____] must be [300][600][900][_____] mm [12][24][36][_____] inches. Appropriate measures will be taken to ensure required overlap exists after cushion placement.

3.5.2 Sewn Seams

**************************************************************************
NOTE: The Designer must specify appropriate seam test requirements. ASTM D1683, the previously used test standard, has been discontinued with no replacement designated.
**************************************************************************

High strength thread should be used so that seam test conforms to ASTM D4884/D4884M. Provide thread meeting the chemical, ultraviolet, and physical requirements of the geotextile, and provide color different from that of the geotextile. Provide seam strength equal to the strength required for the geotextile in the direction across the seam. Overlapping J-type seams are preferable over prayer-type seams as the overlapping geotextile reduces the chance of openings to occur at the seam. Use double sewing, specially for field seams, to provide a safety factor against undetected missed stitches.

3.6 [FIELD TESTING]

**************************************************************************
NOTE: The need for field testing should be based on the size and importance of the project. Field testing should be performed if the geotextile will be in tension.
**************************************************************************

Field test geotextile[ in tension].]

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for furnishing all labor and equipment and performing all work required for clearing and disposal of trees, stumps, clearing fences, buildings, and other structures and disposal of debris, trash, and materials resulting from clearing operations. This section was originally developed for USACE Civil Works projects.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1 GENERAL

NOTE: This guide specification has been prepared for use in reservoir clearing operations. It has two alternates, one which is concerned with the clearing of timber lands and the other one deals with the removal of man-made structures, debris, etc.
No paragraph covering partial payment has been included in this guide specification. If partial payment is to be made, it should be addressed in the contract at the appropriate place (e.g., Section 01 20 00 PRICE AND PAYMENT PROCEDURES). One method, which has been used, is described here in general terms and may be incorporated when necessary. To estimate the value of work completed during each period, the zones are divided into the class of clearing involved. Class A clearing includes, as nearly as can be determined from aerial photographs or other means, all the wooded area with the exception of scattered trees, fringe growth along roads and fences, etc. Class B clearing contains all of the open, cultivated or pasture lands and those relatively open areas containing scattered trees, fringe growth along roads and fences, etc.

The numbers of hectares acreages in each class should be estimated in advance and tabulated under the partial payment clause of the specification and thenceforth not be subject to change even if it is discovered that the original classification may have been in error. The most difficult class is arbitrarily assigned ninety work units for clearing, disposal, and clean-up. The number of work units in the other classes are estimated by comparison with the base class. The final estimate might be as follows:

<table>
<thead>
<tr>
<th>Class</th>
<th>Zone</th>
<th>Areas (hectares acreages)</th>
<th>Multiplication Factor</th>
<th>Work Units</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>1</td>
<td>60</td>
<td></td>
<td></td>
</tr>
<tr>
<td>B</td>
<td>1</td>
<td>15</td>
<td></td>
<td></td>
</tr>
<tr>
<td>A</td>
<td>2</td>
<td>90</td>
<td></td>
<td></td>
</tr>
<tr>
<td>B</td>
<td>2</td>
<td>25</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The value of a work unit is determined by dividing the contract price by the above total. The value of the work completed during any period will be determined by multiplying the number of hectares acres of the various classes completed in each zone, as estimated by the Contracting Officer.
planimetering areas from Government progress maps, by the work units in that class, totaling these figures and multiplying this total by the value of an individual unit as determined above. The estimate of the Contracting Officer will be final. For the purpose of apportioning the classes of work completed during any period, the felling and decking ready for burning or removal is considered as 50 percent of the work required and the removal and/or burning and clean-up will be considered as the remaining 50 percent.

1.1.1 Clearing (Timber and Structure)

1.1.1.1 Payment

Payment will be made for costs associated with furnishing plant, labor, materials and equipments, and performing all operations necessary for clearing (timber and structures) as specified.

1.1.1.2 Unit of Measure

Unit of measure: lump sum.

1.2 DEFINITIONS

1.2.1 Trees

NOTE: Alternate 1.

The line of demarcation between brush and trees, for the purpose of distinguishing clearing requirements, is that trees, as used, will be considered as that woody growth not falling within the limits of brush as defined below.

1.2.2 Brush

NOTE: Alternate 1.

Brush is that growth which is less than 50 mm 2 inches in diameter measured 150 mm 6 inches from the ground on the uphill side and is less than 2 m 6 feet in height measured from the ground on the uphill side.

1.2.3 Structures

NOTE: Alternate 2.

The term "structures" includes buildings or portions thereof, walls, silos, storm or root cellars, cisterns, wells, windmills, pit silos, water towers, etc. Remove or fill structures to the ground surface.
1.3 PROJECT/SITE CONDITIONS

1.3.1 Aesthetics and Pollution Control

**************************************************************************
NOTE: Alternate 1.
**************************************************************************

1.3.1.1 Ground Areas

All ground areas in the zone of normal pool level fluctuations which are disturbed by clearing operations and which would become subject to erosion will be protected or restored.

1.3.1.2 Construction Roads

**************************************************************************
NOTE: Insert type of cover crop and seeding rate, if applicable.
**************************************************************************

All construction roads proposed for use by the Contractor for removing salvaged timber or for access to the work area must be approved, as to location and alignment, prior to construction. Where such roads are determined to be of no value to project operation or will not serve recreational access needs after project construction, the areas occupied by these roads will be restored as nearly as possible to pre-construction conditions by reasonable grading and seeding [_____] [of a native cover crop] along with the planting of seedling trees if in a tree cover area.

1.3.2 Existing Conditions

**************************************************************************
NOTE: Paragraphs of Alternate 1 and 2 should be deleted if not applicable.
**************************************************************************

1.3.2.1 Boundaries

**************************************************************************
NOTE: Alternate 1.
**************************************************************************

When land lines or identifiable topographic features, such as roads, railroads, streams, etc., are used in place of or in addition to contours to designate zone boundaries, the descriptions indicated below should be so modified.

The area to be cleared under this [section] [contract] is divided into two (2) zones having the general limits as defined below and as indicated on the [drawings] [and] [maps] and [aerial photographs], which form a part of this contract.

1.3.2.1.1 Zone 1

Included in this zone is that portion of the reservoir area [bounded by][at a lower elevation than] the [_____] meter foot msl contour line.
1.3.2.1.2 Zone 2

**************************************************************************
NOTE: Use the contour elevation of Zone 1.
**************************************************************************

Included in this zone is that portion of the reservoir area above the [_____] meter foot msl contour line and below the [_____] meter foot msl contour line.

[1.3.2.2 Cemeteries

**************************************************************************
NOTE: Alternate 1.
**************************************************************************

Cemeteries are in the area to be cleared. Do not disturb or destroy any grave marker, or allow any vehicle to pass over a grave, or otherwise disturb the surface of the ground over any grave. Adequately mark the graves to insure that equipment does not work over the areas. Graves and headstones or markers will be relocated by others.

[1.3.2.3 Markings of Zones

**************************************************************************
NOTE: Alternate 1.
**************************************************************************

The [_____] and [_____] contour lines have been established in the field by the Government. The contour lines are identified by stakes on the lines or by painted bands on trees near the lines. The [_____] contour is marked with [_____] paint and the [_____] contour is marked with [_____] paint. [Other boundaries are marked by identifiable topographical features or by section or fractional section lines.]

1.3.2.4 Zones

**************************************************************************
NOTE: Alternate 2.
**************************************************************************

When Alternate 2 is used independently of Alternate 1, the boundaries should be completely described. Similarly, this section should be further modified to include all other applicable portions of Alternate 1.

**************************************************************************

The boundaries of the zones are as described in paragraph BOUNDARIES, subparagraphs ZONE 1 and ZONE 2.

1.3.2.5 Fences

1.3.2.5.1 Zone 1

No clearing of fences is required in Zone 1; however, the Contractor may, as an option, remove any or all fence materials from the area and dispose of such materials off the reservoir area.
1.3.2.5.2 Zone 2

Clear all fences in Zone 2, except in those areas where no timber clearing is required.

1.3.2.6 Structures

Burn combustible materials obtained from removal of structures in accordance with paragraph DISPOSAL OF MATERIAL or dispose of them off the reservoir area. Where filling of structures is required, fill to within 450 mm 18 inches of the ground surface and made with noncombustible materials such as masonry rubble, and other debris. When all available debris has been used in filling, all remaining unfilled portions, together with the above 450 mm 18 inches, completely fill to the ground surface with earth, borrowed as directed by the Contracting Officer. The top surfaces of fills must be neat in appearance and smooth enough not to constitute a hazard to persons or livestock.

PART 2 PRODUCTS

Not used

PART 3 EXECUTION

3.1 CLEARING REQUIREMENTS

**************************************************************************

NOTE: Alternate 1.
**************************************************************************

3.1.1 Brush

The cutting of brush in either zone is not required.

3.1.2 Zone 1

**************************************************************************

NOTE: Use the same elevation which determines the contour bounding Zone 1.
**************************************************************************

Remove all trees and stumps, not defined as brush, that extend above elevation [______], except that no material will be required to be removed any nearer to the ground surface than is specified for Zone 2. Topping of trees and stumps to elevation [______] will be permitted as a Contractor's option.

3.1.3 Zone 2

Remove all trees and stumps, not falling within the classification of brush, to a height not exceeding 150 mm 6 inches above the ground surface measured on the uphill side.

3.1.4 Equipment

A tree crushing machine may be used at the option of the Contractor in all clearing operations.
3.2 DISPOSAL OF MATERIAL

******************************************************************************
NOTES: This paragraph makes general provisions for the Contractors' responsibility for fire damage beyond the clearing area. Notwithstanding these requirements, substantial damage has occurred in reservoir areas above the clearing line, due to fire escaping from areas being cleared. Fires originating in this manner have destroyed timber, ruined choice public use areas, destroyed wildlife habitat, and adversely affected public relations in the areas. Every effort should be made to avoid unnecessary destruction of the natural resources of reservoir areas, including the following actions:

1. The Contracting Officer or the Contractor or both should maintain constant knowledge, by appropriate telephone or radio liaison with personnel of the State forest protection service, relative to the degree of fire hazard and promptly disseminate by appropriate means this information to all others concerned.

2. The Contractor should be required to patrol firebreaks around clearing operations during all periods when there is danger of fire spreading beyond the clearing areas.

3. The Contractor should be required to halt all burning during periods of high fire danger.

It is considered that the provisions of the guide specifications and contract documents give the Contracting Officer the authority to enforce the required safety precautions.

******************************************************************************

3.2.1 General

Completely remove material cleared from the areas by transporting from the Government property or burn within the cleared areas unless otherwise approved by the Contracting Officer. All timber from which saw logs, posts, ties or cordwood can be produced will become the property of the Contractor and in the interest of conservation it is required that the Contractor make a reasonable effort to dispose of material for these purposes. The Contractor may cut timber into convenient lengths at the site but approval must be secured prior to the operation of saw mills within the Government lands. Do not throw or leave cleared material in the creeks or river. After the felling operation has been completed, the timber to be burned must be decked for burning within [_____] days. Remove all felled timber. However, it is intended that all existing down timber in zones one (1) and two (2) will remain in place except dispose solid, floatable material that is larger than 100 mm 4 inches in diameter (regardless of length) and/or over 2.5 m 8 feet in length (regardless of diameter) in the manner prescribed for cleared material. Clean up floatable debris. The cutting of branches and debris remaining after clean-up, to reduce their length in order to avoid removal, will not be permitted.
3.2.2 Burning

NOTE: Specification provisions for burning of material from cleared areas should be written to comply with applicable statutory and regulatory requirements for Prevention, Control, and Abatement of Air Pollution by Federal Activities.

a. The material cleared may be burned within the contract area, and at any time within the contract period provided such burning does not interfere with inhabitants of the area by drastic changes in their accustomed environment, such as addition to air pollution or danger of fire. However, the specific time, location and manner of burning must be subject to approval from the viewpoints of air pollution, governing fire laws and safety.

b. In the interest of conservation, as an option, make available to the general public without charge, the material scheduled for burning. Do not conduct burning operations within 30 m 100 feet of any standing timber or flammable growth. The burning operations are subject to all public law governing such operations and the Contractor will be responsible for any damage to life and/or property resulting from fires that are started by its employees or as a result of its operations.

c. Furnish at the site adequate fire fighting equipment, such as back tanks, flaps, shovels, rakes, etc., to properly equip his personnel for fighting fires. Guard fires at all times and provide constant surveillance until they have burned out or have been extinguished.

d. Burn so thorough that the materials is reduced to ashes, except that occasional charred pieces of logs or branches not exceeding 100 mm 4 inches in diameter and/or 2.5 m 8 feet in length will be permitted to remain. Upon approval, charred material will be buried after it is determined that it could not be disposed of by methods used in the normal burning operation. Dispose material at approved locations and cover within a minimum of 450 mm 18 inches of earth.

3.2.3 Burial

In certain cases, such as along drainage channels in remote areas, cleared material may be disposed of by burial in areas designated for disposal of excess excavation or spoil. When this option is used, care will be taken to insure that all such cleared material will be buried under not less than 450 mm 18 inches of earth. Approval will be obtained for each area selected for debris disposal for burial prior to beginning such operations. Areas to be used for permanent roadways, levees or embankments will not be used for disposal of material from clearing operations. Areas for disposal of cleared materials by burial will not be located within 92 m 300 feet of public road crossings or of project areas to be regularly visited by the public.

3.2.4 Removal from Site

Except as otherwise provided, the Contractor will be permitted to remove felled and trimmed timber from the site of the work. The Contractor will be allowed to stockpile salvaged timber near contour line [_____] at
approved locations. The Government will assume no responsibility for the protection and safekeeping of such material. All stockpiled timber must be removed from Government lands before final acceptance of the work will be made.

3.3 DEBRIS

**************************************************************************
NOTE: Alternate 2.
**************************************************************************

Dispose burn combustible debris in accordance with paragraph DISPOSAL OF MATERIAL. Dispose noncombustible debris in excess of that disposed of as set forth in paragraph STRUCTURES at such locations below elevation [_____] as designated by the Contracting Officer. Debris includes trash of all kinds.

3.4 MARKETABLE MATERIALS

Any of the cleared materials which the Contractor considers marketable becomes its property and remove from the reservoir area.

3.5 LOCATIONS

The locations of structures and debris to be cleared are tabulated below.

NOTE: This guide specification covers the requirements for clearing and grubbing.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1   GENERAL

NOTE: When this specification is used for hazardous waste site remediations, define what materials generated from clearing, grubbing, and tree removal are contaminated and what materials are non-contaminated. The decision on how to define contaminated and non-contaminated materials must be made by the appropriate regulatory authorities and documented in the design analysis.

The following information must be shown on the project drawings:

1. Limits of clearing
2. Limits of grubbing
3. Trees and shrubs to remain in area to be cleared

4. Trees to be removed in areas which are not to be cleared

5. Describe size, density, and type of trees to be cleared and grubbed.

1.1 REFERENCES

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a RID outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

U.S. DEPARTMENT OF DEFENSE (DOD)

DODI 4150.07 (2019) DOD Pest Management Program

1.2 SUBMITTALS

NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up
to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-01 Preconstruction Submittals
   Herbicide Application Plan
SD-03 Product Data
   Tree Wound Paint
   Herbicides; G[, [_____]]
SD-07 Certificates
   Qualifications; G[, [_____]]
SD-11 Closeout Submittals
   Pest Management Report

1.3 QUALITY CONTROL

1.3.1 Regulatory Requirements

NOTE: Herbicides are a type of pesticide. Contact regional pest management consultant to obtain service specific reporting requirements for the use of herbicides.

For Navy projects, contact the cognizant NAVFAC Applied Biologist. Contact information can be found at

SECTION 31 11 00 Page 5
For Army projects, contact the cognizant Army Applied Biologist. Contact information can be found at [http://www.aec.army.mil/services/conserve/pestmanagement.aspx](http://www.aec.army.mil/services/conserve/pestmanagement.aspx).

Comply with DODI 4150.07 for requirements on Contractor's licensing, certification, and record keeping. Maintain daily records using the Pest Management Maintenance Record, DD Form 1532-1, or a computer generated equivalent. These forms may be obtained from the main web site: [https://www.acq.osd.mil/eie/afpm/code/standardlists/dd1532-1.xlsm](https://www.acq.osd.mil/eie/afpm/code/standardlists/dd1532-1.xlsm).

### 1.3.2 Qualifications

For the application of herbicides, use the services of an applicator who is commercially certified in the state where the work is to be performed as required by DODI 4150.07. Submit a copy of the pesticide applicator certificates.

### 1.4 DELIVERY, STORAGE, AND HANDLING

Deliver materials to the site, and handle in a manner which will maintain the materials in their original manufactured or fabricated condition until ready for use.

#### 1.4.1 Storage

Storage of herbicides on the installation will not be permitted unless it is written into the contract.

#### 1.4.2 Handling

Handle herbicides in accordance with the manufacturer's label and Safety Data Sheet (SDS), preventing contamination by dirt, water, and organic material. Protect herbicides from weather elements as recommended by the manufacturer's label and SDS. Spill kits must be maintained on herbicide control vehicles. Mixing of herbicides on the installation will not be permitted unless it is written into the contract.

### PART 2 PRODUCTS

#### 2.1 MATERIALS

##### 2.1.1 Tree Wound Paint

Use bituminous based paint from standard manufacture specially formulated for tree wounds.

##### 2.1.2 Herbicide

**************************************************************************

NOTE: The herbicide must be pre-approved by regional pest management consultant.
**************************************************************************

Provide herbicides currently registered by the EPA or approved for such use by the appropriate agency of the host county and approved by the
Contracting Officer. Select a herbicide that is suitable for the climatic conditions at the project site. Submit manufacturer's label and SDS for herbicides proposed for use.

PART 3 EXECUTION

3.1 PREPARATION

3.1.1 Herbicide Application Plan

Prior to commencing application of herbicide, submit a herbicide application plan with proposed sequence of treatment work including dates and times of application. Include the herbicide trade name, EPA registration number, chemical composition, formulation, application rate of active ingredients, method of application, area or volume treated, and amount applied. Include a copy of the pesticide applicator certificates.

3.1.2 Protection

3.1.2.1 Roads and Walks

Keep roads and walks free of dirt and debris at all times.

3.1.2.2 Trees, Shrubs, and Existing Facilities

[Provide protection in accordance with Section 01 57 19 TEMPORARY ENVIRONMENTAL CONTROLS.] [Protect trees and vegetation to be left standing from damage incident to clearing, grubbing, and construction operations by the erection of barriers or by such other means as the circumstances require.]

3.1.2.3 Utility Lines

Protect existing utility lines that are indicated to remain from damage. Notify the Contracting Officer immediately of damage to or an encounter with an unknown existing utility line. The Contractor is responsible for the repair of damage to existing utility lines that are indicated or made known to the Contractor prior to start of clearing and grubbing operations. When utility lines which are to be removed are encountered within the area of operations, notify the Contracting Officer in ample time to minimize interruption of the service. Refer to Section 01 30 00 ADMINISTRATIVE REQUIREMENTS and Section 01 57 19 TEMPORARY ENVIRONMENTAL CONTROLS for additional utility protection.

3.2 APPLICATION

3.2.1 Herbicide Application

Adhere to safety precautions as recommended by the manufacturer concerning handling and application of the herbicide.

3.2.1.1 Clean Up, Disposal, And Protection

Once application has been completed, proceed with clean up and protection of the site without delay. Clean the site of all material associated with the treatment measures, according to label instructions, and as indicated. Remove and dispose of excess and waste material off Government property.
3.2.1.1 Disposal of Herbicide

Dispose of residual herbicides and containers off Government property, and in accordance with the approved disposal plan, label instructions and EPA requirements.

3.3 CLEARING

NOTE: Any clearing which requires the removal and disposal of structures that obtrude, encroach upon, or otherwise obstruct the work should be indicated and specified in the Section 02 41 00 {DEMOLITION} {AND} {DECONSTRUCTION}.

When grubbing is included as part of the contract, delete requirements for herbicides.

Where loose rocks, boulders, or rock piles are present on the surface of the areas designated to be cleared, appropriate provisions will be inserted to provide for the disposal of such material. Where stone occurs that can be economically used in the project, provision will be made for the proper stockpiling of such stone in a designated area adjacent to the location of its intended use.

If only minor structures will be encountered, such work may be included. Where large structures are to be demolished, the requirements of this work will be covered in Section 02 41 00 {DEMOLITION} {AND} {DECONSTRUCTION}.

Herbicides intended for controlling vegetative growth should be specified and used with caution on hazardous waste sites to avoid contributing to site contamination.

Clearing consists of the felling, trimming, and cutting of trees into sections and the satisfactory disposal of the trees and other vegetation designated for removal, including downed timber, snags, brush, and rubbish occurring within the areas to be cleared. [Clearing also includes the removal and disposal of structures that obtrude, encroach upon, or otherwise obstruct the work.] Cut off flush with or below the original ground surface trees, stumps, roots, brush, and other vegetation in areas to be cleared, except such trees and vegetation as may be indicated or directed to be left standing. Trim dead branches that are 40 mm 1-1/2 inches or more in diameter on trees designated to be left standing within the cleared areas and trim all branches to the heights indicated or directed. Neatly cut close to the bole of the tree or main branches, limbs and branches to be trimmed. Paint, with an approved tree-wound paint, cuts more than 40 mm 1-1/2 inches in diameter. Apply herbicide [at the rate of [_____]] [in accordance with the manufacturer's label] to the top surface of stumps designated not to be removed.

3.3.1 Tree Removal

Where indicated or directed, remove trees and stumps that are designated as
trees from areas outside those areas designated for clearing and grubbing. This work includes the felling of such trees and the removal of their stumps and roots as specified in paragraph GRUBBING. Dispose of trees as specified in paragraph DISPOSAL OF MATERIALS.

[3.3.2 Pruning

[Prune] [Trim] trees designated to be left standing within the cleared areas of dead branches 38 mm 1-1/2 inches or more in diameter; and trim branches to heights and in a manner as indicated. Neatly cut limbs and branches to be trimmed close to the bole of the tree or main branches. Paint cuts more than 32 mm 1-1/4 inches in diameter with an approved tree wound paint.

3.3.3 Grubbing

**************************************************************************

NOTE: Delete the second sentence when this work is included under another section or sections of the project specification.

For hazardous waste sites, the amount of grubbing performed in contaminated areas should be minimized due to potential added costs for disposal of contaminated materials and health and safety concerns.

**************************************************************************

Grubbing consists of the removal and disposal of stumps, roots larger than 75 mm 3 inches in diameter, and matted roots from the designated grubbing areas. Remove material to be grubbed, together with logs and other organic or metallic debris not suitable for foundation purposes, to a depth of not less than 455 mm 18 inches below the original surface level of the ground in areas indicated to be grubbed and in areas indicated as construction areas under this contract, such as areas for buildings, and areas to be paved. Fill depressions made by grubbing with suitable material and compact to make the surface conform with the original adjacent surface of the ground.

3.4 DISPOSAL OF MATERIALS

**************************************************************************

NOTE: Coordinate disposal requirements with 01 57 19 TEMPORARY ENVIRONMENTAL CONTROLS.

**************************************************************************

Dispose of excess materials in accordance with the approved solid waste management permit and include those materials in the solid waste management report.

All wood or wood like materials, except for salable timber, remaining from clearing, pruning or grubbing such as limbs, tree tops, roots, stumps, logs, rotten wood, and other similar materials is the property of the Contractor and dispose of as specified. All non-saleable timber and wood or wood like materials remaining from timber harvesting such as limbs, tree tops, roots, stumps, logs, rotten wood, and other similar materials is the property of the Contractor and dispose of as specified.
### 3.4.1 Saleable Timber

NOTE: Verify the most appropriate option with the natural resources office for the Installation.

When this specification is being used for the remediation of hazardous waste sites or when soil or groundwater are contaminated by hazardous materials, timber removed from these areas is not normally harvested due to liability concerns. When timber is harvested in areas where hazardous materials are present, this paragraph should define how both contaminated and non-contaminated materials will be disposed of. Include requirements describing how both contaminated and non-contaminated materials will be handled, stored and disposed of. These requirements must be coordinated with the Government Forester and Installation environmental staff.

NOTE: Use this paragraph when regional forestry program has a way of hauling or selling stockpiled harvested timber and the Contractor will be required to cut and stack saleable timber for the Government.

Applicable lengths for each class of forest products will vary by geographic region. Consult with the Government forester for the correct log lengths in a particular area. Coordinate with the Government regional forestry program to determine the correct log lengths in a particular area.

Consider felled timber from which saw logs, pulpwood, posts, poles, ties, or fuelwood can be produced as saleable timber. Trim limbs and tops, and saw into saleable lengths of [_____] meters feet for saw logs, [_____] meters feet for pulpwood, [_____] meters feet for poles, [_____] meters feet for ties, and [_____] meters feet for fuelwood, and stockpile adjacent to the site. The stockpile timber will remain the property of the Government.

NOTE: Use this paragraph when the Government will harvest saleable timber prior to award of the contract.

The Government will, by separate contract, harvest all saleable timber from the project site.

NOTE: For Navy only, this option must be approved by NAVFAC legal counsel for NAVFAC projects.

NOTE: Use this paragraph when the Contractor will be required to pay the Government an appraised fair
market value for the saleable timber on the project site. The fair market value must be determined by the Government forester.

Describe the boundaries for the tract of land.

All timber removed from the project site is the property of the Contractor. Reimburse the Government for the fair market value of the timber which the Government has appraised at $[_____] on the tract of land described as follows [______]. Submit payment to the Contracting Officer by cashier's or certified check in the amount of the appraised value, made payable to [the U.S. Treasury] [_____] for deposit into the [Navy Forestry] or [______] account. Make payment within 30 days of the Notice to Proceed.

NOTE: Use this paragraph when the fair market value of the harvested timber does not exceed a nominal value. The fair market value must be determined by the Government forester. The timber will become the property of the contractor. The Contractor permitted to make use of the nonsaleable timber or to dispose of such timber in an approved manner.

All timber removed from the project site is the property of the Contractor.

3.5 CLOSEOUT ACTIVITIES

3.5.1 Herbicides

Upon completion of this work, submit the Pest Management Report DD Form 1532, or an equivalent computer product, to the Integrated Pest Management Coordinator. This form identifies the type of operation, brand name and manufacturer of herbicide, formulation, concentration or rate of application used.

PART 1 GENERAL

1.1 UNIT PRICES

NOTE: When it is determined that lump sum contract is advisable this paragraph will be deleted.

Measurement and payment will be based on completed work performed in accordance with the drawings, specifications, and the contract payment schedules. No payment will be made under this section for excavation, trenching, or backfilling. Payment for such work will be made under Section 31 00 00 EARTHWORK.
1.1.1 Measurement

The length of pipe lines to be paid for will be determined by measuring along the centerline of the various sizes of pipe furnished and installed. Pipe will be measured from center of fitting to center of fitting and from connection to connection to wells or treatment units. No deduction will be made for the space occupied by valves or fittings.

1.1.2 Payment

Payment will be made for off-gas piping at the contract unit price per linear meter linear foot for the various types and sizes of piping, and will be full compensation for pipes, joints, specials, and fittings, complete in place. Payment for valves, valve boxes, and standard valve manholes will be made at the respective contract unit price each for such items complete in place. Payment will include the furnishing of testing, plant, labor, and material and incidentals necessary to complete the work, as specified and as shown.

1.3 SYSTEM DESCRIPTION

Provide off-gas piping system consisting of buried and above ground pipe, pipe supports, fittings, equipment and accessories. Submit Drawings containing graphical relationship of various components of the work, schematic diagrams of the systems, details of fabrication, layouts of particular elements, connections, clearance required for maintenance and operation, and other aspects of the work to demonstrate that the system has been coordinated and will properly function as a unit. Drawings to demonstrate that thermal expansion of plastic pipe exposed to ambient conditions has been incorporated into the design. Submit a written certificate from the testing agency stating that the items have been tested and that they conform to the applicable requirements of the specifications. Indicate the methods of testing used by the testing agency. In lieu of a certificate from a testing agency, published catalog specification data, accompanied by the manufacturer's certified statement that the items are in accordance with the applicable requirements of the specifications will be acceptable as evidence that the items conform with agency requirements.

1.3.1 Design Requirements

**************************************************************************
NOTE: Determine design wind speed from ASCE 7-16, and/or UFC 3-301-01 STRUCTURAL LOAD DATA. Use 161 km/h 100 miles per hour minimum. Use 1.2 kPa 25 psf snow load for most heavy snow climates; delete snow load where maximum snow is insignificant. In some cases, local climates and topography will dictate that a value greater than 197 Pa 25 psf be used for snow loading. This may be determined from ANSI A58.1, local codes, or by research and analysis of the effect of local climate and topography.

Provide seismic requirements, if a Government designer (either Corps office or A/E) is the Engineer of Record, and show on the drawings. Delete the bracketed phrase if seismic details are not included. Pertinent portions of UFC 3-301-01 and Sections 13 48 73 and 23 05 48.19, properly edited, must be included in the contract documents.
**************************************************************************

Provide piping in accordance with 49 CFR 192. Ensure design for installation of plastic pipe above grade has provisions for movement due to thermal expansion and contraction. Provide seismic details in accordance with UFC 3-301-01 and Sections 13 48 73 SEISMIC CONTROL FOR MISCELLANEOUS EQUIPMENT and 23 05 48.19 [SEISMIC] BRACING FOR HVAC [as shown on the drawings].

a. Soil bearing capacity: [_____] MPa psf.
b. Seismic parameters: [_____].
c. Wind speed (maximum): [_____] km/h mph.
d. Ground snow load: [_____] kPa psf.
e. Ambient air temperature (maximum): [_____] degrees C F.
f. Ambient air temperature (minimum): [_____] degrees C F.

1.3.2 Performance Requirements

**************************************************************************
NOTE: Enter names and concentrations of organic chemicals in the blank provided and additional lines or provide a reference to another section of the specification as necessary to provide complete information. Conditions encountered during construction frequently differ from the design conditions and/or worst conditions. Plume migration affects the concentrations that will be encountered during startup and testing. Design velocity range for vapors, gases, and smoke is between 5.1 and 10 m/sec 1,004 and 1,970 ft/min in NFPA 91 Exhaust Systems for Air Conveying of Materials. Consider the requirements of ASTM D543 in selection of pipe materials.

Identify pipe runs on the drawings and fill in the blanks with the maximum positive and negative anticipated gauge pressures.
**************************************************************************

Provide capacity and design of the piping and accessories suitable for 24-hour full load service in an outdoor location. Calculate expansion of plastic pipe exposed to ambient conditions. Provide pipe materials compatible with each of the following off-gas properties.

a. Pipe segment [A-B] [B-C] [C-D] [D-E] [______]:

<table>
<thead>
<tr>
<th>Pressure (gauge maximum)</th>
<th>[_____] MPa psig</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pressure (gauge minimum)</td>
<td>[_____] MPa psig</td>
</tr>
<tr>
<td>Flow rate (maximum)</td>
<td>[_____] cubic m/s cubic ft/s</td>
</tr>
<tr>
<td>Flow rate (minimum)</td>
<td>[_____] cubic m/s cubic ft/s</td>
</tr>
<tr>
<td>Ambient temperature (maximum)</td>
<td>[_____] degrees C F</td>
</tr>
<tr>
<td>Ambient temperature (minimum)</td>
<td>[_____] degrees C F</td>
</tr>
<tr>
<td>Off-gas temperature (maximum)</td>
<td>[_____] degrees C F</td>
</tr>
<tr>
<td>Off-gas temperature (minimum)</td>
<td>[_____] degrees C F</td>
</tr>
</tbody>
</table>

b. Estimated chemical concentrations of [vapor] [off-gas]:

<table>
<thead>
<tr>
<th>pH</th>
<th>Minimum</th>
<th>Average</th>
<th>Maximum</th>
</tr>
</thead>
<tbody>
<tr>
<td>[_____]</td>
<td>[_____]</td>
<td>[_____]</td>
<td></td>
</tr>
</tbody>
</table>
1.4 SUBMITTALS

**************************************************************************
NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.

**************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-02 Shop Drawings

Off-Gas Piping System
1.5 QUALITY ASSURANCE

1.5.1 Contractor Qualifications

Have a minimum of [2] [3] [5] [_____] years of experience in the construction of piping systems for sour gas, condensable gas, off-gas or vapor.

1.5.2 Single Source Supplier

Assign to a single supplier full responsibility for the furnishing of the off-gas piping system. The designated single supplier, however, need not manufacture the system but must coordinate the selection, assembly, installation, and testing of the entire system as specified herein.

1.5.3 Welding

Provide qualifications of welding procedures, welders, and welding operators in accordance with welding and nondestructive testing procedures for pressure piping specified in Section 40 05 13.96 WELDING PROCESS PIPING. Weld structural members in accordance with Section 05 05 23.16 STRUCTURAL WELDING.

1.5.4 Jointing Plastic and Fiberglass Reinforced Pipe

Use manufacturer's prequalified joining procedures. Inspect joints by an
inspector qualified in the joining procedures being used and in accordance with AGA XR0603. Ensure joiners and inspectors are qualified at the job site by a person who has been trained and certified by the manufacturer of the pipe, to train and qualify joiners and inspectors in each joining procedure to be used on the job. Training must include use of equipment, explanation of the procedure, and successfully making joints which pass tests specified in AGA XR0603. Notify the Contracting Officer at least 24 hours in advance of the date to qualify joiners and inspectors.

1.5.5 Pre-Installation Meeting

**************************************************************************
NOTE: Remove this paragraph when conference is not required.
**************************************************************************

[Partnering] [Pre-installation] meeting will be required. Ensure that involved subContractors, suppliers, and manufacturers are [notified] [represented]. Furnish date and time of the conference to the Contracting Officer for approval.

1.6 DELIVERY, STORAGE, AND HANDLING

1.6.1 Packaging

Pack, package and mark plastic pipe in accordance with ASTM D3892.

1.6.2 Cleaners, Solvents and Glues

A safety data sheet in conformance with ANSI Z400.1/Z129.1 must accompany each chemical delivered for solvents, solvent cements, or glues used in pipe connections or pipe installation. Handling must be in accordance with ASTM F402.

1.6.3 Storage

Classify and mark storage facilities in accordance with NFPA 704. Store materials with protection from puncture, dirt, grease, moisture, mechanical abrasions, excessive heat, ultraviolet (UV) damage, or other damage. Handle and store pipe and fittings in accordance with the manufacturer's recommendations. Store piping bundles on a prepared surface and do not stack more than two bundles high.

1.7 SEQUENCING AND SCHEDULING

**************************************************************************
NOTE: Coordinate with Section Section 26 42 13 GALVANIC (SACRIFICIAL) ANODE CATHODIC PROTECTION (GACP) SYSTEM or Section 26 42 17 IMPRESSED CURRENT CATHODIC PROTECTION (ICCP) SYSTEM if steel pipe is allowed. Blowers and control valves are specified in Section 43 11 00.10 OFF-GAS FANS, BLOWERS AND PUMPS.
**************************************************************************

Perform installation as specified in Section 31 00 00 EARTHWORK, except as modified herein or required by ASTM D2774, ASTM D2855, ASTM D3839, or ASTM F402, as appropriate for the pipe material.

SECTION 31 21 00 Page 14
1.8 EXTRA MATERIALS

NOTE: This paragraph covers items to be furnished to the Government by the Contractor for future maintenance and repair. Insert text as required.

Provide extra material consisting of [____]. Provide a special wrench for removal of locking covers for each valve box and for each pressure regulator box.

1.9 MAINTENANCE SERVICE

NOTE: This paragraph covers provisions for maintenance service as applicable to critical systems, equipment, and landscaping. Insert text as required or omit.

Maintenance service includes [____].

PART 2 PRODUCTS

NOTE: If thermoplastic pipe is specified for above ground use, verify that the referenced standards allow use of the specified materials for vapor transport or note the exceptions. Thermoplastic pipe is specified and installed above grade for vacuum applications. The ASME B31.3 advises that "special precautions should be observed" when using thermoplastic pipe to transport compressed gases above ground. Recommendation B of the Plastic Pipe Institute recommends against the use of thermoplastic pipe to transport air or other compressed gases in exposed above ground locations, e.g. in exposed plant piping." The industry standards for use of thermoplastic pipe for transmission of gas, ASTM D2513 and ASTM D3839, both recommend only underground use.

Combustible and explosive properties of the vapor, accumulation of static electrical charge and changes in strength characteristics due to elevated temperatures should be considered in material selection. Consideration should be given to compatibility of the construction materials with the condensate that will accumulate in the system. Select materials to avoid softening and loss of physical properties due to polymer degradation by depolymerization; stiffening or embrittlement due to loss of plasticizers resulting from repeated usage; deterioration of mechanical properties due to swelling; and failure of adhesive or heat fused joints due to interaction with condensate or leachate and physical stress.
See EM 1110-1-4008 Liquid Process Piping for chemical resistivity information.

Delete inapplicable materials or equipment. Options for other material, such as ductile iron in iron pipe sizes, may be added for noncorrosive gases.

2.1 MATERIALS AND EQUIPMENT

Provide materials and equipment that are new and unused, except for testing equipment. Ensure components that serve the same function and that are the same size are identical products of the same manufacturer. Provide piping material and appurtenances suitable for the service intended as specified and as shown on the drawings. Submit manufacturer's descriptive data and technical literature for each piping system, including design recommendations, pressure and temperature ratings, dimensions, type, grade and strength of pipe and fittings, thermal characteristics (coefficient of expansion and thermal conductivity) and chemical resistivity for each chemical constituent in the off-gas stream. Manufacturer's recommended installation procedures including materials preparation, and installations.

2.1.1 Standard Products

Provide material and equipment which are the standard products of a manufacturer regularly engaged in the manufacture of the products and that essentially duplicate items that have been in satisfactory use for at least 2 years prior to bid opening. Provide pipe, valves, fittings and appurtenances supported by a service organization that is, in the opinion of the Contracting Officer, reasonably convenient to the site.

2.1.2 Identification

Provide each piece of pipe bearing the ASTM designation and the ASTM markings required for that designation. Mark each valve in accordance with MSS SP-25 to identify the manufacturer, size, pressure rating, body disc and seat material. Securely attach a tag with the manufacturer's name, catalog number and valve identification.

2.2 DESIGN STRENGTH

Ensure design strength of piping is suitable for the operating pressure and temperature ranges indicated and/or shown. With the exception of vacuum pipe segments [A-B] [B-C] [D-E] [______], do not use thermoplastic pipe to transport air or vapors in exposed above ground locations.

2.3 STEEL PIPE

**************************************************************************

NOTE: Verify that pipe wall thickness conforms to ASME B31.8 for larger sizes and high pressures.

For exposure potential to pressures less than 70 kPa 10 psig and temperatures less than 100 degrees C 212 degrees F and mild chemical exposure, blast surface in accordance with SSPC SP 6/NACE No.3.

For exposure potential to pressures greater than 70 kPa 10 psig and temperatures greater than 100
degrees C 212 degrees F and mild chemical exposure
intermediate options may be appropriate.

For severe chemical exposure, the baked phenolic
system should be used.

**************************************************************************
Provide Schedule 40 steel pipe conforming to [Grade A or B, Type E or S of
ASTM A53/A53M,] [API Spec 5L,] [ASME B31.8,] [or] [NFPA 58]. Provide pipe
threads conforming to ASME B1.20.2MASME B1.20.1. Use fittings for pipe 40
mm 1-1/2 inches and smaller conforming to ASME B16.11. Use buttweld
fittings for pipe 40 mm 1-1/2 inches or less conforming to ASME B16.9.
Provide joint sealing compound conforming to UL FLAMMABLE & COMBUSTIBLE,
Class 20 or less. Use polytetrafluoroethylene tape conforming to ASTM D3308.
Use weld neck flanges. Ensure connections conform to ASTM A181/A181M,
Class 60, carbon steel. Coat carbon steel components with corrosion
resistant [materials.] [materials suitable for exposure to condensates.]
Ensure coatings and finishes are 100 percent holiday free.

2.3.1 Carbon Steel Located Above Grade

**************************************************************************
NOTE: Color must be specified only for the "-S"
systems. The color is automatic (-A, Aluminum; -B,
Black; -W, white) for the other systems.

**************************************************************************
[_____] coat surfaces of aboveground carbon steel components in accordance
with AWWA C218 [three-coat alkyd system 1-91-A] [three-coat alkyd system
1-91-W] [three-coat alkyd system 1-91-S] [four-coat alkyd system 2-91-A],
four-coat alkyd system 2-91-W] [four-coat alkyd system 2-91-S] [three-coat
alkyd/silicone alkyd system 3-91-W] [three-coat alkyd/silicone alkyd system
3-91-S] [three-coat epoxy/urethane system 4-91-W] [three-coat
epoxy/urethane 4-91-S] [three-coat inorganic or organic zinc/epoxy/urethane
5-91-W] [three-coat inorganic or organic zinc/epoxy/urethane 5-91-S] [two-
or three-coat epoxy/coal tar epoxy 6-91-B] [two or three-coat water
reducible epoxy-polyamid 7-91-W] [two or three-coat water reducible
epoxy-polyamid 7-91-S] [three-coat water reducible acrylic or
alkyd-modified acrylic emulsion 8-91-W] [three-coat water reducible acrylic
or alkyd-modified acrylic emulsion 8-91-S] [two or three-coat
epoxy/high-build aliphatic polyurethane over existing coated substrates
9-95-W] [two or three-coat epoxy/high-build aliphatic polyurethane over
existing coated substrates 9-95-S].

2.3.2 Silicone Coating

Blast surfaces of carbon steel components in accordance with
SSPC SP 6/NACE No.3. Provide surface with an alkyd primer 62.5 micrometers
2.5 mils dry film thickness followed by two alkyd modified silicone final
coats.

2.3.3 Zinc Coating

Coat surfaces of carbon steel components with zinc in accordance with
ASTM A123/A123M or ASTM A153/A153M.
2.3.4 Thermoplastic Resin Coating System

2.3.5 Cathodic Protection

Provide buried ferrous pipe systems with cathodic protection.

2.4 COPPER TUBING

Provide copper tubing conforming to ASTM B837.

2.5 POLYVINYL CHLORIDE (PVC) PIPING

Design and fabricate below grade components of the off-gas piping system in accordance with ASTM D2513 except as modified herein.

2.5.1 PVC Pipe

**************************************************************************
NOTE: CPVC in accordance with ASTM F422 provides a heat protection factor that is important near blowers but is not generally necessary for buried piping.
**************************************************************************

Provide pipe in accordance with ASTM F442/F442M, ASTM D2241, SDR [26] [21] [17] [____]. Provide materials conforming to ASTM D1784, Type IV, Grade 1, rigid (23447-B). Use maximum eccentricity of the inside and outside circumferences of the pipe walls of 12 percent. Provide pipe which does not fall, balloon, burst, or weep as defined in ASTM D1598.

2.5.2 PVC Joints

Provide pressure rated solvent cemented bell joints in accordance with ASTM D2672 except where flanged or threaded fittings are required at expansion joints, valves, flowmeter, equipment connections or otherwise shown. Join flanges to pipe by solvent cementing. Use primer conforming to ASTM F656. Use solvent cement conforming to ASTM D2564.

2.5.3 PVC Fittings

Provide fittings in accordance with [ASTM D2466] [ASTM D2467].

2.6 POLYETHYLENE (PE) PIPING

Design and fabricate below grade components of the off-gas piping system in accordance with ASTM D2513 except as modified herein.

2.6.1 PE Pipe

Provide pipe in accordance with ASTM D3035, Schedule [40] [80]. Ensure
wall thickness is SDR [11] [_____]. Ensure melt flow is less than 1.5 g/10 min. with method ASTM D1248, Condition F. Ensure environmental stress crack resistance exceeds 1000 hours, ASTM D1693, Condition C.

2.6.2 PE Joints and Fittings

Provide pressure rated electrofusion fittings in accordance with ASTM F1055, butt heat fusion fittings in accordance with ASTM D3261 or socket-type fittings in accordance with ASTM D2683 except where flanged connections are required at expansion joints, valves, flowmeter, equipment connections or otherwise shown. Join flanges to pipe by heat fusion in accordance with ASTM D2657.

2.7 REINFORCED EPOXY RESIN PIPING

Design and fabricate below grade components of the off-gas piping system in accordance with ASTM D2992 except as modified herein.

2.7.1 Epoxy Resin Pipe

Provide pipe in accordance with ASTM D2517. Provide resin that is chemically resistant to condensates as determined by ASTM C581.

2.7.2 Epoxy Resin Joints and Fittings

Provide joints and fittings in accordance with ASTM D2517.

2.8 DUCT SYSTEMS

******************************************************************************
NOTE: Consult Sheet Metal and Air Conditioning Contractors' National Association (SMACNA) for metal and PVC duct design and construction recommendations. Consult Thermal Insulation Manufacturers' Association (TIMA) for design and construction standards for fiberglass ducts.
******************************************************************************

Provide ductwork in compliance with Section 23 54 19 BUILDING HEATING SYSTEMS, WARM AIR.

2.9 FLANGED CONNECTIONS

2.9.1 Flanges

Provide Class [150] [____], socket weld, flat face flanges in accordance with ASME B16.5. Ensure drilling and dimensions of flanges, bolts, nuts, and bolt patterns are in accordance with ASME B16.5, Class [150] [_____]. Provide bolts and nuts that [conform to ASTM A307] [are 304 stainless steel].

2.9.2 Gaskets

******************************************************************************
NOTE: Use gasket materials compatible with condensates. High temperature gaskets for above 160 degrees C 320 degrees F should be aramid fibers bonded with nitrile butadiene rubber (NBR) or glass fibers bonded with polytetrafluoroethylene. EPDM is
suitable for 100 degrees C 212 degrees F or less. Chloroprene rubber is suitable for 80 degrees C 176 degrees F or less. Florin rubber (i.e. Viton) and nitrile are suitable for 160 degrees C 320 degrees F or less.

Provide gaskets consisting of full face, non-asbestos compressed material compatible with the expected condensates in accordance with ASME B16.21, [3] [1.6] mm [1/8] [1/16] inch minimum thickness, full face or self-centering flat ring type. Provide gaskets consisting of aramid fibers bonded with nitrile butadiene rubber (NBR) or glass fibers bonded with polytetrafluoroethylene suitable for [315] [____] degrees C [600] [____] degrees F service and meeting applicable requirements of [ASME B31.8] [NFPA 58]. [Provide high temperature gaskets which are suitable for above 160 degrees C 320 degrees F.] [Provide chloroprene rubber suitable for [80] [100] degrees C [176] [212] degrees F service.] [Provide EPDM suitable for 100 degrees C 212 degrees F service.] [Provide florin rubber (i.e. Viton) or nitrile rubber suitable for 160 degrees C 320 degrees F service.]

2.9.3 Sealants

Provide sealants conforming to ASTM C920.

2.10 EQUIPMENT AND APPURTENANCES

2.10.1 Manually Operated Valves

Provide ball valves in accordance with MSS SP-72. Provide gate, plug, ball, and check valves in accordance with API Spec 6D. Provide thermoplastic gas shutoffs and valves in accordance with ASME B16.40.

2.10.2 Relief Valves

Provide relief valve with manually adjustable pressure differential for each blower or vacuum pump. Ensure relief valve is [weighted] [spring] [pilot-operated diaphragm type] with a [____] percent accumulation. Ensure relief valve diameter is line sized or as otherwise indicated and rated to relieve [____] cubic meters/s cubic feet per minute at a set pressure of [____] kPa psig or a vacuum of [____] kPa inches Hg. Provide materials consisting of [aluminum] [bronze] [cast iron] [stainless steel] [____] body, [bronze] [316 stainless steel] [____] trim, and [Buna-N] [EPR] [nitrile] [Viton] [Teflon] [____] elastomers. Provide maximum operating temperature and pressure of [____] degrees C F and [____] kPa psi.

2.10.3 Unloading Valves

Include unloading valves to minimize pump/motor overloading during start and stop operations. Provide [pilot-operated diaphragm type with auxiliary solenoid operator] [actuated butterfly valve control by blower system controls] unloading valve. Ensure unloading valve is rated to relieve [____] cubic meters/s cubic feet/minute at a set pressure of [____] kPa psi or a vacuum of [____] mm Hg inches Hg. Provide materials consisting of [aluminum] [bronze] [stainless steel] body, [bronze] [316 stainless steel] trim, and [Buna-N] [EPR] [Viton] [Teflon] elastomers. Provide maximum operating temperature and pressure of [____] degrees C F and [____] kPa psi respectively.
2.10.4 Vacuum Breakers

Provide vacuum breakers to protect blowers and vacuum pumps from damage due to excessive vacuum surges. Provide [pilot-operated diaphragm type with auxiliary solenoid operator] [actuated butterfly valve control by blower system controls] vacuum breakers. Ensure valve is rated to relieve [_____] cubic m/s [cfm] at a set pressure of [_____] kPa [psi] or a vacuum of [_____] kPa [inches Hg]. Provide materials consisting of [aluminum] [bronze] [stainless steel] body, [bronze] [316 stainless steel] trim, and [Buna-N] [EPR] [Viton] [Teflon] elastomers. Provide maximum operating temperature and pressure of [_____] degrees C [F] and [_____] kPa [psi].

2.10.5 Dielectric Fittings

Install dielectric fittings between threaded ferrous and nonferrous metallic pipe, fittings and valves, except where corporation stops join mains. Use dielectric fittings to prevent metal-to-metal contact of dissimilar metallic piping elements and suitable for the required working pressure.

2.10.6 Meters

Gas meters conforming to AGA ANSI B109.2.

2.10.7 Insulation

Provide insulation of above grade exterior pipe, fittings and valves as specified in Section 23 07 00 THERMAL INSULATION FOR MECHANICAL SYSTEMS.

2.10.8 Supports for Aboveground Piping

**************************************************************************
NOTE: Pipe materials differ greatly in their respective changes in size as temperature changes. The thermal expansion coefficient of PE is three times that of PVC pipe. In a buried environment, where the temperature fluctuations should be minimal and the pipe is supported on all sides by soil, thermal expansion is of less concern. However, in systems where the collector pipes are above ground, thermal expansion and contraction must be considered.
**************************************************************************

Furnish pipe hangers and supports complete with necessary inserts, bolts, nuts, rods, washers, and accessories. Design and construction must be in accordance with MSS SP-58. Specific application must be in accordance with MSS SP-58. Provide hanger and supports capable of adjustment after placement of piping. Ensure hangers and supports are the product of one manufacturer. Hot dip galvanize hangers, supports and accessories in accordance with ASTM A123/A123Munless copper or plastic coated. Provide restrained joints and thrust protection. Provide concrete and metal cradles, collars, floor stands, supports, kickers, and block as recommended by manufacturer. Pipe cradle cushion material must be elastomer sheet strapped to pipe to prevent chafing at pipe support. Utilize elastomer sheet around top of pipe to prevent chafing of pipe strap.

2.10.9 Valve Boxes

Provide adjustable extension type valve boxes with screw or slide-type
adjustments constructed of cast iron no less than 5 mm 3/16 inch thick. Provide valve boxes with locking covers that require a special wrench for removal and the word "gas" cast in the box cover.

2.11 FACTORY TESTS

Test [steel piping] [a representative unit of each diameter of steel piping] by the manufacturer or a nationally recognized testing agency in compliance with NACE SP0274.

PART 3 EXECUTION

**************************************************************************

NOTE: Operations required to accomplish construction of plastic piping systems will conform to the requirements of ASTM F402.

**************************************************************************

3.1 EXAMINATION

After becoming familiar with all details of the work, verify all dimensions in the field, and advise the Contracting Officer of any discrepancy before performing the work.

3.2 MANUFACTURER'S REPRESENTATIVE

Provide the services of a manufacturer's field service representative who is experienced in the installation of the materials and equipment furnished and who has complete knowledge of the proper operation and maintenance of the system. Submit the name and qualifications of the manufacturer's representative and written certification from the manufacturer that the representative is technically qualified.

3.3 CONDENSATE CONTROL

Slope off-gas piping uniformly between control elevations to enhance the removal of liquids. Make provisions to collect and drain liquids from [condensation] [mist accumulation] [_____] in each pipe run. Locate liquid removal sumps and traps in the piping systems.

3.4 PRESSURE REGULATOR AND METER INSTALLATION

Install a valve on each side of each meter or regulator for isolating the regulator for calibration, maintenance and removal. Install an insulating joint constructed to prevent flow of electrical current between metallic pipe and the meter or regulator.

3.4.1 Pressure Regulators

**************************************************************************

NOTE: Delete inapplicable requirements. Remove reference to bypasses around pressure regulators unless continuity is imperative and the bypass is regulated to prevent possible over pressure of downstream lines.

**************************************************************************

Install pressure regulators [450 mm 18 inches above the ground on the riser] [where shown]. Provide a 10 mm 3/8 inch tapped fitting equipped
with a plug on both sides of the regulator for installation of pressure gauges for adjusting the regulator. Install regulators and valves in rectangular reinforced concrete boxes. Use boxes large enough so that required equipment can be properly installed, operated, and maintained. Extend sidewalls above ground line. Provide boxes with [steel door] [cast iron manhole] covers with locking provisions and 100 mm 4 inch diameter vents.

3.4.2 Meters

Install meters in accordance with ASME B31.8.

3.4.3 Vents

Locate discharge stacks, vents, or outlet ports of devices where gas can be discharged into the atmosphere without undue hazard. Terminate vents in the outside air in rain and insect resistant fittings. [Locate the open end of the vent where gas can escape freely into the atmosphere, away from any openings into the building and above areas subject to flooding.] [Provide stacks and vents with fittings to preclude entry of water.]

3.5 INSTALLING PIPE UNDERGROUND

******************************************************************************
NOTE: Coordinate Section 31 00 00 EARTHWORK and details on the drawings to assure that pipe bedding materials are appropriate for the allowed pipe.
******************************************************************************

Perform installation as specified in Section 31 00 00 EARTHWORK, except as modified herein; and as required by ASTM F402 and ASTM D2855 for using solvents and cleaners, ASTM D2774 for polyvinyl chloride and polyethylene pipe, and ASTM D3839 for fiberglass pipe.

3.5.1 Cathodic Protection

******************************************************************************
NOTE: Cathodic protection is mandatory for underground ferrous pipelines. The type and design of cathodic protection will be in accordance with UFC 3-570-02A. Stations will be provided for testing the cathodic protection system.
******************************************************************************

Provide cathodic protection for ferrous piping installed underground as specified in [Section 26 42 13 GALVANIC (SACRIFICIAL) ANODE CATHODIC PROTECTION (GACP) SYSTEM] [Section 26 42 17 IMPRESSED CURRENT CATHODIC PROTECTION (ICCP) SYSTEM].

3.5.2 Valve Boxes

Install valve boxes at each underground valve except where concrete or other type of housing is indicated. When the valve is located in a roadway, protect the valve box by a suitable concrete slab at least 1 square meter 3 square feet. When in a sidewalk, place the top of the box in a concrete slab 600 mm 2 feet square and set flush with the sidewalk. Support valve boxes separately, not resting on the pipe, so that traffic loads cannot be transmitted to the pipe.
3.5.3 Magnetic Tape

When non-metallic piping is installed underground, place foil backed magnetic tape above the pipe to permit locating with a magnetic detector.

3.5.4 Pipe Coatings

Repair any damage to the protective covering during transit and handling before installation.

3.6 INSTALLING PIPE ABOVEGROUND

With the exception of vacuum pipe segments [A-B] [B-C] [D-E] [_____] as indicated and/or shown, do not install thermoplastic pipe aboveground. Install vertical pipe plumb in all directions. Install perpendicular piping parallel to building walls. Piping at angles and 45 degree runs across corners will not be accepted unless specifically shown. Install small diameter piping generally as shown when specific locations and elevations are not indicated. Locate piping to avoid ducts, equipment, and beams. Install piping to avoid obstructing corridors, walkways, work areas, and like spaces. Provide a minimum headroom clearance of 2.2 m 7 feet under piping, unless otherwise indicated. Provide temporary caps or plugs at pipe openings at the end of each day's work. Run piping in groups where practicable. Provide minimum clearance of 25 mm 1 inch between pipe and other work.

3.6.1 Hangers and Supports

Install pipe hangers and supports in accordance with MSS SP-58 at locations where pipe changes direction. Install hanger rods straight and vertical. Chain, wire, strap or perforated bar hangers will not be permitted. Do not suspend hangers from piping. Where proper hanger or support spacing does not correspond with joist or rib spacing, suspend pipe from structural steel channels attached to joists or ribs. Prevent contact between dissimilar metals when supporting copper tubing, by use of copper plated, rubber or vinyl coated, or stainless steel hangers or supports. Isolate thin walled stainless steel piping from carbon steel by use of plastic coated hangers or supports or by taping at points of contact with PVC or vinyl. Use galvanized or stainless steel hangers and supports in basins or submerged locations. Provide maximum support spacing, unless otherwise shown or approved for standard weight steel pipe, as follows:

<table>
<thead>
<tr>
<th>Pipe Size</th>
<th>Spacing</th>
</tr>
</thead>
<tbody>
<tr>
<td>Less than 50 mm</td>
<td>2 m6 feet</td>
</tr>
<tr>
<td>50 to 75 mm</td>
<td>3 m10 feet</td>
</tr>
<tr>
<td>Greater than 75 mm</td>
<td>4 m12 feet</td>
</tr>
</tbody>
</table>

Maximum support spacing for pipe other than standard weight steel must be two-thirds of the corresponding spacing for steel pipe unless otherwise shown or approved.

3.6.2 Insulation

Furnish and install insulation in accordance with Section 23 07 00 THERMAL
INSULATION FOR MECHANICAL SYSTEMS.

3.6.3 Coatings or Finishes

**************************************************************************

NOTE: Where the using service has specific requirements for color coding differing from the color specified, this paragraph will be modified accordingly and coordinated with paragraph, Identification and UFGS 09 97 02 PAINTING: HYDRAULIC STRUCTURES. Off-gases from landfills often consist of large quantities of Methane (CH4), Hydrogen Sulfide (H2S) and Carbon Dioxide (CO2) with a lesser amount of other organic compounds present. Phenolic or epoxy type coatings are generally recommended for this type of service.

**************************************************************************

Provide coatings and finishes in accordance with Section 09 97 02 PAINTING: HYDRAULIC STRUCTURES. Repair damage to the factory covering during transit and handling before installation. Painting is not required where piping is insulated, stainless steel, galvanized steel or nonferrous. Clean factory painted items requiring touching-up in the field of foreign material and prime and top coat with the manufacturer's standard factory finish. Paint exposed ferrous surfaces with two coats of enamel paint. Solvent clean factory primed surfaces before painting. Prepare and prime surfaces that have not been factory primed in accordance with the enamel paint manufacturer's recommendations.

3.7 JOINTING PIPE

Join non-metallic piping by performance qualified joiners using qualified procedures in accordance with AGA XR0603. Inspect joints by an inspector qualified in the joining procedures being used and in accordance with AGA XR0603.

3.7.1 O-Ring Joints

Clean jointing surfaces and adjacent areas before making joint. Lubricate and adjust gaskets and "O"-rings in accordance with manufacturer's recommendations. Check each gasket for proper position around full circumference of the joint after "O"-rings are compressed and before pipe is brought fully home. Jointing pipe must be done in accordance with ASTM D3139 and manufacturer's recommendations.

3.7.2 Mechanical Joints

Center the plain end and push into the bell. Firmly press gasket evenly into the bell. Slip gland to the bell for bolting. Oil the bolt threads. Tighten bolts alternately 180 degrees opposite to each other to seat the gasket evenly. Apply bituminous coating to ferrous bolts and nuts before assembly. Use maximum torque on bolts as follows:

<table>
<thead>
<tr>
<th>Bolt Size (mm/inch)</th>
<th>Applied Torque (Nm/ft-lb)</th>
</tr>
</thead>
<tbody>
<tr>
<td>165/8</td>
<td>6850</td>
</tr>
<tr>
<td>Bolt Size (mminch)</td>
<td>Applied Torque (Nm-ft-lb)</td>
</tr>
<tr>
<td>-------------------</td>
<td>--------------------------</td>
</tr>
<tr>
<td>193/4</td>
<td>10880</td>
</tr>
<tr>
<td>251 inch</td>
<td>12290</td>
</tr>
<tr>
<td>321-1/4</td>
<td>149110</td>
</tr>
</tbody>
</table>

### 3.7.3 Flanged Joints

### 3.7.4 Expansion Couplings

Provide expansion couplings in tension to facilitate their removal. Set stretcher bolts for maximum allowable elongation of expansion coupling as recommended by the manufacturer. Provide expansion couplings as shown and as recommended by the manufacturer.

### 3.7.5 Destructive Joint Tests

**************************************************************************
NOTE: Destructive tests are provided as a designer option. Destructive tests are considered useful in assuring that good joints will be made. Delete the paragraph if this option is not exercised.
**************************************************************************

Each day, prior to making [heat fusion] [adhesive] [or] [solvent welded] joints, make a joint of each size and type to be installed that day by each person assembling these joints that day and destructively test. Cut at least 3 longitudinal straps from each joint. Visually examine each strap. Ensure strap does not contain voids or discontinuities on the cut surfaces of the joint area, and is deformed by bending, torque, or impact, and if failure occurs, it must not initiate in the joint area. If a joint fails the visual or deformation test, ensure the qualified joiner who made that joint does not make further field joints in plastic pipe on this job until that person has been retrained and requalified. Record results of the destructive tests to include the date and time of the tests, size and type of the joints, ambient conditions, fusion iron temperature and names of inspectors and joiners.

### 3.8 CONNECTIONS

### 3.8.1 Transitions Between Types of Pipe

Provide necessary adapters, specials and connector pieces when connecting different types and sizes of pipe or pipe furnished by different manufacturers. Encase underground connecting joints with 150 [_____] mm [6] [_____] inches minimum, Class B concrete unless otherwise shown, or recommended by manufacturer. Make connections between piping and equipment, where required, using [approved] [proper] fittings to suit the actual conditions.
3.8.2 Connections to Off-Gas Source and Discharge Points

Connect the off-gas pipelines to the source and discharge locations. Notify the Contracting Officer, in writing, 10 days before final connections and activation of the system.

3.8.3 Connection to Equipment

**************************************************************************
NOTE: Coordinate the drawings and specifications for blowers and treatment equipment.
**************************************************************************

Provide connections to the equipment in accordance with approved procedures. Only isolate equipment [immediately on each side of the equipment] [at the valve location shown on the drawings].

3.8.4 Location of Existing Piping

Locations of existing piping shown should be considered approximate. Contractor is responsible for determining exact location of existing piping which may be affected by the work during earth moving operations.

3.8.5 Removing Existing Pipelines from Service

Do not remove pipelines from service unless specifically listed or approved by Contracting Officer. Notify the Contracting Officer at least [48] hours prior to removing each pipeline from service.

3.9 PRESSURE AND LEAKAGE TESTS

Perform tests on [pipe segments as shown] [the system as a whole] [sections that can be isolated]. Test joints in sections prior to backfilling when trenches have to be backfilled before the completion of other pipeline sections. Furnish labor, materials and equipment for conducting the tests which are subject to inspection during the tests. The Contractor is responsible for the cost of repair, replacement, and retesting required because of failure to meet testing requirements. Prior to testing the system, blow out the interior, clean and clear of foreign materials. Remove meters, regulators, and controls before blowing out and cleaning and reinstall after clearing of foreign materials. Maintain safety precautions for pressure testing during the tests. Notify Contracting Officer [_____] [48] hours in advance of pressure, leakage and/or vacuum testing. Conduct tests in the presence of the Contracting Officer unless otherwise directed. During the test, completely isolate the entire system from compressors and other sources of pressure. Perform testing with due regard for the safety of employees and the public during the test. Keep persons not working on the test operations out of the testing area while testing is proceeding. Conduct leakage test only after satisfactory completion of pressure test.

3.9.1 Bubble Tests

Test each joint in accordance with ASTM E515 prior to backfilling or concealing any work.

3.9.2 Pressure Testing

**************************************************************************
NOTE:  Thermoplastic piping should not be pressure tested with air.  Specify test pressure (including Class Location) to be used in accordance with ASME B31.8.  Test pressure will not be less than 1.5 times the design pressure, but not exceeding 1.5 times the maximum rated pressure of the lowest-rated component in the system.  Test pressures should recognize the weakest component of each segment tested for the design pressure and the maximum allowable operating pressure.

Place and compact backfill to at least the pipe centerline before testing.  Allow concrete for blocking to reach design strength and backfill and compact to assure restraint by harnessed joints before testing.  Fill section to be tested slowly with [air.] [water, and expell air.  Install corporation cocks as necessary to remove air.]  Apply test pressure for one hour and observe gauge pressure.  Check leaks continuously while test pressure is being maintained.  Test off-gas piping system after construction and before being placed in service using [water] [air] as the test medium.  Continue pressure test for at least [24] [36] [48] hours from the time of the initial readings to the final readings of pressure and temperature.  Do not make the initial test readings of the instrument for at least 1 hour after the pipe has been subjected to the full test pressure, and make neither the initial nor final readings at times of rapid changes in atmospheric conditions.  Ensure temperatures are representative of the actual trench conditions.  There must be no indication of reduction of the test pressure, [_____] kPa psig, applied at the lowest elevation of the pipeline section, during the test after corrections have been made for changes in atmospheric conditions in conformity with the relationship \( T(1)P(2)=T(2)P(1) \), in which \( T \) and \( P \) denote absolute temperature and pressure, respectively, and the numbers denote initial and final readings.  Repair and retest lines which fail to hold specified test pressure or which exceed the allowable leakage rate.

3.9.3  Leakage Testing

Allow pipe to stand full of water at least 12 hours prior to starting leakage test.  Examine exposed pipe, joints, fittings and valves.  Stop visible leakage, and replace the defective pipe, fitting or valve.  Refill the line under test to reach the required test pressure.  Place the amount of water permitted as leakage in a container attached to the supply side of the test pump.  Seal the container.  Do not attach other source of supply to the pump or line under test.  Pump water into the line with the test pump to hold [_____] kPa psig for [2] [4] [8] hours.  Measure water remaining in the container and the amount used during the test and record on the test report.  Consider test as failed upon exhaustion of supply and/or inability to maintain the required pressure.

3.9.4  Vacuum Testing

Perform test on [the entire system] [individual sections] as approved by the Contracting Officer.  Seal openings in system or section to be tested.  Pull vacuum [_____] kPa psig for one hour (isolating system from vacuum by closing valves).  Allow system to normalize and then record the initial vacuum readings.  Record vacuum at intervals of [15 minutes] [1 hour] [_____] for the duration of the [8] [_____] hour test.  Repair and retest measurable leakage (loss of vacuum) after corrections have been made for changes in atmospheric conditions in conformity with the relationship
T(1)P(2) = T(2)P(1), in which T and P denote absolute temperature and total pressure, respectively, and the numbers denote initial and final readings.

3.9.5 **Hanger Acceptance Testing**

Bring pipe systems up to operating pressures and temperatures. Recycle systems to duplicate operating conditions. Submit reports of all inspections or tests, including analysis and interpretation of test results. Identify each report and test methods used, and record test results.

3.9.6 **Demonstration**

Upon completion of the work and before final acceptance, submit a **Statement of Satisfactory Installation** signed by the principal officer of the contracting firm stating that: the installation is satisfactory and in accordance with the contract plans and specifications; the manufacturer's prescribed procedures and techniques have been followed; and at a time designated by the Contracting Officer. Provide the services of a qualified engineer for a period of no less than [8] [_____] hours to instruct a representative of the Government in the contents of the **operation and maintenance manuals** for the equipment furnished under this Section. Submit [6] [_____] copies, in indexed booklet form, of site specific operation and maintenance manual for the piping system including system operation, system maintenance, equipment operation, and equipment maintenance manuals described below. If operation and maintenance manuals are provided in a common volume, ensure they are clearly differentiated and separately indexed. Ensure the field instructions cover the items contained in the bound instructions.

a. The System Operation Manual includes but is not limited to the following:

   (1) Maps showing piping layout and locations of system valves and line markers.

   (2) Step-by-step procedures required for system startup, operation, and shutdown. Index system components and equipment to the maps.

   (3) Isolation procedures and valve operations to shut down or isolate each section of the system. Index valves and other system components to the maps.

   (4) Descriptions of Site Specific Standard Operation Procedures including permanent and temporary pipe repair procedures, system restart and test procedures for placing repaired lines back in service, and procedures for abandoning piping and system components.

   (5) Descriptions of Emergency Procedures including: isolation procedures including required valve operations with valve locations indexed to the map, recommended emergency equipment, and checklist for major emergencies.

b. The Equipment Operation Manual includes but is not limited to detail drawings, equipment data, and manufacturer supplied operation manuals for equipment, valves and system components.

c. The System Maintenance Manuals include but are not limited to:
(1) Maintenance check list for entire system.

(2) Descriptions of site specific standard maintenance procedures.

(3) Maintenance procedures for installed cathodic protection systems.

(4) Piping layout, equipment layout, and control diagrams of the systems as installed.

(5) Identification of pipe materials and manufacturer by location, pipe repair procedures, and jointing procedures at transitions to other piping materials or piping from different manufacturer.

d. The Equipment Maintenance Manuals include but are not limited to the following:

(1) Identification of valves and other equipment by materials, manufacturer, vendor identification and location.

(2) Maintenance procedures and recommended maintenance tool kits for valves and equipment.

(3) Recommended repair methods, either field repair, factory repair, or whole-item replacement for each valve component or piece of equipment or component item.

(4) Routine maintenance procedures, possible breakdowns and repairs, and troubleshooting guide.

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for constructing radon mitigation systems in new buildings, existing buildings and facilities, including constructing radon mitigation systems enclosures, when required.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

RADON MITIGATION FOR NEW CONSTRUCTION

NOTE: Consult the current EPA radon map and EPA documents for each state for additional information concerning radon zones.

For new construction in Zone 1 areas as defined on "EPA Map of Radon Zones", or when testing identifies radon concentrations equal to or greater than 4 pCi/L, passive radon mitigation systems should be incorporated into the original building design. The design should include provisions to permit installation of exhaust fans, if necessary, after testing the building under occupied conditions.
Criteria for radon mitigation in new construction is specified in EPA 625-R-92-016, (1994, Third Printing with Addenda) and the current version of "Radon Mitigation Standards for Schools and Large Buildings."

Materials (aggregate for capillary water barrier and poly(vinyl chloride) (PVC) pipe) currently in use for constructing new buildings, when properly arranged as indicated and specified in EPA 625-R-92-016, will provide a passive radon mitigation system. A separate specification section on radon mitigation for new construction seems unnecessary considering the materials are addressed in Division 02 and Division 15 sections and the installation will be shown on the drawings.

**************************************************************************
**************************************************************************

NOTE: A simple, effective, efficient, and economical radon mitigation system is little more than a PVC vent pipe (one suction point) exhausted to the atmosphere without a fan (passive system). For large areas requiring mitigation, the system could include several vent pipes connected to a single outlet with an appropriately sized in-line fan (active system). Depending on the distances between suction points, several individual vent pipes with or without in-line fans may be more practical.

This guide specification provides criteria and material requirements for constructing radon mitigation systems, post mitigation testing and constructing gypsum wallboard enclosures to conceal the radon mitigation systems in occupied spaces.

**************************************************************************
**************************************************************************

NOTE: The Designer should include unit price items to address post mitigation radon testing. Estimate the quantity and specify as unit price items in Section 00 21 13, INSTRUCTIONS TO BIDDERS or Section 01 20 00 Price and Payment Procedures per standard practice of the activity preparing the contract.

**************************************************************************
**************************************************************************

NOTE: The work may involve a historic property. The designer must coordinate review of the proposed work with the appropriate cultural resources manager (CRM) and cultural resource laws and regulations, as part of the environmental review and permitting process. Consultation with stakeholders, including the state historic preservation office, may be required, and work involving historic properties will likely be required to confirm to the Secretary of the Interior's Standards for the Treatment of Historic Properties (usually at the REHABILITATION

SECTION 31 21 13 Page 4
level). See [https://www.nps.gov/tps/standards/four-treatments/treatment-rehabilitation.htm](https://www.nps.gov/tps/standards/four-treatments/treatment-rehabilitation.htm)

PART 1   GENERAL

1.1 SUMMARY

NOTE: For work in the continental United States, Alaska and Hawaii select picoCuries per liter (pCi/L) as the unit of measure. For work elsewhere in the world Becquerels per cubic meter (Bq/cu m) may be the required unit of measurement. Consult with the Contracting Officer and use the unit of measure familiar to the prospective Contractors.

Provide all work necessary to reduce and maintain radon concentration levels below [148 Becquerels per cubic meter (Bq/cu m)][4.0 picoCuries per liter (pCi/L)] in various buildings specified herein. Perform mitigation system installation, and perform post-mitigation testing and monitoring for radon.

1.2 REFERENCES

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

1.3 DEFINITIONS

1.3.1 Active Soil Depressurization (ASD)

A family of radon mitigation systems involving mechanically-driven soil depressurization, including sub-slab depressurization (SSD), sub-membrane depressurization (SMD), block wall depressurization (BWD) and crawl space depressurization (CSD).

1.3.2 Contract Documents

Documents furnished to prospective bidders/proposers containing information and specifying criteria and project requirements for diagnostic testing, design, construction and monitoring of multiple radon mitigation systems.
The documents include this specification and the drawings listed in and accompanying this specification.

1.3.3 Long Term Radon Detectors

**************************************************************************
NOTE: For work in the continental United States, Alaska and Hawaii select pCi/L as the unit of measure. For work elsewhere in the world Bq/cu m may be the required unit of measurement. Consult with the Contracting Officer and use the unit of measure familiar to the prospective Contractors.
**************************************************************************

Alpha track, electret ion chamber, or approved equivalent. Devices capable of sensing and recording the presences of radon during a time period of 91 days to 12 months which when analyzed provide a numeric value, measured in [Bq/cu m][pCi/L], for radon concentrations during the time exposed.

1.3.4 Pressure Differential Gauge

A tool used to measure the PFE created by an ASD system. Calibrate the gauge in accordance with national standards and the manufacturer's recommendations. The gauge must be capable of readings to 0.25 Pa 1/1000 in water column.

1.3.5 Pressure Field Extension (PFE)

The distance that a pressure change, created by drawing soil-gas through a suction point, extends outward in a sub-slab gas permeable layer, under a membrane, behind a solid wall or in a hollow wall.

1.3.6 Qualified Mitigation Professional

Regardless of team composition, a "Qualified Mitigation Professional" for the purposes of this document is defined as: "An individual that has demonstrated a minimum degree of appropriate technical knowledge and skills specific to radon mitigation of schools and large buildings: a) as established in certification requirements of the National Radon Proficiency Program (NRPP) or the National Radon Safety Board (NRSB); and b) as required by statute, state licensure or certification program, where applicable."

1.3.7 Short Term Radon Detectors

**************************************************************************
NOTE: For work in the continental United States, Alaska and Hawaii select pCi/L as the unit of measure. For work elsewhere in the world Bq/cu m may be the required unit of measurement. Consult with the Contracting Officer and use the unit of measure familiar to the prospective Contractors.
**************************************************************************

Charcoal, electret ion chamber, or approved equivalent. Devices capable of sensing and recording the presences of radon during a time period of 48-hours to 90 days which when analyzed provide a numeric value, measured in [Bq/cu m][pCi/L], for radon concentrations during the time exposed.
1.3.8 Suction Hole

Location at which vacuum is created for sub-slab communication testing.

1.3.9 Suction Point

Vertical standpipe penetrating into the soil gas environment containing radon and serving as the conduit to exhaust radon gas to the atmosphere.

1.3.10 Test Hole

Location at which pressure readings are taken during sub-slab communication testing. Readings are used to evaluate potential effectiveness of a sub-slab depressurization system.

1.4 SYSTEM DESCRIPTION AND REQUIREMENTS

1.4.1 Performance Requirements

**************************************************************************
NOTE: For work in the continental United States, Alaska and Hawaii select pCi/L as the unit of measure. For work elsewhere in the world Bq/cu m may be the required unit of measurement. Consult with the Contracting Officer and use the unit of measure familiar to the prospective Contractors.
**************************************************************************

1.5 SUBMITTALS

**************************************************************************
NOTE: Review Submittal Description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item if the submittal is sufficiently important or complex in context of the project.
**************************************************************************

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the
District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.

******************************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-03 Product Data

Respirators; G[, [_____]]
Radon Mitigation Systems Components
Radon Mitigation Systems Enclosure Components

SD-06 Test Reports

Post Mitigation Testing; G[, [_____]]

SD-07 Certificates

Worker Protection Plan; G[, [_____]]
Medical Certification; G[, [_____]]
Worker Notification; G[, [_____]]
Respiratory Protection Program; G[, [_____]]
Contractor Qualifications; G[, [_____]]
Contractor Experience; G[, [_____]]
Testing Laboratory Certification; G[, [_____]]
Proof Of Current Calibration For Testing Devices; G[, [_____]]
Radon Mitigation System Inspection; G[, [_____]]

SD-08 Manufacturer's Instructions

Radon Mitigation Systems Components
Radon Mitigation Systems Enclosure Components

SD-10 Operation and Maintenance Data

Radon Mitigation Systems, Data Package 2; G[, [_____]]

Submit in accordance with Section 01 78 23 OPERATION AND MAINTENANCE DATA.

SD-11 Closeout Submittals

Radon Detector Location Log; G[, [_____]]

Respirator Program Records; G[, [_____]]

1.6 RADON DETECTOR LOCATION LOG

Prepare and provide to the Contracting Officer a Radon Detector Location Log for each building detailing the identity and location of each short term and long term radon detector. Prepare the log using copies of the "Device Placement Log" contained in EPA 402-R-92-014, and provide the appropriate information as line items. In addition to the log, on a copy of the building floor plans, locate and identify each short term and long term detector.

1.7 WORKER HEALTH AND SAFETY

Comply with OSHA, state and local standards or regulations relating to worker safety and occupational radon exposure. Prepare a worker protection plan in accordance with 29 CFR 1910.1096, [OPNAV M-5090.1,] [EM 385-1-1,] and EPA 402-R-93-078.

1.7.1 Worker Protection Plan

The worker protection plan must address, at a minimum occupational radon exposure, safe use of all job site equipment including safe practices when using ladders or scaffolding; safe procedures for crawl space work and avoidance of job site hazards; discussion of hantavirus symptoms; fire and life safety issues; confined space access; handling caustic solvents and bonding chemicals; appropriate use of personal protective equipment; respiratory protection program; suspected contaminants such as asbestos, lead paint, mold or other toxins that may exist; safety data sheets (SDS); ventilated work areas as required to reduce occupational radon exposure. Adhere to 29 CFR 1926.59 and provide the Contracting Officer with a copy of the SDS for all materials brought to the site.

1.7.2 Worker Exposure Records

Maintain records of worker exposure to radon sufficient to verify that workers are exposed to less than four working level months (WLM) in any 12-month period.

1.7.3 Medical Certification

Provide a written certification for each worker and supervisor, signed by a licensed physician indicating that the worker and supervisor has met or exceeded all of the medical prerequisites listed herein and in 29 CFR 1910.1096 and 29 CFR 1926.103 as prescribed by law. Submit certificates prior to the start of work.
1.7.4 Worker Notification

Train workers exposed to radon about the hazards of exposure to radon and the need to apply protective measures when working in areas with elevated radon concentrations. Training must comply with 29 CFR 1910.1096. Submit a notification signed by each worker acknowledging they have been properly trained regarding the hazards of radon exposure.

1.8 RESPIRATORY PROTECTION PROGRAM

Establish and implement a respirator program as required by 29 CFR 1910.1096, and 29 CFR 1926.103. Submit a written description of the program to the Contracting Officer. Submit a written program manual or operating procedure including methods of compliance with regulatory statutes.

1.8.1 Respirator Program Records

1.8.2 Respirator Fit Testing

Conduct a qualitative or quantitative fit test conforming to 29 CFR 1926.103 for each worker required to wear a respirator, and any authorized visitors who enter a regulated area where respirators are required to be worn. A respirator fit test must be performed prior to initially wearing a respirator and every 12 months thereafter. If physical changes develop that will affect the fit, a new fit test must be performed. Functional fit checks must be performed each time a respirator is put on and in accordance with the manufacturer's recommendation.

1.8.3 Respirator Selection and Use Requirements

Provide respirators, and ensure that they are used as required by 29 CFR 1910.1096, 29 CFR 1926.103 and in accordance with CGA G-7 and the manufacturer's recommendations. Respirators must be approved by the National Institute for Occupational Safety and Health NIOSH, under the provisions of 42 CFR 84, for use in environments containing radon. For air-purifying respirators, the particulate filter must be high-efficiency particulate air (HEPA)/(N-,R-,P-100). The initial respirator selection and the decisions regarding the upgrading or downgrading of respirator type must be made by the Contractor's Designated IH based on the measured or anticipated airborne radon concentrations to be encountered.

1.8.3.1 Respirators

Provide personnel with respiratory protection as indicated in 29 CFR 1926.103. Breathing air must comply with CGA G-7.

1.9 QUALITY ASSURANCE

**************************************************************************
NOTE: Some states require only State listed mitigation contractors to perform radon mitigation work in their State. Determine the requirements for the State in which the work will be performed, and include the bracketed text if such is the case, otherwise delete.
**************************************************************************
1.9.1 Contractor Qualifications and Experience

Within 15 days after award, submit written evidence or data demonstrating that the Contractor and one or more subcontractors employed by the Contractor possess the qualifications and experience specified below.

1.9.1.1 Contractor Qualifications

The person responsible for diagnostic testing, construction and on-site supervision, as required by the specifications, must have successfully completed the requirements of and maintaining a current certification issued by either the National Radon Proficiency Program (NRPP) or the National Radon Safety Board (NRSB) as a qualified mitigation professional. Alternatively, in a State with legislation requiring mandatory credentialing for this work, compliance with the State legislation is acceptable. Evidence showing successful completion of the requirements of the NRPP or the NRSB must include copy of current certification document and documentation issued by the State. [Listing in the State of [_____] is required.]

1.9.1.2 Contractor Experience

Submit written evidence demonstrating that the Contractor has successfully designed and installed at least [two] [_____] radon mitigation systems of the same or similar to the type required herein. The Contractor must have [3][5][_____] years of experience installing radon mitigation systems. Experience proof must include but not be limited to:

a. The contract name and number, completion dates of the project and the total cost of the project;

b. The names, telephone numbers and fax number of the facility or installation for whom the radon mitigation system design, construction and testing were performed;

c. The name, telephone number and fax number of a supervisory level point of contact at each facility or installation who has knowledge of the Contractor's performance.

1.9.1.3 Qualified Mitigation Professional

A Qualified Mitigation Professional must be physically present or ensure a responsible person is present during onsite activities and immediately available to direct, instruct and oversee activities of other individuals, mitigation installers and other professionals engaged in installation activities for the mitigation system(s). The qualified mitigation professional must have [3][5][_____] years of experience installing radon mitigation systems.

1.9.2 Testing Laboratory

Submit testing laboratory certification as proof that the testing laboratory performing radon detector analysis has successfully completed the requirements of the National Radon Safety Board (NRSB) or the National Radon Proficiency Program (NRPP) and is qualified and authorized to perform such analysis. Alternatively, in a State with legislation requiring mandatory credentialing for this work, compliance with the State
legislation is acceptable. [Listing in the State of [_____] is required.]

1.9.3 Diagnostic Testing Equipment

Submit proof of current calibration for testing devices used in performing diagnostic testing.

1.9.4 On-Site Supervision

No work at the site will be permitted without the presence of a person possessing the qualifications specified elsewhere in this section, namely certification issued by either the National Radon Proficiency Program, (NRPP) or the National Radon Safety Board (NRSB) as a qualified mitigation professional, or the State equivalent, where applicable.

1.9.5 Preconstruction Conference

******************************************************************************************
NOTE: Specify additional or modified requirements to be addressed in the preconstruction safety conference within the bracket if different from that described. Confer with the appropriate Construction Office and Safety and Occupational Health Office representatives to make this determination. For Army projects refer to EP 415-1-260, Chapter 9, Resident Engineers Management Guide. If this conference is addressed in another specification section, reference the appropriate section.
******************************************************************************************

Conduct a safety preconstruction conference to discuss the details of the Worker Protection Plan, Accident Prevention Plan (APP) including the AHAs required in specification section 01 35 26 GOVERNMENTAL SAFETY REQUIREMENTS [____]. The safety preconstruction conference must include the Contractor and their Qualified Mitigation Professional, Designated IH and Project Supervisor and the Contracting Officer. Deficiencies in the APP will be discussed. Onsite work must not begin until the APP has been accepted. [____]

1.10 DELIVERY, STORAGE AND HANDLING

1.10.1 Delivery of Products

Deliver materials to the site in an undamaged condition. Deliver proprietary items in manufacture's original unopened and undamaged containers of packages with manufacture's name and brand and other pertinent data such as specification number, type, and class, date of manufacture. Schedule deliveries of materials to coincide with scheduled installation.

1.10.2 Storage and Handling

Carefully store materials off the ground to provide proper ventilation, drainage and protection against weather and dampness. Protect materials from marring, staining, rust, damage and overload and from contaminants such as grease, oil and dirt. Store materials at temperatures recommended by the manufacturer. Handle material to avoid damage such as chipping and breaking. Replace damaged material.
1.11 PROJECT CONDITIONS

1.11.1 Building Descriptions

**************************************************************************

NOTE: Provide a general description for each building and address conditions which may affect the work or the cost of accomplishing the work. For each building, address the following as appropriate for the areas in which work is to be accomplished:

1. Type of construction for the exterior walls, interior walls and partitions and the floor in contact with or above soil containing radon gas. Indicate thickness of concrete slab and aggregate beneath the concrete slab.

2. Number of floors.

3. Type of roof, flat or pitched. If pitched roof, overhang size. Type of roof covering.

4. Do rooms/spaces have suspended ceilings? This could be shown on the drawings if not consistent throughout the building.

5. Will the building and individual rooms or spaces be occupied or unoccupied during construction? Will access to the building or individual room or spaces be restricted in any way which would delay the start of work each day?

6. Restrictions with respect to penetrations to the building exterior, such as no roof penetrations, if any.

7. Restrictions on penetrating the concrete floor slab with respect to what may be embedded in the concrete slab (i.e. rebar spacing, electrical grounding grid embedded in the concrete slab).

8. Restrictions with respect to routing vent pipe on the building interior or exterior, if any. Vents may not be desired on the exterior of a particular side of the building.

The sample paragraph below may be used as a starting point for each building description.

**************************************************************************

[ Building No. [_____] is a three story, brick faced (CMU backed), slab-on grade structure with a partial basement on the southeast corner of the building. Concrete slab is approximately [_____] mm inches thick and the aggregate beneath the concrete slab is approximately [_____] mm inches thick. Interior partitions are gypsum wallboard on metal studs except where indicated otherwise on the drawings. The roof is flat and covered with single ply rubber membrane. Except for the basement, mechanical rooms and closets, all rooms have suspended acoustical ceilings located approximately 450 mm 18 inches below the structural floor or roof above. ]
The building will not be occupied during the contract period. Roof penetrations are not permitted and the south elevation must remain unchanged as a result of the work. Penetrations to the building exterior must be through the roof only. All elevations must remain unchanged as a result of the work.

PART 2 PRODUCTS

2.1 RADON MITIGATION SYSTEMS

2.1.1 System Performance

**************************************************************************
NOTE: For work in the continental United States, Alaska and Hawaii select pCi/L as the unit of measure. For work elsewhere in the world Bq/cu m may be the required unit of measurement. Consult with the Contracting Officer and use the unit of measure familiar to the prospective Contractors.
**************************************************************************

Radon mitigation systems must reduce and maintain radon concentration levels below [148 Bq/cu m][4.0 pCi/L] after activation of the mitigation systems.

2.1.1.1 System Piping

Route radon mitigation systems piping so as not to interfere with the daily operations and functions of the building occupants. Keep visibility of the systems to a minimum. Enclose each radon mitigation system in occupied spaces, however, all operating components must be accessible for maintenance and repair. All spaces must be considered to be occupied spaces except for mechanical and electrical rooms, warehouses, storerooms, janitor closets, crawl spaces, [_____] and attic spaces. Enclosures are not required for portions of systems installed above suspended acoustical ceilings.

2.1.1.2 System Outlet Location

**************************************************************************
NOTE: In climates where condensation is subject to freezing and ice build-up at the discharge point above the roof line, include the bracketed text, otherwise delete.
**************************************************************************

Mitigation system discharge points must be as specified in ANSI/AARST RMS-LB and EPA 402-R-93-078. Prevent foreign objects from entering the outlet. [Rain caps are not permitted.] Maintain water tight seal through all penetrations to the building exterior.

2.1.1.3 System Failure Warning Monitor

Provide a means to detect and announce each radon mitigation system failure. System failure is defined as:

b. Mechanical failure: fan or other mechanical failure.
c. System leakage: pipe breakage or crack.

Provide an audio or visual annunciator device to indicate system failure and locate the annunciator device in an occupied space. Conform to the requirements of ANSI/AARST RMS-LB and EPA 402-R-93-078.

2.1.1.4 Air Cleaners

Do not use air cleaners as a radon reduction method.

2.1.1.5 Ventilation Devices

Do not use devices that solely increase ventilation as a radon reduction method.

2.1.1.6 Back Drafting

Do not allow radon mitigation systems to cause back drafting of building chimneys.

2.1.2 Radon Mitigation Systems Components

Mechanical and electrical materials, fabrication, construction and installation must conform to the following industry standards:

b. In-line Tubular Centrifugal Fans: AMCA 210 and UL listed.

c. Electrical Work: NFPA 70, NEMA MG 1, ANSI/AARST RMS-LB and EPA 402-R-93-078, No. 12 AWG minimum wire size, solid copper installed in EMT or surface metal raceway.

e. Sealants: ASTM C920, polyurethane, Type S, Grade P for horizontal application, Grade NS for vertical application, Class 25, Use T.

f. Crawl space soil-gas retarder membrane must be minimum [40][60] mils thick.

******************************************************************************
NOTE: Include mock downspouts and fittings only when round PVC piping is not acceptable for aesthetic reasons.
******************************************************************************

[ g. Mock Downspouts and Fittings: Aluminum, ASTM B209M ASTM B209, minimum 0.81 mm 0.032 inch thick, color to match existing. Seal seams and joints. Use downspout only on the building exterior above the fan with appropriate round to downspout shape PVC adapter.

] 2.2 RADON MITIGATION SYSTEMS ENCLOSURES

******************************************************************************
NOTE: Select the first bracketed paragraph for enclosure materials and construction when the
project involves only radon mitigation work. Select the second bracketed paragraph when the project also involves building renovations which require project specification sections addressing the work listed in the second bracketed paragraph.

**************************************************************************
*************
NOTE: When selecting the MPI painting/coating designations, determine whether an eggshell, semi-gloss or gloss finish is desired.
**************************************************************************

[ Radon mitigation systems enclosure components, materials, fabrication, construction and installation for concrete, wood studs and furring, metal studs and furring, gypsum wallboard, sealants and painting must conform to the requirements specified in the respective specification sections addressing this work contained in the project specification.

PART 3   EXECUTION

3.1  RADON MITIGATION SYSTEMS INSTALLATION

3.1.1  Furnishings

**************************************************************************
*************
NOTE: Choose one of the following options. In most projects, the Government will remove furniture and equipment before the Contractor begins work. In this case the first paragraph should be used.
**************************************************************************
Furniture and equipment will be removed from the area of work by the Government before radon mitigation work begins.

Furniture and equipment will remain in the building. Cover and seal furnishings with 0.15 mm 6-mil plastic sheet or remove from the work area and store in a location on site approved by the Contracting Officer.

3.1.2 Installation

a. Provide radon mitigation systems as indicated in the approved design drawings, as specified in ANSI/AARST RMS-LB, EPA 402-R-93-078 and as required by the specifications and standards referenced herein for the respective materials using workmen skilled in the trades involved. Install piping plumb and parallel to existing walls, partitions and ceilings as appropriate, slope horizontal runs to drain, and secure in place in a rigid and substantial manner.

b. Seal new and existing floor slab penetrations in accordance with EPA 402-R-93-078 and as specified herein. Prevent entry of soil gas into the building and exhausting of conditioned air via the radon mitigation system. Seal cracks and openings around floor slab penetrations with polyurethane sealant. Provide backer rod or comparable filler material as required. Insure that all penetrations to the building exterior are weathertight.

c. Lay work out in advance. Exercise care where cutting, channeling, chasing or drilling floors, walls, partitions, ceilings or other surfaces as necessary for proper installation, support or anchorage. Patch and repair damage to buildings, piping and equipment using workmen skilled in the trades involved.

d. Coordinate all work with the Contracting Officer.

3.1.3 Supervision

Installation of the radon mitigation systems must be supervised by a qualified mitigation professional.

3.1.4 Electrical Work

3.1.5 Mechanical Work

3.1.6 System Identification

NOTE: For NAVFAC projects include the bracketed text, otherwise delete.
Label all components of the radon mitigation systems including, but not limited to, piping (every 3 meters 10 feet), enclosures, fans, electrical conduit (every 3 meters 10 feet) and circuit breakers. Labels must read:

Radon Reduction System. Do Not Turn Off.
Public Works Office Phone [_____]

[ or as specified by the Contracting Officer.]

3.2 RADON MITIGATION SYSTEM ENCLOSURES INSTALLATION

Provide enclosures as indicated in the approved design drawings and as required by the specifications and standards referenced herein for the respective materials using workmen skilled in the trades involved. Install enclosures plumb, level and parallel to existing walls, partitions and ceilings as appropriate, and secure in place in a rigid and substantial manner.

3.3 POST MITIGATION FUNCTIONAL EVALUATION/INSPECTION

3.3.1 ASD Systems

In conjunction with activating an ASD system, the suction in system piping must be measured and recorded along with at least one PFE measurement that is conducted under closed-building or normal operating conditions. It is recommended that both measurements be made under conditions that reflect normal building operation when significantly occupied and include consideration for worst-case conditions.

3.3.1.1 PFE Measurement

Obtain PFE measurements at more than one point distant from each suction point(s) to verify intended design using a differential pressure gauge capable of reading to 0.25 Pa 1/1000 in water column. Record PFE test location and close in a nonpermanent fashion to facilitate any future needs (e.g. diagnosing a system when radon tests do not indicate success in achieving mitigation goals).

3.3.2 Non-ASD Systems

Measurements of airflow volume, pressure and other system parameters that are applicable to the method chosen must be recorded after installation.

3.4 FIELD QUALITY CONTROL

3.4.1 Radon Mitigation System Inspection

Inspect and approve in writing by a qualified mitigation professional each radon mitigation system. Verify compliance with the design, ANSI/AARST MALB, ANSI/AARST RMS-LB and the presence of fire stops. Provide the Radon Mitigation System inspection to the Contracting Officer. Deficiencies identified in the inspection report must be corrected by the Contractor at no additional cost to the Government.

3.4.2 Post Mitigation Testing and Monitoring

Perform post mitigation radon testing in the buildings as specified in ANSI/AARST RMS-LB, EPA 402-R-93-078 and herein.
3.4.2.1 Short Term

**************************************************************************
NOTE: For work in the continental United States, Alaska and Hawaii select pCi/L as the unit of measure. For work elsewhere in the world Bq/cu m may be the required unit of measurement. Consult with the Contracting Officer and use the unit of measure familiar to the prospective Contractors.
**************************************************************************

Test each radon mitigation system as described below.

a. Test each radon mitigation system for effectiveness no sooner than 24-hours nor later than 15 days after activation of the radon mitigation system. Perform all testing in accordance with ANSI/AARST MALB, ANSI/AARST RMS-LB and all local, state and Federal requirements. Provide short term radon detectors (charcoal, electret ion chamber or approved equivalent) at the rate of one detector per 186 square meters 2,000 square feet but not less than one detector per enclosed space, except for closets. On copies of the building floor plans, locate and identify each short term detector and provide short term detector data on copies of the "Device Placement Log" contained in EPA 402-R-92-014.

b. At the end of the testing period, collect the detectors and send the detectors to the testing laboratory for analysis. Provide radon test results of the effectiveness of the mitigation systems not later than 30 days after collecting the detectors. Radon test results must be sent from the testing laboratory directly to the Contracting Officer with one copy to the Contractor. Complete the line item information on the "Device Placement Log."

c. Radon test results above [148 Bq/cu m][4.0 pCi/L] require system redesign and installation modifications as necessary to achieve radon test results below [148 Bq/cu m][4.0 pCi/L]. Submit design modifications to the Government for review and approval. After approval of the design modifications, provide installation modifications to the radon mitigation system and retest for effectiveness. Repeat this short term test procedure until test results below [148 Bq/cu m][4.0 pCi/L] are achieved.

d. System modifications (as-built systems installations) must be reflected in the Contractor's design documents (drawings and design narrative).

3.4.2.2 Long Term

**************************************************************************
NOTE: For work in the continental United States, Alaska and Hawaii select pCi/L as the unit of measure. For work elsewhere in the world Bq/cu m may be the required unit of measurement. Use the unit of measure familiar to the prospective Contractors.
**************************************************************************

After acceptance of the radon mitigation systems, provide for long term testing (8 to 12 months), see below.
a. Perform all testing in accordance with ANSI/AARST MALB, ANSI/AARST RMS-LB and all local, state and Federal requirements. Provide long term radon detectors (alpha track, electret ion chamber or approved equivalent) at the rate of one detector per 186 square meters 2,000 square feet but not less than one detector per enclosed space, except for closets. Locate and identify each detector on copies of the building floor plans and in the Radon Detector Location Log. After installing the detectors, furnish the completed detector documentation and mailers to the Contracting Officer.

**************************************************************************

NOTE: Depending upon the resources available at the activity or facility, select the appropriate paragraph for collecting the long term detectors.

**************************************************************************

[ b. At the end of the testing period, collect the detectors, request return of the detector documentation and mailers from the Contracting Officer and send the detectors to the testing laboratory for analysis. Radon test results must be sent from the testing laboratory directly to the Contracting Officer with one copy to the Contractor. Complete the line item information in the Radon Detector Location Log.

][c. At the end of the testing period, the Contracting Officer will collect and send the detectors to the testing laboratory for analysis. Radon test results must be sent from the testing laboratory directly to the Contracting Officer with one copy to the Contractor.

] d. Radon test results above [148 Bq/cu m][4.0 pCi/L] require system redesign and installation modifications as necessary to achieve radon test results below [148 Bq/cu m][4.0 pCi/L]. Submit design modifications to the Government for review and approval. After approval of the design modifications, provide installation modifications to the radon mitigation system and retest for effectiveness. Repeat the short term and long term test procedures specified herein until test results below [148 Bq/cu m][4.0 pCi/L] are achieved.

e. Payment for work required because long term testing results in readings above [148 Bq/cu m][4.0 pCi/L] will be made from the funds identified in the "Schedule of Prices" for the work required under this paragraph and defined under the paragraph POST MITIGATION TESTING - SCHEDULE OF PRICES DATA included herein. Payment of these funds will be made only after the Contracting Officer has received the radon testing results from the testing laboratory and the readings for the long term testing are below [148 Bq/cu m][4.0 pCi/L].

f. Final system modifications (as-built systems installations) must be reflected in the Contractor's design documents (drawings and design narrative).

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for tunnel excavation for underground construction by blasting. Tunnel Excavation guide specifications for excavation using mechanical methods such as Tunnel Boring Machine (TBM) or roadheader presently do not exist but may be developed in the future. This specification is currently for use in tunnel excavation in bedrock conditions equivalent to at least two tunnel diameters below top of rock (i.e., ledge) only. For mixed-face or soft ground tunneling conditions (i.e., soil-like conditions), consider alternate mechanical excavation methods to account for anticipated ground conditions for appropriate equipment selection and methods of ground support and groundwater control. For localized ground conditions including fault zones or other specialized ground conditions, revise specification to account for potentially adverse rock characterization conditions identified in the Geotechnical Baseline Report or other geotechnical design documents. This section was originally developed for USACE Civil Works projects.

For projects on a naval facility, consult with local NAVFAC office, Naval Ordinance Safety and Security Activity (NOSSA), and NAVSEA on requirements. NAVSEA OP5 Ammunition and Explosive Safety Ashore manual dictates many of the requirements and NOSSA has the final determination on blasting on a Navy installation above or underwater. Reference NAVSEA OP5 manual and contact local Explosives Safety Officer and Planner for the base prior to revising the specification. Overall NOSSA approval process can take 12-18 months depending on the level of approval required.

Adhere to [UFC 1-300-02](#) Unified Facilities Guide
Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

**************************************************************************

PART 1   GENERAL

**************************************************************************

NOTE: For USACE: Consult with Subject Matter Experts (SME) from the Geotechnical Engineering, Structural Engineering, Engineering Geology, and Materials Community of Practice or District Office that has most recently completed a similar type of underground construction project, while editing this section, to be appraised of recent, specific requirements, guidance, excavation methods or understandings for the subject project.

Consult with or have Specification reviewed by a Subject Matter Experts in Underground Construction for projects involving Tunnel Excavation as a primary component of a project, or where Underground Construction issues are particularly challenging.

There are likely decisions and/or requirements of other agencies, the Safety Manual, and/or internal offices/divisions/ branches, which could have an influence upon a project's underground construction specifications. Some of these issues may be: concerns from federal, state, and local jurisdictions and agencies; public use of nearby federal, state and/or local properties near or adjacent to the project; evaluations of acceptable construction vibrations, noise and/or pressures affecting individuals or reaching nearby structures; natural resource impact reviews, negotiations and/or requirements; constraints on the excavation means and methods; pre-construction inspections; special studies to facilitate lower cost of the bids or to encourage more bid submissions; the acquisition strategy for the payment; and, other concerns specific to the project.

This Tunnel Excavation guide specification covers the construction of underground facilities by means of blasting in rock and includes mucking. The details on excavation are typically covered by a
separate Rock Excavation specification.

The following minimum requirements for project information will be indicated on the project drawings:

1. Surface elevations, existing and new.

2. All utilities, whether trenched, buried, at the surface or overhead to distances well beyond the project's limits;

3. Spatial location and record of all soil and rock borings and test pits, instrumentation, and/or geophysical surveys including soil and rock classifications and the pertinent engineering properties. For example this data may include, but is not limited to, weathered rock, material strength, bit drops, circulation loss, voids, ground water observations, SPT, Recovery, RQD, RMR, lab testing results, permeability, stratigraphy, geologic features and structure, and topsoil thickness encountered in boring (NOTE: This is a list of examples of data pertinent to the tunnel design that may be provided in the project drawings or GBR/GDR but does not include all possible engineering properties or conditions of soil and rock that characterize a specific site.);

4. Reference to project Geotechnical Data Report (GDR), Geotechnical Interpretation Report (GIR) and/or Geotechnical Baseline Report (GBR) for additional site characterization information not contained on the project drawings.

5. Location and limits of hard material, whether rock or concrete, or other building materials;

6. Excavation or demolition limits, and clearing, stripping and grubbing limits, and tolerances of excavation;

7. Details of special limits that may require line drilling, presplitting, reduced subdrilling, and/or specialty blasting practices;

8. Location of borrow and disposal area, if located on Government property; or on site (as some sites may or may not remain government property, and disposal sites may be under control of project partners);

9. Hydrological, hydraulic and impoundment data, where applicable; and,

10. Details of all rights-of-way within the project boundaries.

**************************************************************************

SECTION 31 23 00.00  Page 6
1.1 METHOD OF MEASUREMENT

Tunnel support for the various support categories must be measured and paid by the individual components comprising each support category (e.g., Rock Bolts, Steel Arch Ribs, Shotcrete), under their respective specification or special provision section.

Tunnel Excavation must be measured by the meter cubic meter linear foot cubic yard excavated in accordance with the 'B' line payment limit shown on the Drawings. Tunnel drainage must be measured and paid under Section 01 20 00 PRICE AND PAYMENT PROCEDURES.

1.2 BASIS OF PAYMENT

The accepted quantities measured as specified above must be paid for at the contract unit price for the pay items listed below.

<table>
<thead>
<tr>
<th>Pay Item</th>
<th>Pay Unit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tunnel Excavation</td>
<td>Meter, Cubic Meter, Linear Foot, Cubic Yard</td>
</tr>
</tbody>
</table>

Payment for Tunnel Excavation must constitute full compensation for all excavation, scaling, scaling reports, support, blasting, blasting reports, removal, hauling and disposal of excavated materials, construction ventilation and illumination, control of water and groundwater inflow including groundwater testing, supply of potable water, and all other work necessary for completion of the tunnel in accordance with the Contract Documents.

**NOTE:** The coordination with other federal, state, and local jurisdictions and agencies, the public, and private entities must be completely resolved before finalizing the specifications. A project's excavation and/or foundation requirements, for which, dense materials are being removed, may require navigation, highway, structural and/or other regulations and codes to be followed. Depending upon the proximity of public-use areas, private residences or businesses, and the project's location within a county or township, various accommodations will need to be required for the protection of the public, and the safety of private entities regarding local laws, regulations, and ordinances. Avoiding natural resource impacts may overlay other measures and require: seasonal or daily time limitations of the initiation of the individual blast patterns; special observers for some or all the underground construction work; special studies or monitoring while blasting operations is being conducted; and, other potential considerations.
Agency coordination will vary by project. Be certain that all government stakeholders have been involved with planning of the project and approved of all requirements for the specifications. List those important navigation or safety stakeholders. When there are navigable waters near the excavation zone, list in the controlled navigation perimeter's distance during the warning period of a shot. While the distance is project specific, the minimum distance is typically 300 m \(1,000 \text{ ft}\).

It is essential that the agency/service person, using these Guide Specifications to prepare Plans and Specifications coordinate with the planners and environmental compliance specialists within their agency/Service to ensure that all appropriate restrictions and mitigation measures for hazards associated with tunnel excavation and underground construction are incorporated into the Plans and Specifications. Failure to comply with the requirements of applicable Federal or state laws and regulations could result in project delays or stoppages, as well as the potential for increased project costs.

**************************************************************************

1.3 SCOPE

This work must consist of excavation and disposal of all material within the rock tunnel limits indicated on the plans, in accordance with these specifications and in conformity to the lines, grades, stations and tolerances shown on the plans or as established in the field by the Contracting Officer. Some general guidelines to maintain the inherent strength of the ground surrounding the tunnel opening have been included. In addition, the work also includes geotechnical instrumentation for monitoring rock displacement and water management in the tunnel; including but not limited to, furnishing, installing, and monitoring of optical survey targets in the tunnel, collection and interpretation of data and furnishing all other necessary material, equipment and labor incidental to such work, [furnishing of optical survey targets], including installation and monitoring of instruments in accordance with the specifications. The Contractor must monitor all geotechnical instrumentation and interpret the data obtained from them. The data must be made available to the Contracting Officer [upon request][within 24 hours of reading].

The breakage of rock and hard/unyielding materials may be conducted by any means unless otherwise stated herein. If the contractor elects to use drilling and blasting for breakage or displacement of units, this entire section is applicable and covers activities associated with drilling and blasting for rock excavation at the surface for portal and shaft construction, or underground tunneling operations. Contained herein are procedures for all activities relating to drilling; blasting and the transportation, storage and use of explosives; breakage and displacement of rock. The Contractor's blasting program and methods are those necessary to accomplish the excavation shown on the Contract drawings in accordance with the provisions specified herein. Contractor's blasting plan must address site-specific conditions affecting the control, quantity, and magnitude of explosives fired in all blasting operations to prevent injuries to persons.
and avoid damage to all structures, properties, governmental and nonprofit entities, commerce and businesses, and natural resources and their habitat.

1.4 RELATED WORK SPECIFIED ELSEWHERE

**************************************************************************
NOTE: These specifications for related work specified elsewhere are not all inclusive. Add and remove specifications as needed for the project.

List specifications that are related, such as Earthwork, Excavation, Soil and Rock Anchors, Temporary Environmental Controls, Shotcrete, Natural Resources, are typical specs related depending on the project.

The specifications without numbers listed below presently do not have a corresponding UFGS Guide Specification. The designer will need to write a project-specific specification to address those features of work

1.5 REFERENCES

**************************************************************************
NOTE: Add and remove references as needed for the project. Reference the appropriate state and local laws, regulations and ordinances concerning blasting where the project is to occur.

This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature
to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

ASTM INTERNATIONAL (ASTM)

ASTM D2487  (2017; E 2020) Standard Practice for Classification of Soils for Engineering Purposes (Unified Soil Classification System)

1.6 RELATED ATTACHMENTS AND SPECIFICATIONS

-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

NOTE: Geotechnical Data Report (GDR) and Geotechnical Baseline Report (GBR) Importance. Project-specific site data should be presented in Geotechnical Data Report (GDR); design interpretations of the expected subsurface conditions and expected behavior should be presented in the Geotechnical Baseline Report (GBR). GDR/GBR data must be consistent with information presented
in the project specifications and drawings without conflict. Agencies may require different types of documents; there may be a Geotechnical Interpretive Report (GIR).

Location and record of all soil and rock borings and test pits, including soil and rock classifications and their properties, weathered rock, bit drops and voids, ground water observations, and topsoil thickness encountered in boring.

Location and limits of hard material, whether rock or concrete, or other building materials.

"Geotechnical Data Report" (GDR) dated [____], prepared by [____].
"Geotechnical Baseline Report" (GBR) dated [____], prepared by [____].
"Geotechnical Interpretive Report" (GIR) dated [____], prepared by [____].

1.7 DEFINITIONS

NOTE: Delete definitions that will not be used in the specification text for a specific project. A complete list of frequently used tunneling terms can be found in Appendix B of the EM 1110-2-2901, blasting definitions can be found in the GLOSSARY of the EM 1110-2-3800, and other references. Recommend only including definitions not already referenced in the EM and definitions to further define the work on the specific project in the specification. It may be necessary to add definitions depending on what the Earthwork and/or Excavation specifications for the project have terms for Rock, Weathered Rock, Sound Rock, Voids, Sediment, etc.

1.7.1 Controlled Blasting

NOTE: This section may be applicable for the shaft/portal blasting construction.

Controlled blasting refers to blasting techniques used to better distribute the explosive charge to minimize impacts such as fracturing and loosening of the rock beyond the design excavation line (overbreak) and limit vibration effects. This is accomplished by using small diameter, decoupled charges in closely spaced blastholes placed on the perimeter of an excavation. Methods including but not limited to line drilling, and pre-splitting (pre-shearing) cushion blasting, and buffer zone blasting.

1.7.2 Airblast

Airblast are the overpressure waveforms that move through air as audible and sub-audible sound waves. These are also called compression waves. Airblast is one of the three, primary adverse impacts from blasting.
1.7.3 Vibrations

NOTE: There are other impacts that may be related to blasting that should be considered, such as ground settlement, disruption to structures or activities, hazardous environments.

Vibrations are the second of the three, primary adverse impacts from blasting. The third primary adverse impact from blasting is flyrock. Vibrations are the result of various wave forms emanating from the detonation or deflagration of ignited materials from a shot pattern. Peak particle velocity (PPV) is defined as the maximum absolute value among the three ground vibration velocities measured in the vertical, longitudinal, and transverse directions over the period of a record. Peak, total vector-sum particle velocity is the peak value over the full-time history of each time-unit's value of the square-root sum of the squared, component velocities. Velocity units are expressed in centimeters per second (cps) or inches per second (ips).

1.7.4 Initial Support

Installed at and adjacent to the excavation face following a heading advance to minimize ground movement and loosening and to maintain stability of the opening prior to construction of the permanent lining. Initial support for the rock tunnel generally refers to all elements of rock support required to provide a safe, stable rock excavation at all times during construction. Elements of rock support include, but are not limited to, such items as steel ribs, timber blocking, spiling, rock dowels and anchors, steel straps, welded wire fabric or shotcrete.

1.7.5 Additional Initial Support

May include rock bolts and dowels, crib and lagging, steel straps, spot-holds, steel sets, steel liner plates, shotcrete and pre-reinforcement spiling in addition to the initial support types and quantities for the support categories as shown on the Contract Drawings. Additional ground support measures should be installed in a systematic or non-systematic manner, for local stabilization and safety during tunneling operations.

1.7.6 Final Lining

NOTE: Tailor this paragraph to the type of final lining for the project, this may be a cast-in-place or precast reinforced concrete liner, steel liner that is backfilled with contact grout, or left unlined, maybe with shotcrete or reinforced (steel fiber) shotcrete or other.

[Cast-in-place reinforced concrete, steel] lining that is installed after the tunnel has been excavated and supported with initial support. Backfill concrete and contact grout are also included in the final lining.
1.7.7 Design (Excavation) Line

**************************************************************************
NOTE: This nomenclature should be defined during
the development of the plans and specifications as
it will be specific for each project.
**************************************************************************

A line within which no unexcavated material must remain. Only shotcrete,
structural steel rib supports with limited blocking, rock dowels, including
bearing plates and metal hardware, and tie rods may extend beyond the
design line as shown on the Drawings. The minimum concrete cover over
these elements is shown on the Drawings. Embedments shown on the Drawings
within the design line must be placed as shown. The Contractor may select
the size of the excavated opening provided that finished minimum excavation
tolerances are maintained and the design line requirements and diameter
constraints given in this section are satisfied.

1.7.7.1 A-line (Theoretical Excavation Line)
The A-line, shown in the contract drawings is the line within which
unexcavated material must not be permitted to remain.

1.7.7.2 B-line (Pay Line)
The B-line shown in the contract drawings is the outside limit to which
measurement for payment for excavation must be made. Measurement for
payment must be made to this line regardless of whether the limits of the
actual excavation are inside or outside of the B-line. Excavations beyond
the B-line performed by the Contractor for purpose or reason except as
shown on the Drawings or as may be ordered in writing by the Contracting
Officer, must be at the expense of the Contractor.

1.7.8 Heading
A general term used to refer to the advancing (excavation) tunnel face.

1.7.9 Face
The position of the underground works that has been advanced the furthest
for the respective section of the overall construction sequence adopted for
the large span tunnels. Also referred to as "Working Face" or "Heading."

1.7.10 Forward Area
Is that area within which the initial ground support is to be installed
behind the heading (depends on rock mass conditions, stand up time, and
heading advance rate).

1.7.11 Initial Ground Support
**************************************************************************
NOTE: Other common terminology may include wood
lagging and liner plate (gasketed and un-gasketed),
splines, strapping, mesh, steel sets, steel-fiber
reinforced shotcrete, expandable bolts.
**************************************************************************
NOTE: In addition, the initial support systems indicated on the Drawings for additional openings in the tunnel, must form part of the Permanent Support.

The support system installed after an excavation advance within the tunnel forward area to minimize ground deformation and loosening and to maintain stability and safety of the opening. Initial support measures include, but may not be limited to, rock bolts and dowels for rock reinforcement, shotcrete lining, steel ribs, and pre-reinforcement for the duration of construction and prior to installation of the permanent support.

1.7.12 Length of Advance Interval

Length of the unsupported span of ground exposed during one excavation advance increment (depends on rock mass conditions, stand up time, and heading advance rate).

1.7.13 Line Drilling

Line drilling may be applicable in and around tie-in structures where precise ground control is needed. Within tunnel blasting operations, perimeter holes, back holes or heading rounds may be line drilled for overbreak control along the rib, springline and through the crown. Typically line drilling is applied during shaft or portal construction.

1.7.14 Excessive Overbreak

The amount of ground unintentionally removed beyond the pay line, or B-Line. The Contractor should attempt to minimize overbreak.

1.7.15 Over-Excavation

Excavation of ground beyond the theoretical excavation line, or A-Line.

1.7.16 Probe Hole

An exploratory hole drilled in advance of an excavation to explore ground conditions or water infiltration conditions. Supplemental probe holes are those installed in addition to the probe holes shown on the Drawings or required herein and at the direction or approval of the Contracting Officer.

1.7.17 Scaling

Consists of barring, wedging, and picking to remove loose, shattered, or unstable pieces of rock around the heading advance. Individual pieces not in accordance with the specified tolerance must also be removed during scaling.

1.7.18 Shotcrete

Mortar or concrete conveyed through a hose and pneumatically projected at high velocity onto a surface.

1.7.19 Staged Excavation

NOTE: Advancing multiple headings is often performed in poor ground or for larger final tunnel
dimensions, where a top (left and/or right) heading is advanced, supported then the other heading or bench removed, potentially also removing the center support system separating the headings.

Sequence of excavation by which the final excavation is divided into a group of smaller drifts, also referred to as slashes and cuts, or top heading and bench.

1.7.20 Support Type

Method of excavation and initial support defined in the Drawings for use at a particular location.

1.7.21 Tights or Underbreak

Projections of rock in a tunnel inside the minimum excavation profile (A-line) that need to be removed prior to placement of lining.

1.7.22 Water Sheet or Panning and Drain Hose

PVC-sheet, PVC-pan and PVC-hose used to collect and drain off ground water from areas at either the excavated surface behind the shotcrete lining or to collect and drain seepage through the shotcrete lining.

1.7.23 Smooth Wall Blasting

**************************************************************************

NOTE: Smooth wall blasting can be used around openings and sensitive structures.
**************************************************************************

Refers to a technique involving perimeter holes drilled along the excavation limits which are lightly loaded to remove the final burden and are fired on the last delay of the detonation sequence. The objective is to obtain smooth walls with minimum overbreak and minimal damage to the rock outside the excavation limits.

1.7.24 Hangfire

Occurs where the explosive in the borehole begins burning and may eventually detonate when the fire reaches the area of the base charge of the failed detonator. This detonation may take place a few seconds after the blasting machine was fired or a few minutes later.

1.8 RESTRICTIONS

Tunnels must be excavated and supported using a continuous or incremental excavation- observation-support approach to provide the necessary and justifiable levels of ground control and permanent stabilization. The use of a staged excavation approach with integral, concurrent initial support and permanent stabilization of the tunnel periphery is fundamental to the successful execution of the project and recognizes that tunnel spans of different dimensions must be developed in variable and fractured rock mass conditions.

Do not begin underground tunnel blasting excavation operations until the following conditions have been met:
1. Do not begin tunnel excavation until all required submittals in paragraph SUBMITTALS have been submitted and the Contracting Officer has reviewed and approved the submittals.

2. Pre-construction inspections near the tunnel excavation have been completed by the Contracting Officer and pre-construction documents have been provided to Contractor.

3. Installation of geotechnical and structural instrumentation for monitoring surface structures near the tunnel excavation have been completed and initialized by the Contractor.

4. All issues related to health and safety have been met and all submittals have been made in accordance with OSHA requirements, EM 385-1-1, and other applicable codes and regulations of Federal, State, and local agencies having jurisdiction.

5. Required personnel with qualifications specified in paragraphs BLASTING PERSONNEL and TUNNELING PERSONNEL are available on site to perform work.

6. Temporary construction power substation has been installed and tested in accordance with the Division 16 specifications.

7. Blasting will not be carried out without the prior approval of the Contracting Officer.

8. The Contractor must take all necessary precautions to prevent premature detonation of explosive charges.

9. The Contractor must be responsible for safe transportation, storage, security/guarding and use of explosives, blasting agents, primers, initiators, and ancillary equipment and materials in accordance with 29 CFR 1910.109, 29 CFR 1926-SUBPART U, and all applicable federal, state, and local Regulations. All cost associated with the transportation, storage, security/guarding and use of explosives must be considered incidental to the cost of tunnel excavation and included in their respective unit costs.

10. Vibration monitoring equipment must be installed, calibrated and operating before blasting begins.

11. Public notification and meeting held.

1.9 SUBMITTALS

**************************************************************************

NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.
For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.

**************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-01 Preconstruction Submittals

**************************************************************************

NOTE: The following Submittal requirements are for tunnel excavation using excavation methods and should be included in all project specifications.

Several other considerations include Tunnel and Confined space rescue team training and setting up an independent emergency communication lines within the tunnel. If the local fire department is not trained in confined space tunnel or mine rescue, they may have to be trained in confined space tunnel/mine rescue procedures prior to excavation of tunnel or a private specialty company can be hired for rescue services as required by federal, state, and local work ordinances.

Haul routes for muck disposal can also be an issue in densely populated areas. Haul routes may need to be coordinated with local and state officials as required by local ordinances.

1.10 COORDINATION

******************************************************************************
NOTE: The following paragraph can be used if working with multiple stakeholders/owners.
******************************************************************************
Underground construction employing blasting methods will be in the vicinity of the [existing lock, railroad, and highway, and river barge, train, hospital highway traffic, utilities and businesses] and their operation will not be impeded or delayed beyond that which has been coordinated with [TVA, U.S. Coast Guard, U.S. Army Corps of Engineers - [____] District, [____] environmental or natural resources offices, [____] Department of Transportation, local government entities,] [ [____] Railroad, regional or local utilities, and/private businesses]. Include a coordination and traffic control sub-plan as part of the Blasting Safety Plan, with the appropriate authorities that mitigates navigation and traffic delays in the Master Blasting Plan.

Coordinate, through the Contracting Officer, with other Contractors working onsite to minimize work stoppages during blasting.

1.11 LIABILITY

******************************************************************************
NOTE: This section can be included in the front end documents (General Conditions) instead of here, consult with Contracting Officer.
******************************************************************************
Compliance with provisions in the contract will not relieve the Contractor of their responsibility for damages or injuries caused by, related to or arising out of blasting or associated blasting activities. The Contractor assumes all liability and hold and save the Government, its agents, officers, and employees harmless for all claims for personal injuries, property damage, or other claims arising out of or in connection with the handling of explosives or blasting under this contract.
PART 2   PRODUCTS

2.1   STORAGE AND USE OF EXPLOSIVES

2.1.1  General

NOTE: The specification writer may choose to list reasons the Contracting Officer may restrict the use of various tunnel excavation methods such as blasting, but not always necessary. Confirm and follow applicable federal, state, and local regulations and guidance on the transport, storage and use of all Explosive materials and components. State and local agencies and/or authorities may not easily allow the receipt of Explosives in a timely manner. State and local agencies and/or authorities may have specific reporting, certifications, adverse impact concerns, or distance regulations from the blast zone to private properties governing the use of Explosives. The Agency/Service may wish to allow storage of Explosives on federal premises. The winning contractor should independently assess and cite in the Master Blasting Plan all applicable federal, state, and local laws, regulations, ordinances, or authorities that impact the transportation and storage of Explosives if authorized on the project.

Store, transport, handle, use, and otherwise secure explosives in accordance with best practices as approved by the Contracting Officer and in accordance with all Federal, State and Local laws and regulations. Comply with all special rules, regulations and ordinances that may be made by the authorities having jurisdiction, or by the Contracting Officer, regarding construction of, and storage in, magazines and precautions in handling and transporting explosives for blasting. Times and imposed restrictions concerning the use of explosives must be conducted in accordance with Federal State, and local regulations. The Contracting Officer reserves the right to establish further restrictions or time windows when blasting will not be allowed beyond the Federal State, and local requirements. The Contractor is responsible for all claims for damages and injuries caused by or arising out of blasting activities. Perform all blasting operations in accordance with the current edition of EM 385-1-1.

2.1.2  Blasting Products

NOTE: This paragraph may need to be adjusted, for some projects it is not appropriate to allow bulk explosives, such as in karst conditions because the bulk explosives could fill voids if care is not taken while loading to monitor the amount being added to each hole.

All blasting caps used on the project must be one year or less of age. Millisecond delay, [shock tube] initiators, must be used as the initiation
system. To ensure the accuracy of firing times of blasting caps, it is required that each cap period come from one lot number. Mixing of lot numbers for one cap period is strictly prohibited. All explosives used on the project must be six months or less of age or no older than one half the shelf life shown on the explosives manufacturer's technical data sheet for that product. Cartridge [and bulk] explosives may be used in different sections of the project. Ammonium nitrate and fuel oil (ANFO) is not allowed in wet environments.

**************************************************************************

NOTE: In projects where controlled blasting techniques are required to produce final walls which require presplit blasting, only explosives designed for this application must be allowed. Ammonium nitrate and fuel oil (ANFO) is not to be allowed in wet environments. Consider requiring cartridge explosives within a specified distance from new structure which requires neat excavation lines, i.e., "Bulk explosives such as ANFO or bulk emulsion or emulsion blends will not be allowed for production blasts at the area within 60 meters 200 feet of it or within 15 meters 50 feet of presplit walls."

**************************************************************************

Explosives that do not meet the manufacturer's specifications must not be used. When, in the opinion of the Contracting Officer, blasting product is either of excessive age or appears to be in a deteriorated condition, all work must cease until the products age and quality can be determined. Blasting products without date and batch codes are / will not be permitted on site. The Contracting Officer may require products to be tested by an independent organization to determine its performance as compared to the manufacturer's data sheet. If product performance or composition deviates by more than 10 percent from the manufacturer's data sheet, that lot number will be rejected. The Contractor is responsible for required testing and no additional compensation will be made for product testing directed by the Contracting Officer.

2.1.3 Magazines

**************************************************************************

NOTE: Two paragraph options here first paragraph is for where explosives must be stored off site (off site magazine). The other covers the storage of explosives onsite. The designer will need to ensure these requirements are fully detailed and the appropriate regulations are followed.

**************************************************************************

Explosives must be stored offsite. Obtain all necessary Federal and State magazine permits. Magazines must be located at safe distances as defined by the Bureau of Alcohol, Tobacco and Firearms (ATF) in addition to the State of [_____] requirements. There must be no permanent explosive storage or overnight explosive storage on site. Procure off-site explosive storage and expect to have daily explosives deliveries to the site. Secure a permit to transport explosives from the [_____] Highway Patrol when the amount of explosives to be transported exceeds 454 kilograms 1000 pounds, and transport explosives in accordance with 49 CFR 177 when carried on public highways.
Explosives may be stored onsite. Obtain all necessary Federal and State magazine permits. Magazines must be located at safe distances as defined by the Bureau of Alcohol, Tobacco and Firearms (ATF) in addition to the State of [_____] requirements. Secure a permit to transport explosives from the [_____] Highway Patrol when the total weight of explosives to be transported is less than 454 kilograms 1001 pounds, and transport explosives in accordance with 49 CFR 177 when carried on public highways.

2.1.4 Magazine Keeper

Each magazine keeper must be experienced and familiar with the laws and general practices concerning the handling, care, use, and storage of explosives and detonators. The magazine keeper is responsible for maintaining a cleared area around each magazine. The magazine keeper will not be required to perform duties that interfere with their duties as magazine keeper and being physically present at the magazines for every entry to the magazines for delivery, disbursement, and review of explosives at the magazines. If explosives are delivered and returned daily from the manufacturer or supplier to the project, the driver of the truck will serve as the magazine keeper.

2.2 SAFETY EQUIPMENT

NOTE: This section requires tailoring for the specific project design and geology.

a. Provide safety equipment and monitoring instruments according to requirements of Safety and Health Plan in accordance with Section 01 35 26 GOVERNMENT SAFETY REQUIREMENTS, to be included in the Materials Handling Plan as required in Section 01 33 00 SUBMITTAL PROCEDURES.

b. Provide personal protective equipment for protection against respirable dust, and all other protective measures that may be deemed necessary for dust control as per Federal Requirements. Submit the details of the Dust Suppression System.

c. All rock reinforcement, including spiling and other ground support in accordance with the requirements set forth in Section 31 68 13 SOIL AND ROCK ANCHORS and 03 37 13 SHOTCRETE.

d. Lattice girders and shotcrete lining must be in accordance with the requirements of Section XX XX XX GROUND SUPPORT SYSTEMS, and Section 03 37 13 SHOTCRETE.

e. Steel sets must be in accordance with the requirements of Section XX XX XX GROUND SUPPORT SYSTEMS, and Section XX XX XX REINFORCING STEEL.
f. Shotcrete materials must be in accordance with the requirements of Section 03 37 13 SHOTCRETE.

g. Water sheet and drain hoses as part of temporary construction measures to drain off local water inflows:

1. PVC sheet, or approved equal by the Contracting Officer, for application at exposed ground surface or shotcrete surface.

2. Flexible PVC hose with end couplings as required

2.3 PROBEHOLE DRILLING EQUIPMENT

A continuous probe must be maintained at [_____] meters [_____] feet, or least [_____] tunnel diameters ahead of the tunnel face. If the probing results indicate the presence of poor ground requiring the installation of pre-reinforcement, the Contractor must make adjustments as necessary to achieve the required excavation profile prior to excavating through the anticipated poor ground. During the probing operation the Contractor must monitor and measure the amount of in-flowing water.

Probe hole drilling equipment must be capable of drilling a minimum [_____]-inch diameter holes through sound and decomposed rock and concrete. Provide all necessary core hole drilling personnel, equipment, and accessories.

**************************************************************************
NOTE: Designer of record to provide input on the flow pressures for packer tests. Consideration must be taken by reviewing other data such as other data (piezometers, pressure cells, rock mass features).
**************************************************************************

The drill must be suitable for drilling in wet ground conditions, highly sheared or fractured zones, and through fault gouge. The drilling equipment must be capable offsetting packers in the hole against a pressure of [_____] kg/cm² [_____] psi.

PART 3 EXECUTION

**************************************************************************
NOTE: Consult with a District Office that has most recently completed a similar type of blasting, while editing this section, to be appraised of recent, specific requirements, guidance, blasting and underground excavation developments or understandings for the subject project.
**************************************************************************

**************************************************************************
NOTE: This specification is for use for tunnel excavation. For mixed face tunneling conditions, revise specification to account for anticipated ground conditions. This specification requires a Geotechnical Baseline Report (GBR) that defines the ground properties, conditions, and behavior related to tunnel excavation, support, and constructability along the tunnel alignment, portals, or along separate tunnel segments that is expected. The
Geotechnical Data Report (GDR) contains all the testing, and rock mass characterization data used to characterize the conditions and behavior of the ground along the tunnel alignment to establish the base line conditions for the project. The GBR defines what constitutes a differing site conditions for claim resolution per the frameworks of the contract.

3.1 GENERAL

NOTE: This paragraph should agree with the designations under paragraph SUBMITTALS, the Master Blasting Plan will always be for approval. The Individual Shot Plan may be approved ("G") or accepted ("FIO").

Obtain approval, or revise for approval, of the submitted Master Blasting Plan and Individual Shot Plans, acquire all required permits, and comply with all laws, regulations, ordinances, applicable safety code requirements, and regulations relative to the transportation, handling, storage, and use of explosives and the protection of life and property. Perform vibration and airblast monitoring at the Contracting Officer's specified locations to record blast effects. The peak particle velocity must be limited to the values in Paragraph BLAST EFFECTS MONITORING in these specifications. Minimize rock over-break and blast damages beyond the design excavation line. The Contracting Officer will, always, have the authority to prohibit or halt the blasting operations, if it is apparent that the required lines and grades and stable rock slopes are not being obtained with the methods being employed. Adhere to the general requirements as outlined below:

a. Care must be exercised to minimize overbreak, to prevent immediate or subsequent rock falls from within the tunnel or from portal areas and other rock slopes outside the tunnel, and to preserve the integrity of the rock outside the limits of tunnel excavation.

b. Clean working conditions must be always maintained inside the tunnel. All muck, slush, grout spills, and any other material not required for tunneling must be removed from the tunnel in a timely manner.

c. Detailed construction sequencing must be the responsibility of Contractor, consistent with the requirements of these Specifications, and those shown on the Contract Drawings.

d. Perform work in a manner that minimizes safety hazards and exposure of personnel and equipment to hazardous and potentially hazardous conditions in accordance with specified safety requirements and Contractor's Safety and Health Plan.

e. Minimize ground movement at the tunnel face and in the surrounding excavation, and prevent ground loss, subsidence, and movement in surface features, overlying structures, and utilities above and around the vicinity of the tunnel excavation.

f. Provide additional face and excavation stabilization by means of
discretionary ground support wherever ground conditions dictate.

g. In case of stoppages, maintain qualified personnel on-duty to monitor conditions that may threaten stability of the heading.

h. If monitoring of ground vibrations and air blast indicate that vibration levels, or noise levels are exceeding response levels as defined under paragraph BLAST EFFECTS MONITORING, and Section XX XX XX TUNNEL INSTRUMENTATION; adjust procedures for excavation and initial support installation in accordance with the accepted Contingency Plan to reduce the levels to within acceptable limits.

i. Maintain sufficient quantities of shotcrete materials at the tunnel face, ready for immediate application, during the entire excavation period. Excavation will not be permitted without this requirement being met or as approved by the Contracting Officer.

**************************************************************************
NOTE: The need to maintain sufficient quantities of tunnel support materials/equipment will vary per project. Define this quantity during design phase and incorporate in GBR. The Government will map the tunnel according to ASTM D4879.
**************************************************************************

j. As the excavation progresses, the Contracting Officer will perform inspection, photogrammetry, LiDAR scanning, and geologic mapping or other documentation of the exposed tunnel sections. This mapping will be accomplished after excavation and either before or in conjunction with support installation. The Contractor must provide cleaning of the heading and completed crown and sidewalls and a safe means of access to these areas to allow this mapping. Mapping of the crown and sidewalls will be conducted for documentation of the actual geologic conditions encountered and assessment of rock mass characteristics of the heading. The Contractor should assume that this inspection and mapping will be performed once each shift for a period of minimum [20 minutes] in each heading. Lighting and access will be provided for close inspection of the face. Where necessary the excavated surfaces may need to be cleaned by air or water jets to provide surfaces suitable for mapping, as directed by the Contracting Officer; provided, however, such cleaning will be minimal in areas where softer materials can be gouged out to depths greater than three inches. The Contractor must cease operations to the extent necessary to permit such mapping as directed by the Contracting Officer. Such work will be coordinated by the Contracting Officer in a manner to avoid undue disruption to Contractor's operations.

k. Establish and maintain surveyed tunnel station markers throughout both lined and unlined excavated tunnel. Placed station markers indicating the tunnel stationing at 50 feet intervals by spray painting the rock or shotcrete surface in a color to contrast with background. Intermediate station markers should be made at 10-foot intervals with visible paint marks located at or near tunnel spring-line

l. Sequence and Direction of Construction:

1. Sequence and direction of tunneling to be as shown on the drawings and as reviewed by the Contracting Officer.
m. Temporary niches or adits, temporary or future pump sump pits and other temporary openings:

1. Excavate these temporary openings conforming to excavation and support criteria of this Specification and as reviewed by the Contracting Officer.

2. Seal all temporary openings with [4,000-psi] 28-day strength concrete in accordance with the requirements of Section 03 30 00 CAST-IN-PLACE CONCRETE when no longer needed, before installation of the final lining and Contract completion and as reviewed by the Contracting Officer.

n. Survey:

1. Contractor is responsible for the development and implementation of a surveying program capable of satisfying all survey and accuracy requirements. This program is subject to the review of the Contracting Officer prior to the commencement of the work. The review does not release the Contractor of liabilities associated with or dependent on this part of the work.

2. Design and implement a functional underground network and determine all required measurements and the required accuracy of each measurement including horizontal angles, zenith angles, azimuth angles, distances, and height differences. Include analysis of required redundancy and measure of internal reliability associated with each planned observation.

3. Design and implement a functional surface control network, stations, positions, measurements, and accuracies. Measurements may include Global Positioning System (GPS) vectors, horizontal angles, zenith angles, azimuth angles, distances, and height differences. Include analysis of required redundancy and measure of internal reliability associated with each planned observation.

4. Obtain survey information prior to completing the last [100] feet of the tunnel excavation. Adjustments to line and grade to the tunnel over the last [100] feet may be necessary to meet project requirements. The purpose of conducting the survey is to obtain the true centerline alignment in 3-dimensions to locate the connections as shown on the Drawings. Vertical and horizontal alignment should be taken along both invert/sidewall construction joints. The center point on the invert is assumed as the dividing line between both invert/sidewall joints.

5. Obtain start point alignment for the survey from the surface at [_____] data for alignment consisting of at least 2 benchmarks with known elevation and geographic coordinates enabling tie-in to [NGVD29, NAVD88] elevation and the [_____] State Plane Coordinate System, respectively.

6. Perform in-tunnel survey to an accuracy of ½-inch in the horizontal and vertical dimensions. Record sufficient survey points to enable the complete horizontal and vertical profile of tunnel alignment to be detailed. Some tunnel alignment curves may not necessarily be circular arcs; they may be based on complex parabola or other geometric shape forms.
7. Assume that station of [_____] are as indicated in historical documents. All new survey stationing must reference these stations.

8. A survey was completed on [______]. This information is available and must be reviewed by the Contractor, prior to conducting the tunnel survey.

9. Shaft centerline is the basis of all tunnel stationing up and down station of the shaft centerline.

10. Calibration and data processing:
   
a. Calibrate all survey instrumentation as required and as recommended by instrument manufacturer.

   b. Data reduction must incorporate calibrations and meteorological correction, and reduction of measurements to the ellipsoid and thence to the [_____] State Plane Coordinate System. Correct distance measurements by electro-optical distance measurement instrument (EODMI) for scale, cyclic error, zero error, and meteorological effects. Correct azimuth angles using the Laplace correction and include the deflection of the vertical components on angles and azimuth measurements.

   c. Data regression processing must include least squares adjustments, as required. Employ data outlier detection. Determine horizontal and vertical confidence intervals.

3.2 TEMPORARY SYSTEMS

**************************************************************************
NOTE: Review applicable consideration in EM 385-1-1, Ch. 26 and/or consult with a Safety professional with tunneling background. Ensure groundwater conditions and overall regime through rock mass is well understood by tunnel reach and rock type.
**************************************************************************

a. Provide, operate, and maintain a complete groundwater control/treatment system to collect water from within the tunnel and shaft and suitably treat it before discharge in accordance with the requirements of Section XX XX XX CONTROL OF WATER.

b. Water entering the tunnel from all sources must be controlled, managed, and disposed of in a manner to prevent damage to the tunnel and surrounding property and in accordance with all Federal, State, and local regulations.

c. Design, furnish, install, operate, and maintain a temporary lighting system in all underground and other working areas in strict compliance with all applicable Federal, State, and local regulations.

d. The system must provide a minimum light level in accordance with OSHA requirements and EM 385-1-1. In case of failure of the lighting system, provide an emergency lighting system in all work areas in strict compliance with all applicable Federal, State, and local regulations, and industry standards.
e. Design, furnish, install, operate, and maintain temporary ventilation during all phases of construction complying with all applicable Federal, State, local regulations, and industry standards. Operate and maintain the entire temporary ventilation system. Details of the Contractor's ventilation system must be presented to the Contracting Officer for agreement at least 60 days prior to its installation.

f. Two battery-operated handlamps of 20-Watts minimum power must be provided and maintained at each working face and portal for emergencies and inspection of the work.

g. Electric heaters or radiators having exposed coils or elements must not be allowed in the tunnels.

h. All main electrical cables installed within the tunnels must comply with all applicable Federal, State, and Local Requirements.

**************************************************************************
NOTE: Designer will need to ensure safety requirements in specification at a minimum follow OSHA/EM385/MSHA.
**************************************************************************

i. Provide additional floodlighting and ventilation locally as required at active ground support installation, shotcrete, and other locations, and provide portable floodlighting and ventilation equipment, as needed, for localized construction operations. Equipment for short-term use may be battery-operated.

j. For Contract requirements regarding temporary construction power, refer to Section XX XX XX TEMPORARY LIGHT AND POWER and Section XX XX XX TEMPORARY ELECTRICAL SYSTEM.

k. In all parts of the Underground Works, the atmosphere inhaled by those present must contain not less than 19.5 percent and maximum of 22.0 percent of oxygen and must not contain a concentration of contaminates such as gases, vapors and dusts greater than is safe for the health of the construction personnel having regard to the effects of exposure time, temperature, humidity and the combined effects of several contaminants. The concentration of inflammable contaminants must not exceed 10 percent of the lower explosive limit (minimum explosive concentration).

l. Wet drilling should be used. Where possible, drilling should be carried out using hollow bits with continuous water feed to reduce dust. Always wear suitable protective equipment.

**************************************************************************
NOTE: The potential for contaminants or hazardous conditions must be defined by the project owner (in the GBR) and assumed by the Contractor. If the conditions differ, owner is responsible for conditions more adverse than the baseline for this condition.
**************************************************************************

m. The Contractor must be responsible for obtaining all information necessary to determine what concentrations of contaminants are
harmless, without prejudice to the adoption of such lower figures as may be stated by competent authorities or directed by the Contracting Officer. The atmosphere inhaled by the workmen and other authorized persons in all parts of the tunnel must not contain more than 5 ppm of nitrous fumes (measured as NO₂) for longer than 10 minutes after each blast, 30 ppm of nitrous fumes as an absolute maximum, 50 ppm of carbon monoxide as an absolute maximum, 5,000 ppm of carbon dioxide as an absolute maximum, or for other contaminants. The Safety Professional must field calibrate air quality monitoring instrumentation in accordance with manufacturer's recommendations.

n. In all parts of the Underground Works, throughout the period in which explosives or other materials producing contaminants are used, and at such time as may be necessary to maintain the standard of purity of air required in this subsection, clean fresh air must be supplied by forced ventilation, using an exhaust system at the face or other method as agreed by the Contracting Officer, at a rate not less than the greater of the following:

1. [_____] cubic meters[_____] cubic feet per hour per person present in a tunnel;
2. [_____] meters[_____] feet per hour per kilowatt of combustion-engine generated power operating simultaneously in the heading.

o. The Contractor must take special measures to minimize the effect of particular sources of fumes. These measures must include the use of efficient and properly maintained exhaust smoke washers (scrubbers) for all internal combustion engines in the tunnel. Gasoline engines must not be permitted in the tunnel.

p. The means of dealing with blasting fumes must include, but not be limited to water sprays on muck piles after blasting and ventilation of the Underground Works immediately after blasting for as long as necessary to restore the purity of the atmosphere.

q. Notwithstanding requirements of this subsection the method of ventilation and treatment of fumes, including blasting fumes, must be subject to whatever tests may be necessary in the opinion of the Contracting Officer. The Contractor must provide, maintain, and use as directed by the Contracting Officer, an instrument approved by the Contracting Officer to measure the velocity of air, and an approved gas detector. Maintenance of the gas detectors must include the supply of all detector tubes.

3.3 SAFETY PROCEDURES FOR DRILL AND BLAST UNDERGROUND EXCAVATION

****************************************************************************************************

NOTE: Use below for general blasting safety procedures for drill and blast tunnel construction.
Consider other Tunnel H&S issues which are related to tunnel operations, equipment, slip-trip-fall, cave-ins.

****************************************************************************************************

3.3.1 General Blasting

Ensure all work completed under this Contract is executed safely. Follow
the safety procedures outlined in EM 385-1-1. EM 385-1-1 will govern all activity unless more stringent safety requirements are specified here and in other applicable Federal, State, and local laws, regulations, and ordinances.

a. All blasting work must be carried out using controlled perimeter drilling and smooth wall blasting techniques to control the geometry of, and to minimize damage to, the final excavation profile and to minimize overbreak.

b. Only non-electric detonation systems must be used for tunnel blasting, unless another detonation system is approved by the Contracting Officer. Cap and fuse or safety fuse is prohibited. The Contractor will be allowed to use one electric blasting cap per round to initiate the shot. The electric blasting cap must not be tied into the blasting circuit until [traffic has been stopped and] the area has been secured.

c. The Contractor must carry out controlled blasting to achieve a blast surface that exhibits a regular fracture plane between perimeter holes with minimal overbreak. The excavation surface must be scaled to remove all loose and hollow sounding rock to leave a solid, intact surface. Special care must be required with such procedures in highly fractured rock.

d. If the methods of drilling and blasting do not produce a consistent, uniform profile with minimal overbreak within the tolerances specified, the Contractor must undertake further test blasts until a method is established that results in an excavation profile to the specified tolerances.

e. The blasting technique must be such as to ensure reproducibility of the blasting pattern, accurate positioning of drillholes and precision in drilling. It may include the use of a template, or other techniques as may be proposed by the Contractor, all of which must have the prior approval of the Contracting Officer, for setting out the blasting pattern.

f. During the progress of the excavation, this technique must be varied as necessary to suit rock conditions exposed and to obtain the best practicable excavation surface after blasting, to the satisfaction of the Contracting Officer.

g. All blasting rounds must incorporate smooth wall blasting techniques.

h. Blasting must not be carried out within [_____] hours of the application of shotcrete within [_____] meters [_____] feet of the face.

i. The shot firing and detonator delays pattern must be such that the peak particle velocity (PPV) must not exceed the requirements of paragraph BLAST EFFECTS MONITORING.

**************************************************************************
NOTE: The section below should be used when rock blasting excavation techniques are required.
**************************************************************************
3.3.2 Public Notice of Blasting Operations

At least thirty calendar days, and prior to blasting operations, prepare and submit to the Contracting Officer a public government notification letter of the proposed blasting activities. The Government will distribute copies of this notification letter by certified mail to law enforcement, local governments, public utilities, [public users of project recreational facilities,] and residents and commercial interests located within 0.8 kilometers one half mile of the blast site. This notification letter must contain at minimum:

a. Name, address, telephone number and e-mail address of the Contractor;

b. Plan maps identifying the specific areas in which blasting will take place, and major and secondary roads, geographic features and auxiliary features;

c. Proposed duration of blasting activities, and on which days of the week and hours of the day that blasts can be expected to occur;

d. Vehicular and pedestrian traffic control measures to be taken;

e. Methods to limit access to the blasting area; and,

f. Types, patterns and duration of audible warning and all clear signals to be used before and after blasting.

3.3.3 Public Meetings

***********************************************************************
NOTE: Communicate with the project manager and stakeholders about whether specific requirements for a meeting or multiple meetings are needed. It may be necessary to advertise the meeting in a local newspaper and specify the meeting room capacity.
***********************************************************************

Fifteen calendar days prior to commencing tunneling operations, provide for the approved Project Manager, Tunneling Superintendent, Seismic Specialist, Blasting Specialist and Blasting Consultant (as applicable) to attend a public information meeting to be conducted on an evening to be determined by the Contracting Officer. This meeting will inform the public about the anticipated tunneling and underground construction operations, including the need to use blasting (as applicable). The Project Manager and Tunneling Superintendent must make a short presentation on tunneling and underground construction and answer questions pertaining to concerns that may impact the public. The Blasting Specialist, Blasting Consultant and Seismic Specialist must make a short presentation of blasting operations and answer questions pertaining to public concerns dealing with the tunneling and blasting operations, the magnitude of ground vibrations, airblast and potential for flyrock that may impact the public. Distribute points of contact for the public and local entities in the event of concerns related to the blasting program.

3.3.4 Warnings and Signals

Establish a method of warning all employees on the job site of an impending blast following the guidance of the EM 385-1-1. The signal must consist of a five-minute warning signal to notify all in the area that a blast will be
fired in five minutes. A second warning signal must be sounded one minute before the blast. After the blast is over, sound an all-clear signal, after the blast site has been inspected for misfires by the Blaster-In-Charge to provide notification to all personnel in the area that the blasting operation is finished. No personnel other than the Blaster-In-Charge must enter the blast area until it has been determined to be all clear.

3.3.5 Time Restrictions

**************************************************************************
NOTE: Research the specific State and local requirements. This paragraph will need to be tailored for the specific site conditions, for example, avoiding blasting during rush hours in the morning and afternoon. Most locations prohibit blasting on Sunday but may allow on Saturdays and some Holidays.
**************************************************************************

Blast only during daylight hours, one-half hour before sunrise and one-half hour after sunset, and between [_____] AM and [_____] PM, local time, on weekdays and only during the approved time periods each day and at the same time each day, in concert with the approved closure time for area roads. No blasting is allowed on Saturdays, Sundays, or official holidays recognized by the Federal Government or the State of [or Commonwealth of ][_____] unless consent is granted by the [State Fire Marshal]. Drilling activities and blasthole loading are not time restricted, except as noted in Section 01 14 00 WORK RESTRICTIONS.

3.3.6 Lightning Detection Equipment and Safety

**************************************************************************
NOTE: This section is needed when conducting blasting at the surface for shaft or portal blasting.
**************************************************************************

Furnish, maintain, and operate Lightning Detection Device during the entire period of blasting operations and during the periods that explosives are used at the site. Equipment must provide real time audio and visual alarm/signal and detection based on combined detection of electromagnetic, electrostatic, light wave spectral and audio disturbances, or a commercial service based on these as a minimum as approved. Equipment must be capable of detecting lightning within 40 kilometers 25 miles, as minimum, of the blast area.

**************************************************************************
NOTE: Obtain technical feedback from the rest of the design team for minimum lightning detection distance.
**************************************************************************

When and where the lightning detection device indicates a blasting hazard potential, immediately evacuate personnel from all areas where drilling is being conducted or explosives are present. When a lightning detector indicates a blasting hazard, perform the following:

a. Clear the blasting area of all personnel. Place guards at all access points to the blast area.
b. Immediately notify the Contracting Officer of the potential hazards and precautions being taken.

c. Terminate the loading of holes and secure the unused explosives to an approved location.

d. When the hazard dissipates, inform the Contracting Officer that the drilling and loading of holes will continue.

3.3.7 Check for Misfires

**************************************************************************
NOTE: Federal, or local entities may have different regulations applicable to the minimum time required before entering blast site after firing the shot. The more stringent regulation must apply.

If a misfire is declared, then the appropriate regulations must be followed for wait time and handling the misfire.
**************************************************************************

The Blaster-In-Charge must closely inspect the entire blast area following a blast to check for misfires and guard against rock fall or cave-in before commencing work in the tunnel. It is the responsibility of the Blaster-In-Charge to go into the shot area and check all holes to make sure that all explosives have been detonated.

3.3.8 Misfire Handling Procedures

Should a visual inspection indicate that complete detonation of all charges did not occur, only critical personnel involved in the blasting operation or excavation of the unexploded material are allowed within the established blasting area. Restrict access to the blast site until the Blaster-In-Charge and the Blasting Specialist indicate the site is safe. If the misfire poses problems that cannot be safely corrected by the Blaster-In-Charge or the Blasting Specialist, a consultant, or an explosives company representative skilled in correcting misfires must be brought to site to resolve the problem. Compliance with this or any other provision in the Contract must not relieve the Contractor of responsibility for damages or injuries caused by, related to, or arising out of blasting or associated blasting activities. Detail the misfire procedures in the Blasting Safety Plan including the distance of the restricted area when a misfire is discovered.

3.4 BLASTING PERSONNEL

3.4.1 Blasting Consultant

**************************************************************************
NOTE: Depending on the scope of the project, it may not be necessary to require a Blasting Consultant. This will be determined during design, an Agency/Service Blasting SME or Government Blasting Consultant should be consulted to discuss this. Projects where slope blasting, away from sensitive structures minor and lightly used public areas may be a consideration to not including this
requirement. One option is to still require a blasting consultant to be engaged but only for reviewing the Master Blasting Plan and engaged on very serious issues with the blasting (exceedance of vibration and/or airblast limits, misfires, flyrock, or excessive backbreak and/or overbreak). Excessive backbreak will need to be defined prior to issue of the specifications. This specification is geared towards IFB (Invitation for Bid) where there is no mechanism to select contractors prior to award. If another contract mechanism is used it may be necessary to include the bracketed text requiring a letter of commitment from the consultant.

The Blasting Consultant, Blasting Specialist, Blaster-In-Charge, and Vibration Specialist cannot be the same person, unless a justifiable request is presented and approved by the Contracting Officer. Retain a recognized Blasting Consultant to assist in the blast design. The Blasting Consultant must be approved by the Contracting Officer prior to the submission of the Master Blasting Plan. Submit the Blasting Consultant's Qualifications including resume, experience, current blasting licenses, credentials and training and a formal letter of commitment from the consultant verifying their availability on an "as needed" basis for the duration of the Contract prior to the award of the Contract. The consultant must be an expert in the field of drilling and underground blasting who has derived their primary source of income by providing specialized underground blasting and underground blasting consulting services. The consultant must not be an employee of the Contractor, explosives manufacturer, or explosives distributor or other sub-contractor. There must be no additional cost to the Government for the Blasting Consultant's duties, even when required by the Government.

NOTE: The paragraph below should be used when controlled blasting techniques are required.

The Contractor's Blasting Consultant with the Blasting Specialist must develop controlled blasting techniques to be utilized in the areas specified in the drawings during the Test Blasting program. The Blaster-In-Charge is responsible for the technical application of the controlled blasting methods specified during and following the Test Blasting. The Blasting Consultant must modify controlled blasting methods, as necessary, to meet safety requirements, airblast and vibration limits, and protect rock to be left intact. Proposed controlled blasting methods must be submitted to the Contracting Officer for approval.

The Blasting Consultant must review the Master Blasting Plan and Individual Shot Reports, attend the public meetings and be available for consultation on an "as needed" basis, as determined by the Contractor, Contracting Officer, or both. The Blasting Consultant is not required to be on the job site for review of the Master Blasting Plan or Individual Shot Reports. The Blasting Consultant must submit a short, signed Blasting Consultant's Report each month stating that the Blasting Consultant has briefly reviewed the Individual Shot Reports including blast videos, and problems, concerns or errors in the reports were addressed. This report is due within [_____] days after the end of the month.
3.4.1.1 Blasting Consultant's Qualifications

The consultant must be able to demonstrate involvement in at least [15] projects with underground blasting. The consultant must have as a minimum the credentials and experience outlined below:

a. The consultant must have at least 20 [_____] years of experience in general construction blasting within [_____] meters [_____] feet of protected structures, [natural resource concerns and environmentally sensitive areas], final tunnel periphery, and presplit shaft or walls.

NOTE: "Natural resource concerns and environmentally sensitive" areas need to be defined elsewhere in this guide specification. Depending on the scope of the project and state requirement the number of short courses, seminars and conferences can be adjusted.

b. The consultant must be able to demonstrate that he has attended at least [15] short courses, seminars, or conferences on blasting technology, or university engineering class studies on blast design during the past [20] years including a complete understanding of blasting seismology with emphasis on vibration frequency, acceleration, and displacement (ground strain).

c. For the past 10 years the consultant must have derived their primary source of income from providing specialized blasting consulting services.

d. Project list will contain a description of the projects, details of the blast plans, and modifications made during the project.

e. The names and telephone numbers of at least three project owners with enough knowledge of the projects to verify the submitted information.

f. The Blasting Consultant must be approved by the Contracting Officer prior to the beginning of drilling and blasting work including submission of the Master Blasting Plan.

g. Hands-on experience as a blaster for at least three years.

3.4.1.2 Issues Requiring the Blasting Consultant

If problems with vibration, airblast, smooth wall blasting, or production blasting, or adverse impacts on natural resources occur the Contracting Officer will require the Contractor to immediately summon the approved Blasting Consultant and have their presence on site within 10 days after the problem develops for the following:

a. To approve the blasting plans for each individual blast.

b. To be present to review the blasthole layout on the ground before drilling begins.

c. Observe blasthole loading.

d. To sign each blasting plan and each Individual Shot Report, at no
additional cost to the Government. The Blasting Consultant must have full authority to stop or delay blast they consider unsafe.

e. To submit and sign a written checklist that all necessary precautions were reviewed and followed by the drilling and blasting crews. The checklist must be as defined under the section on Individual Shot Reports. The signed checklist must be attached to each blasting report.

f. Submit Blasting Consultant's Reports after each site visit.

3.4.2 Blasting Specialist

Submit the Blasting Specialist's Qualifications including resume, experience, education, training, and valid blasting licenses of the Blasting Specialist for approval, at least 60 days before drilling and blasting operations commence. The Blasting Specialist must be approved before submission of the Master Blasting Plan. Detail the experience and training, which qualifies the specialist for work under this Contract. The duties of the Blasting Specialist are to prepare all necessary paperwork, to conduct quality control and to coordinate with the Contracting Officer on all issues dealing with underground blasting. The Blasting Specialist must be an employee of the Contractor on the job site each day.

a. The Blasting Specialist must have at least 10 years of verifiable experience utilizing underground controlled blasting techniques.

b. Within the last five years, the specialist must have completed at least five days of classroom training that has familiarized the specialist with the most current drilling and controlled blasting methods.

c. In the last five years he must have been responsible for the blast design or execution of large underground rock excavation projects similar in scope and complexity as this project.

**************************************************************************
NOTE: Include this sentence under paragraph a. if the project requires precision presplitting: [or projects where at least 30,500 meters 100,000 linear feet of Precision Presplitting was used].
**************************************************************************

d. Their credentials must include a list of the projects, including the location, duration, scope, description, geologic conditions, and the challenges that developed though the course of the projects and how the challenges were resolved.

e. Each project description must be accompanied with photos which exhibit the Blasting Specialist's competency and ability to create the designed tunnel periphery and shaft configuration if blasting at portals or shafts, to the specified tolerances. The list of projects must also contain the names and phone numbers of the project owner or their representative, Contracting Officer, or project engineers who has enough knowledge to verify the submitted information. The Contracting Officer will invalidate project submitted as reference that cannot be verified.

3.4.3 Blaster-In-Charge

**************************************************************************
NOTE: Some USACE projects may require an Alternate Blaster-In-Charge based on the frequency, size, and complexity of the blasting operations. The Alternate Blaster-In-Charge must meet the same qualification requirements as the Blaster-In-Charge.

Submit the Blaster-In-Charge's Qualifications including resume, experience, education, blasting licenses and training of the Blaster-In-Charge for approval, at least 60 days prior to the commencement of drilling and blasting. Also submit the Contractor's Federal ATF License. Detail the experience and training, which qualifies the Blaster-In-Charge for work under this Contract. The Blaster-In-Charge is responsible for preparing the Individual Shot Plans that will be approved by the Blasting Specialist. The Blaster-In-Charge is responsible for marking the blasthole locations for drilling, accounting for the relevant geology, loading the blastholes according to the Individual Shot Plans and firing the blast.

a. The Blaster-In-Charge must be a licensed blaster in the State of [_____] per that State's regulations or issuing agency.

b. The Blaster-In-Charge must have a minimum of 10 years of experience.

c. The Blaster-In-Charge credentials must include a list of the projects, including the location, duration, scope, description, geologic conditions, and the challenges that developed though the course of the projects and how the challenges were resolved. Each project description must be accompanied with photos, which exhibit the Blaster-In-Charge's competency and ability to design the blast. [Create the designed shaft configuration or tunnel periphery to the specified tolerances.] The list of projects must also contain the names and phone numbers of the project owner or their representative, Contracting Officer, or project engineers who has enough knowledge to verify the submitted information. The Contracting Officer will invalidate project submitted as reference that cannot be verified.

3.4.4 Magazine Keeper

Each magazine keeper must be experienced and familiar with the laws and general practices concerning the handling, care, use, and storage of explosives and detonators. The magazine keeper is responsible for maintaining a cleared area around each magazine. The magazine keeper will not be required to perform duties that will interfere with their duties as magazine keeper. If explosives are delivered daily from the manufacturer, the driver of the truck will serve as the magazine keeper.

3.4.5 Vibration Monitoring Specialty Firm

NOTE: This requirement is a new format from previous specifications. The firm is submitted for approval, having the appropriate experience and the firm must have on staff the Seismic Specialists and Seismograph Technicians, typically a firm is subcontracted by the Contractor and having multiple experienced people approved allows them to have flexibility on supporting the site work. The people coming to the project or responding to the work must be within the group approved but does not need to be
Retain the services of a vibration monitoring specialty firm that specializes in the prediction, monitoring and control of ground vibration and airblasts applicable for tunneling. The firm must have experience conducting installation of seismographs for vibration monitoring, communicating vibration and airblast results, and developing and maintaining a site attenuation curve. The firm must have on staff at least two Seismic Specialists that specialize in vibration monitoring and analysis. The firm must have on staff at least four Seismograph Technicians that have five years or more experience with seismograph installation and vibration monitoring. Submit resumes for all personnel and for the firm for approval citing, in additional to other pertinent data, experience, training, and education, at least 60 days prior to the commencement of blasting. The Seismograph Technicians must be persons capable of setting up the seismographs at designated locations, effectively recording the blast, and appropriately interpreting results. The Seismic Specialists must interpret the seismograph records to ensure that the seismic data must be effectively utilized in the control of the blasting operations with respect to the existing structures. The Seismograph Technicians must supervise the placement, operation and maintenance of the seismographs. The Seismic Specialists must conduct the airblast and particle velocity regression analysis as described in this Section. The Contracting Officer may require the Seismic Specialists and Seismograph Technicians to be present during the test blast program, production blasting, or both.

3.4.6 Structural Inspection/Evaluation Technician

NOTE: This may be required for shaft/portal blasting/excavation. Depending on proximity of the tunnel it may be needed to document condition of structures in proximity to the work. Designers will need to determine project requirements/needs.

NOTE: Five years should be considered the minimum experience requirement. Depending on the project it might be necessary to increase the minimum if there is a special concern (i.e., complex ground conditions) or sensitive structures, consult with USACE SME to help determine appropriate experience requirements.

Pre and Post Blast structural inspections must be performed by technicians with at least [five] years' experience in pre-blast and post blast surveys in the State of [______]. Submit a copy of the qualifications and certificates to the Contracting Officer.

3.5 TUNNELING PERSONNEL

3.5.1 Project Manager

Perform the work under the direct supervision of an experienced project manager with a minimum of 15 years (or as approved by the Contracting
Officer) in civil and heavy construction of which a minimum of five years' experience (or as approved by the Contracting Officer) is in tunnel construction, including a minimum of two projects, or as directed by the Contracting Officer. Substitutions for the project manager during the Contract period should not be made without prior written acceptance by the Contracting Officer. Substitute personnel must have the same qualifications specified herein for the position to be held.

3.5.2 Tunneling Superintendent and Supervisors

**************************************************************************
NOTE: The nomenclature of tunneling "supervisors" could vary based on geographic location. Foreman or Shifters are common terms for supervisor.
**************************************************************************

Submit for approval the qualifications. Perform the work under the direct supervision of an experienced tunneling superintendent and tunneling supervisors with experience requirements in accordance with Section [____], or as directed by the Contracting Officer. In addition, the Tunneling Superintendent's experience should include at least one project of a comparable size to this Project within the previous ten years (or as approved by the Contracting Officer). Duties of the tunneling superintendent and tunneling supervisors should include the requirements set forth in Section [____]. Substitutions for the tunnel superintendent during the Contract period should not be made without prior written acceptance by the Contracting Officer. Substitute personnel must have the same qualifications specified herein for the position to be held.

**************************************************************************
NOTE: Use qualification criteria requirements for drill and blast tunnel superintendents and supervisors as described below.
**************************************************************************

Tunneling superintendents and supervisors must have a minimum of 15 years of comparable experience in supervising the excavation and support of tunnels in similar ground using the same construction methods and must have all necessary licenses and permits required by local agencies or others having jurisdiction. Supervisors and superintendents must have experience on at least two projects with full face hard rock drill and blast tunnel excavation. Tunneling must not be performed unless the tunneling superintendent, supervisors, drillers and miners meeting the above experience requirements are on site and in actual supervision of this portion of the work.

The following duties are also part of the responsibilities of tunneling supervisors and superintendents:

a. Supervising excavation to ensure safety and quality of construction.

b. Meeting daily [at the start of each shift] with the Contracting Officer at the tunnel face to discuss ground conditions encountered and corresponding excavation and support requirements including additional initial support and keeping records thereof.

c. Devising and implementing additional initial support measures as required by ground conditions or as directed by the Contracting Officer, coordinating remedial measures when ground loss at mined
tunnel heading or instability of mined tunnel occurs, or appears likely to occur.

**************************************************************************
NOTE: It is standard practice to have drill and blast supervisors (in addition to Tunneling superintendents, Consultants, Blaster) in drill and blast tunnel construction. Nomenclature of these positions may vary depending on geographic area.
**************************************************************************

3.5.3 Drill and Blast Supervisors

Drill and blast supervisors must have a minimum of 10 years of experience in designing, supervising, loading, and firing of blasts for shaft or tunnel excavations, as applicable, and must have all licenses and permits required by state and local agencies and others having jurisdiction. Submit for approval the qualifications.

3.5.4 Geotechnical Engineer or Engineering Geologist

**************************************************************************
NOTE: A licensed professional must be used, that may vary on the state, since some do not license Engineering Geologists or Geotechnical Engineers. Tailor this section appropriately for your project needs.
**************************************************************************

Contractor's Geotechnical Engineer or Engineering Geologist must be a licensed Civil Engineer, Professional Geologist or Engineering Geologist in the State of [_____] with a minimum of 10 years' experience designing underground excavations and constructing such excavations, installing slope stabilization support, designing tunnel and underground support, evaluating rock mass properties, and groundwater conditions for large underground excavations.

The Geotechnical Engineer or Engineering Geologist must have worked on a minimum of two projects with full face hard rock drill and blast tunnel excavation. Tunneling must not be performed unless the Geotechnical Engineer or Engineering Geologist meeting the above experience requirements is on site and in actual supervision of this portion of the work. Submit for approval the qualifications.

The Contractor's Geotechnical Engineer or Engineering Geologist to provide inspection of excavations and evaluate rock and groundwater conditions during construction. The Geotechnical Engineer or Engineering Geologist must perform pre-construction and periodic site visits throughout construction to assess site conditions. The Geotechnical Engineer or Engineering Geologist must update the excavation, dewatering plans, geologic mapping, rock support mapping, and rock mass characterization as construction progresses to reflect changing conditions and changes in contract rock support based on in-situ conditions observed. The Geotechnical Engineer or Engineering Geologist must submit a written Monthly Excavation Status Report that informs the Contractor and Contracting Officer of the status of the excavation and provide an accounting of the Contractor's adherence to the plans and address present or potential problems or issues with ongoing construction. The Geotechnical Engineer or Engineering Geologist must be available to meet...
with the Contracting Officer and Government representatives throughout the Contract duration.

3.6 PRE-CONSTRUCTION DOCUMENTS

**************************************************************************
NOTE: The section below should be used when rock blasting excavation techniques are required.
**************************************************************************

3.6.1 Tunnel Excavation Plan

The following documents must be submitted to the Contracting Officer at least 60 days prior to commencing excavation:

a. A drawing of proposed tunneling operations. The drawing must include detailed working drawings of mobilization, proposed methods, and sequence of excavating and disposing of materials for each portion of the work, drilling and blasting, ventilation, illumination, installation of ground support including placing of shotcrete, steel sets and rock reinforcement, dimensions for excavation and types of equipment to be used.

b. A method statement of the proposed tunneling operations. This method statement must include details of the Contractors proposed tunnel-logging system such as the NGI "Q" system or Rock Mass Rating (RMR) system for determining ground support, as defined in the GBR, in concert with guidelines provided in Chapter 7 Design of Initial Support, EM 1110-2-2901. The report must present details of proposed methods and sequences of excavating and disposing of materials for each portion of the work, probing ahead of the tunnel face, pre-grouting, drilling, and blasting, ventilation, illumination, placing Shotcrete, steel sets and rock reinforcement, surveying, monitoring, and construction equipment to be used.

c. Catalog cuts of drilling, mucking and transportation equipment to be used.

d. Contingency Plan for the excavation and support of the tunnels in the event that monitoring of blasting operations in accordance with Section [_____] and monitoring of ground deformations in accordance with Section [_____] TUNNEL INSTRUMENTATION. Refer to EM 1110-2-1009 for further guidance on instrumentation. Indicate vibrations or movements exceeding threshold values defined in the drawings.

e. The following Optical Survey Target Details must be submitted to the Contracting Officer for approval:
   1. Manufacturer's address, phone number and name of the contact person.
   2. List and description of special modifications if there are changes.
   3. Description of instrument's operational principle.
   4. Plans or diagrams of instrument.
   5. Maintenance requirements.
6. Reading procedures, including sample data, and data processing calculations.

7. Complete data on all tests done to calibrate instruments or verify accuracy.

f. Working Drawings - The following must be submitted in accordance with the specifications:

1. Drawings and details of the initial support of all excavations.

2. Procedures for the control [, treatment ] and disposal of groundwater and water supplied for use during tunneling.

3. Methods and equipment for measuring and recording groundwater inflow. Methods, equipment, guidelines, and criteria for the use of fissure grouting must be proposed by the Contractor in method statement as required in Section 31 73 19 TUNNEL AND SHAFT GROUTING.

g. Instruments for monitoring air quality.

h. The following records of work accomplished must be submitted to the Contracting Officer within 24-hours of the installation of geotechnical instrumentation measuring tunnel convergence:

1. A list of instruments installed, including instrument identification numbers, calibration, elevation, orientation, stationing, offset, and initial coordinates as applicable to each instrument or installation.

2. Drawings showing details of installed instruments. All dimensions and materials used must be fully identified.

3. A statement describing the procedure used for the installation of each instrument.

i. Complete working drawings and system description of proposed equipment, materials, and method for handling water within the tunnel, measurement of pumped water, and disposal methods.

3.6.2 Blasting

3.6.2.1 Master Blasting Plan

Submit a Master Blasting Plan at least [_____] days prior to commencing drilling and blasting operations that includes a section called Blasting Safety Plan for review and approval. The Master Blasting Plan must contain the full details of the typical drilling and blasting patterns [and control for line drilling and for the presplit, buffer and production blasting, in the situation where controlled blasting is required for the project]. The Master Blasting Plan must contain the following information, at a minimum:

a. Typical plan and section views drawn to scale of proposed drill patterns including free face, burden, blasthole spacing, relief hole data, [burn, v, fan] cut design, blasthole diameters, blasthole angles, lift height and subdrilling depth, where allowed except for the blast that will carry the excavation to foundation grade where subdrilling is restricted as specified in the article SUBDRILLING. Base the typical
b. Typical loading diagrams for each blast design being proposed showing type and amount of explosives, primers, boosters, decks, initiators and location and depth of stemming in each blasthole.

c. Typical initiator sequence of blastholes including delay times and delay system.

d. Predicted vibration and airblast amplitudes, and the mathematical equations used to calculate them. The Contractor must monitor the results of the test blasts and with the seismic data collected can determine the site-specific ground vibration equations and the site specific airblast equations for the project. After the first 10 blasts the Individual Shot Plans must use the site-specific estimates at the 95 percent confidence level.

**************************************************************************
NOTE: Some states or counties may have specific vibration amplitude and airblast equations for specific locations.
**************************************************************************

e. Manufacturer's data sheets, including Safety Data Sheet (SDS), for all explosives, primers, and initiators to be employed. Provide copies of SDS for all explosives and detonators and define specific details about hazard communication programs for employees and specify where copies of SDS will be kept.

f. The Master Blasting Plan submittal is for quality control and record keeping purposes. Approval of the Master Blasting Plan does not relieve the Contractor of responsibility for the accuracy and adequacy of the plan when implemented in the field. Retain the professional services of a Blasting Consultant to assist with the blast designs included in the Master Blasting Plan.

g. Provide the Test Blast Plan and procedures for test blasting and modifying shot plans during production blasting in the Master Blasting Plan. Also provide the expected results from each shot including, but not limited to, the likely maximum peak particle velocity and airblast levels at the nearest inhabited structures.

h. Indicate that the Individual Shot Report design and blast record documents must provide all the data of each blast in sufficient detail.

i. Include samples of all completed submittal forms and diagrams (Pre-Blast Surveys, Individual Shot Plan, Drilling Logs, Individual Shot Reports, Individual Shot Vibration Monitoring Report, Results of Vibration and Airblast Monitoring, and Individual Shot Video).

j. Manufacturer's specifications on equipment to be used including but not limited to drills, air compressors, drill bits, drilling equipment specifications, manufacturer's literature of the drill rods, bits, casing.

k. Plans for construction sequencing line drilling, presplitting, blasting, and mucking operations to complete the rock excavation within the limitations of the peak particle velocities. Describe the change
in placement of the seismographs with regards to the progression of blasting and excavation. Provide the names of individuals responsible for the instruments, data retrieval, and analyses.

1. Single Sheet plan view showing location of all seismographs. This sheet must be amended and resubmitted whenever seismographs are moved.

m. Sample checklist that the Contractor will use to ensure that all required information is included in each blasting plan.

n. **Survey Control Plan:** Establish survey control as approved by the Contracting Officer for horizontal and vertical control of all line drill, presplit and production blasts. Assure that all blast holes are drilled on the specified pattern and at the location and the depths as detailed in the blast plan.

### 3.6.2.2 Blasting Safety Plan

In addition to the Master Blasting Plan, a Blasting Safety Plan must also be prepared, as specified, and outlined in **EM 385-1-1**, Section 29. All blasting work must be conducted in accordance with the requirements specified in **EM 385-1-1**.

**************************************************************************

**NOTE:** Minimum safe distance from blast point will vary with each project. Federal, state, and local regulations must be taken into consideration. Ensure NEPA, 408 permits, and environmental studies incorporated the blast safety radius.

**************************************************************************

The required minimum safe distance for shaft blasting or when blasting at portal is [_____] meters [_____] feet from the blast point. All the public[, including swimming and boating recreationists] must be excluded from the safety zone during blasts, including pre- and post-blast operations. The safety zone must be marked with an intrusion prevention barrier and high hazard warnings.[ Patrol by boat before and during blasting to prevent the recreational public from entering the safety zone.]

The Blasting Safety Plan must provide a complete description of the clearing and guarding procedures that must be employed to ensure personnel, staff, visitors, and all other persons are at safe locations during blasting. A Blasting Safety Plan simply stating: "all regulations will be followed" is not acceptable and will be rejected. This plan must be developed and signed by the Contractor's Blasting Specialist with input from the Contractor's Site Safety and Health Officer (SSHO) with the intent to show how the Contractor's procedures and methods meet or exceed applicable rules, regulations and standards established by the Regulatory Agencies, codes and professional societies, and specifications listed herein. This information must include detailed descriptions and maps, when appropriate of traffic control, visible warning signs or flags, audible warning signals, method of determining blast areas (all areas affected by potentially harmful blast effects), access blocking methods, guard placement and guard release procedures, primary initiation method, and the system by which the Blaster-In-Charge must communicate with site security guards or other appropriate site supervisory personnel. The Blasting Safety Plan must be in accordance with and include items required in the **EM 385-1-1**, Section 29, **29 CFR 1910.109**, **29 CFR 1926-SUBPART U**.
The Blasting Safety Plan must state that explosive distributor will be delivering explosives on the day of the planned operation and recovering unused explosives at the end of the day. In the event of lightning detected at 16 kilometers or less from the project site requirements for ceasing operations must be described. Provide a plan for controlling the temporary onsite storage of explosives or of securing an area of loaded holes until the threat has passed.

The Blasting Safety Plan must contain detailed descriptions of how and from where explosives will be transported and used at the various project work areas, and a map of the transportation route. The Blasting Safety Plan must explain how explosive transport vehicles will satisfy all applicable ATF, OSHA, Federal, State, and local regulations. The Blasting Safety Plan must also include the following:

a. Specific details about hazard communication programs for employees.

b. Equipment that will be used to monitor the approach of lightning in such event, the site evacuation and site security plans, and the criteria for determining if the site is safe to re-occupy.

c. Methods for preventing spills or losses of explosives, drilling fluids, oil, or other pollutants onto the ground during handling and blast hole loading operations. Include details of spill containment and contingency plans for quickly and effectively cleaning up spilled materials.

d. Method of safe and approved disposal of all explosive packaging materials.

e. Detailed contingency plans for detection and disposal of misfires resulting from cutoffs or other causes, hangfires, inadvertent initiator extraction, or accidental loss of downlines. A narrative describing in detail job steps, controls, and hazards associated with but not limited to hung or bridged powder, overloaded holes, cutoffs during placement of blast mats, failure of communication system during pre and post blasting protocols, recovery protocols for unexploded objects (UXO).

f. Misfire mitigation procedures, including but not limited to restrictions of entry, securing the area prior to investigating and inspection, additional safety measures, time-sequence of operations, and mitigation protocols.

g. Fire Prevention Plan details, including tobacco smoking policies, procedures and limitations for work involving open flames or sparks, description and location of firefighting equipment, and firefighting and evacuation plans.

h. Digital copies of a valid [state] blasting license for the Blaster-In-Charge, Blasting Specialist and all personnel required to have one.

i. State required certifications for the Contractor's explosives supplier's Federal, ATF Explosives license or permit.

j. Other required county or state permits required for explosive transportation, use and offsite storage.
k. Explosive transporters' commercial driver's licenses with HazMat endorsements.

l. When a misfire is declared the Blaster-In-Charge must wait 1 hour before inspecting site and provide proper safeguards for excluding employees from the danger zone except those necessary to do the work.

m. Submit updates, modifications, and additions to the Master Blasting Plan in an appropriate and timely manner.

n. Complete project team organization with duties, responsibilities and authorities clearly defined. This organizational outline must also include names, addresses, resumes, responsibilities, and qualifications of all personnel authorized to sign for, receive and use explosives on this Contract.

[ o. Traffic Control Plan.

]3.6.2.3 Pre-Blast Surveys

**************************************************************************
NOTE: During design consult with the stakeholders to determine what Pre-Blast Survey needs to be conducted and whether access is allowed, or special considerations are needed. This needs to be outlined in the specifications for a proper bid to be made for the scope. It is important to include the entire Project Development Team in design to ensure all project features of importance are documented before blasting. Lessons learned on one lock where blasters caused damage and it was not realized until well after the work was completed. The Government had no means to prove the damage occurred from blasting because there was no Pre-Blast Survey of the structures damaged.
**************************************************************************

Prior to the commencement of blasting, conduct a Pre-Blast Survey of any nearby buildings, structures and utilities within [_____] meters [_____] feet from the blast area that may potentially be at risk of blasting damage to document pre-existing conditions. The survey extent and method used must be acceptable to both the Contractor's insurance company and the Contracting Officer. Provide a letter from the insurance company to the Contracting Officer certifying that the proposed survey extent and methods are acceptable. The Contractor is responsible for damages or injuries resulting from blasting. Submit all Pre-Blast Surveys 30 calendar days before the start of blasting. There will be no blasting allowed until the Pre-Blast Survey is submitted and approved by the Contracting Officer. Provide owners of surveyed features a copy of their feature's Pre-Blast Survey results before or with the notice of blasting commencement. Notify owners and occupants of local buildings prior to the commencement of blasting. Perform the following when conducting Pre-Blast Surveys:

a. Provide methodology to be used in conducting the Pre-Blast Survey and listing of structures, determined from the survey to be sensitive, with reasons for these structures being sensitive.

b. Each structure must be documented (including high resolution photography and digital video) as to its construction, foundation type,
condition, and closest distance to excavation blasting. The general condition and all observable defects of each structure must be documented. This includes measurements of the defects.

c. The Commodity storage facilities that may be impacted by blasting must be addressed by the Contractor for safety and continued operation during the blasting program.

d. Freestanding structures (such as retaining walls) must be inspected on the exterior and on the interior as a room. All concrete walks, driveways, and structures must be inspected for cracks, level condition, holes, and defects.

e. Industrial structures, silo/elevators and special facilities, and office space must be described relative to their present conditions and tolerance to vibration. Besides the inspection of walls, columns and stairwells, the Contractor must survey the work areas and structures for distress.

f. An inspection of accessible structures must be made and a list of all structures, which could not be surveyed or refused to allow survey, must be completed. The dates of possible subsequent surveys and physical constraints prohibiting the survey must be documented. The requirement to perform Pre-Blast Surveys is not an indication of Right-of-Entry by the Contractor. Right-of-Entry associated with Pre-Blast Surveys, monitoring during blasting and Post-Blast surveys are the responsibility of the Contractor. In the event a property or properties identified as significant or intended to be included in the Surveys and monitoring are not included because access was denied, indicate this occurrence including the points of contact, dates contacted, and reasons provided for denial of access (if given.)

g. Certify that the survey was prepared prior to the start of blasting under this Contract. Submit a copy of the Pre-blast survey in conjunction with the Master Blasting Plan.

3.7 RECORD KEEPING

**************************************************************************
NOTE: The paragraph below applies to all excavation techniques.
**************************************************************************

Daily records should be maintained as excavation progresses and one copy of such records must be submitted to the Contracting Officer [before 12:00 PM] of the following workday. Keep such other records as deemed necessary. The following data must be included in the daily record for each tunnel heading:

a. Station of tunnel heading faces at start and end of each work shift.

   1. Daily As-built Survey: While tunnel excavation is in progress, submit to the Contracting Officer a daily as-built survey record showing line, level, and grade of centerline of tunnel at the invert relative to the theoretical alignment and profile and actual excavated tunnel cross-sections compared to the theoretical cross-sections shown on the Contract Drawings.

b. Type, quantity, and location of initial support and additional initial
support installed. Geologic mapping and excavation records that comply with EM 1110-1-1804 Appendix B and C.

c. Evaluation of in-tunnel monitoring results.

d. Probe hole records in accordance with paragraph DRILLING LOGS of this Section.

e. Number of workers employed per shift for each workday categorized by union trade, idle equipment, active equipment, and site visitors.

1. Air quality and gas monitoring data. Line and grade survey reports.

2. Water inflows, if encountered, with locations and estimates of rates.

3. Overbreak.

4. Other geological and unusual features such as faults, shears, crushed or soft zones, and raveling areas.

3.7.1 Individual Shot Plan

The Blasting Plan must be consistent with the general concepts, designs and layouts shown in the approved Master Blasting Plan. The number of rows of blastholes and the number of blastholes per row can be changed from one individual shot plan to the next. Provide reasons and technical justification for all significant changes from the Master Blasting Plan.

Submit a Blasting Plan for each blast at least [24] hours prior to the planned initiation of drilling. The results of the previous blast are to be jointly evaluated by the Contractor and Contracting Officer prior to the submission of the Individual Shot Plan. The Individual Shot Plan must contain but be not limited to the following:

a. Plan view, and at least two sectional views drawn to scale, of the shot pattern showing blasthole locations, inclinations and designations;

b. Individual blasthole depths, diameters, blasthole spacings, burden, depth intervals of stemming and depth of subdrill;

c. Type of shot, i.e. test, production, pre-split, line drilling or buffer and shot number;

d. Orientation and elevation of the collar and bottom of all blast holes;

e. Total volume of blasted material in cubic meters cubic yards;

f. Description of type of blast and indication if blast is on final slopes or invert;

g. Amount, type, diameter and depth of explosives, stemming and delay in each hole, and amount, type, and location of boosters and centering devices and the lift elevation;

h. Plan view of blasthole shot pattern showing in-hole and surface delays and firing times of each blasthole or decked charge;

i. Anticipated time and date of blast;
j. Survey coordinates using State Plane coordinate system and, if appropriate, a local coordinate system;

k. Significant geologic features, and techniques planned for mitigating their influence upon results must be included in plan and section with appropriate elevations;

l. Estimated/anticipated peak particle velocities and maximum peak airblast predictions at seismographs located at protected structures using site specific data and regression analysis and the accurate distances from the blast to seismographs;

m. Name of Contractor;

n. Name, signature, and license number of the Blaster-In-Charge;

o. The maximum charge weight per delay, pattern and sequence of delays, and firing times for the blast;

p. Type of detonators, initiation and down hole lines;

q. Powder factors both in charge weight per cubic yard of material shot and in charge weight per meter per foot of total drillhole depth;

r. An elevation sketch of a typically loaded hole depicting each hole pattern, top of overburden elevation, top of rock elevation, bottom of hole elevation and diameter of hole, sub-drilling, decking charges, locations of explosives and stemming, and the locations of primers, boosters.

s. The location of the blast area on a scale plan map of the project indicating the location of the shot, and the distance and directional relationship between all seismic equipment and the nearest structure subject to damage using a scaled distance measured in a horizontal line from the blast site to the nearest building, structure, or facility.

t. A minimum of [_____] high resolution photos, taken with a camera with a resolution of at least twelve megapixels, of the entire blast area, preferably from above, of surface and open face, tunnel working face, tunnel crown, tunnel periphery, tunnel floor; of the shot and surrounding rock to document conditions prior to the shot.

u. Blastholes must not be drilled until the Individual Shot Plan for them is approved. Evaluate problems or impediments of the prior shot and implement solutions for those issues with the next Individual Shot Plan. Provide the Individual Shot Plan to the Contracting Officer electronically. The Contracting Officer will review the plan and send comments to the Contractor within 24 hours of receiving the plan if the plan is submitted between Monday and not later than close of business Thursday.

v. Include a tabular listing by hole in the ascending time order of delays by the describing: row and number within the row of the shot hole, total delay time, the total charge weight of explosive materials for the entire hole, top of sound rock elevation, bottom hole elevation, stemming elevations, and detonator, primer and booster elevations in the hole, by hole in the ascending total delay time order of delays by describing: row and number within the row of the shot; and for each
3.7.2 Drilling Logs

The drillers are required to keep precise drilling logs on each blasthole to show the depth of the geological features. At minimum, each drilling log must include:

a. Blast number;

b. Blasthole designation and location station number, bench number and type of blast (production, presplit, buffer[, and other types]);

c. Blasthole depth, inclination and diameter;

d. Elevation of top of blasthole;

e. Subdrill depth as permitted in the article SUBDRILLING;

f. Depth(s) of geologic structural features, e.g., voids, gouge or mud seams, soft weathered or altered zones, rusty intervals, changes in rock chip color, and other features encountered in the blasthole pertinent to loading the hole;

g. Relative penetration rates;

h. Start and end times of drilling;

i. List blasthole misalignment; and

j. Soft seams within the rock and sudden feed pressure changes on the drill;

k. If qualitative descriptors are used (e.g., soft, moderately hard, hard,
UFGS

very hard, decomposed, highly weathered, moderately weathered, slightly weathered, unweathered), ensure consistency between drill operators in logging using these terms. Blasting Specialist and Blaster-In-Charge must ensure drillers are using consistent terminology between drillers. [Log soil and rock in accordance with ASTM D2487, ASTM D5434, ASTM D6032/D6032M.] Submit an example of the Drilling Logs with the Master Blasting Plan. Copies, both hard and electronic PDFs, of these drilling logs must be provided to the Contracting Officer at least 24 hours prior to loading blastholes. The drilling logs must be used to determine the proper design and loading of blastholes and for locating the depths for use of stemming decks across intersected geological features to protect against blowout, flyrock and unusual or hazardous blasting effects.

**************************************************************************

NOTE: The paragraph below may be necessary where preventing subdrilling and foundation damage is critical.

**************************************************************************

[ Survey the elevation at the collar of each production hole in the final blast to foundation grade to ensure that the production blastholes are not subdrilled below final foundation grade, except as permitted in article SUBDRILLING. The survey must be included in the Individual Shot Plan.]

3.7.3 Individual Shot Reports

**************************************************************************

NOTE: The Contractor must plan on multiple tunnel headings so that production can be maintained on schedule. The GBR may include recommendations as to how many headings can be expected in the project.

**************************************************************************

As a minimum, the Individual Shot Report must be the same form used in the Individual Shot Plan but provide all "as-built" information required for the blast plan. Furthermore, the Individual Shot Report must better describe part of the blasting operation that wasn't adequately described by the Individual Shot Plan including information on misfires, observed field conditions, and information how the Blaster-In-Charge compensated for compromising field conditions, such as increased stemming amounts, or stemming decks where voids, cracks, spalls or mud seams were identified and resolved. The Blasting Specialist is responsible for recording all explosives loaded in the blasthole and for accurate documentation of daily blasting activities. The Individual Shot Reports are for quality control and record keeping. Review of, and comments on, the blast reports by the Contracting Officer will not relieve the Contractor of responsibility for the accuracy and adequacy of the blast design. Submit the Individual Shot Report no later than 24 hours after the blast. No additional blast will be drilled or loaded in the immediate area of the completed blast until the previous day's Individual Shot Report is submitted to the Contracting Officer. The report must include at minimum the following information:

a. Blast number (i.e., R-L3-PS1);

b. Date and specific time the blast was initiated;

c. Blasthole designations, locations;
d. Amount, type and depth of explosives, decking, stemming, and delay in each hole;

e. Plan and section views, drawn to scale, of drill pattern including free face, burden, blasthole spacing, blasthole diameters, blasthole angles and azimuths, blasthole number, lift height, and subdrill depth. Show in-hole and surface delays, as well as actual firing times of each blasthole or decked charge. Use different symbols to distinguish the production, buffer, presplit and line-drilled blastholes. Include a north arrow, stationing, and scale on each plan view. Label the direction of the sections on the sections. Include section parallel to, and perpendicular to the blasthole rows. Show final grade and slope lines as appropriate in the sections. Show the location of the two video recorders on the plan in relation to the blast.

f. Drilling logs for presplit, line, buffer, and production blastholes. Each drill hole must be logged by the driller to provide additional information to the Blaster-In-Charge during loading operations. Drilling Logs must contain information pertinent to the rock characteristics and blast operations. At the minimum, drill logs must contain geological information on pertinent geologic structure, soft or weathered zones, voids, penetration rate changes, and driller's notes.

g. Loading diagram showing type, diameter, amount and depth interval of explosive, primers, initiators and location, depth, and type of stemming for each blasthole. Show the charge weight of each type of explosive and the total explosive load per delay or per hole.

h. Diagrams showing the delay system in the initiation sequence in each blasthole and the location and delay time of all surface delays of each blast. Indicate which blastholes are firing with a delay of less than 8 milliseconds.

i. Trade names and sizes of all explosives, primers, and initiators to be employed.

k. A description of all personal injuries and property damage caused by the blast; when the measured maximum peak particle velocity or airblast exceeded by 10 percent the anticipated values from the Blasting Plan; and, all problems with the Warning System and problematic results of the blast, such as overbreak or large fragmentation, or with the shot pattern, such as misfires.

l. The vibration and airblast report described in paragraph Vibration and Airblast Monitoring. Include a comparison of predicted and actual measured values.

m. Signature of the Blasting Specialist specifying that the Blasting Specialist has reviewed the Individual Shot Report for accuracy and completeness.

n. Signature of the Blaster-In-Charge.

o. Note if mats are used [or required by the Contracting Officer ]then list the type of blasting mats or other protective covering used.

p. A brief weather description at or near the time of the detonation such
as cloudy, clear, partly cloudy, and foggy, with approximate wind
direction and velocity, and temperature.

q. Updated or "as-built" Plan drawings depicting the blast hole pattern
and the delay pattern employed as well as pounds of explosives
utilized, hazard incidents, and blast holes not loaded.

r. Copies of drilling records and originals of the blast monitoring data.

s. A plan view map [of each bench ]showing the location of each completed
blast.

**************************************************************************
NOTE: A pre-blast photograph may be required for
some project, if so then including them with the
post-blast photographs in the shot report may be
required.
**************************************************************************

t. Include photos, after the shot, taken from the same locations and at
the same resolution as the blasting plan photos. Include the blasting
plan photos in the shot report.

u. Include an updated as-built tabular listing by hole in the ascending
time order of delays by the describing: row and number within the row
of the shot hole, total delay time, the total charge weight of
explosive materials for the entire hole, top of sound rock elevation,
bottom hole elevation, stemming elevations, and detonator, primer and
booster elevations in the hole, by hole in the ascending total delay
time order of delays by describing: row and number within the row of
the shot; and for each seismic monitoring location the closest
approach, the square-root scaled distance, the cube-root scaled
distance, and the estimated PPV and airblast overpressure.

v. Include two log-peak particle velocity versus square root scaled
distance as per RI8507 diagrams for each seismograph.[ One diagram
including all shots.][ The second including only data from the last 10
shots.]

Include seismic records with peak displacement, velocity, and
accelerations at their respective frequencies. Site curve modification
may be required to ensure that vibration levels[ structure of
interest][ are] acceptable.

If a recorded seismic value appears anomalous, the Contracting Officer
may request that the vibrations monitoring specialist interpret all the
collected seismic records from the seismographs for that blast and
provide an explanation of the anomalous readings. Anomalous readings
include, but are not limited to, unusually high or low particle
velocities, failure of a seismograph to trigger, or atypical wave forms
on the paper record. No additional blasting will be allowed until the
issue is resolved to the Contracting Officer's satisfaction.

w. Signatures of the Blasting Specialist and Blaster-In-Charge will be
considered as proof that the shot was laid out, drilled, loaded, and
wired as designed.[ Proof of the Blasting Specialist and Blaster-in
Charge's qualification must include remaining below the allowable peak
particle velocities at all structures.][ Inability to remain below the
allowable vibration levels may be cause for dismissal of either or both
The Blasting Specialist must oversee all loading operations and collect and keep accurate records of the information required for each Individual Shot Report. Submit an example of an Individual Shot Report to the Contracting Officer for approval at least 30 days before commencement of blasting. Failure to submit satisfactory Individual Shot Reports must result in suspension of additional drilling and blasting until the Contractor complies with this requirement. The Blasting Specialist will make sure that the drilling logs are used by the blaster when blastholes are loaded to prevent overloading in soft or weak rock in the borehole. The Blasting Consultant must develop a checklist of tasks that must be completed and checked off by the Blasting Specialist for each blast. Complete the tasks in an orderly fashion before a blast is fired. Submit the draft checklist for approval. Submit the completed and signed daily checklist with the Individual Shot Report.

Supplement the Individual Shot Reports with the original digital copy of the printed results of vibration and airblast monitoring showing peak readings and frequencies for each blast to the Contracting Officer. This submittal must also include the distance from the blast to the seismograph in meters feet as well as the maximum kilograms pounds of explosive per delay. The seismograph locations must be clearly marked and located on a map in the blast report. Supplement the Individual Shot Report with the original, handwritten, field notes showing field changes on the approved blasting plan.

3.7.4 Daily Explosive Material Consumption

Accurate daily records must be kept and account for each piece of explosive, detonator, and equipment from the time of delivery at the site until its discharge and used. No explosives must be accepted until it is plainly labeled and delivered as new stock in sound condition. Dates of manufacture and lot numbers must be recorded for all explosives delivered to the site. Temporary containers for explosives must be approved in advance by the Contracting Officer. Remaining or unused explosives must be inventoried each day and discrepancies that would indicate a theft or loss of explosive material must be reported immediately as specified in Paragraph Report of Loss.

3.7.5 Report of Loss

Should a loss or theft of explosives occur, all circumstances and details of the loss or theft must be immediately reported to the nearest office of the Bureau of Alcohol, Tobacco, Firearms and Explosives and to the local law enforcement authorities and the Contracting Officer. The Blasting Specialist must prepare a memorandum describing and explaining problems in the accounting of explosives used.

3.7.6 Individual Shot Videos

**************************************************************************
NOTE: Video size can be a point of discussion, larger files come out of the new high quality 1080 HD and 4K videos. It may be necessary to require a frames/second or use of HD/4K videos. It is likely technology will change faster than this guide specification. This paragraph can be updated by project. The use of sFTP allows for the larger
files.
**************************************************************************
When blasting at portal(s) and shafts, record each blast with high resolution digital video cameras from two designated locations, approximately perpendicular to one another, that provide side, front and rear views of the blast and area above it. The Contractor should anticipate at least one designated video camera location when blasting underground for each shot. The video images must not contain other text than the shot number, date, and time. Include metadata consisting of the blast ID, date, and time of the blast. Index the two video recordings to properly identify each blast. Submit the proposed locations of the two video recorders on a map with the Individual Shot Plan for approval. Furnish electronic file copies of video recordings on the sFTP within 24 hours of a blast. If the Contracting Officer requests that a copy of the video be submitted earlier, then deliver a copy within one hour of the request. Maintain a digital video library of all blasts. All drilling and blasting activities must cease after the 24 hours from the previous blast if the video recordings of the previous blast are not furnished to the Contracting Officer.

3.7.7 Post-Blast Surveys
**************************************************************************
NOTE: Pre- and Post-Blast Inspections and the Structural Inspection/Evaluation Specialist would only be required if there are structures or facilities requiring such inspections. Eliminate the paragraphs referencing Pre- and Post-Blast Inspections and the Structural Inspection/Evaluation Specialist if the project does not have a requirement for these inspections.
**************************************************************************
Post-blast surveys must be conducted at locations, where a reasonable notice of damage from blasting has been provided. Post-blast surveys will be conducted by, or under the supervision of, the Structural Inspection/Evaluation Specialist, who will also sign and date each survey. The survey extent and method used must be acceptable to both the Contractor's insurance company and the Contracting Officer. The post-blast surveys must be conducted within a week of the notice of damage from blasting. The Contractor is responsible for damages or injuries resulting from blasting. Submit a copy of all post-blast surveys within two business days of the on-premises surveys to both the structure's owner and the Contracting Officer.

3.7.8 Probe Hole Drilling
**************************************************************************
NOTE: The design team must evaluate expected ground conditions including but not limited to: zones of intensely jointed rock mass due to faults, shears, etc., rock types, weathering profiles, groundwater regime, other pertinent geological information available from the site investigations to determine the adequate length of probing ahead of tunnel. This information must be included in the Geotechnical Baseline Report as a recommendation.
Insert gallons per minute (gpm) based upon results of packer tests performed, or other estimates of water inflow. In lieu of available project data, assume nominal amount of water on the order of 15–20 gpm. The inflow information must be included in the GBR and/or GDR.

The number of supplemental probe holes expected for the project must be determined during design phase and clearly listed as a recommendation in the GBR.

Typically these probe holes are incidental to the tunnel excavation pay item (cu.f. or cu.m), designer should ensure this is stated in the specification or include a CLIN for payment.

**************************************************************************

a. The Contracting Officer must be informed 24 hours prior to probing activities in the tunnel so that the Government may be present during the probe hole drilling. The results of probing ahead along with proposed amendments to excavation profile, sequence or support must be submitted to the Contracting Officer; immediately upon completion of the probing.

b. Probe holes must be drilled to provide advance warning of abnormal inflow of water or degradation in rock quality, which might occur. Probe hole locations and extent of hole drilling is shown on the Drawings and will be modified as needed in the field as approved by the Contracting Officer. The Contracting Officer may direct supplemental probe holes to be drilled based on ground conditions. Exploratory probe holes may also be required to explore the nature of subsurface formations or following grout operations to investigate the effectiveness of the grouting program.

c. If the inflow of water from the probe hole exceeds [_____] gpm, supplemental probe holes will be required, at the direction of the Contracting Officer, to probe the extent and character of the ground, and to drain the water, or for use as grout holes. If directed by the Contracting Officer, grout the face of the tunnel heading in accordance with Section 31 73 19 TUNNEL AND SHAFT GROUTING.

d. Probe holes must be drilled to a minimum of [_____] meters [_____] feet measured along the drilled hole and will overlap to maintain at least one hole a minimum of [_____] meters [_____] feet ahead of the plane of the tunnel face at all times. The Contracting Officer may reduce the drilling length based on ground conditions.

e. During probe hole drilling, the Contractor should stop at a minimum of each 3 meters 10 feet of hole advance to measure water flow and water pressure. The Contracting Officer waive this requirement on a hole-by-hole basis if little or no water is encountered.

f. Probe hole must be terminated [_____] meters [_____] feet beyond the first groutable feature, as determined by the Contracting Officer.

g. Probe holes must be sealed by grouting through a packer close to the first water producing feature to prevent water flows into the tunnel while the tunnel face is advanced.
h. If, in sections of the tunnel excavation, drilling is directed by the Contracting Officer for supplemental probe holes, other operations should be suspended or modified as may be necessary to permit such drilling; and the Contractor will not be entitled to compensation for delay nor will the Contractor be entitled to extension of time, such stopping of work being deemed an ordinary delay to be expected during construction operations.

**************************************************************************
NOTE: A conservative estimate for the number of supplemental probe holes should be defined in the GBR. Define how these supplemental probe holes are to be paid.
**************************************************************************

i. Follow format requirement in paragraph DRILLING LOGS.

3.8 BLAST EFFECTS MONITORING

**************************************************************************
NOTE: The vibration and air blast monitoring are covered under Section 31 23 06.00 BLASTING - SURFACE; it must be included when conducting blasting work.
**************************************************************************

3.8.1 Convergence Monitoring Construction Requirements

3.8.1.1 General Tolerance

The instruments must be installed as close as practicable to the locations [shown on the Drawings][or as established in the field by the Contracting Officer]. The Contractor must submit to the Contracting Officer for consent, all final instrument locations prior to their installation. Where instruments are shown on the contract drawings to be installed in clusters, the Contractor must install all instruments shown within a [_____] mm [_____] in. radius

3.8.1.2 Availability of Data

The Contractor must monitor all instruments and provide data obtained to the Contracting Officer within a maximum of [24 hours] after taking the readings unless otherwise directed by the Contracting Officer.

Instrument monitoring data must not be disclosed to third parties and must not be published without the prior written approval of the Contracting Officer.

3.8.1.3 Instrument Installation Sequence

Optical survey targets must be installed following scaling and within [_____] meters [_____] feet of the advancing tunnel face.

3.8.1.4 Installation Requirements

The Contractor must assign an instrument identification number to each instrument. Each instrument identification number must be permanently affixed to a suitable material, such as the stamping of a brass tag. The
tag must be attached to the instrument or must be secured at the instrument location.

Optical survey targets must be installed as shown on the drawings.

3.8.1.5 Protection of Instruments

Full responsibility must be borne by the Contractor for protecting the instruments from damage caused by construction operations. Damaged instruments must be promptly replaced or repaired, as directed by the Contracting Officer, at the expense of the Contractor.

The instruments must be clearly marked and protected to avoid being covered by shotcrete. Access must be maintained to permit reading of instruments. Shotcrete applied around instruments must be removed immediately.

3.8.2 Rock Damage Control

The rock formations are known to contain geological features including variable weathering, alteration, fracturing and shearing, voids, weathered joints, and gouge seams. Rock cores recovered during drilling investigations disclose the site's geological conditions and are available for review by the Contractor. The Contractor is encouraged to review the [Geotechnical Data Report, Geotechnical Baseline Report, other reports provided with bid documents or made accessible], the drill core, drill core photographs, cut slopes, and all geotechnical and structural information available before planning and conducting blasting operations.

Use stemming decks across weak or open geological features to confine the energy into the hard rock and minimize explosive gas penetration into these features. No rock mass damage, uplift or shifting or significant overbreak will be tolerated. Control drilling accuracy and delay timing to provide proper relief toward the free face away from final rock slopes. Blasting damage or breakage into the excavation walls will be mitigated at the Contractor's expense. Damage is defined as the loosening of rock beyond the B-line, opening of joints in the final wall and rock block displacement in the final wall. If damage occurs to the final wall that requires remediation, it must be the responsibility of the Contractor to prove that the blasting method employed did not cause the damage.

3.9 TEST BLASTING

**************************************************************************
NOTE: The test blasting may be highly specific for the project site. The designer may have a way to carry out the test blasting to have the Contractor demonstrate satisfactory results. Typically, the main reason for test blasting is to gain understanding of how the blasting on the site causes vibrations/air blast on monitored structures, develop a site attenuation curve to design future blasts with vibration in mind. The other is to demonstrate results, line drilling and presplitting that meets the specifications and no damage to final faces and foundation grade when blasting at portals or final tunnel or shaft periphery when blasting underground. Typically, the test blasting occurs in an area where there is room for failure, if a test presplit causes significant back break it won't be.
to a finished face and can be removed

The following is typical test blasting language.

**************************************************************************
Submit the Test-Blast Plan for review and approval. Approval of the revised plan will not relieve the Contractor of their responsibility to produce safe and satisfactory results as set forth by these specifications.

Prior to commencing full-scale blasting operations in a different rock type, weathering grade or new bench elevation, demonstrate the adequacy and effectiveness of the proposed blasting plan by drilling, blasting, and excavating short test sections, not exceeding [15.3] meters [50] feet in length, to determine which combination of method, hole spacing, and explosive loads produces the proper split. If more than one presplit design is tested in one test blast, each presplit design section must be at least [6] meters [20] feet in length along the surface.

The first opening blast starting from a level plane that has only vertical relief (i.e., a sinking cut), must not be used as the production test blast. However, its results must be considered when designing the test blasts. The opening blast must be excavated to full depth if possible before drilling the blastholes for the test blast. The test blast must incorporate the planned methods of presplitting and must be near the center of the excavation and at least [4.5] meters [15] feet away from the final excavation walls [or invert]. The Contracting Officer has the option to adjust the location of the test blast areas to optimize for geology. Anticipate blasting up to 10 test sections with at least one test at each different geologic condition and underground blast design. The location of the test blast section must be approved in advance. The Contracting Officer may direct the Contractor to use test section lengths less than [15.2] meters [50] feet if field conditions warrant.

Unless otherwise directed, begin the presplit test blast with presplit holes spaced at [61] centimeters [24] inches center to center. Requirements for presplit and production blasting operations are covered elsewhere in this specification but apply to test blasts.

Do not drill ahead of the test shot area until the test section has been as fully excavated as possible and the results have been evaluated by the Contracting Officer. If the results of the test blast(s) are unsatisfactory, in the opinion of the Contracting Officer, the Contractor's Blasting Consultant must revise the blast design as necessary to achieve the specified results. Unsatisfactory test blast results include poor fragmentation beyond the indicated lines and grade, extensive overbreak, flyrock, ground vibration, airblast or violation of other requirements or these specifications. All costs incurred by the Contractor in adopting revised blasting methods necessary to produce acceptable test blast results will be borne by the Contractor.

If during the progress of the work, the methods of drilling and blasting do not produce the desired result of an undamaged rock slope or tunnel design excavation lines within the specified tolerances, perform additional test sections by drilling, blasting, and excavating short sections, not exceeding [15.2] meters [50] feet in length, until a technique is developed that produces the desired results. No additional compensation will be made for the additional test sections.

At the conclusion of the test blast program, produce a Post-Test Blast

SECTION 31 23 00.00 Page 59
Evaluation Report which examines all reports, surveys, test data, and other pertinent information and conclusions reached. Submit a Test Blast Evaluation Report prepared by the Blasting Consultant and Blasting Specialist after testing blasting is completed.

3.10 BLASTHOLE DRILLING - PORTALS AND SHAFTS

Survey the elevation at the collar of each production hole in the final blast to foundation grade when at the portal excavation or to depth of advance when blasting in the tunnel to ensure that the production blastholes are not subdrilled below final foundation grade. The survey must be included in the Individual Shot Plan and must not be changed without prior approval from the Contracting Officer. Drill production blastholes according to the patterns in the approved Individual Shot Plan. Prior to commencement of drilling of production blastholes, all holes must be located by survey and clearly marked and numbered. Drill the production blastholes within two blasthole diameters of the marked collar location. The blastholes must have no more than a plus or minus [_____] meter foot horizontal tolerance at the bottom. If holes are drilled outside of these tolerances, except for geologic reasons, fill the holes with crushed stone or neat grout and re-drill them at the approved location as directed by the Contracting Officer at no additional expense to the Government.

After drilling of blastholes at the portals, place approved, reusable plastic blasthole markers in each hole to identify all blasthole locations and keep material from falling into the holes. Check, measure and record the depth of all blastholes as soon as the drill is retracted from the blasthole. If a blasthole has become plugged or is unable to be fully loaded, re-drill or clean out those holes with air prior to commencement of loading operations. Check and measure the depth of all blastholes in a shot to ensure each blasthole is open to the original drilled depth prior to loading of holes. If a blasthole is found not to be open to the drilled depth, re-drill the blast hole to the proper depth at the Contractor’s expense. If holes are too deep, fill the holes to the proper depth with crushed stone. When drilling and blasting at the portal areas, blasthole loading and drilling may be ongoing concurrently in a shot area; nonetheless, drilling must be separated from loaded holes by a distance equivalent to at least the depth of the loaded hole but in no case less than 15.2 meters 50 feet.

When blasting for portal excavation, the Contracting Officer may require inclined boreholes to reduce toe burdens and backbreak.

3.11 PRODUCTION BLASTING

The Contractor must provide a detailed narrative for the proposed sequence of production blasting for the project in the Master Blasting Plan, to be evaluated and approved by the Contracting Officer. The proposed sequence must be tailored primarily towards conducting a safe blasting operation and overall responsible, prudent, and professional blast design in efforts to keep overbreak, flyrock, vibration and airblast levels to a minimum. If in the opinion of the Contracting Officer satisfactory results in the production blasts are not being produced, the Contracting Officer reserves the right to require changes in the blast design which could include variables such as burden, spacing, bench height, timing sequence and delays, subdrill depths, explosive loads, detonators, blast matting and the use of air decks or stemming in borehole bottoms. Such required revisions will be at no additional cost to the Government.
NOTE: The proposed language below can be used as guidance when both presplit, and production blasting are used in the project. THE PRODUCTION BLASTING SECTION WILL BE HEAVILY TAILORED FOR THE PROJECT. THIS IS GENERAL TEXT THAT CAN BE ADJUSTED.

The drilling of presplit and production blastholes must be done one pattern at a time. Advanced drilling of adjacent presplit or production blastholes will not be permitted. The presplit wall conditions must be evaluated after each blast by both the Contractor and the Contracting Officer before the adjacent presplit blasting plan can be approved or drilled whenever possible.

The sequence of Production and Presplit blasting for a single blast must be as follows:

1. Submit an individual shot plan.
2. Individual shot plan approved, or revisions requested before approval.
3. Conduct drilling and submit Drilling Logs to Contracting Officer and Blaster-In-Charge.
5. Conduct rock removal, scaling, and rock reinforcement Joint Evaluation of results by Contractor and Contracting Officer.
6. Submit an Individual Shot Plan for the subsequent blast in that work area.
7. Prepare enough planned blasting areas in advance to maintain the project schedule.

The presplit wall conditions must be evaluated by the Contractor and the Contracting Officer after the Contractor exposes a minimum of [2.4] meters [8] feet (vertical) of the wall. If [2.4] meters [8] feet of exposure is not sufficient to determine the condition of the presplit wall, reinforce the exposed wall as necessary, then expose a minimum additional [2.4] meters [8] feet (vertical) of wall. Repeat this downward to the toe of the presplit wall or until the Contracting Officer can determine if the presplit wall condition is adequate before approving the Individual Shot Plan for the adjacent presplit blast. Evaluate the effects of each production blast on the presplit and line drilled walls before submitting a blasting plan for the next blast.

The drilling tolerance must be evaluated and if drill tolerance exceeded the allowable tolerance then benches will be reduced in height to where the drilling tolerance was obtained on the subsequent blasts.
3.12 SUBDRILLING

NOTE: Subdrilling is typically not utilized in underground blasting, however it may be a component required for shaft excavations for connecting surface blasting operations with the underground environment. If Section 31 23 06.00 BLASTING - SURFACE is being used, tailor that specification for the project or include language here.

3.13 PRESPLITTING

NOTE: Presplitting is typically not utilized in underground blasting, however it may be a component required for shaft or portal excavation for surface blasting operations. If Section 31 23 06.00 BLASTING - SURFACE is being used, tailor that specification for the project or include language here. Precision presplitting may also be utilized in these situations. It is a form of presplitting with closer spaced holes with an even lighter explosive load.

3.14 STEMMING

NOTE: Stemming may be used in shaft sinking operations using controlled blasting methods. Stemming is not typically used in tunnel heading advance. Depending on the geology of the project site this paragraph should be tailored to the project, for example in places with karst geologic conditions a more detailed procedure should be specified, or contractor required to submit a procedure for dealing with larger voids.

Variations in rock hardness, structure, and other geological conditions encountered at depth will require the Contractor to stem the blast holes through soft weak areas, shears, open joints, and voids; therefore, close attention will be taken to classify the rock while drilling the blast holes. Where necessary, holes will be stemmed with dry, angular, well-graded crushed stone from .3-cm to 1-cm 1/8-inch to 3/8-inches in diameter without fines. The Blasting Consultant may submit a written, signed request to use drill cuttings for applications such as in presplit blastholes, must be submitted to the Contracting Officer for approval. Wet holes must not be stemmed with drill cuttings. No separate payment is made for stemming.

NOTE: Include tolerance for each proposed structure
3.15 REQUIRED MUCKING

Required mucking operations should adhere to the details of the Muck Handling Plan. Prior to mucking operations, the Blaster-In-Charge and Tunneling Superintendent should perform an explosive safety check to ensure that all explosive materials have been detonated with the last tunnel heading advance. Undetonated explosive materials should be disposed of in advance of mucking operations in accordance with 29 CFR 1926-SUBPART U.

Muck and scaling follow each shot after firing for inspection of the heading, bottom of the shot lift, or foundation. Drilling and loading for the next shot must not be allowed before the required mucking of the previous shot. This requirement may be waived temporarily when in the opinion of the Contracting Officer, the Contractor's blasting is satisfactory (i.e., no backbreak, overbreak, vibration cracking, exceedance of vibration or airblast thresholds).

NOTE: The following paragraph should be tailored for the specific project, the GBR will provide recommendation on this distance. The Contracting Officer reserves the right to require additional ground support beyond that systematically required in the drawings.

Notwithstanding this requirement, the face must fully be dug out after every shot to a distance not less than [_____] meters [_____] feet prior to drilling and loading the next shot to allow inspection and evaluation of the shot face and allow for adjustments to the blast design for adjacent shots. Required mucking after each shot must be reinstated, when in the opinion of the Contracting Officer blasting is unsatisfactory. Excavation support deemed necessary by the Contractor[ or Contracting Officer] for the safety of personnel in the excavation will be installed as the excavation proceeds. Blasting of the next heading advance or lift will not be permitted until the excavation has been accepted by the Contracting Officer.

The mucking system(s) must not restrict other operations including handling and erecting of initial support system materials.

For rail mucking systems, a track with ties and ballast or direct fixation system must be maintained for safe operation of trains. The head of the rails must not be submerged in water or covered with tunnel muck or other debris. Upon completion of excavation of the tunnel, remove all such trackwork prior to placement of final lining.

Submit for review at least [sixty (60)][_____] days before the start of tunnel excavation the Muck Handling Plan, the methods, procedures, and details of the proposed mucking system. Submit for review the manufacturer's information for the proposed equipment including, but not limited to, specifications, drawings, details, maintenance procedures and requirements, operating procedures, and such other information as may be requested by the Contracting Officer.
3.16 SCALING

**************************************************************************
NOTE: Typically, a level of scaling is required for each project to remove loose, unstable rock prior to mucking operations or prior to required bolting application or other methods of stabilization before carrying out additional excavation operations
**************************************************************************

A program of frequent inspection and scaling must be maintained in all portions of the tunnel. Immediately after each blast, the roof and walls of rock excavations must be inspected by experienced and suitably equipped scalers who must dislodge and scale down all loose and unstable rock. Scale loose and unstable or unsafe appearing material remaining on the tunnel periphery or rock slopes at the portal areas as the excavation proceeds. Perform scaling immediately after each blasting round. The removal must be accomplished by compressed air or water jetting, pry bars, rock picks, hoe-ramming, excavator bucket or other means as approved by the Contracting Officer. Drilling of the next blasting round will not be allowed until the current excavation has been properly scaled and all initial ground support has been installed as determined by the Contracting Officer. No separate payment will be made for scaling.

3.17 GROUTING

Conduct pre-excavation and post-construction grouting in accordance with Section 31 73 19 TUNNEL AND SHAFT GROUTING and as shown on the Contract Drawings.

If groundwater exceeds [____] liters per minute (lpm) gallons per minute (gpm) during probe hole advancement during tunnel construction the Contractor's Engineering Geologist or Geotechnical Engineer will submit a grouting and excavation plan or establish protocols for excavation if certain inflows exceed threshold lpm gpm values prior to tunnel excavation. The Contracting Officer must be informed of the implementation of the aforementioned grouting plan if groundwater inflows exceed excavation plan established inflow thresholds.

3.18 INITIAL SUPPORT

**************************************************************************
NOTE: A UFGS for TUNNEL EXAVATION SUPPORT is being developed. The designer will need to include Initial Support as listed here and Permanent support. Often the contractor will be responsible for designing their own initial ground support types, and may not be defined in the GBR or specs. Alternatively, the GBR may give conceptual initial support types (spacing, types, lengths, etc...) to bid on but give multiple support Types that may be applied along different alignment stationing depending on the geologic conditions. Tailor this section as appropriate.
**************************************************************************

3.18.1 Support Classes and Support Class Ranges

All stations indicating limits of typical support classes referenced herein
or as shown on the Contract Drawings are only approximate and may vary due
to the geological and hydrological conditions encountered in the field.
Tunnel excavation support classes, as shown on the Contract Drawings, are
the minimum to be installed and should be adjusted above and beyond the
said minimum based on the actual ground conditions encountered and be
determined in the field in consultation between Contractor and the
Contracting Officer.

Each support class defines installation of a specific initial support
system. The support elements are as specified in Section XX XX XX TUNNEL
EXCAVATION SUPPORT and as shown on the Contract Drawings.

Initial support measures have been derived based on anticipated ground
conditions and the need to provide stabilization of the tunnel openings for
enlargements to cavern size openings under this Contract or future
contracts.

Excavation and support measures delineated hereafter are typical and should
be supplemented by additional initial support measures as required by
ground conditions encountered or as directed by the Contracting Officer.
To minimize ground movement; the initial support must be installed
following each heading round blast and as close to the working face as
practical in accordance with Section XX XX XX TUNNEL EXCAVATION SUPPORT.

**************************************************************************
NOTE: Verify that a Geotechnical Baseline Report
has been prepared for the project and has been
referenced in Section Related Attachments and
Specifications.
**************************************************************************

a. Ground support guidelines for the tunnel excavation are shown on the
Drawings and provided in the GBR. In addition to the ground support
shown on the contract plans, the Contractor must install such ground
support as necessary to always ensure the stability of the excavation
and the safety of the construction personnel. Ground support installed
by the Contractor without agreement or instruction from the Contracting
Officer must be for the Contractors convenience and at the Contractor's
expense.

b. The ground support must be installed as soon as practicable after
tunnel excavation to minimize loosening or movement of the surrounding
ground. The Contractor must be responsible for providing confirmation
that the ground support system has produced a stable excavation. The
support layouts shown on the contract drawings are a guide only and
must be modified as required on the field during tunnel excavation.

c. The approval of the proposed excavation and support sequence by the
Contracting Officer or failure to call attention upon improper or
inadequate application of the related excavation sequence or tunnel
support, pre-support, or face support or to require respective change
must not relieve the Contractor of responsibility for the integrity of
the tunnel support or the proper execution of the work.

[ d. Lengths of excavation rounds shown on the contract drawings are maximum
values and may have to be reduced due to the ground conditions
encountered.
e. Pneumatically projected concrete, either fiber reinforced Shotcrete or plain Shotcrete must comply with provisions set forth in Section 03 37 13 SHOTCRETE.

f. Rock reinforcement for tunnel excavation must comply with Section 31 68 13 SOIL AND ROCK ANCHORS.

g. Steel arch ribs, liner plates and additional ground support elements must comply with Section XX XX XX TUNNEL EXCAVATION SUPPORT.

3.19 EXCAVATION SEQUENCE FOR TUNNELS

Tunnel excavation must be accomplished in either a full face or top heading and bench format as indicated on the contract drawings. All initial support must be applied or installed prior to drilling subsequent rounds.

3.20 STABILIZATION TYPES

[_____] ground support categories have been developed for the stabilization of the main tunnels as defined in Section XX XX XX TUNNEL EXCAVATION SUPPORT.

An estimate has been made as to the lengths of each of the ground support categories required to stabilize the tunnel. The estimated lengths are shown on the contract drawings and presented in the Geotechnical Baseline Report (GBR). Actual stabilization requirements may vary from those estimated based on the geologic conditions encountered. In accordance with Section 01 35 26 GOVERNMENTAL SAFETY REQUIREMENTS, the Contractor must be responsible for the safety of the work and for accomplishing the permanent stabilization of the tunnel opening.

3.21 EXCAVATION FOR TRENCHES AND SUMPS

Excavation for trenches and sumps must conform with Section 31 00 00 Earthwork and as shown on the contract drawings.

3.22 EXCESS EXCAVATION

**************************************************************************
NOTE: The type/class of shotcrete used to fill overbreak areas in the tunnel should be defined by the designer in early stages of the development of the bid documents. Similarly, the type of material used to fill overbreak in the tunnel invert must also be defined during early stages of the project design.
**************************************************************************

Excavation outside of the B-Line shown on the Drawings must be filled with Class I, II, III Shotcrete in accordance with Section 03 37 13 SHOTCRETE at the expense of the Contractor. Overbreak excavation in the tunnel invert must be filled with [compacted crushed rock, lean concrete].

3.23 TOLERANCES

The tunnels must be excavated in accordance with the A-line dimensions shown on the Drawings. No unexcavated rock or other material must protrude within the A-line.
3.24 CONTROL OF WATER

NOTE: This section will likely be incorporated into a future UFGS for Tunnel Dewatering. This section will need to be heavily tailored for your project needs. Adhere to the current version of the ETL 1110-2-586 DEWATERING: Methods, Installation, and Performance Monitoring.

a. The Contractor is responsible for control of water in the tunnel during construction and must take all means necessary for such control. Control of water must include but not be limited to, furnishing, installing, operating, and maintaining pumps and other equipment including temporary measuring devices must as per (b) below, constructing temporary ditches and drains and keeping ditches and drains free to carry all water to sumps or other disposal areas; and disposal of all water, tested daily, draining or pumped from the tunnel. Disposal of water must conform to all applicable Federal, State, and local laws.

b. Automatic measuring devices must be furnished by the Contractor and must be employed to measure the flow rate of water coming out of the tunnel portals. Water piped in for construction operations and water exiting at the portals must be separately measured. The difference between the total flow rate out of and the total flow rate into the tunnel must be considered the rate of groundwater inflow to the tunnel. This rate of flow must be measured and recorded on a [daily basis][hourly basis] for information only.

c. Fissure grouting must mean grouting carried out in the rock mass surrounding the Underground Works to stem water flows emanating from fissures in the rock where if left un-stemmed the inflows could initiate instability. Pressure grouting must be carried out when instructed by the Contracting Officer and, where necessary the Contractor must carry out lugeon permeability tests to establish the extent of the fissure to delineate zones that will take grout. Further requirements are in SECTION 31 73 19 TUNNEL AND SHAFT GROUTING.

3.25 PERMANENT TUNNEL DRAINAGE

A drainage geotextile must be installed on the walls and crown of the excavation against the shotcreted surface at locations where actual flows of water are encountered and at other locations as shown on the Drawings or as may be required to the satisfaction of the Contracting Officer. The installation must comprise full coverage for ground support in accordance with Section XX XX XX TUNNEL EXCAVATION SUPPORT.

The drainage membrane must be fixed and sealed to the approval of the Contracting Officer so that the placing of shotcrete does not block or obstruct the drainage geotextile.

Geotextile must be installed in accordance with Section XX XX XX and Waterproof Membrane must be installed in accordance with Section XX XX XX.

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for underwater (from overwater vessels and platforms) blasting and blasting near a water body with adverse impacts for any use of blasting, most commonly submerged rock excavation and/or submerged structural demolition. If any of the materials being blasted and excavated are known to be, or during the contract period may possibly be, above water, also use Section 31 23 06.00 BLASTING - SURFACE. For projects on a naval facility, consult with local NAVFAC office, Naval Ordnance Safety and Security Activity (NOSSA), and NAVSEA on requirements. NAVSEA OP5 Ammunition and Explosive Safety Ashore manual dictates many of the requirements and NOSSA has the final determination on any blasting on a Navy installation above or underwater. Reference NAVSEA OP5 manual and contact local Explosives Safety Officer and Planner for the base prior to revising the specification. Overall NOSSA approval process can take 12-18 months depending on the level of approval required.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).
NOTE: Consult with an office that has most recently completed a similar type of underwater or near-water blasting, while editing this section, to be appraised of recent, specific requirements, guidance, blasting developments or understandings for the subject project. Consult with, or have the specifications reviewed by, a subject matter expert in blasting for projects where blasting issues are particularly challenging or where protections to the public, structures/facilities, and/or natural resources will require project-specific designs or activities.

There are likely decisions and/or requirements of other agencies, the Safety Manual, and/or internal departments, which could have an influence upon a project's blasting specs. Some of these issues may be: navigational concerns and dealing with federal, state, and local jurisdictions and agencies; public use of nearby federal, state and/or local properties near the project; evaluations of acceptable vibrations and/or pressures affecting individuals or reaching nearby structures; natural resource (environmental) impact reviews, negotiations and/or requirements; cultural resource impact reviews for their considerations and/or requirements; constraints on the drilling or blasting procedures; pre-blast inspections; special studies to facilitate lower cost of the bids or to encourage more bid submissions; the acquisition strategy for the payment; and, other concerns specific to the project. If there are required natural resource protections, there will need to be resolutions concerning specialty firms or professions, including all of the appropriate references, designing the activity(-ies) for the project, and the Contractor's conduct of the activity(-ies), in full or part, or the Contractor's coordination with a government agency(-ies) or external office(s) conducting the activity(-ies).

The following information will be indicated on the project drawings:

1. Surface elevations, existing and new; Applicable datum for elevations and spatial coordinates will be stated clearly for reference.

2. All utilities, whether trenched, buried, at the surface or overhead to distances well beyond the project's limits;

3. Location and record of all soil and rock borings and test pits, including soil and rock
classifications and their properties, weathered rock, bit drops and voids, ground water observations, and topsoil thickness encountered in boring;

4. Location and limits of hard material, whether rock or concrete, or other building materials; with caveats as to uncertainty as appropriate;

5. Excavation or demolition limits with tolerances;

6. Details of any special limits that may require line drilling, presplitting, reduced subdrilling, and/or specialty blasting practices;

7. Location of borrow and disposal area, if located on Government property;

8. Hydrological, hydraulic and impoundment data, where applicable; and,

9. Details of all rights-of-way within the project boundaries.

**************************************************************************

1.1 SCOPE

The breakage of rock and hard/unyielding materials may be conducted by any means, unless otherwise stated herein. If the contractor elects to use drilling and blasting for breakage or displacement of any units, this entire section is applicable and covers activities associated with drilling and blasting for rock excavation at the surface. Contained herein are procedures for all activities relating to drilling; blasting and the transportation, storage and use of explosives; breakage and displacement of rock. The Contractor's blasting program and methods are those necessary to accomplish the excavation shown on the Contract drawings in accordance with the provisions specified herein. Control the quantity of explosives fired in all blasting to prevent injuries to persons and to avoid damage to all structures, properties, governmental and nonprofit entities, commerce and businesses, and natural resources and their habitat.

1.2 RELATED WORK SPECIFIED ELSEWHERE

**************************************************************************

NOTE: List any specifications that are related, such as Excavation, Earthwork, Demolition, Temporary Environmental Controls, Natural Resources, Shotcrete are typical specs related, depending on the project.

**************************************************************************

Section [______]

1.3 REFERENCES

**************************************************************************

NOTE: Add and remove references as needed for the project. Reference the appropriate state and local laws, regulations and ordinances concerning blasting where the project is to occur.

SECTION 31 23 01  Page 7
This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

**************************************************************************

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

INTERNATIONAL SOCIETY OF AUTOMATION (ISA)

ISEE PSBS (2017) ISEE Performance Specification for Blasting Seismographs

NATIONAL FIRE PROTECTION ASSOCIATION (NFPA)

U.S. ARMY CORPS OF ENGINEERS (USACE)

U.S. Code (USC)

16 USC 470 National Historic Preservation Act
16 USC 668 Bald and Golden Eagle Protection Act
16 USC 1361 Marine Mammal Protection Act
16 USC 1531 Endangered Species Act
16 USC 1801 Magnuson-Stevens Act
33 USC 1251 Clean Water Act
33 USC 1401 Marine Protection, Research and Sanctuaries Act
42 USC 4321 National Environmental Policy Act
1.4 DEFINITIONS

NOTE: Delete definitions that will not be used in the specification text for a specific project. A complete list of blasting definitions can be found in the GLOSSARY of the EM 1110-2-3800. Recommend only using definitions not already in GLOSSARY in the EM and those definitions to further stipulate the work on the specific project in the specification. It may be necessary to add definitions depending on what the Earthwork and/or Excavation specifications for the project have terms for Rock, Weathered Rock, Sound Rock, Voids, Sediment, etc.

1.4.1 Controlled Blasting

Controlled blasting refers to blasting techniques used to better distribute the explosive charge to minimize adverse impacts. For underwater blasting, adverse impacts may be cited for the public's and contracted personnel's safety, lessening the fracturing of the rock being blasted, surrounding facilities' protection, and the avoidance of impacting natural resources or their habitats. Controlled blasting techniques must be deployed, such as careful loading to the pattern's design using the drilling log for each shot hole, stemming effectively the top of firm rock and any soft zones or voids, carefully observing maximum charge weight per delay, using delays between holes and rows of 25 milliseconds or greater, and avoiding rifling plumes by proper blasting techniques.

1.4.2 Flyrock

NOTE: Choose the distances for the project, the typical values are listed. Edit definition as needed for project site.

Flyrock is one of the three primary adverse impacts from blasting. Flyrock is defined as any airborne projectile flying the lesser distance of either 60 m 200 ft horizontally from the shot pattern or one-half the distance between the shot pattern and the Contractor work limits, whichever distance is the lesser.

1.4.3 Green Concrete

NOTE: If no concrete placement is expected on the project then delete this definition. If concrete placements will occur when blasting operation is
ongoing, further define green concrete here and include appropriate thresholds and monitoring for the green concrete in Part 3. There needs to be limits on vibrations when there is green concrete because of the strength loss due to vibrations while curing. Involve the Structural Engineer project development team members in these determinations.

Green concrete is recently placed concrete that has initiated setting but may have substantial strength reduction from strong vibrations before the concrete has fully cured. Green concrete also includes the materials of shotcrete or cementitious grouts. Each Individual Shot Plan is required to consider vibrations emanating from its blast pattern reaching the location of the reported newly placed concrete to remain below allowable vibration levels depending upon the age of the concrete. Note the paragraph GREEN CONCRETE.

1.4.4 Pressure Waves

Pressure Waves, both Airblast (or noise) and Underwater Pressure Waves, are one of the three, primary adverse impacts from blasting. Airblast and Underwater Pressure Waves are solely compression waves passing through the air or water, respectively. Their units of measure may be in terms of pressure, Pascals (Pa) or pounds per square inch (psi), or in terms of the logarithmic scale, Decibels (dB). Note that pressures in dB have different reference values for Airblast and Underwater Pressure Waves, so the pressure waves through air are of a lower magnitude than pressure waves through water with the same numeric dB value.

1.4.5 Rock, Hard/Unyielding Material, Weathered Rock, Voids (Bit Drops), Sediment

1.4.5.1 Rock

Rock is natural solid, interlocking material with firmly cemented, laminated, and crystalline fabric, foliated masses or conglomerate deposits, none of which can be removed without systematic drilling and blasting, drilling and the use of expansion jacks or feather wedges, or the use of high-energy mechanical devices; and, so classified for this project as submerged large boulders, [masonry, or concrete other than pavement exceeding the capacity of the awarded contractor's underwater excavation capacity,] which may be the minimum volume of 0.38 cubic meter 0.50 cubic yard.

1.4.5.2 Hard/Unyielding Material

NOTE: Depending upon the acquisition strategy and measurement and payment, hard materials should typically be included in lump sum payment.

Hard/Unyielding materials comprise weathered rock, dense consolidated deposits, or conglomerate materials which are not included in the definition of "rock" with stones greater than 25.4 mm 1.0 inch in any dimension. These materials usually require the use of heavy excavation equipment or high-energy mechanical devices for breakage or displacement to remove the materials.
1.4.5.3 Weathered Rock

Weathered rock, for underwater percussion-drilling logging, is any original rock unit that has been altered to a weaker state that will not retain stemming when explosives are loaded into that material.

1.4.5.4 Voids

Voids, for underwater percussion-drilling logging, is any rapid bit drop with little or no resistance to the downward drilling pressure. Voids may be water or sediment filled, which may possibly determine that the original rock unit has been altered to a weaker state that will not retain the gaseous detonation products when the explosives are shot.

1.4.5.5 Sediment

Sediment is both: the loose to firm material that may be dredged above the surface of weathered or firm rock, which cannot be easily dredged; and the infill of voids as solid particles.

1.4.6 Unstable Material

Unstable materials are loose, submerged sediment that are easily displaced by water flow or turbulence and by vibrations or incidental impact.

1.4.7 Vibrations

Vibrations are one of the three, primary adverse impacts from blasting. Vibrations are the result of various wave forms emanating from the detonation or deflagration of ignited materials from a shot pattern. Peak particle velocity (PPV) is defined as the maximum absolute value among the three ground vibration velocities measured in the vertical, longitudinal, and transverse directions over a time of a record. Peak, total vector-sum particle velocity is the peak value over the full, time history of each time-unit's value of the square-root sum of the squared, component velocities. Velocity units are expressed in centimeters per second (cps) or inches per second (ips).

1.5 SYSTEM DESCRIPTION

Boring logs are [shown on the drawings] [appended to the SPECIAL CONTRACT REQUIREMENTS or GDR]. Bottom-sounding surveys are provided as contoured maps, as precise to the vertical and lateral tolerance on the date of the survey.

The subsoil investigation report and samples of materials taken from subsurface investigations may be examined at [______]. These data represent the best subsurface information available; however, variations may exist in the subsurface between boring locations.
1.5.1 Classification of Excavation

**************************************************************************
NOTE: Inapplicable portions will be deleted. Other classifications of excavation may be utilized as required. For underwater blasting, resolve whether there is any potential for anthropogenic materials, such as concrete or pavement, or lost shipping debris that must be included in paragraph DEFINITIONS above and paragraph CLASSIFICATIONS herein.

If no consideration will be given to the nature of the materials, then all excavation will be designated as unclassified excavation. Otherwise, finish the specified excavation on a classified basis, in accordance with the following designations and classifications.

**************************************************************************

1.5.1.1 Common Submerged Excavation

Include common excavation with the satisfactory removal and disposal of all materials not classified as rock or hard/unyielding materials. Include the removal of any concrete or masonry structures or pavements that may be encountered in the submerged excavation zone under this classification.

1.5.1.2 Rock Excavation

Submit notification of encountering rock and/or hard/unyielding materials in the project. Include rock excavation with blasting, excavating, grading, disposing of material classified as rock, and the satisfactory removal and disposal of boulders 1/2 cubic meter yard or more in volume; solid rock; rock material that is in ledges, bedded deposits, and unstratified masses, which cannot be removed without systematic drilling and blasting; firmly cemented conglomerate deposits possessing the characteristics of solid rock impossible to remove without systematic drilling and blasting; and hard materials as defined herein [requires inclusion of appropriate definition of hard materials for the project].

If at any time during excavation, including excavation from borrow areas, the Contractor encounters material that may not be classified as rock excavation, uncover such material, and notify the Contracting Officer. Do not proceed with the excavation of this material until the Contracting Officer has classified the materials as common excavation or rock excavation and has taken cross sections as required. Failure on the part of the Contractor to uncover such material, notify the Contracting Officer, and allow ample time for classification and cross sectioning of the undisturbed surface of such material will cause the forfeiture of the Contractor's right of claim to any classification or volume of material to be paid for other than that allowed by the Contracting Officer for the areas of work in which such deposits occur.

1.5.2 Blasting

Drilling and blasting are not required activities for breakage of materials to allow excavation. Should the Contractor elect to conduct drilling and blasting, the Contractor must perform the blasting in accordance with this section. The Contractor is responsible for all claims for damages and
injuries caused by, or arising out of, blasting activities and its adverse impacts, as noted in the FAR.

Perform blasting in accordance with EM 385-1-1 and in conformance with all Federal, State, and local laws, regulations, and ordinances. Submit notice 30 days prior to starting work. Submit a Master Blasting Plan for approval, prepared and signed by the Blasting Specialist that includes: a listing of all federal, state and local regulations and ordinances to conduct blasting at the project; the support documentation and certifications for all proposed blasting personnel; information and data sheets for all the explosives to be used at the project; the design approach to blasting; outlines of all required reports and formats for all the forms of the respective reports; and, the procedures to control all the adverse effects of blasting. Use the non-electric blasting caps for all underwater blasting. Obtain written approval prior to performing any blasting and notify the Contracting Officer 24 hours prior to blasting. Include provisions for storing, handling, and transporting explosives as well as for the blasting operations in the plan.

1.6 SUBMITTALS

**************************************************************************
NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.

**************************************************************************

Government approval is required for submittals with a "G" or "S"
classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-01 Preconstruction Submittals

Master Blasting Plan; G, SO
Blasting Safety Plan; G, SO

1.7 COORDINATION

**************************************************************************

NOTE: The following paragraph can be used if working with multiple stakeholders/owners.
**************************************************************************

Blasting will be in the vicinity of the [existing lock, railroad, and highway, and river barge, train, highway traffic, utilities and businesses] and their operation will not be impeded or delayed beyond that which has been coordinated with [TVA, U.S. Coast Guard, U.S. Army Corps of Engineers - [_____] District, [_____] environmental or natural resources offices, [state_] Department of Transportation, [_____], [_____] Railroad, regional or local utilities, and/private businesses]. A coordination plan, with the appropriate authorities that mitigates [navigation and traffic delays], in the Master Blasting Plan.

Coordinate, through the Contracting Officer, with other Contractors working onsite to minimize work stoppages during blasting.

1.8 LIABILITY

Compliance with provisions in the contract will not relieve the Contractor of their responsibility for any damages or injuries caused by, related to, or arising out of blasting or associated blasting activities. Notwithstanding federal, state, and local laws, regulations and ordinances, the Contractor assumes all liability and hold and save the Government, its agents, officers, and employees harmless for any and all claims for personal injuries, property damage, or other claims arising out of or in connection with the handling of explosives or blasting under this contract.

PART 2 PRODUCTS

2.1 TRANSPORTATION, STORAGE AND USE OF EXPLOSIVES

**************************************************************************

NOTE: Confirm and follow federal, state, and local
regulations and guidance on the transport, storage and use of all Explosives. State and local agencies and/or authorities may not easily allow the receipt of Explosives in a timely manner. State and local agencies and/or authorities may have specific reporting, certifications, adverse impact concerns, or distance regulations from the blast zone to private properties governing the use of Explosives. The Agency/Service may wish to allow storage of Explosives on federal premises. The winning contractor should independently assess and cite in the Master Blasting Plan all federal, state, and local laws, regulations, ordinances, or authorities that impact the transportation and storage of Explosives. Consider requiring cartridge explosives for water sensitive explosive materials or allowing the use of those bulk explosive that are not water sensitive, i.e., "Bulk explosives such as ammonium nitrate and fuel oil (ANFO) or bulk emulsion or emulsion blends will not be permitted."

2.1.1 General

Store, transport, handle, use, and otherwise secure explosives in accordance with best practices as approved by the Contracting Officer and in accordance with all Federal, State and Local laws and regulations. Comply with all special rules and regulations that may be made by the authorities having jurisdiction, or by the Contracting Officer, regarding construction of, and storage in magazines and precautions in blasting. Times and imposed restrictions concerning the use of explosives must be conducted in accordance with local, State, and Federal regulations. The Contracting Officer reserves the right to establish restrictions or time windows when blasting will not be allowed.

2.1.2 Blasting Products

2.1.2.1 Requirements

All explosive materials to be used on site must be proposed for approval in the Master Blasting Plan. Cartridge and bulk explosives may be used in different sections of the project. All explosive materials used on the project must be six months or less of age or no older than one half the shelf life shown on the explosives manufacturer's technical data sheet for that product. Millisecond delay, shock-tube initiators, must be used as the initiation system. To ensure the accuracy of firing times of blasting caps, it is required that each cap period come from one lot number. Mixing of lot numbers for any single cap delay period within a shot pattern is strictly prohibited. For underwater blasting's ability to displace rock against the water load, the minimum delay both between shot holes and shot rows will be 25 milliseconds.

2.1.2.2 Prohibited Explosive Materials

Explosives that do not meet the manufacturer's specifications must not be used. When, in the opinion of the Contracting Officer, any explosive materials is either of excessive age or appears to be in a deteriorated condition, all work must cease until the products age and quality can be determined. Blasting products without date batch codes will not be
permitted on site. The Contracting Officer may require any explosive materials to be tested by an independent organization to determine its performance as compared to the manufacturer's data sheet. If explosive materials' performance or composition deviates by more than 10 percent in any manner from the manufacturer's data sheet, that lot number will be rejected. The Contractor is responsible for any required testing and no additional compensation will be made for any product testing directed by the Contracting Officer.

Bulk explosives, which are water sensitive, are strictly prohibited.

Detonation Cord is strictly prohibited for initiation transmission through the air and water to the shot holes. An approved non-electric shock tubing, proposed in the Master Blasting Plan, must be used to transmit the firing initiation to each shot hole. Detonation cord may be used within the shot hole by proper connection to the shock tubing beneath the highest elevation of firm-rock stemming.

2.1.3 Magazines

**************************************************************************
NOTE: Determine whether not allowing onsite explosive storage magazines will be an adverse impact that will limit bidders. If the project has sufficient area of restricted open property, explosive magazines may be allowed onsite. For example, a rural federal project may have sufficient property to accommodate the stand-off distances from the magazine to other residential or essential structures to easily allow an onsite magazine, especially if the adjacent non-federal property owners might not wish to have a magazine on their property. Recognize that there will be at least two daily trips with appropriate explosive-transport vehicles between the magazine and the coming shot pattern. Delete the first paragraph, "No explosives ... explosive magazines.", if onsite magazines will be allowed.
**************************************************************************

[ No explosives will be stored onsite. There must be no permanent explosive storage or overnight explosive storage onsite. The Contractor will either obtain daily deliveries of the explosives to the site from a manufacturer or supplier or secure offsite explosive magazines.

] When the Contractor will maintain the explosive magazines, obtain all necessary Federal and State magazine permits for the magazines. Magazines must be located at safe distances as defined by the Bureau of Alcohol, Tobacco and Firearms (ATF), in addition to the State of [____]'s requirements. Procure off-site explosive storage and expect to transport the daily volume of explosives to the site. Secure a permit to transport explosives from the State of [____]'s Highway Patrol when and if required, and transport explosives in accordance with 49 CFR 177 when carried on public highways.

The Contractor must have two temporary magazines on board the drilling and loading barge of sufficient volume to hold the largest day's use of explosives and initiators separately. These temporary magazines must meet all ATF requirements and all regulations and ordinances of state and local
government. No explosives may remain overnight in the temporary magazines. A daily-use log of explosives delivered, loaded by shot hole through the day, and removed at the last shift must account for the use of all explosives.

2.1.4 Magazine Keeper

Each magazine keeper must be experienced and familiar with the laws and general practices concerning the handling, care, use, and storage of explosives and detonators. The magazine keeper is responsible for maintaining a cleared area around each magazine. The magazine keeper will not be required to perform any duties that will in any way interfere with their duties as magazine keeper and being physically present at the magazines for every entry to the magazines for delivery, disbursement, and review of explosives at the magazines.

If explosives are delivered and returned daily from the manufacturer or supplier to the project, the driver of the truck will serve as the magazine keeper.

PART 3 EXECUTION

3.1 GENERAL EXCAVATION AND REMOVAL

**************************************************************************

NOTE: Delete inapplicable sections. The coordination with other federal, state, and local jurisdictions and agencies, the public, and private entities must be completely resolved before finalizing the specifications.

While it is not typical to have low tolerances for the horizontal variation of submerged walls or for the vertical variation of submerged pay grades, some projects may require limited control of the walls and grades in underwater blasting. Before resolving the project's underwater tolerances, determine an easy and effective means to survey the submerged walls and grades, and further assess to what precision such surveys may accurately estimate horizontal and vertical variations over short distances.

Presplitting would be an unusual requirement for underwater blasting, even in shallow water, because of the accuracy of knowing the exact horizontal location of the Top of Firm Rock. In projects where controlled blasting techniques are required to produce final walls which require presplit blasting, only explosives designed for this application must be allowed.

Specific underwater blasting impacts' requirements, negotiated or specified with environmental agencies and offices, must be fully determined, and in some cases designed, for the project before the specs may be finalized. Some requirements, like seasonal restrictions on underwater blasting or the prohibition of detonation cord in the open air and...
water, may easily be included. Other requirements, such as the required use of a bubble curtain, should be avoided if possible, because of its difficulty in its proper use, maintenance, and storage, but when required will need to be designed by an appropriate experienced professional for inclusion of the designed element in the specifications.

Perform the excavation of every type of material encountered within the limits of the project to the lines, grades, and elevations indicated and as specified. Dredging, breakage, displacement, and excavation of all the materials will be accomplished by appropriate techniques and with special care, such that no individuals, cited natural resources, structures, navigation and other sensitive features, and activities suffer any adverse effects from blasting. Perform the submerged removal in accordance with the typical sections shown and the tolerances specified in paragraph SUBMERGED MATERIAL DISPOSAL.

The Contractor's blasting program and methods will be those controlled blasting techniques necessary to accomplish the excavation shown on the contract drawings in accordance with the procedures specified in this section. Make necessary plans, examinations, surveys, and test blasts to determine the quantity of explosives that can be fired to accomplish the breakage (or displacement) and removal of materials without injuries to persons, and aquatic wildlife (or other natural resources), or damage to personal or public property. Test blasts will be performed to slowly build to acceptable loading and timing of production shot patterns, to verify that the monitoring network performs as designed, to begin to assemble monitoring data collection, and to resolve that the submerged material is adequately broken or displaced for removal. Use the test blasting results to optimize remainder of work. The blasting program must abide by all applicable Federal, state, and local laws, regulations, and ordinances established for the project's location.

Process any and all claims of public entities, companies and private citizens arising from the transportation, storage, and use of explosives promptly in an acceptable time period set by the Contracting Officer Representative (COR); in particular, all injury and property damage claims must be acknowledged by the Contractor, or their representative, and be submitted immediately as directed by the COR to the Contracting Officer providing name of claimant, location, time and description of alleged injury, and damage, and estimated value. The claimed injury or damage will be evaluated and inspected by an appropriate specialist within 48 hours following initial notification, and processed to a conclusion (honored, denied, or compromised) within 90 days after cessation of all blasting on the contract; but, in no case will the claims remain unresolved for a period exceeding 6 months (180 calendar days). Submit evaluation and inspection results and actions taken to the Contracting Officer on a weekly basis.

3.1.1 Removal of Submerged Materials

NOTE: Determine whether varied submerged materials being excavated may be placed in other submerged low-elevation zones that allows undifferentiated placement of the excavated volumes to the pay grade. There may be requirements to place certain
materials in specific locations by the submerged material's type. Different projects may require disposal only above water or only below water.

3.1.1.1 Sediment Within the Project Limits for Removal Displacement

Sediment vertically above the project limits for removal may be excavated, removed, or displaced by any means, including dredging, prior to action upon deeper materials. Sediment may be left in place for removal by mechanical means after the breakage of deeper materials allows those materials to be removed. Unless the Disposal of Materials requires differentiation of materials below or above the water surface, the sediment may be removed and placed in the disposal zone before or after the excavation of deeper materials.

3.1.1.2 Breakage of Rock and Hard/Unyielding Materials for Excavation and Disposal

NOTE: Determine whether the sentence below, "The lateral dimensions ... azimuthal direction." is required. If it is necessary for specific project, determine the lateral distances the azimuthal directions that meet the project's needs. If it is not necessary for specific project, delete the sentence.

Blasting may be conducted to break or displace the rock and hard/underlying materials into sizes that may be removed by dredging or excavation equipment. Test blasting will be conducted to determine the parameters for the following production blasting. Care must be taken to prevent damage to any of the remaining specified materials, features or structures noted in the drawings; and avoid adverse effects from blasting to personnel, the public, natural resources, structures, and features. The lateral dimensions of any blast plan must not exceed [_____] m [_____] ft horizontally in any azimuthal direction. The Contractor must curtail blasting activities in designated areas when, in the opinion of the Contracting Officer, damage to in-place units or adverse impacts may have occurred. Blasting will be curtailed in these designated areas until both remediation, as directed by the Contracting Officer, has been completed, and the Contractor has resolved a means to conduct the blasting without the damage or adverse impacts.

3.1.2 Disposal of Materials Within the Project Limits

NOTE: The Guide Spec presumes that all dredged and/or excavated materials below the water surface may be placed below a specified elevation(s) in submerged, low-elevation zones already surveyed and provided in drawings. If any materials must be removed from the project area and/or will be placed by material type and/or within certain tolerances, compaction requirements and/or by having been dewatered, additional disposal sections and references to those locations of placement or disposal will be required to be added.
Transport and place all dredged, displaced, or excavated materials within the limits of the disposal zones below the specified elevations, according to the requirements specified in paragraph SUBMERGED MATERIAL DISPOSAL.

3.2 SAFETY PROCEDURES

3.2.1 General

Ensure all work completed under this Contract is executed safely. Follow the safety procedures outlined in EM 385-1-1. EM 385-1-1 will govern all activity unless more stringent safety requirements are specified in other applicable Federal, State, and local laws, regulations, and ordinances.

NOTE: Additional narrative may need to be added on coordination with other federal, state, or local entities before acceptance of the Master Blasting Plan for critical items and required limitations, which have been included within paragraphs SAFETY PROCEDURES, OPERATIONAL REQUIREMENTS, and IMPACT MONITORING. There may be compliance obligations for the Contractor, the Contracting Officer and/or other entities regarding those critical items and required limitations. For example, if a Marine Mammal Watch Program is required to avoid blasting while marine mammals are near the loaded, underwater shot array, then the CO, the Contractor and the entity requiring the watch program should schedule and meet both to discuss and to have a mutual understanding relative to project of the Marine Mammal Protection Plan.

3.2.2 Weekly Coordination Meeting

Coordinate all blasting schedules with the Resident Engineer's Office and Contracting Officer at least one week in advance and hold a weekly blasting coordination meeting with the Resident Office. Provide an agenda for the blasting coordination meeting that lists project's prior week's shots, the forecasted shot schedule, and displays a scale site plan showing the locations of the schedule shots. The Blasting Specialist, Blaster in Charge, and Seismic Specialist are required to participate in discussion of agenda items and lessons learned.

3.2.3 Public Notice of Blasting Operations

Thirty days, prior to any blasting operations, prepare and submit to the Contracting Officer a public government notification letter of the proposed blasting activities. The Government will distribute copies of this notification letter by certified mail to local governments, law enforcement, public utilities, public users of project recreational facilities, and residents and commercial interests located within 0.8 kilometers one half mile of the blast site. This notification letter must contain at minimum:

a. Name, address, telephone number and e-mail address of the Contractor;

b. Plan maps identifying the specific areas in which blasting will take
place, and major and secondary roads, geographic features and auxiliary features;

c. Duration of blasting activities, and on which days of the week and hours of the day that blasts can be expected to occur;

d. Vehicular and pedestrian traffic control measures to be taken;

e. Methods to limit access to the blasting area; and,

f. Types, patterns and duration of audible warning and all-clear signals to be used before and after blasting.

3.2.4 Public Meetings

**************************************************************************
NOTE: Communicate with the project manager and all stakeholders about whether specific requirements for a meeting or multiple meetings are needed. It may be necessary to advertise the meeting in a local newspaper and specify the meeting room capacity.
**************************************************************************

Fifteen calendar days prior to any blasting operations, provide the approved Blasting Specialist, Blasting Consultant, and Seismic Specialist to attend a public-relations meeting to be conducted on an evening to be determined by the Contracting Officer. This meeting will inform the public about the anticipated blasting operations. The Blasting Specialist, Blasting Consultant, and Seismic Specialist must each make a short presentation of blasting operations and answer any questions pertaining to public concerns dealing with the blasting operations, the magnitude of vibrations, airblast and potential for flyrock that may impact the public, and the project's required natural resource activities. Distribute points of contact should the public and local entities have an event of concern related to the blasting program.

3.2.5 Warnings and Signals

Establish a method of warning all employees on the job site of an impending blast following the guidance of EM 385-1-1. The signals must consist of a five-minute warning signal to notify all in the area that a blast will be initiated in five minutes. A second warning signal must be sounded one-minute before the blast. After the blast is over, sound an all-clear signal, once the blast site has been inspected for misfires by the Blaster in Charge to notify all in the area that the blasting operation is finished. No personnel other than the Blaster in Charge must enter the blast area, until it has been determined to be all clear.

3.2.6 Notification to Navigation

**************************************************************************
NOTE: Use the following paragraphs when working in or near navigable waters or navigation lock. The notice may need to be coordinated with multiple federal, state, or local agencies, which could include the U.S. Coast Guard, a Corps of Engineers' District Office, an entity of a District Office (e.g., a Lock), a state agency, a local agency for a harbor or its police or fire department, and other

SECTION 31 23 01 Page 22
offices.

**************************************************************************

Notify the [_____] a minimum of [14] [_____] calendar days prior to the commencement of blasting operations to allow for sufficient time to send out navigation notices. The information to be supplied will include the dates and time window of blasting operations.

3.2.7 Navigation Control During Drilling, Loading, and Blasting Operations

**************************************************************************

NOTE: Determine the number of patrol vessels required for the specific project. At least one patrol vessel should be required unless the AO totally controls the water surface far beyond the size of the excavation zone. Correct the second and third paragraphs with such determination for the specific project.

Placement of buoys in the third paragraph is also project specific. Resolve whether buoys are required and the distance beyond the shot pattern or excavation zone that the buoys should be positioned.

**************************************************************************

Notify the Coast Guard 24 hours prior to a scheduled blast and 2 hours prior to the actual blast's initiation. Contact should be made with: US Coast Guard's contact, whose name and an alternate's name will be provided at time of contract award.

Operate [two] patrol vessel[s] during blasting operations equipped with a visible yellow flashing light, audible horn, and radio with a hailer, whose sole function will be to monitor and maintain security in the blast area. Use patrol vessels during all blasting operations. Inspect and insure there is no vessel traffic within the work area prior to the firing of the blasting caps and until such time as the Contractor has sounded the "All-Clear Signal".

Establish and maintain a warning system as required by EM 385-1-1 and as stated in paragraph WARNINGS AND SIGNALS. Equip and maintain the floating plant with radio equipment capable of communications with the Coast Guard. The Contractor, after each blast, upon inspecting the area, notify the Coast Guard and Contracting Officer if all clear or misfire is noted. Buoy the area with warning signs. The warning signs are to be legible from a distance of [_____] m [_____] ft and contain the message "DANGER - EXPLOSIVES IN USE" visible on either side of the sign. Station patrol vessels at the drill barge and remain in the blasting area during all blasting operations. Land oriented access control and visual observation locations will be determined and approved by the Contracting Officer.

3.2.8 Lightning Detection Device

Furnish, maintain, and operate lightning detection equipment during the entire period of blasting operations and during the periods that explosives are used at the site. Equipment must provide real time audio and visual alarm/signal and detection based on combined detection of electromagnetic, electrostatic, light wave spectral and audio disturbances, or a commercial service based on these, as a minimum for approved. Equipment must be capable of detecting lightning within 40 kilometers 25 miles as a minimum.
of the blast area. Provide the equipment after approval. When and where the lightning detection device indicates a blasting hazard potential, immediately evacuate personnel from all areas where drilling is being conducted or explosives are present. When a lightning detector indicates a blasting hazard, perform the following actions.

a. Clear the blasting area of all personnel. Place guards at all access points to the blast area.

b. Immediately notify the Contracting Officer of the potential hazards and precautions being taken.

c. Terminate the loading of holes and secure the unused explosives to an approved location.

d. When the hazard dissipates, inform the Contracting Officer that the drilling and loading of holes will continue.

3.2.9 Drill-Boat or Barge Safety

All onboard day magazines must be permanently secured to the deck as required by the Coast Guard. No high explosives will be stored on the boat or barge deck in the open except for the one case that is to be loaded immediately into the shot holes. Any explosives remaining on deck must be returned to the day magazine prior to the firing of any blast. The firing line reel or spool will be mounted on the rig in a manner that it cannot be lost overboard. An approved blasting machine will be used for detonation regardless of the number of caps used. No electric blasting system can be used. The amount of explosives permitted aboard the drill boat or barge at any one time will be subject to the approval of the Contracting Officer, but in no case will such amount exceed the amount permitted by appropriate codes and regulations.

Make necessary arrangements to prevent damage to any vessel, moored or underway, building or structure and to preserve the crew or occupants thereon from exposure to injury because of the Contractor's operations. Automatic fire extinguishers of an appropriate type must be installed on air compressors and in all engine compartments abroad vessels (drill boats, barges) where explosives are stored, handled, and used. The Contracting Officer may require additional arrangements. Have a Certified Marine Survey of all floating plant proposed for underwater blasting work on this contract performed prior to starting any work and provide the results to the Contracting Officer. Remote fuel shut-offs and fire-signaling devices must be provided aboard the drill boat.

3.2.10 Inspection for the All-Clear Signal

The Blaster in Charge must thoroughly inspect the entire blast area for a minimum of five minutes following a blast. The five-minute delay between blasting and commencing work is needed to ensure that no misfires have occurred. Details of the misfire procedures were provided in the Blasting Safety Plan, including the distance of the restricted area when a misfire is discovered.

3.2.10.1 Check for Misfires

During the five-minute delay, it is the responsibility of the Blaster in Charge to enter and inspect the shot-pattern area and verify for all loaded shot holes that all explosives have been detonated.
3.2.10.2 Misfire-Handling Procedures

Should an inspection indicate that complete detonation of all charges did not occur, only critical personnel involved in the blasting operation or excavation of the unexploded material are allowed within the established shot-pattern area. Restrict the site until the Blaster in Charge or the Blasting Specialist indicate the site is safe. If the misfire poses problems that cannot be safely corrected by the Blaster in Charge or the Blasting Specialist, a consultant, or an explosives company representative skilled in correcting misfires must be called to resolve the problem. Provide within 60 minutes of the recognition of a misfire, a notice to the Contracting Officer and all applicable agencies and offices for public safety. Compliance with this or any other provision in the Contract will not relieve the Contractor of responsibility for any damages or injuries caused by, related to, or arising out of blasting or associated blasting activities.

Provide the details of the misfire and the correction measures in the Individual Shot Report for shot with the misfire to the Contracting Officer and the emailed addressees the next business day.

3.2.11 Natural Resource Protection (Environmental Resource Protection)

******************************************************************************

NOTE: During the planning process for projects requiring underwater blasting, the agency/Service responsible for construction would have conducted an environmental impact analysis of the project, including blasting impacts, and coordinated with applicable Federal and state Natural Resource agencies, under the authorities of a number of environmental laws. For example, an Environmental Assessment (EA) or Environmental Impact Statement (EIS) would have been completed per the requirements of the National Environmental Policy Act. Often mitigation is suggested or required by the reviewing agencies. These mitigation techniques could be as simple as the design of well stemmed shot-holes to reduce pressure entering the water column or the use of small repelling charges to scare fish from the blasting zone. The responsible, reviewing agencies could also require extensive planning and design for such mitigation techniques as post-blast monitoring studies or the design and use of an effective bubble curtain system to reduce blast pressures. If marine mammals are in the project area, the Marine Mammal Act comes into play. Depending on the project, the National Marine Fisheries Service (NMFS) has required the use of Marine Mammal Watch Programs to ensure that marine mammals are not within a specified distance from the blast prior to detonation. These distances (in the form of pressure limits) are often provided by the NMFS and the monitoring is conducted by specialized companies with specialists in the identification of marine mammals. The NMFS has also required near-field pressure monitoring to confirm Watch Program distances and far-field acoustic monitoring to
ensure that sound levels are below levels causing auditory damage. The major environmental laws that may require mitigation or place restrictions on project blasting are listed under paragraph REFERENCES. (If there are no requirements under an environmental law, then the no mitigation would be required under that law and the reference should be deleted). However, additional Federal and state laws may also apply, depending on the project. Coordination with other federal, state, and local agencies and jurisdictions, the public, and private entities must be completely resolved before finalizing the Specifications. It is essential that the agency/service person, using these Guide Specifications to prepare Plans and Specifications, coordinate with the planners and environmental compliance specialists within their agency/Service to ensure that all the blasting restrictions and mitigation measures are incorporated into the Plans and Specifications. Failure to comply with the requirements of Federal or state laws and regulations could result in project delays or stoppages.

**************************************************************************

The Contractor is required to utilize the following to avoid and minimize techniques designed to mitigate the impacts of underwater blasting that have been developed, in coordination with other Federal agencies, in compliance with the federal, state, and local environmental laws and regulations and with applicable regulations and requirements of Section 01 57 19 TEMPORARY ENVIRONMENTAL CONTROLS. All activities requiring the Contractors' action or coordination are included in paragraph NATURAL RESOURCE ASSESSMENTS, Mitigation and Monitoring. The Contractor has full responsibility for not violating all the mitigation requirements. Associated fines for violations will be borne by the Contractor.

[3.2.11.1 National Environmental Policy Act

Write detailed description of work to be performed by the Contractor here. If there is no required work under 42 USC 4321 then the section should be deleted and renumbered.

][3.2.11.2 Endangered Species Act

Write detailed description of work to be performed by the Contractor here. If there is no required work under 16 USC 1531 then the section should be deleted and renumbered.

][3.2.11.3 Marine Mammal Protection Act

Write detailed description of work to be performed by the Contractor here. If there is no required work under 16 USC 1361 then the section should be deleted and renumbered.

][3.2.11.4 Bald and Golden Eagle Protection Act

Write detailed description of work to be performed by the Contractor here. If there is no required work under 16 USC 668 then the section should be deleted and renumbered.

SECTION 31 23 01  Page 26
3.2.11.5  Marine Protection, Research and Sanctuaries Act

Write detailed description of work to be performed by the Contractor here. If there is no required work under 33 USC 1401 then the section should be deleted and renumbered.

3.2.11.6  Magnuson-Stevens Act

Write detailed description of work to be performed by the Contractor here. If there is no required work under 16 USC 1801 then the section should be deleted and renumbered.

3.2.11.7  Clean Air Act

Write detailed description of work to be performed by the Contractor here. If there is no required work under 42 USC 7401 then the section should be deleted and renumbered.

3.2.11.8  Clean Water Act

Write detailed description of work to be performed by the Contractor here. If there is no required work under 33 USC 1251 then the section should be deleted and renumbered.

3.2.11.9  National Historic Preservation Act

Write detailed description of work to be performed by the Contractor here. If there is no required work under 16 USC 470 then the section should be deleted and renumbered.

3.2.11.10 Additional Federal Environmental Laws

Write detailed description of work to be performed under Federal environmental laws by the Contractor that are not listed in paragraph REFERENCES. If there is no required work under this Federal law, then the section should be deleted and renumbered.

3.2.11.11 State and Local Environmental Laws and Regulations

Write detailed description of work to be performed by the Contractor here. If there is no required work under an applicable state and local laws and regulations, then the section should be deleted and renumbered.

3.3  OPERATIONAL REQUIREMENTS

******************************************************************************
NOTE: The coordination with other federal, state, and local jurisdictions and agencies, the public, and private entities must be completely resolved before finalizing the specifications. A project’s excavation and/or foundation requirements, for which submerged, dense materials are being removed, may require navigation, highway, structural and/or other regulations and codes to be followed. Depending upon the proximity of public-use areas, private residences or businesses, and the project’s location within a county or township, various accommodations will need to be required for the protection of the
public, and the safety of private entities regarding local laws, regulations, and ordinances. Avoiding natural-resource impacts may overlay other measures and require seasonal or daily time limitations of the initiation of the individual blast patterns; special observers for some or all the blasting; special studies or monitoring while the blasting is being conducted; and other potential considerations.

Agency coordination will vary by project. Be certain that all government stakeholders have been involved with planning of the project and approved of all requirements for the specifications. List those important navigation or safety stakeholders in 3.3.2. When there are navigable waters near the excavation zone, list in 3.3.2 the controlled navigation perimeter's distance during the warning period of a shot. While the distance is project specific, the minimum distance is typically 300 m 1,000 ft.

**************************************************************************

3.3.1 Coordination

3.3.1.1 Schedules

Coordinate schedules for blasting with the proper authorities, federal, state, local. No blasting will be conducted unless the Contractor is notified by the appropriate parties that blasting may proceed. In addition, if channel restrictions of navigable waters are required for drilling and blasting, the Contractor will coordinate with the U.S. Coast Guard.

3.3.1.2 Permits

Obtain all necessary permits from the state and local authorities to transport explosives and all blasting agents necessary, and to perform blasting operations on site. The Contracting Officer will be notified in writing that all permits have been obtained and will be furnished copies of all permits.

3.3.2 Navigational, Lock or Vessel Control During Excavation and Removal

Various agencies and offices, [____], must be notified of the scheduled blasting times for coordination. The Contractor must assure that no vessels are within, nor on a heading and speed to be within, [____] m [____] ft of the shot pattern during the 5-minute warning.

3.3.3 Work Restrictions

**************************************************************************

NOTE: While it is not typical to have low tolerances for the horizontal variation of submerged walls or for the vertical variation of submerged pay grades, some projects may require limited control of the walls and grades in underwater blasting. Before resolving the project's underwater tolerances, determine an easy and effective means to survey the submerged walls and grades, and further assess to
what precision such surveys may estimate horizontal and vertical variations over short distances. Presplitting would be an unusual requirement for underwater blasting, even in shallow water, because of the precision of knowing the horizontal location and vertical relief of the presplit walls. In projects where controlled blasting techniques are required to produce final walls which require presplit blasting, only explosives designed for this application must be allowed.

List all the restrictions for blasting agreed to by various agencies and offices in the sentence of the first paragraph, "The restrictions include: [______]." Such restrictions may need to be detailed elsewhere in the specs, and may include any or all or the following: public notices; vessel traffic control by patrolling and through the Coast Guard; blast initiation only during daylight hours; prohibiting the use of bulk explosives; assuring confined detonations within sound rock; limiting the maximum charge weight of explosives per delay; assuring that airblast and vibration remain below acceptable levels; recording all shots with videography and blast seismographs; seasonal restrictions to lessen the likelihood of a species in the blasting area; and, the use of fish-repelling noise immediately preceding every shot. Some specialty requirements will require careful consideration for their need and will require the design input of experienced specialists. These specialty requirements include, but are not limited to, underwater pressure wave monitoring or mitigation by use of an air curtain. The design or limitation of the action is stated in these paragraphs. The Contractor's actions or coordination of required Natural Resource activities are listed in paragraph NATURAL RESOURCE ASSESSMENTS, MITIGATION AND MONITORING.

There are a variety of restrictions upon blasting to assure that there are no adverse impacts to the public and upon commerce, and to avoid harm to surrounding structures and to the natural resources and their habitats. The restrictions include: [______]. Several restrictions that are not fully detailed elsewhere within this chapter are noted in this paragraph.

3.3.3.1 Confined Detonations

The rock excavation after blasting will be more effective if each loaded drill hole is well confined by stemming within sound rock. The intent is to confine the gaseous detonation products of each shot hole, such that no rifling plumes, the visual result, are produced in any shot patterns. The premature release of the gaseous products reduces or eliminates effective fracturing and displacement and causes large water-borne pressures potentially damaging to natural resources. Drill-hole logging is required to recognize the depth of firm rock and voids, and to adjust the designed Individual Shot Plan loading of each shot hole with explosives and stemming according to the position of sound rock relative to the paid elevation of
removal. Video recording of each blast will detail the effectiveness of avoiding rifling plumes.

3.3.3.2 Temporal, Weekly and Seasonal Restrictions for Blasting

**************************************************************************
**NOTE: Determine the times, days, and dates that blasting is permitted. Typically, blasting is only allowed during business hours on business days and Saturdays, particularly when there may be vibratory blasting impacts at residential, business and/or commercial structures. Specialty or critical facilities may require other temporal and vibratory restrictions. Usually, blasting is restricted from being conducted on Sundays and federal holidays. There may need to be date restrictions for specific local or regional events. In coordination with state and local entities, revise the paragraphs for your specific project.**
**************************************************************************

Blast initiation is permitted: during daylight, business hours on business days; on Saturdays to [______]; and, on Sundays and federal holidays to [______]. Regardless of the season, blast initiation is only permitted, during the period from one-hour after sunrise to one-hour before sunset. The Contractor will not be constrained by weather conditions, except for lightning, for underwater blasting in depths of water greater than 0.9 m (3.0 ft) for which airblast is often negligible. Drilling and blasting will not be permitted during the following seasonal periods: [______].

3.3.3.3 Allowable Vibration

**************************************************************************
**NOTE: Vibration monitoring is required for every blasting project. The paragraph’s narrative is a generic description for most projects, where the nearest structure/facility is: Standard Construction Timber Frame, Brick, and Concrete Buildings; Lock Monoliths; Powerhouse Switchyard; Highway and Railroad Bridges; Buried Utilities; and Wells and Aquifers. Some projects may require assessment by a trained experienced blasting specialist or structural engineer of lower allowable vibration criteria at critical or historic or special structures or facilities or structures with continuous occupants. Vibrations can cause the occupants of structures to become physically uncomfortable at levels well below the allowable vibration levels to avoid damage to the structure itself. Projects with a Powerhouse and Electrical Power Relay Equipment or Pipelines, besides those with continuous occupants, should be evaluated for lower allowable vibration criteria. Some projects could utilize the assessment by a trained experienced blasting specialist or structural engineer to include higher allowable vibration criteria for those projects where typical structures/facilities are more than twice the distance of the closest approach of blasting to:**
**************************************************************************
Steel and Reinforced-Concrete Structures; Mass Concrete Monoliths; and Cured Shotcrete.

Alternate language and charts for this section:

TABLE 1 below gives standards for allowable peak particle velocities as they relate to a variety of common construction materials. Do not exceed these vibration limits.

These vibration limits must not be incorporated in the blast design. Many projects have been constructed utilizing a fraction of these allowable values. Properly design the blasts, set allowable vibration limits, and maintain proper control throughout the duration of construction. The Contractor is responsible for all damages caused directly by, or as a result of the blasting operations. Compliance with this or any other provisions in the Contract must not relieve the Contractor of responsibility for any damages or injuries caused by, related to, or arising out of blasting or associated blasting activities.

Here are two examples of vibration tables. The first is more generic and should be used the section shows for a specific project also requiring an initial peak particle velocity for test blasting ramp up.

</tbody>
</table>

Note that older deteriorated structures or utilities and structures housing computers or other sensitive equipment may require lower peak particle velocity limits than those provided in Table 1. Also, buried pipelines owned by private utility companies or bridge structures owned by other agencies may be subject to lower limiting values imposed by the owner. The safe vibration limits and charge weights per delay to achieve these vibration limits must be established by the Seismic Specialist and the Blasting Consultant. Vibration limits for all non-government owned structures must conform to the laws of the State of [____]. The text below can be used referring to the graph in NFPA 495 in lieu of site specific developed for the project.

The Contractor must conduct all the required monitoring as noted in paragraph IMPACT MONITORING. The Contractor must conduct all blasting by controlled blasting methods to avoid exceeding the allowable vibration in applicable federal, state, and local laws, regulations and ordinances at all structures and facilities, as monitored by blast seismographs.

The allowable vibration at any structure or facility must not exceed the maximum PPV of **5.0 centimeters/second (cm/s) 2.0 inches/second (ips)**, nor exceed the PPV amplitude in the Frequency versus Particle Velocity Graph Figure in NFPA 495 (Figure 11.2.1) for the frequency of the half-cycle amplitude.

**NOTE:** The section pertaining to Green Concrete may be removed and its definition removed, if the concern for newly placed concrete, shotcrete and/or cementitious grouts is not applicable. The period of hours is broad, because neither the exact time of the blast nor of the material placement will be known exactly. Values of allowable PPV have not been included greater than 2.0 ips, because above 2.0 ips will adversely affect ordinary structures.
and individuals within those structures. Further, most concrete structures should be limited to allowable PPV at or below 4.0 ips.

3.3.3.4 Limiting Blast-Induced Vibrations at Green Concrete

NOTE: Some guidelines for peak particle velocities related to time intervals after placing mass concrete/shotcrete/grout curtains are given in Tables 2 and 3 should be considered when designing a blast. The specification writer must include a limitation of the allowable vibration when there is green concrete expected on the project. Table 2 has two option, one is more conservative, designer should make engineering decision which to use or adjust based on data. There are other potential charts that can be used:

**TABLE 2: VIBRATION LEVELS FOR GREEN MASS CONCRETE/SHOTCRETE/GROUT**

During the performance period, other construction activities may be placing concrete at varied locations on or near the project. The Contractor will coordinate with other project contractors or will be informed on the prior business day by the Contracting Officer concerning the likely placement of concrete near the project.

a. The Contractor will assure that a seismograph is monitoring vibrations from blasting at a location, which is closer to the blast pattern than the Green Concrete. Seismic monitoring must be conducted near the
concrete placement from prior to placement until 72 hours after placement.

b. The table below indicates that maximum allowable peak particle velocity (PPV) permitted, relative to the age of the recently-place concrete, as measured at an acceptable location or within 15 m 50 ft of the most recently placed concrete on the side of closest approach to the blast.

<table>
<thead>
<tr>
<th>Age of Concrete (hours)</th>

c. Adjust all blasting to conform to the table's maximum allowable PPV at the seismograph near the Green Concrete. See paragraph IMPACT MONITORING.

3.3.3.5 Allowable Airblast

**************************************************************************
NOTE: Airblast is rarely a concern with underwater blasting. Some provision for allowable airblast should be provided within this paragraph. Air blast limits should follow most stringent regulation as some states have a threshold more stringent than some agencies.
**************************************************************************

The Contractor must conduct all the required monitoring as noted in paragraph IMPACT MONITORING. The Contractor must conduct all blasting by controlled blasting methods to avoid exceeding the allowable airblast in applicable federal, state, and local laws, regulations and ordinances at all structures and facilities, as monitored by blast seismographs. Peak airblast overpressure must be held below [133 dB (linear peak scale), 100. Pascals (Pa) 0.015 pounds/square inch (psi)] at the nearest residential or inhabited structure or other designated location.

3.4 BLASTING PERSONNEL

**************************************************************************
NOTE: Depending on the scope and duration of the project, it may be prudent to require the Contractor to provide a named and approved alternate for some positions. Several positions are required to continuously perform blasting responsibilities, even when one individual is not available onsite for that role's responsibilities.
**************************************************************************

3.4.1 Blasting Consultant

**************************************************************************
NOTE: Depending on the scope of the project, it may not be necessary to require a Blasting Consultant. This will be determined during design, a USACE Blasting SME should be consulted to discuss this. Projects with few critical blasting limitations, far from sensitive structures or from heavily used public areas, or with few Natural Resource issues
may not need a Blasting Consultant. One option is to still require a blasting consultant to be engaged, but only for reviewing the Master Blasting Plan and engaged on serious blasting issues with the blasting (misfires, shot hole rifling loss of confinement, exceedance of vibration and/or airblast limits, approaching Natural Resource limitations without being able to properly break and displace rock) as and if the issues develop.

The Blasting Consultant, Blasting Specialist, Blasting Administrator, Blaster in Charge, and Vibration Specialist cannot be the same person. Retain a recognized Blasting Consultant to assist both with the project's blast design and with the resolution of any blasting issues for the project. The Contractor must submit the Blasting Consultant's expertise submission within [15] [_____] days of the Notice to Proceed. The Blasting Consultant must be approved by the Contracting Officer's Representative two weeks prior to the submission of the Master Blasting Plan.

3.4.1.1 Blasting Consultant's Responsibilities

The Contractor's Blasting Consultant must be available to review the Master Blasting Plan, assist with controlled blasting techniques, and resolve difficult or complex issues with blasting for the project. The Blasting Consultant will recommend controlled blasting methods, as necessary, to meet safety and natural resource requirements, retain airblast and vibration within the allowble limits, and protect the rock foundation. Proposed controlled blasting methods must be submitted in the Master Blasting Plan.

The Blasting Consultant must provide advice for, and review, the Master Blasting Plan, attend the public meeting(s), and be available for consultation on an "as needed" basis, as determined separately by the Contractor or by the Contracting Officer. The Blasting Consultant is not required to be at the project site for review of the Master Blasting Plan or of any specific shot plans or records. The Blasting Consultant must be present at the project site for any required shot issue or, if requested, for the subsequent shot following a misfire or significant exceedance of any onsite blasting issues.

The Blasting Consultant must provide a written summary of all site visits and special assignments within [2] [_____] business days of performing such actions to both the Contractor and the Contracting Officer's representative.

The Blasting Consultant must submit a short, signed Blasting Consultant's Report each month stating that he/she has briefly reviewed the individual shot documents, including blast videos, and has collaborated with the Contractor on all issues, concerns, or errors in the individual shot documents. This report is due within [3] [_____] business days after the end of the month.

If problems with vibration, airblast, rifling of a shot hole producing a water column plume, or production blasting occur, the Contracting Officer
will require the Contractor to immediately summon the approved Blasting Consultant and have their presence on site within 10 days after the problem develops to:

a. Approve each Individual Shot Plan;

b. Observe in person shot-hole drilling, logging, revision to that hole's plan, and loading with the full authority to stop or delay any blast he/she considers unsafe;

c. Review and sign each Individual Shot Record at no additional cost to the Government; and,

d. Submit and sign a written checklist that all necessary precautions were reviewed and followed by the drilling and blasting crews.

The checklist must be as defined under the section on Individual Shot Reports. The signed checklist must be attached to each Individual Shot Report.

3.4.1.2 Blasting Consultant's Expertise

The consultant must be able to demonstrate involvement in at least 15 projects with controlled blasting. The consultant must provide, as a minimum, the credentials and experience for each outlined following items:

a. The consultant must have at least 10 years of experience in construction blasting within 75 m 250 ft of protected structures, and had consultation on three underwater blasting programs;

b. The consultant must be able to demonstrate that he has attended at least 15 short courses, seminars, or conferences on blasting technology, or university engineering class studies on blast design during the past 20 years, including a complete understanding of blasting seismology with emphasis on vibration frequency, acceleration, and displacement (ground strain);

c. For the past 10 years the consultant must have derived their primary source of income from providing specialized blasting consulting services;

d. A list of recent projects containing a description of the projects' details, summarize the blasting plans, and any modifications made during the projects from your consulting;

e. Provide the names and telephone numbers of contacts, who have sufficient stature with, and knowledge of, their individual project to verify the submitted information in competency and ability, for at least three recent projects;

f. Hands-on experience as a blaster for at least 3 years; and,

g. The Blasting Consultant, Blasting Specialist, Blaster in Charge, and Seismic Specialist cannot be the same person.

3.4.1.3 Blasting Consultant's Qualifications Submissions

Submit the resume, education, experience, current blasting licenses and credentials, and training of the proposed Blasting Consultant, and a formal
letter of commitment from the consultant verifying their availability on an "as needed" basis for the duration of the Contract. The consultant must be a drilling and blasting expert, who has derived their primary source of income by providing specialized blasting and blasting consulting services. The provided consultation must have included at least three, large underwater blasting projects. The consultant must not be an employee of the Contractor, an explosives manufacturer, an explosives distributor, or any other sub-contractor. There must be no additional cost to the Government for the Blasting Consultant's duties, even when required by the Government.

3.4.2 Blasting Specialist

The Blasting Specialist is the Contractor's employee most responsible for the project's blasting and conducting all coordination and providing all documentation for the underwater blasting. The Blasting Specialist must coordinate with the Contracting Officer on all issues dealing with blasting. The Blasting Specialist must be on the job site each day. The Contractor must submit the Blasting Specialist's expertise submission within [15] [_____] days of the Notice to Proceed. The Blasting Specialist must be approved by the Contracting Officer's Representative two weeks prior to the submission of the Master Blasting Plan.

3.4.2.1 Blasting Specialist's Responsibilities

The Blasting Specialist is responsible for the project's blast design, preparing and submitting all necessary blasting documentation, and conducting quality control. The Contractor may employee a documentation assistant to aid the Blasting Specialist with all the blasting documentation creation and submissions. The Blasting Specialist is solely responsible for the accuracy and timely submission of all blast documentation.

3.4.2.2 Blasting Specialist's Expertise

The Blasting Specialist must be able to demonstrate involvement in at least three projects with underwater blasting. The Blasting Specialist must provide, as a minimum, the credentials and experience for each outlined following items:

a. The proposed individual must have at least 10 years of verifiable experience utilizing controlled blasting techniques and have had conducted controlled blasting on three underwater projects;

b. Within the last five years, the proposed individual must have completed at least five days of classroom training that has familiarized the person with the most current drilling and controlled blasting methods;

c. The proposed individual must be a licensed blaster in the State of [_____] and hold all credentials that may be required by local jurisdictions;

d. In the last five years the proposed individual must have been responsible for the blast design or execution of underwater rock excavation projects, similar in scope and complexity as this project;

e. The names and telephone numbers of contacts, who have sufficient stature with, and knowledge of, their individual project to verify the submitted information in competency and ability, for at least three
f. The Blasting Consultant, Blasting Specialist, Blaster in Charge, and Seismic Specialist cannot be the same person.

3.4.2.3 Blasting Specialist's Qualifications Submission

Submit the resume, education, experience, current blasting licenses and credentials, and training of the proposed Blasting Specialist. Their credentials must include a list of the projects, including the location, duration, scope, description, geologic conditions, and the challenges that developed though the course of the projects and how the challenges were resolved.

3.4.3 Blaster in Charge

The Blaster in Charge may create the Individual Shot Plan for approval by the Blasting Specialist. The Blaster in Charge, in the absence of the Blasting Specialist, is the Contractor's employee responsible for on-deck supervision of all underwater blasting activities and its documentation. The Contractor must submit the Blaster-in-Charge's expertise submission within [15] days of the Notice to Proceed. The Blaster in Charge must be approved by the Contracting Officer's Representative two weeks prior to the submission of the Master Blasting Plan.

3.4.3.1 Blaster-in-Charge's Responsibilities

The Blaster in Charge, in the absence of the Blasting Specialist, is responsible for on-deck supervision of the drilling, shot-hole logging, possible revisions of the Individual Shot Plan, loading or abandoning of individual shot holes, and firing the blast. The Blaster in Charge is responsible for: the accurate placement of the shot holes' locations for drilling; conducting the drilling and shot-hole logging accurately; accounting for the relevant geology within each shot-hole's log; assuring the careful recording of every shot-hole's log and their submission with the Individual Shot Report; loading the blastholes according to the Individual Shot Plan or the revision thereto based on the shot-hole's log; coordinating the likely time of the blast pattern's initiation; coordinating all notices of imminent blasting and providing the signaling before and after the shot; initiating the blast; performing the post-blast inspection; providing the All-Clear signal or instituting the notices and actions for a misfire; and, providing the documentation for, and signing, the Individual Shot Report.

3.4.3.2 Blaster-in-Charge's Expertise

The Blaster in Charge must be able to demonstrate involvement in at least two projects with underwater blasting. The Blaster in Charge must provide, as a minimum, the credentials and experience for each outlined following items:

a. The proposed individual must have verifiable experience in equivalently responsible roles for controlled blasting projects for at least 3 years and with underwater projects;

b. Within the last 5 years, the proposed individual must have completed at least five days of classroom training that has familiarized the person with the most current drilling and controlled blasting methods;
c. The proposed individual must be a licensed blaster in the State of [_____] and hold all credentials that may be required by local jurisdictions; and,

d. The Blasting Consultant, Blasting Specialist, Blaster-in-Charge, and Seismic Specialist cannot be the same person.

3.4.3.3 Blaster-in-Charge Qualifications Submission

Submit the resume, experience, current blasting licenses and credentials, and training of the proposed Blaster-in-Charge. Their credentials must include a list of the projects, including the location, duration, scope, description, geologic conditions, and the challenges that developed through the course of the projects and how the challenges were resolved.

3.4.4 Blasters

The Contractor may elect to employ multiple Blasters. Each Blaster is a Contractor's employee responsible for on-deck, underwater drilling and blasting activities under the supervision of the on-deck, Blasting Specialist or Blaster in Charge, whoever is present. The Blaster in Charge or a Blaster will log each shot hole, as the hole is being drilled. Each Blaster must be approved by the Contracting Officer's Representative after the submission of the Master Blasting Plan.

Blaster qualifications require each Blaster must be able to demonstrate prior experience with drilling and blasting. The proposed individuals must be a licensed or certified blaster in the State of [_____] and hold all credentials that may be required by local jurisdictions. Submit the resume, experience, current blasting licenses and credentials, and training of each proposed Blaster with the Master Blasting Plan.

3.4.5 Blasting Administrator

**************************************************************************
NOTE: For smaller projects this position may not be necessary. The Blasting Administrator was added for large projects to aid the Blasting Specialist with paperwork.
**************************************************************************

The duties of the Blasting Administrator are to be the direct assistant of the Blasting Specialist in preparing all necessary paperwork, and in performing quality control on all issues dealing with blasting. The primary function is to assist the Blasting Specialist in the preparation and completion of submittals, prepare the detailed post blast report, and the individual shot videos for submittal to the Contracting Officer, and submit the drilling logs with the post blast report. The Blasting Administrator cannot sign any paperwork. The Blasting Administrator must be approved by the Contracting Officer.

Blasting Administrator's qualifications require the Blasting Administrator to possess the following minimum qualifications and experience:

a. Holds a current Blaster's license;

b. Have prior experience in underwater blasting;

c. Must have completed at least five days of classroom training within the
last five years that has equipped the person with the most current knowledge in blasting procedures; and the software to be used on the project; and,

d. Have proven proficiency with blasting software and spreadsheets.

3.4.6 Vibration Monitoring Specialty Firm

**************************************************************************
NOTE: This is requirement is a new format from previous specifications. The firm is submitted for approval, having the appropriate experience and the firm must have on staff the Seismic Specialists and Seismograph Technicians, typically a firm is subcontracted by the Contractor and having multiple experienced people approved allows them to have flexibility on supporting the site work. The people coming to the project or responding to the work must be within the group approved but does not need to be a single person anymore.
**************************************************************************

Retain the services of a vibration monitoring specialty firm that specializes in the prediction, monitoring, and control of ground vibration and airblasts. The firm must have experience conducting installation of seismographs for vibration monitoring, communicating vibration and airblast results, and developing and maintaining a site attenuation curve. The firm must have on staff at least two Seismic Specialists that specialize in vibration monitoring and analysis. The firm must have on staff at least four Seismograph Technicians that have five years or more experience with seismograph installation and vibration monitoring. Submit resumes for all personnel and for the firm for approval citing, in additional to other pertinent data, experience, training, and education, at least 60 days prior to the commencement of blasting. The Seismograph Technicians must be persons capable of setting up the seismographs at designated locations, effectively recording the blast, and appropriately interpreting results. The Seismic Specialists must interpret the seismograph records to ensure that the seismic data must be effectively utilized in the control of the blasting operations with respect to the existing structures. The Seismograph Technicians must supervise the placement, operation, and maintenance of the seismographs. The Seismic Specialists must conduct the airblast and particle velocity regression analysis as described in this Section. The Contracting Officer may require the Seismic Specialists and Seismograph Technicians to be present during the test blast program, production blasting, or both.

3.4.7 Seismic Specialist

The Contractor will retain the services of an independent, seismic-monitoring firm with employees capable of monitoring, assessing, and predicting vibrations and airblast due to blasting. The Seismic Specialist must be an employee of the independent, seismic-monitoring firm, and must not be an employee of the Contractor. The Seismic Specialist will conduct, or assure the actions are being taken to obtain, the required blast seismograph monitoring for the project. The Seismic Specialist will supervise all Seismograph Technicians deployed to the project to deploy and maintain all the seismographs for recording vibrations and airblast, and to properly retain, store and submit all seismic records of the blasting. The Contractor must submit the independent, seismic-monitoring
3.4.7.1 Seismic Specialist's Responsibilities

The Seismic Specialist must be a person able to deploy blast seismographs, effectively record and transmit the seismic data, comprehensively assess, and interpret seismic data regarding the monitored blast's parameters, and remotely supervise the firm's Seismograph Technicians. The Seismic Specialist must also interpret the seismic records to ensure that the seismic data will be effectively utilized in the control of the blasting operations with respect to the existing structures and conduct of an optimized blasting program.

3.4.7.2 Seismic Specialist's Expertise

The Seismic Specialist must be able to demonstrate monitoring deployment, seismic data assessment and interpretation, prediction of vibration and airblast from blasting, and remote supervision of field personnel for five blasting projects. The Seismic Specialist must provide, as a minimum, the credentials and experience for each outlined following items:

a. The proposed individual must have verifiable experience in equivalently responsible roles for controlled blasting projects for at least 3 years;

b. Within the last five years, the proposed individual must have completed at least five days of classroom training concerning seismic monitoring equipment, data telemetry, and seismic data interpretation;

c. The Blasting Consultant, Blasting Specialist, Blaster in Charge, and Seismic Specialist cannot be the same person. The proposed Seismic Specialist and Structural Inspection/Evaluation Specialist may be the same person.

3.4.7.3 Seismic Specialist Qualifications' Submission

Submit the credentials of the proposed seismic-monitoring firm with documentation for the Seismic Specialist. Submit the firm's history for this office, if there are multiple offices, years under the present office's leadership, the regional extent of clients, the approximate number of projects in the past year, and the number of present employees at this office. Submit the resume, education, experience, credentials, and training of the proposed Seismic Specialist. Their credentials must include a list of the projects, including the location, duration, scope, description, and the monitoring challenges that developed though the course of the projects and how the challenges were resolved. The documentation must provide experience and capability for the proposed Seismic Specialist to provide remote blast monitoring and supervision of support personnel while the individual is not on site.

3.4.8 Seismograph Technicians

The approved, independent, seismic-monitoring firm may provide Seismograph Technicians to assist the Seismic Specialist with the project's vibration and airblast monitoring. Each Seismograph Technician must be approved by the Contracting Officer's Representative after the submission of the Master Blasting Plan.
Each Seismograph Technician must be able to demonstrate prior experience with blast seismic monitoring on a prior project of equivalent size and similar telemetry requirements. The proposed individuals must have the required training and hold all credentials that may be required by local jurisdictions. Submit the resume, experience, credentials, and training of each proposed Seismograph Technician with the Master Blasting Plan.

3.4.9 Structural Inspection/Evaluation Specialist

*******************************************************************************************************************************************
NOTE: Pre- and Post-Blast Inspections and the Structural Inspection/Evaluation Specialist would only be required if there are structures or facilities requiring such inspections. Eliminate the paragraphs referencing Pre- and Post-Blast Inspections and the Structural Inspection/Evaluation Specialist if the project does not have a requirement for these inspections. The Structural Inspection/Evaluation Specialist must be experienced in both pre- and post-blast inspections. While there may be an advantage to this person being a registered professional engineer, it is more important that the specialist have experience in evaluating potential blasting effects by post-blast inspections. Consider whether a registered professional engineer is a requirement, as the most experienced persons may not be registered professional engineers or may be difficult for a bidder to acquire for some projects
*******************************************************************************************************************************************

Pre- and Post-Blast structural inspections must be performed by specialists with at least five years' experience in pre-blast and post-blast surveys.[The Structural Inspection/Evaluation Specialist must be a Registered Professional Engineer in the State of [______], who is qualified to conduct structural evaluations.] Submit the resume, education, experience, credentials, and training of the proposed Structural Inspection/Evaluation Specialist to the Contracting Officer with the Master Blasting Plan. The proposed Seismic Specialist and Structural Inspection/Evaluation Specialist may be the same person.

3.4.10 Magazine Keeper

The Magazine Keeper and an Alternate are the Contractor's employees responsible for explosive magazines and its record keeping. The position of Magazine Keeper is required only if the Contractor elects to have explosives' magazines under his control. The Magazine Keeper must be approved by the Contracting Officer's Representative after the submission of the Master Blasting Plan.

The Magazine Keeper must be familiar with the laws and general practices concerning the handling, care, use, and storage of explosives and detonators. The Magazine Keeper must be responsible for maintaining a cleared area around each magazine, and accounting for by record the throughput of explosives and detonators. The Magazine Keeper must be present for any transfer of explosives and detonators into or out of the magazines. The Magazine Keeper must not be required to perform any duties that will in any way interfere with his or her duties as Magazine Keeper.
The Magazine Keeper must be able to demonstrate prior experience with explosives' magazines. The proposed individual must hold all credentials that may be required by the State of [_____] and local jurisdictions. Submit the resume, experience, credentials, and training of the proposed Magazine Keeper with the Master Blasting Plan.

3.5 RECORD KEEPING

3.5.1 Pre-Blast Surveys

**********************************************************************************************************************************************
NOTE: Pre- and Post-Blast Inspections and the Structural Inspection/Evaluation Specialist would only be required if there are structures or facilities requiring such inspections. Eliminate the paragraphs referencing Pre- and Post-Blast Inspections and the Structural Inspection/Evaluation Specialist if the project does not have a requirement for these inspections. The lateral distance to the nearest structures by azimuth may vary by project. Typically, only those nearest structures to the excavation zone requiring blasting in a general azimuthal direction are surveyed. Example, if there are many structures within 1,000 feet (if that is the resolved lateral distance) for a specific project, only the closest structures at ~700 feet to the south and at ~850 feet to the east would need to be surveyed. For the example project those structures within 1,000 feet of the excavation zone are protected by the pre-blast surveys of the structures closer to the excavation zone on the same azimuth. If any of the structures or facilities are critical or sensitive features or if there is some public or governmental concern, it may be prudent to conduct the pre-blast surveys for all the structures within 1,000 ft, not just the closest by azimuth. The lateral distance also may need to be increased for certain projects. The Agency may seek rights-of-entry for these structures proposed for surveys with the announcement of the Public Meeting. Those owners, who decline the right-of-entry, miss their opportunity to document that there were no prior defects, so that Post-Blast Surveys could document the damage but would not have a Pre-Blast Survey to show there was no previously existing damage given the owner's claim of new blasting damage.

**********************************************************************************************************************************************

Prior to the commencement of blasting, conduct a pre-blast survey of nearest buildings, structures, and utilities within 300 m 1,000 ft from the blast area by azimuth about the blasting zone to document pre-existing conditions. The pre-blast surveys will be conducted by, or under the supervision of, the Structural Inspection/Evaluation Specialist, who will also sign and date each survey. The survey extent and method used must be acceptable to both the Contractor's insurance company and the Contracting Officer. Submit a copy of all pre-blast surveys at least two weeks prior to the first Test Blast. Provide owners of surveyed structures a copy of
their Pre-Blast Survey before, or with the notice of, blasting commencement. Notify owners and occupants of local buildings 10 days prior to the commencement of blasting.

Perform the following when conducting pre-blast survey.

a. Provide methodology to be used in conducting the pre-blast survey and listing of structures, determined from the survey to be sensitive, with reasons for these structures being sensitive.

b. Each structure must be documented (including photography and video recordings) as to its construction, foundation type, condition, and closest distance to excavation blasting. The general condition and all observable defects of each structure must be documented.

c. The Commodity storage facilities that may be impacted by blasting must be addressed by the Contractor for safety and continued operation during the blasting program.

d. Freestanding structures (such as retaining walls) must be inspected on the exterior and on the interior as a room. All concrete walks, driveways, etc. must be inspected for cracks, level condition, holes, and defects.

e. Industrial structures, silo/elevators and special facilities, and office space must be described relative to their present conditions and tolerance to vibration. Besides the inspection of walls, columns and stairwells, the Contractor must survey the work areas and structures for distress.

f. An inspection of accessible structures must be made and a list of all structures, which could not be surveyed or refused to allow survey, must be completed. The dates of possible subsequent surveys and physical constraints prohibiting the survey must be documented.

g. Certify that the survey was prepared prior to the start of any blasting under this Contract.

3.5.2 Post-Blast Surveys

***********************************************
NOTE: Pre- and Post-Blast Inspections and the Structural Inspection/Evaluation Specialist would only be required if there are structures or facilities requiring such inspections. Eliminate the paragraphs referencing Pre- and Post-Blast Inspections and the Structural Inspection/Evaluation Specialist if the project does not have a requirement for these inspections.
***********************************************

Post-blast surveys are not typically required. Post-blast surveys must be conducted at any location, where a reasonable notice of damage from blasting has been provided. Post-blast surveys will be conducted by, or under the supervision of, the Structural Inspection/ Evaluation Specialist, who will also sign and date each survey. The survey extent and method used must be acceptable to both the Contractor's insurance company and the Contracting Officer. The post-blast surveys must be conducted within a week of the notice of damage from blasting. Submit a copy of all
post-blast surveys within two business days of the on-premises surveys to both the structure's owner and the Contracting Officer.

3.5.3 Daily Explosives' Magazine Inventory and Daily Explosives' Accounting

Accurate daily records must be kept by the Magazine Keeper, who must account for each piece of explosive, detonator, and equipment from the time of delivery at the magazine until its discharge in use or return to the magazine. If explosive products will be delivered and returned daily, the records of the driver must agree with the amount used in the day and a copy of each driver's record must be provided with the Daily Blasting and Removal Log submission. No explosive can be accepted until it has been plainly labeled and delivered as new stock in sound condition. Dates of manufacture and lot numbers will be recorded for all explosives delivered to the site. No explosive material older than 1 year will be used. Containers for explosives must be approved in advance by the Contracting Officer. Remaining inventory must be checked each day and any discrepancies must be immediately reported, regardless of the potential of accounting error, loss, or theft of explosive material.

Should a loss or theft of explosives occur, all circumstances and details of the loss or theft must be immediately reported to the nearest office of Alcohol, Tobacco and Firearms, as well as to the local law enforcement authorities and the Contracting Officer's representative.

3.6 BLASTING DOCUMENTS

3.6.1 Master Blasting Plan

The Master Blasting Plan must be submitted for approval by the Contracting Officer 45 days before the first anticipated Test Blast. No blasting may be conducted prior to the approval of the Master Blasting Plan. No deviation from the Master Blasting Plan will be conducted by the Contractor. Any request for change or revision to the Master Blasting Plan must be provided in writing and approved by the Contracting Officer before such change or revision can be performed. The Contractor will submit a Test Blasting Plan within the Master Blasting Plan that includes calculations for all noted adverse impacts. Non-electric blasting caps must be used for all underwater shots. The Master Blasting Plan must contain provisions for storing, handling, and transporting explosives, as well as for the blasting operations. The means of surveying and locating the shot-hole positions horizontally and vertically must be described in detail within the Master Blasting Plan. Provide a signed statement by the Blasting Consultant that the plan represents a safe and efficient set of means and methods with which to achieve the goals of the work. The Master Blasting Plan must be submitted with the signature and date of the Blasting Specialist. The Contracting Officer will have a minimum of 30 calendar days review of the revised plan. The Contractor may elect, or may be required, to revise and resubmit the Master Blasting Plan or a portion thereof; additional time will be allotted for review by the Contracting Officer.

**************************************************************************
NOTE: Add or delete sections of the Master Blasting Plan, as appropriate. Include within the Master Blasting Plan.
**************************************************************************
3.6.1.1 Proposed Blasting Personnel

Submit all the approved and proposed blasting personnel and their required information from paragraph BLASTING PERSONNEL. List and copies of licenses, permits, and clearances required, including permit numbers, when applied for, and date of approval or anticipated approval by Federal, State, and local concerns. Provide their police records for every approved and proposed blasting individual. Submit the complete Project Team Organization with duties, responsibilities and authorities clearly defined. Identify the on-site Safety Officer and include a listing of all personnel authorized to sign for, receive and use explosives on this contract.

3.6.1.2 Explosives and Blasting Equipment

Submit all the explosives, their use, and their data sheets for the project. Data sheets, which include the products' specific gravity and water resistance, for all explosives and blasting agents that may be used.

3.6.1.3 Blasting Safety Plan

Submit Blasting Safety Plan, that is in accordance with EM 385-1-1, Section 29, and all other Federal, state, and local regulations. Implement all other applicable safety requirements in addition to that required below. Include, as a minimum, the following items.

a. Permanently secure all onboard magazines to the deck as required by all applicable Code of Federal Regulations.

b. Do not store explosives on the boat or barge deck in the open except for the one case that is to be loaded immediately into the shot holes. Return explosives remaining on deck to the day magazine prior to the firing of any blast. Clearly identify the location of the day magazine in the 'Blasting Safety Plan'.

c. Mount the non-electric, shock tubing spool on the rig in a manner that it cannot be lost overboard. Use an approved blasting machine for detonation regardless of the number of caps used. Do not use an electric blasting system.

d. Limit the amount of explosives aboard the drill boat at any one time to be in accordance with the amount permitted by appropriate codes and regulations. Do not exceed the amount permitted.

e. Make arrangements to prevent damage to any vessel, moored or underway, building or structure and preserve the crew or occupants thereon from exposure to injury as a result of the Contractor's operations. The Contracting Officer may require additional arrangements.

f. Perform a certified marine survey of all floating plant proposed for underwater blasting work on this contract prior to starting any work.

g. Install automatic fire extinguishers of an appropriate type on air compressors and in all engine compartments aboard vessels including but not limited to (drill boats, barges) where explosives are stored, handled, and used.

h. Provide remote fuel shut-offs and fire signaling devices aboard the drill boats.
i. Coordination Plans with the local Coast Guard office to provide notice of blasting and for vessel traffic control.

j. Alert sequence signals and public notice of blasting and all clear. See paragraph PUBLIC NOTICE OF BLASTING OPERATIONS in this section.

3.6.1.4 Navigation Control Plan

Submit the Navigation Control Plan in accordance with EM 385-1-1, Section 29, and all other Federal, state, and local laws and regulations. Implement all other applicable safety requirements in addition to that are required below.

Develop a Navigation Control Plan, which is incorporated into the Master Blasting Plan, that will provide the procedures required to maintain safe passage of all vessels within [____], during the project. The Contractor will maintain a 1/2 channel to a depth of [____] m ft below the low water datum for [____] for all marine traffic through [_____] during the project. The 1/2 channel will always be maintained, except during blasting events.

The Contractor will buoy the area with floating warning signs. The warning signs will be legible from a distance of 60 m 200 ft and must contain the message "DANGER - EXPLOSIVES IN USE" visible on either side of the sign.

Operate two or more patrol vessels during blasting operations equipped with a visible yellow flashing light, audible horn, and radio with a hailer, whose sole function will be to monitor and maintain security in the blast area. A patrol vessel will be stationed at the drill barge and remain in the blasting area during all blasting operations. Land oriented access control and visual observation locations should be determined and approved by the Contracting Officer. Inspect and insure there is no vessel traffic within the buoyed work area prior to providing the Shot's Warning Signals and until such time as the "All Clear Signal" has sounded. Establish and maintain a warning system as required by the Corps of Engineers Safety Manual. Equip and maintain floating plant with radio equipment capable of communications with the Coast Guard. After each blast, upon inspecting the area, immediately notify the U.S. Coast Guard and the Contracting Officer of the all clear or of a misfire.

Maintain the work areas that are not completed and accepted by the Corps to a depth of [____] m ft below the low water datum for [____]. In addition, for work located along the channel centerline, remove immediately obstructions that have impacted the main channel above a depth of [____] m ft below the low water datum for [____], prior to the "All Clear Signal," for marine traffic to resume.

The Corps of Engineers will provide clearance surveys, following rock blasting activities along the centerline of the main channel. The clearance surveys will be conducted immediately following a blast, to ensure that no rock material has fallen into the 1/2 channel used for marine traffic.

3.6.1.5 Production Blasting Design

**************************************************************************
NOTE: Have an experienced person, who is provided with the work restrictions, determine the maximum

SECTION 31 23 01 Page 47
charge weight per delay, when potential natural-resource impacts are being considered or have been accepted/negotiated. In absence of potential natural-resource impacts, the maximum charge weight per delay will not specifically be resolved. The allowable PPV at specific monitoring locations will govern the charge weight per delay designed for each shot pattern. The monitoring data for smaller charge weights per delay will be assembled from the Test-Blasting program.

Include within the Master Blasting Plan the detailed design of all required safety, protective, and natural-resource actions required of the Contractor or the engagement of a specialty subcontractor by the Contractor. Some of these safety, protective, and natural-resource actions for a project may include: special monitoring of a critical or essential facility or of a government or commercial structure; a fish repelling charge sequence prior to firing every shot pattern; an avian or mammalian watch program for assurance that a shot is not initiated at a time when the cited species is present; underwater pressure wave monitoring; and/or, an air-curtain mitigation program.

**************************************************************************
No blasting, including the Test Blasting, may differ from the approved Master Blasting Plan. Shot-hole drilling must not begin until the Master Blasting Plan is approved in writing. Reflect changes to the blasting or monitoring procedures, equipment, plant, products or personnel in a revised Master Blasting Plan or portion thereof. Obtain approval from the Contracting Officer, in writing, prior to implementation of any Master Blasting Plan changes or revisions.

Confine the loaded charge with angular, granular stemming materials, placed within competent rock, to perform the most work and to avoid a rifling plume from occurring within any shot hole. See paragraph STEMMING. The shortest delay period both between two adjacent shot holes and between two adjacent shot rows in the shot pattern is 25 milliseconds (ms). The maximum charge weight per delay may not exceed [_____] kg [_____] pounds of all combined explosives and blasting agents in each 25-ms delay period.

Include in the Production Blasting Design Section, as a minimum, the following items.

a. Proposed method of transportation, storage, and handling of explosives.

b. Procedure for monitoring the blast operations and handling misfires.

c. Plan showing the intended layout of the shot-hole patterns, timing and sequence, anticipated burden dimensions and depth of sub-drilling for a specified maximum charge weight per delay. Identify each drill hole by a unique, sequential identifier.

d. Typical size, depth, and spacing of blast holes; methodology to assure loading of explosives is only within sound rock; the maximum load density (in pounds per foot of drill hole length) and the maximum powder factor (in pounds of explosive per cubic yard of rock shot);
type of explosive and method of loading and detonating; procedure to
confine the charge with stemming; and maximum number of holes to be
detonated for a production shot pattern. Initiation system to be
deployed and the means to assure each shot hole fires on its own delay.

e. Sequencing of delays for each shot hole that will be employed during
blasting and the maximum explosive loading in pounds of explosive per
delay.

f. Indication as to whether decking or boosters will be used.

g. Type and number of drill frames, including drill hole diameter, and
expected production rates/day.

h. Type of blast seismographs to be used, manufacturer, and when last
calibrated or certified, and types of video cameras.
i. The formats of all logs and reports to be used throughout the life of
the project designed to record pertinent data before, during, and after
the blasting operation. Pertinent information includes, but not be
limited to, those items specified in paragraphs detailing the
submittals.

j. Names, office mailing addresses and phone numbers of Contractor's
representatives (Blasting Consultant, Blasting Specialist, Blaster in
Charge, and Seismic Specialist) to which any informational inquiries
may be addressed.

k. Location plan, manufacturer's literature, and parameters to be used in
site selection for the blast seismographs and video cameras. The
location of any other monitoring equipment, when used.

l. The methods that will be used to prevent all cited adverse impacts
during the blasting activities, including protection of natural
resources.

m. Complete list of floating plant involved in production blasting
operations.

n. Within the blasting plan consider the multiple types of commercial
vessels that will be on the water over the period of the excavation and
removal program. Notify the sail/yacht clubs, etc., of plans to blast
in advance and what traffic control and proximity restrictions will be
implemented.

o. Submit the means and methods to be used to recover and dispose of all
shock cord/tubing and initiation transmission-line debris immediately
following each shot.

3.6.1.6 Test-Blast Plan

**************************************************************************
NOTE: Have an experienced person, who is provided
with the work restrictions, determine the first test
shot's number of shot holes, the initial maximum
charge weight per delay for the test blasting, and
the second test blast's number of shot holes. For
some underwater blasting projects, the restrictions
may be so limiting that the initial charge weight

SECTION 31 23 01 Page 49
per delay will be quite low, perhaps kg, 5 lb per 25 ms delay. Other large projects with few natural-resource concerns and great lateral distances to non-federal structures may have a large initial charge weight per 25 ms delay. The former projects may have a production blasting allowable maximum charge weight per delay.

Test Blasting is the initial blasting for the project starting with lower explosive loading in shot holes and fewer shot-holes in each initial shot pattern. The purpose of the Test Blasting is to safely build to the level of Production Blasting and to accumulate data to avoid shot-hole rifling and the cited adverse effects from blasting. An Individual Shot Plan must be provided for each Test Blast.

A minimum of three shots are required for the Test Blasting. Increase the number of shot holes loaded and the maximum charge weight per delay of subsequent test and production shot patterns only if the prior test shot was apparently successful. An apparently successful shot pattern is defined as a properly fired pattern without rifling plumes that has seemed to have been effective prior to excavation and has remained below the maximum, peak particle velocity values, as prescribed in paragraph ALLOWABLE VIBRATION. For the next immediate test shot pattern, use a smaller number of loaded drill holes and a smaller maximum charge weight per delay, if (1) the prior shot pattern had a rifling plume [and][or] (2) underestimated the recorded, PPV by 25 percent at any monitoring location [and][or] (3) had any type of misfire, damage or injury or accident or claim thereof.

a. Limit the first test shot to [3] [_____] total drilled shot holes in a single row and have a maximum charge weight per delay of [_____] kg [_____] lb of explosive materials per 25-ms delay.

b. Limit the second test shot to [7] [_____] total shot holes in a single row of the shot pattern of the Contractor's choosing and to a maximum charge weight per delay of double the first shot's maximum charge weight per delay, if the first test shot was completely satisfactory.

c. The third and any further test shot patterns may use double the number of the shot holes of the preceding satisfactory shot, included within two or more shot rows, and double maximum charge weight per delay of the preceding satisfactory shot [to the production-shot maximum allowable charge weight per delay of [_____] kg [_____] lb of explosive materials per 25-ms delay].

A Test-Blast Evaluation Report must be provided within two business days to the Contracting Officer's representative in writing and by e-mail to the cited e-mail address listing once the last Test Blast has reached the explosive load per shot hole and the number of shot holes and rows to conduct Production Blasting.

3.6.2 Individual Shot Plans

NOTE: The Master Blasting Plan must provide the format of the Individual Shot Plan for approval with the Master Blasting Plan. Include within list item 3.6.2 b.(6) all special duties and/or actions.
required for the project that have been established for protection of individuals, natural resources, and/or structures.

The Contractor must submit an Individual Shot Plan 24 hours prior to any subsequent drilling and blasting for that shot pattern. The format may utilize a spreadsheet for ease data entry but requires an actual signature and handwritten date for its submission.

Prior to each blast, including Test Blasts, the Contractor must submit for the Contracting Officer's documentation a plan detailing all the data required in the Individual Shot Plan's format of the approved Master Blasting Plan. The plan will provide all the pertinent aspects of the blast design including, but not limited to, the loading, firing, delay sequence, and special considerations. The Individual Shot Plan will provide the location and depth of holes, inclination of all holes that will not be vertical, the proposed depth and the spacing of the blast holes, amount, and strength of explosives per hole and per pattern, the proposed sequence of firing and time delays, and estimated time and day for the pattern's initiation. Each proposed shot pattern will be designed by the Contractor's Blasting Specialist with changes being determined by observation of the way the rock breaks as the operations progress. The Contractor must take such precautions as are necessary to prevent displacement, cracking or damaging the rock outside the prescribed limits of dredging or excavation. The rock outside the limits of the dredging must be left in as sound and undamaged a condition as possible.

a. Submit an Individual Shot Plan to the Contracting Officer, with the anticipated plan for the next shot pattern prior to drilling the shot holes. Furnish each submitted Individual Shot Plan as a signed paper copy and in digital form to the e-mail listing required by the Contracting Officer. The Individual Shot Plan may be developed in a format that easily provides data that remains the same for the actual shot information in the Daily Blasting and Removal Log and the Individual Shot Report with its included reports.

b. The Individual Shot Plan includes, as a minimum, the following items:

1. The shot pattern's name/number, coordinate locations of the outermost holes of the shot pattern, any specific purpose for the shot, the anticipated time, date, weather conditions, and the water conditions and its elevation at the anticipated time of the shot;

2. The total number of holes to be shot, the shot-hole diameter, the total weight of explosives, number of delays, load density and powder factor for the shot, the maximum charge weight per delay, the closest approach, scaled distance and estimated PPV and airblast overpressures at each monitoring location;

3. A large-scale plan map depicting the proposed layout of shot hole pattern, timing and delay sequence;

4. An elevation sketch showing a typical hole's loading from the water surface to the bottom of the drill hole with an elevation scale, including the elevation of the removal grade, the top of sound rock, the top and bottom elevation of stemming, the top and bottom position of explosive materials, and the position of all
detonators, boosters and primers in the hole;

(5) A tabular listing, which may be a printed spreadsheet page, by hole in the ascending total delay time order by the describing: row and number within the row of the shot hole, total delay time, the total charge weight of explosive materials for the entire hole, the largest charge weight of any deck within a hole on a separate 25-ms delay if any, top of sound rock elevation, bottom hole elevation or the top of stemming elevation at the bottom of a shot hole that was over-drilled in depth and backfilled, stemming elevations, and detonator, primer and booster elevations in the hole;

(6) The estimated PPV and airblast overpressure at each seismograph location and the lateral close approach distance from the shot pattern to each seismograph;

(7) the means to remove and dispose of all shock cord/tubing and/or initiation transmission-line debris immediately following the shot;

**************************************************************************
NOTE: Complete the required Natural Resource activities that the Contractor must either conduct or initiate the shot with coordination of other offices for them to conduct the required Natural Resource activities of paragraph NATURAL RESOURCE ASSESSMENT.
**************************************************************************

[ 8] The Contractor must employ a Natural Resource Subcontractor, submitted to the Contracting Officer to [list activities] and the Contractor must conduct the shot in coordination with other offices as they perform [list activities]; and

] (9) The name, title, and signature of the Blasting Specialist providing the form with the date of the signature.

3.6.3 Test-Blast Evaluation Report

Provide a report summarizing the Test Blasting and submit the report with the Individual Shot Report of the first apparently successful production shot.

3.6.4 Individual Shot Reports

The Contractor must submit an Individual Shot Reports, both in writing to the Contracting Officer and by e-mail distribution to the required e-mail addresses, on the next business day and prior to any subsequent drilling and blasting for the next shot pattern. The supporting reports related to each shot pattern, which was not included with the Individual Shot Report, must be provided with their required data by the submission date of each supporting submission. The Individual Shot Report may utilize the spreadsheets, maps, and sketches of that shot's Individual Shot Plan, which have been corrected or revised for the actual shot-hole use, loading, timing firing, and observed or recorded impacts.

The Contractor must submit for the Area Office's documentation a specific set of reports of all the actual information from an initiated shot pattern, including Test Blasts, required in the Individual Shot Report's
format of the approved Master Blasting Plan. The record will provide all the pertinent aspects of the blast design including, but not limited to: the time, date and weather conditions at the blast's initiation; proposed shot holes that were abandoned; the actual shot holes' positions and elevations of stemming, loading, decking, its delay and firing sequence, and special considerations; the total weight of explosives and the maximum charge weight per delay for the pattern; all pertinent factors about signaling and providing the all-clear signal; the peak particle velocity of all seismographs; and, any delays to shot initiation and all blast impediments, including by not limited to, shot-hole rifling plumes, observed impacts from blasting, misfiring, and reports of damage from blasting. The Individual Shot Report will include or be followed with all the supporting reports from the shot pattern. Each Individual Shot Report will be signed by the Contractor's Blasting Specialist or Blaster in Charge, whoever initiated the shot pattern's firing. The Contractor must take such precautions as are necessary to prevent displacement, cracking or damaging the rock outside the prescribed limits of dredging or excavation. The rock outside the limits of the dredging must be left in as sound and undamaged a condition as possible.

a. The Individual Shot Report may be developed in a format that easily provides data that remains the same from the proposed design of the Individual Shot Plan and the actual shot information for the shot's supporting reports and in the Daily Blasting.

b. The Individual Shot Record includes, as a minimum, the following items:

1. The shot pattern's name/number, coordinate locations of the outermost holes of the shot pattern, any specific purpose for the shot, the anticipated time, date, weather conditions, water conditions and its elevation at the time of the shot;

2. The total number of holes to be shot, the shot-hole diameter, the total weight of explosives, number of delays, load density and powder factor for the shot, the maximum charge weight per delay, the closest approach, scaled distance and recorded PPV and airblast overpressures at each monitoring location;

3. A large-scale plan map depicting the layout of shot hole pattern, timing, and delay sequence;

4. A tabular listing, which may be a printed spreadsheet page, by the loaded shot hole in the ascending total delay time order by the describing: row and number within the row of the shot hole, total delay time, the total charge weight of explosive materials for the entire hole, the largest charge weight of any deck within a hole on a separate 25-ms delay if any, top of sound rock elevation, bottom hole elevation or the top of stemming elevation at the bottom of a shot hole that was over-drilled in depth and backfilled, stemming elevations, and detonator, primer and booster elevations in the hole;

5. The recorded PPV and airblast overpressure at each seismograph location and the lateral close approach distance from the shot pattern to each seismograph;

6. The removal and disposal of all shock cord/tubing and initiation transmission-line debris immediately following the shot[; each required safety, protective, and natural-resource action conducted

SECTION 31 23 01 Page 53
for the initiated shot with their supporting data];

(7) A short narrative of any peculiarities or impediments or adverse impacts or accident/misfire with the shot, if any;

(8) The name, title, and signature of the Blasting Specialist providing the form with the date of the signature.

3.6.4.1 Drilling Logs

The Blaster in Charge or a Blaster with the assistance of the driller will log each shot hole, as the hole is being advanced. No drilling will be initiated without the Blaster in Charge or a Blaster to log the hole by a measurement means of drill bit's depth, the downward rig pressure, advancement rate of drilling, and air-water return of cutting with the driller's full assistance. The log must record the material encountered at the drill bit's depth to a precision of 0.03 m 0.1 ft. The drilling for each shot hole must be assessed to determine, and the log must record, the vertical depth/elevation of encountering sediment, weathered rock, the Top of Firm Rock, and voids to the total drilled depth. The shot-hole logs for all the shot holes in a shot pattern must be provided at the same time as the Individual Shot Report. An acceptable sample drilling log is provided in EM 1110-2-3800.

3.6.4.2 Individual Shot Vibration Monitoring Report

After each shot, submit an Individual Shot Vibration Monitoring Report, which will require the use of blast seismographs, to measure the vibration created from the blasting activities. Submit the Individual Shot Vibration Report to the Contracting Officer by or before Noon of the second business day following the shot, which is being reported. Submit each Individual Shot Vibration Report as a signed paper copy and in digital form to the e-mail listing required by the Contracting Officer. This will be provided at the pre-construction meeting.

Direct the specialty firm providing the seismic specialist, with approval of the Contracting Officer, to place blast seismographs, consisting of three component seismographs, (1) at important structures, and (2) other locations designated by the Contracting Officer. At least [three] [_____] seismograph locations will be required for every blast during this project. [ Place additional seismographs at each specified monitoring locations.]

Samples of possible Individual Shot Vibration Report formats are in EM 1110-2-3800, pp B-9 and B-10. The minimum required information to be submitted in the Individual Shot Vibration Report includes:

a. Date and time of recording from each seismograph;

b. Type (brand and model) of three-component seismographs used, serial #, and position name;

c. Who performed, and the date of, the most recent calibration of each seismograph, and its sensitivity;

d. The firm and employee who placed the blast seismograph;

e. Seismograph installation procedures to prevent disturbance during monitoring, vandalism, and damage, and whether the seismic data is
being telemetered or downloaded individually;

f. Set trigger levels;

g. Maximum for each of the three, component PPV in units of centimeters per second (cps) inches per second (ips), the maximum total vector-sum peak particle velocity in units of centimeters per second (cps) inches per second (ips), and a log-log graph of all maximum total vector-sum peak particle velocity versus square-root scaled distance in units of sqr meter/kilogram (sqr m/kg) sqr feet/pound (sqr ft/lb) for all seismic records of all prior shots for this project;

h. A graph of the PPV versus frequency for each seismograph location that triggered;

i. The maximum airblast overpressures in units of kilopascals (kPa) pounds per square inch (psi) at any triggered monitoring location and the results from noise tests before blasting in the first report;

j. A narrative description of any peculiarities or impediments or adverse impacts or accident/misfire for the shot; and,

k. The name, title, and signature of the Seismic Specialist processing and interpreting the data and providing the report with the date of the signature.

3.6.4.3 Individual Shot Videos

The Contractor will make a video recording of each shot pattern in a clear and consistent manner. Video recording must include date, time, and location. The digital video file must be furnished with the Individual Shot Report in a format noted within the Master Blasting Plan and approved by the Contracting Officer. The submission must be made to the Project Office and to all on the e-mail address listing. A library of blast videos will be maintained for all blasts and will be readily cross referenced with individual blast plans and post blast evaluations.

3.6.4.4 Reports of Required Safety, Protective, and Natural Resource Programs

Specify the data submission for required safety, protective, and natural-resource actions. A summary report must be submitted by noon [2] [_____] business days after the shot of the [special monitoring of a critical or essential facility or of a government or commercial structure, [and][or] an avian or mammalian watch program for assurance that a shot is not initiated at a time when the cited species is present, [and][or] underwater pressure wave monitoring, [and][or] other agreed/negotiated program].

3.6.5 Daily Blasting and Removal Log

The Contractor must submit a Daily Blasting and Removal Log, both in writing to the Contracting Officer and by e-mail distribution to the required e-mail addresses, on the next business day. The Daily Blasting and Removal Log summaries all the drilling and blasting activities, surveying, dredging [and][or] removal of spoils, and disposal operations for any day that one or more of those operations were conducted. The Daily Blasting and Removal Log will be signed by the designated representative of the Contractor, approved in the Master Blasting Plan.
3.7 DRILLING AND BLASTING

3.7.1 Underwater Shot Holes

No drilling will be initiated without the Blaster in Charge or a Blaster to log the hole and confirm the proper positioning of the shot hole. For underwater blasting, the Contractor must be prepared to: drill; log the hole; resolve the units encountered in drilling; reassess the Shot Plan's intent for that particular shot hole; load explosives, boosters, initiators and delays, place stemming in sound rock; and raise the firing line. If a shot hole cannot be drilled or cleaned out, the Contractor will be required to re-drill that shot hole or properly correct the shot design to delete that hole.

3.7.2 Shot Hole Logging

The Blaster in Charge or a Blaster will log each drilled hole, as the hole is being drilled. The Blaster in Charge or a Blaster will log the shot hole by a measurement means of drill bit's elevation, the downward rig pressure, advancement rate of drilling, and air-water return of cutting with the driller's full assistance. The shot holes must be logged during drilling and measured upon completion with a weighted tape for its full depth before any explosives are loaded into any of the holes.

If any holes are too deep, then these holes will be filled to the proper depth with stemming. Repeated, significant voids, 0.2 m 0.5 ft or larger, must be reported to the Contracting Officer. The Blasting Consultant may need to assess the issue of voids. Should voids become confinement issue blasting will be delayed until the Contracting Office is satisfied that potential problems related to blasting around the void have been properly addressed.

3.7.3 Stemming

All shot holes must have appropriately sized stemming material of the proper vertical placement length to optimize the blast design. Loss of explosive confinement can be due to improper stemming material type and poorly placed stemming. Tamped stemming must be placed from the top of firm rock (or hard material), as determined from the drilling log, to the top of the explosive charge. Stemming must also be used to fill voids, if any, as noted on the drilling log of that shot hole.

3.7.3.1 Stemming Material

Stemming must consist of well-graded, crushed, angular stone without fines. The gradation of the crushed, angular stone is between 3.0 mm 1/8 inch and 10.0 mm 3/8 inch in diameter. No soil or drill cuttings or rounded particles of the noted grading may be used as stemming material.

3.7.3.2 Length of Stemming

The minimum vertical length of tamped stemming within rock, or hard materials, of a shot hole must be the greater of 0.60 m 2.0 ft or eight times the shot hole's diameter. This minimum length of stemming must be placed in firm rock, or hard materials, to contain the gaseous products of detonation both below the top of firm rock and on either side of (above or below) voids, if any, with an explosive charge.
3.7.4 Loading Shot Holes

Stemming, decking, shot hole explosives' loading, and shot plan revisions for each shot hole must be made upon completion of drilling to the total depth from the logging of that underwater shot hole. Resolve whether to abandon the shot hole or load the hole from the Shot Plan's intent and the information resolved by the shot hole's log.

3.8 IMPACT MONITORING

Monitoring of the blasting may be required for public safety or natural-resource protection. The Contractor will be responsible for the payment and services of one or more, independent, third-party firms to conduct the required monitoring. The Contractor will make available the schedule and blasting documents to coordinate with other specialists monitoring issues for: the public's safety; environmental concerns for air, water, and property; natural resource protection; and the safety of structures and features.

**************************************************************************

NOTE: Delete inapplicable sections. The coordination with other federal, state, and local jurisdictions and agencies, the public, and private entities must be completely resolved before finalizing the specifications.

**************************************************************************

3.8.1 Public-Use Area Effects

The Contractor will provide personnel, patrolling vessels or vehicles, and the signage necessary to assure safe distances from all shot patterns are maintained and physically monitored at public-use areas on land or on water, and at occupied structures or highways or other features requiring control.

3.8.2 Airblast and Seismic Monitoring

**************************************************************************

NOTE: Determine the number of seismographs required for the project by the nearer structures or features to protect and their general azimuthal direction. Every blasting program should have at least three blast seismographs deployed. More seismographs may be needed at the project temporarily for green concrete or other temporary considerations or by the request of the Contracting Officer. While airblast is rarely a concern for underwater blasting, airblast should be recorded at a minimum of three seismograph locations in different azimuthal directions.

**************************************************************************

Airblast and vibration monitoring must conform to current industry standards and use equipment developed for blast monitoring. The Contractor will hire a subcontracted specialty firm, independent of the Contractor's firm and other sub-contractors to locate, maintain, and record the airblast and vibrations from every shot. The subcontracted seismic firm through their employee, the Seismic Specialist, will monitor the [three] seismic
positions shown on the plans or accepted by the Contracting Officer. Additional seismographs may be required temporarily for (green) concrete placement or other temporary considerations or as required by the Contracting Officer for specific airblast or vibration issues due to blasting suspected at locations without seismographs. The seismic records and the Individual Shot Vibration Monitoring Reports will inform the Contractor of the actual airblast and vibration parameters from every shot and assure the government that the blasting has remained within the allowable airblast and vibration levels.

Provide 3 blast Seismographs capable of sampling rates of 15,000 samples per second or higher that meets ISEE PSBS. The 15,000 samples per second accuracy is required to acquire reproducible vibration readings. Each seismograph provided to the project must have been calibrated by the manufacturer within six months of its installation. No seismograph may be used at the project may have manufacturer's calibration longer than eleven months prior to its date of use. The units must be self-contained except for external geophones and microphones. The seismographs without erasing the stored data must be capable of telemetering the digital data or downloading the digital data to a portable device. The units must be programmed with specific data for each site of seismograph placement, which includes seismograph location, geophone burial or mounting method, calibration signal, date, and time of the record. The seismographs must be housed in protective enclosures, if vandalism or high-traffic concerns or weather or other conditions could limit the continuous, proper recording by the seismographs.

The blast seismographs must not be placed inside of a structure, unless required for the designated purpose and authorized by the Contracting Officer. The seismographs should not be placed near a structure unless the intent is to measure that particular structure's specific response to the blast. The microphone must be positioned to avoid wave reflections of the airblast from the vertical, front or side of a structure, wall or rock face. The microphone should be placed at a height of 0.91 m 3.0 ft. The geophone for each seismograph must appropriate for buried in soil or for being physically secured to rock or sidewalk or pavement or a concrete foundation.

The seismographs must be operated continuously beginning [seven] days before the first anticipated Test Blast. All The airblast and vibration amplitudes' maximal, frequencies of those amplitudes, repeated occurrences, and other parameters for the first period of operation before the first Test Blast will be reported as the project's background conditions in the first Individual Shot Vibration Monitoring Report.

The seismographs must be operated continuously until the excavation has been approved by the Contracting Officer. The seismograph may be removed from the project and replaced after their initial deployment, if there will be no blasting for a period of seven days or longer and if there will be no explosives stored onsite during that period.

3.8.3 Individual Shot Videos

Record every shot pattern's blast with Full High Definition, 1080p, digital video recordings with a minimum of 30 frames per second from two designated locations, approximately perpendicular to one another, that provide side and front or rear views of the blast and area above it. The video images must not contain any other text than the shot number. Include metadata consisting of the blast ID, date, and time of the blast. Index
the two video recordings to properly identify each blast. Submit the proposed locations of the two video recorders on a map with the Individual Shot Plan. Furnish electronic file copies of video recordings on the sFTP within 24 hours of a blast. If the Contracting Officer requests that a copy of the video be submitted earlier, then deliver a copy within one hour of the request. Maintain a digital video library of all blasts.

3.8.4 Air, Water or Land Protections

The Contractor will assure that all escaping or released gases, fluids, and solids are within applicable limits of all federal, state, and local laws, regulations, ordinances, and guidelines. Any releases of fluids or solids that are not such limits will be immediately reported, mitigated, retained, and removed from the project.

**************************************************************************
NOTE: This section should emphasize the importance of recovering all shock tube. Additional details could include typical methods of recovery and best practices for the containment of shock tube.
**************************************************************************

The Contractor will remove all shock cord/tubing and initiation transmission-line debris immediately following each shot. Submit means and methods for removal in Master Blasting Plan.

**************************************************************************
NOTE: Delete inapplicable NATURAL RESOURCE ASSESSMENTS, MITIGATION AND MONITORING paragraphs that are not required by coordination with other federal, state, and local jurisdictions and agencies, the public, and private entities, which must be completely resolved before finalizing the specifications. Each of the paragraphs for Natural Resources will require a design by a qualified professional(s), who has experience with such activity(ies). The activity's paragraph text for the Contractor's action must be written for the specific project and unique Natural Resource requirements. None of these activities or other possible required actions or coordination by the Contractor have generic or standard approaches, much less narratives. The Contractor may be required to hire a specialty contractor to perform the designed assessment, mitigation, or monitoring, or to coordinate the blasting with an external organization responsible for the activity.
**************************************************************************

3.8.5 Natural Resource Assessments, Mitigation and Monitoring

[____]

3.8.5.1 Fish-Repelling Noise

[____]
3.8.5.2 Watch Program

[_____

3.8.5.3 Post-Blast Fish Surveys

[_____

3.8.5.4 Air-Curtain Mitigation

[_____

3.8.5.5 Underwater Overpressure Monitoring

3.9 EXCAVATION VERIFICATION

**************************************************************************
NOTE: This Blasting Section presumes that the excavation(s) will fully achieve the required vertical and lateral limits. This paragraph references the location of the verification procedures by its section in the specifications.
**************************************************************************

Conduct the verification of the completed excavation, as specified in Section [EXCAVATION], Paragraph [SURVEYS].

3.10 SUBMERGED MATERIAL DISPOSAL

**************************************************************************
NOTE: The Guide Spec presumes that material disposal will properly place any onsite material disposal. This paragraph references the location of the material disposal procedures by its section in the specifications.
**************************************************************************

Transport and place all dredged, displaced, or excavated materials within the limits of the disposal zones below the specified elevations, as specified in Section [DISPOSAL].

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for blasting at the ground surface and the avoidance of adverse impacts for any use of blasting, most commonly rock excavation. If during the contract period any of the materials being blasted and excavated are known to be, or may possibly be, near a water body or below water, also refer to Section 31 23 01 UNDERWATER BLASTING. For projects on a naval facility, consult with local NAVFAC office, Naval Ordinance Safety and Security Activity (NOSSA), and NAVSEA on requirements. NAVSEA OP5 Ammunition and Explosive Safety Ashore manual dictates many of the requirements and NOSSA has the final determination on any blasting on a Navy installation above or underwater. Reference NAVSEA OP5 manual and contact local Explosives Safety Officer and Planner for the base prior to revising the specification. Overall NOSSA approval process can take 12-18 months depending on the level of approval required.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).
NOTE: Consult with a District Office that has most recently completed a similar type of blasting, while editing this section, to be appraised of recent, specific requirements, guidance, blasting developments or understandings for the subject project.

Consult with or have Specification reviewed by a Subject Matter Expert in Blasting for projects involving Blasting as a primary means of removing materials or where Blasting issues are particularly challenging.

There are likely decisions and/or requirements of other agencies, the Safety Manual, and/or internal offices/divisions/branches, which could have an influence upon a project's blasting specs. Some of these issues may be: concerns from federal, state, and local jurisdictions and agencies; public use of nearby federal, state and/or local properties near the project; evaluations of acceptable vibrations and/or pressures affecting individuals or reaching nearby structures; natural resource impact reviews, negotiations and/or requirements; constraints on the drilling or blasting procedures; pre-blast inspections; special studies to facilitate lower cost of the bids or to encourage more bid submissions; the acquisition strategy for the payment; and, other concerns specific to the project.

This blasting guide specification covers the blasting of rock and including mucking. The details on excavation are typically covered by a separate Rock Excavation specification.

The following information will be indicated on the project drawings:

1. Surface elevations, existing and new;

2. All utilities, whether trenched, buried, at the surface or overhead to distances well beyond the project's limits;

3. Location and record of all soil and rock borings and test pits, including soil and rock classifications and their properties, weathered rock, bit drops and voids, ground water observations, and topsoil thickness encountered in boring;

4. Location and limits of hard material, whether rock or concrete, or other building materials;

5. Excavation or demolition limits, and clearing,
stripping and grubbing limits, and tolerances of excavation;

6. Details of any special limits that may require line drilling, presplitting, reduced subdrilling, and/or specialty blasting practices;

7. Location of borrow and disposal area, if located on Government property; or on site (as some sites may or may not remain government property, and disposal sites may be under control of project partners);

8. Hydrological, hydraulic and impoundment data, where applicable; and,

9. Details of all rights-of-way within the project boundaries.

******************************************************************************

NOTE: The coordination with other federal, state and local jurisdictions and agencies, the public, and private entities must be completely resolved before finalizing the specifications. A project's excavation and/or foundation requirements, for which, dense materials are being removed, may require navigation, highway, structural and/or other regulations and codes to be followed. Depending upon the proximity of public-use areas, private residences or businesses, and the project's location within a county or township, various accommodations will need to be required for the protection of the public, and the safety of private entities in regard to local laws, regulations and ordinances. Avoiding natural resource impacts may overlay other measures and require: seasonal or daily time limitations of the initiation of the individual blast patterns; special observers for some or all the blasting; special studies or monitoring while the blasting is being conducted; and, other potential considerations.

Agency coordination will vary by project. Be certain that all government stakeholders have been involved with planning of the project and approved of all requirements for the specifications. List those important navigation or safety stakeholders. When there are navigable waters near the excavation zone, list in the controlled navigation perimeter's distance during the warning period of a shot. While the distance is project specific, the minimum distance is typically 300 m 1,000 ft.

It is essential that the agency/service person, using these Guide Specifications to prepare Plans and Specifications coordinate with the planners and environmental compliance specialists within their agency/Service to ensure that all the blasting
restrictions and mitigation measures are incorporated into the Plans and Specifications. Failure to comply with the requirements of Federal or state laws and regulations could result in project delays or stoppages.

1.1 SCOPE

The breakage of rock and hard/unyielding materials may be conducted by any means unless otherwise stated herein. If the contractor elects to use drilling and blasting for breakage or displacement of any units, this entire section is applicable and covers activities associated with drilling and blasting for rock excavation at the surface. Contained herein are procedures for all activities relating to drilling, blasting and the transportation, storage and use of explosives; breakage and displacement of rock. The Contractor's blasting program and methods are those necessary to accomplish the excavation shown on the Contract drawings in accordance with the provisions specified herein. Control the quantity of explosives fired in all blasting to prevent injuries to persons and to avoid damage to all structures, properties, governmental and nonprofit entities, commerce and businesses, and natural resources and their habitat.

1.2 RELATED WORK SPECIFIED ELSEWHERE

NOTE: List any specifications that are related, such as Earthwork, Excavation, Rock Bolts, Temporary Environmental Controls, Shotcrete, Natural Resources, are typical specs related depending on the project.

Section 01 33 00 SUBMITTAL PROCEDURES

1.3 REFERENCES

NOTE: These publications are not all inclusive, and it must remain the responsibility of the Contractor to obtain, know, and comply with applicable Federal, State, and Local regulations not included in the references. In case of a conflict between the regulations and specifications, the Contracting Officer will determine which applies.

Add and remove references as needed for the project. Reference the appropriate state regulations on blasting for where the project is to occur.

This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically
place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

ASTM INTERNATIONAL (ASTM)

ASTM D2487 (2017; E 2020) Standard Practice for Classification of Soils for Engineering Purposes (Unified Soil Classification System)

ASTM D5434 (2012) Field Logging of Subsurface Explorations of Soil and Rock

INTERNATIONAL SOCIETY OF AUTOMATION (ISA)

ISEE PSBS (2017) ISEE Performance Specification for Blasting Seismographs

U.S. ARMY CORPS OF ENGINEERS (USACE)

U.S. NATIONAL ARCHIVES AND RECORDS ADMINISTRATION (NARA)

29 CFR 1910.109 Explosives and Blasting Agents

29 CFR 1926-SUBPART U Blasting and the Use of Explosives

49 CFR 177 Carriage by Public Highway

1.4 DEFINITIONS

NOTE: Delete definitions that will not be used in the specification text for a specific project. A complete list of blasting definitions can be found in the GLOSSARY of the EM 1110-2-3800 and other references. Recommend only using definitions not already in GLOSSARY in the EM and definitions to further the define the work on the specific project in the specification. It may be necessary to add definitions depending on what the Earthwork and/or Excavation specifications for the project have terms
for Rock, Weathered Rock, Sound Rock, Voids, Sediment, etc.

1.4.1 Blast Site

The area where explosive material is handled during the loading of blastholes, including 15.2 m 50 feet in all directions from the perimeter formed by loaded holes. A minimum of 9.1 m 30 feet may replace the 15.2 m 50 feet requirement if the perimeter of loaded holes is marked and separated from non-blast site areas by a barrier. The 15.2 m 50 feet or 9.1 m 30 feet distance requirements, as applicable, apply in all directions along the full depth of the blasthole.

1.4.2 Blast Area

The area of a blast within the influence of flying rock and eject gases, and concussion that may cause injury to persons or property.

1.4.3 Buffer Zone

Buffer Zone is defined as a designated section of rock between a slope to be formed by line drilling or pre-splitting during excavation and the production blast. The explosives in each blast hole and the burden in the buffer zone must be reduced to prevent damage to the final rock slopes.

NOTE: Choose one of the following sentences depending on when to shoot the buffer holes, sometimes it is appropriate to shoot them as a separate shot in order to further control the excavation and prevent backbreak.

The buffer zone blastholes must be fired in sequence after the adjacent production blastholes.

The buffer zone blastholes must be fired as a separate blast, after the adjacent production shot.

1.4.4 Controlled Blasting

Controlled blasting refers to blasting techniques used to better distribute the explosive charge to minimize impacts such as fracturing and loosening of the rock beyond the design excavation line (overbreak). This is accomplished by using small diameter, decoupled charges in closely spaced blastholes placed on the perimeter of an excavation. Methods including but not limited to line drilling, and pre-splitting (pre-shearing) cushion blasting, and buffer zone blasting.

1.4.5 Flyrock

NOTE: Choose the distances for the project, the typical values are listed. Edit definition as needed for project site.

Flyrock is defined as any airborne rock flying more than 61 meters 200 feet
horizontally or **12 meters 40 feet** vertically from the blast or if flyrock travels more than one-half the distance between the blast and the Contractor work limits, whichever distance is the lesser.

### 1.4.6 Green Concrete

**NOTE:** If no concrete placement is expected on the project then delete this definition. If concrete placements will occur when blasting operation is ongoing, further define green concrete here and include appropriate thresholds and monitoring for the green concrete in Part 3. There needs to be limits on vibrations when there is green concrete because of the strength loss due to vibrations while curing. Involve the Structural Engineer project development team members in these determinations.

Concrete that has undergone initial setting but has not hardened to design strength. Green concrete also includes the materials of shotcrete or cementitious grouts. Each Individual Shot Plan is required to consider vibrations emanating from its blast reaching the location of the reported newly placed concrete to remain below allowable vibration levels depending upon the age of the concrete. Note the paragraph Green Concrete.

### 1.4.7 Line Drilling

Line drilling is defined as a controlled excavation technique consisting of a series of closely spaced holes (spacing minimum of twice the hole diameter) that are either not loaded with explosives or lightly loaded and are drilled along the excavation line. The line drill hole spacing must be no greater than twice the hole diameter.

### 1.4.8 Pre-Splitting

Pre-splitting is defined as a method of controlled blasting utilizing a row of closely spaced, (typically **30 centimeters 12 inches** or larger), lightly loaded blastholes placed on the perimeter of the excavation and fired before the production blast. The purpose of the pre-split blast is to form a crack between blastholes without serious damage, overbreak, heaving or cracking of the final wall.

### 1.4.9 Precision Pre-Splitting

**NOTE:** The loading density for precision pre-splitting holes needs to be evaluated and selected based on project design. The value may be reduced accordingly.

Precision pre-splitting is defined as a special pre-splitting method which utilizes closely spaced blastholes (**61 centimeters 24 inches** or less center to center) with light explosives loads (no more than **0.5 kilograms 0.2 pounds** of explosive per .3 meter foot of blasthole) to supply only sufficient energy to shear the web of rock between holes without any damage to the Presplit wall.
1.4.10 Airblast

Airblast are the overpressure waveforms that move through air as audible and sub-audible sound waves. These are also called compression waves.

1.4.11 Vibrations

Vibrations are one of the three, primary adverse impacts from blasting. Vibrations are the result of various wave forms emanating from the detonation or deflagration of ignited materials from a shot pattern. Peak particle velocity (PPV) is defined as the maximum absolute value among the three ground vibration velocities measured in the vertical, longitudinal and transverse directions over the period of a record. Peak, total vector-sum particle velocity is the peak value over the full-time history of each time-unit’s value of the square-root sum of the squared, component velocities. Velocity units are expressed in centimeters per second (cps) or inches per second (ips).

1.5 SUBMITTALS

**************************************************************************

NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.

**************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are
Contractor Quality Control approval. [for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-01 Preconstruction Submittals

Blasting Consultant's Qualifications; G[, [___]]

1.6 COORDINATION

**************************************************************************
NOTE: The following paragraph can be used if working with multiple stakeholders/owners.
**************************************************************************

Blasting will be in the vicinity of the [existing lock, railroad, and highway, and river barge, train, hospital highway traffic, utilities and businesses] and their operation will not be impeded or delayed beyond that which has been coordinated with [TVA, U.S. Coast Guard, U.S. Army Corps of Engineers - [_____] District, [_____] environmental or natural resources offices, [_____] Department of Transportation, local government entities, [_____] Railroad, regional or local utilities, and/private businesses]. Include a coordination and traffic control sub-plan as part of the Blasting Safety Plan, with the appropriate authorities that mitigates navigation and traffic delays in the Master Blasting Plan.

Coordinate, through the Contracting Officer, with other Contractors working onsite to minimize work stoppages during blasting.

1.7 LIABILITY

Compliance with provisions in the contract will not relieve the Contractor of their responsibility for any damages or injuries caused by, related to or arising out of blasting or associated blasting activities. The Contractor assumes all liability and hold and save the Government, its agents, officers, and employees harmless for any and all claims for personal injuries, property damage, or other claims arising out of or in connection with the handling of explosives or blasting under this contract.

PART 2 PRODUCTS

2.1 STORAGE AND USE OF EXPLOSIVES

2.1.1 General

**************************************************************************
NOTE: The specification writer may choose to list reasons the Contracting Officer may restrict blasting but not always necessary. Confirm and follow federal, state and local regulations and guidance on the transport, storage and use of all Explosives. State and local agencies and/or authorities may not easily allow the receipt of Explosives in a timely manner. State and local agencies and/or authorities may have specific reporting, certifications, adverse impact concerns, or distance regulations from the blast zone to private properties governing the use of Explosives. The Agency/Service may wish to allow storage of Explosives on federal premises. The winning contractor should independently assess and cite in the Master Blasting Plan all federal, state and local laws, regulations, ordinances or authorities.
that impact the transportation and storage of Explosives.

**************************************************************************
Store, transport, handle, use, and otherwise secure explosives in accordance with best practices as approved by the Contracting Officer and in accordance with all Federal, State and Local laws and regulations. Comply with all special rules, regulations and ordinances that may be made by the authorities having jurisdiction, or by the Contracting Officer, regarding construction of, and storage in, magazines and precautions in handling and transporting explosives for blasting. Times and imposed restrictions concerning the use of explosives must be conducted in accordance with local, State, and Federal regulations. The Contracting Officer reserves the right to establish further restrictions or time windows when blasting will not be allowed beyond the Local, State, and Federal requirements; these windows may include times of day of high traffic volumes, times when school traffic is present, or during funerals. The Contractor is responsible for all claims for damages and injuries caused by or arising out of blasting activities. Perform all blasting operations in accordance with the current edition of EM 385-1-1.

2.1.2 Blasting Products

**************************************************************************
NOTE: This paragraph may need to be adjusted, some projects it is not appropriate to allow bulk explosives, such in karst because the bulk explosives could fill voids if care is not taken while loading to monitor the amount being added to each hole.

**************************************************************************
All blasting caps used on the project must be one year or less of age. Millisecond delay, [shock tube] initiators, must be used as the initiation system. To ensure the accuracy of firing times of blasting caps, it is required that each cap period come from one lot number. Mixing of lot numbers for any one cap period is strictly prohibited. All explosives used on the project must be six months or less of age or no older than one half the shelf life shown on the explosives manufacturer's technical data sheet for that product. Cartridge [and bulk] explosives may be used in different sections of the project. Ammonium nitrate and fuel oil (ANFO) is not allowed in wet environments.

**************************************************************************
NOTE: In projects where controlled blasting techniques are required to produce final walls which require presplit blasting, only explosives designed for this application must be allowed. Ammonium nitrate and fuel oil (ANFO) is not to be allowed in wet environments. Consider requiring cartridge explosives within a specified distance from any new structure which requires neat excavation lines; i.e. "Bulk explosives such as ANFO or bulk emulsion or emulsion blends will not be allowed for production blasts at the area of the Labyrinth Weir foundation or within 61 meters 200 feet of it or within 15.2 meters 50 feet of presplit walls."

**************************************************************************
Explosives that do not meet the manufacturer's specifications must not be used. When, in the opinion of the Contracting Officer, any blasting product is either of excessive age or appears to be in a deteriorated condition, all work must cease until the products age and quality can be determined. Blasting products without date and batch codes will not be permitted on site. The Contracting Officer may require any product to be tested by an independent organization to determine its performance as compared to the manufacturer's data sheet. If product performance or composition deviates by more than 10 percent in any manner from the manufacturer's data sheet, that lot number will be rejected. The Contractor is responsible for any required testing and no additional compensation will be made for any product testing directed by the Contracting Officer.

2.1.3 Magazines

**************************************************************************
NOTE: Two paragraph options here first paragraph is for where explosives must be stored off site (off site magazine). The other covers the storage of explosives onsite. The designer will need to ensure these requirements are fully detailed and the appropriate regulations are followed.
**************************************************************************

Explosives must be stored offsite. Obtain all necessary Federal and State magazine permits. Magazines must be located at safe distances as defined by the Bureau of Alcohol, Tobacco and Firearms (ATF) in addition to the State of [_____] requirements. There must be no permanent explosive storage or overnight explosive storage on site. Procure off-site explosive storage and expect to have daily explosive deliveries to the site. Secure a permit to transport explosives from the [_____] Highway Patrol when the amount of explosives to be transported exceeds 454 kilograms 1000 pounds, and transport explosives in accordance with 49 CFR 177 when carried on public highways.

**************************************************************************
NOTE: If explosives will be stored in an onsite magazine, it will be required to follow the requirements in EM385-1-1, including a submittal for an Explosive Site Safety Plan and the following paragraph can be used.
**************************************************************************

Explosives may be stored onsite. Obtain all necessary Federal and State magazine permits. Magazines must be located at safe distances as defined by the Bureau of Alcohol, Tobacco and Firearms (ATF) in addition to the State of [_____] requirements. Secure a permit to transport explosives from the [_____] Highway Patrol when the total weight of explosives to be transported is less than 454 kilograms 1001 pounds, and transport explosives in accordance with 49 CFR 177 when carried on public highways.

2.1.4 Magazine Keeper

Each magazine keeper must be experienced and familiar with the laws and general practices concerning the handling, care, use, and storage of explosives and detonators. The magazine keeper is responsible for maintaining a cleared area around each magazine. The magazine keeper will not be required to perform any duties that will in any way interfere with their duties as magazine keeper, and being physically present at the
magazines for every entry to the magazines for delivery, disbursement and review of explosives at the magazines. If explosives are delivered and returned daily from the manufacturer or supplier to the project, the driver of the truck will serve as the magazine keeper.

PART 3 EXECUTION

3.1 GENERAL

**************************************************************************
NOTE: This paragraph should agree with the designations under paragraph SUBMITTALS, the Master Blasting Plan will always be for approval. The Individual Shot Plan may be approved ("G") or accepted ("FIO").
**************************************************************************

Obtain approval, or revise for approval, of the submitted Master Blasting Plan and Individual Shot Plans, acquire all required permits, and comply with all laws, regulations, ordinances, applicable safety code requirements, and regulations relative to the transportation, handling, storage, and use of explosives and the protection of life and property. Perform vibration and airblast monitoring at the Contracting Officer's specified locations to record blast effects. The peak particle velocity must be limited to the values in Paragraph BLAST EFFECTS MONITORING in these specifications. Minimize rock over-break and blast damages beyond the design excavation line. The Contracting Officer will, always, have the authority to prohibit or halt the blasting operations, if it is apparent that the required lines and grades and stable rock slopes are not being obtained with the methods being employed.

3.2 SAFETY PROCEDURES

3.2.1 General

Ensure all work completed under this Contract is executed safely. Follow the safety procedures outlined in EM 385-1-1. EM 385-1-1 will govern all activity unless more stringent safety requirements are specified here and in other applicable Federal, State, and local laws, regulations, and ordinances.

3.2.2 Weekly Coordination Meeting

Coordinate all blasting schedules with the Resident Engineer's Office at least one week in advance and hold a weekly blasting coordination meeting with the Resident Office. Provide an agenda for the blasting coordination meeting that lists the prior week's shots, the forecasted shot schedule and displays a scale site plan showing the locations of the scheduled shots. The Blasting Specialist, Blaster in Charge, and Seismic Specialist are required to participate in discussion of agenda items and lessons learned.

3.2.3 Public Notice of Blasting Operations

At least thirty calendar days, and prior to any blasting operations, prepare and submit to the Contracting Officer a public government notification letter of the proposed blasting activities. The Government will distribute copies of this notification letter by certified mail to law enforcement, local governments, public utilities, public users of project recreational facilities, and residents and commercial interests located...
within 0.8 kilometers one half mile of the blast site. This notification letter must contain at minimum:

a. Name, address, telephone number and e-mail address of the Contractor;

b. Plan maps identifying the specific areas in which blasting will take place, and major and secondary roads, geographic features and auxiliary features;

c. Proposed duration of blasting activities, and on which days of the week and hours of the day that blasts can be expected to occur;

d. Vehicular and pedestrian traffic control measures to be taken;

e. Methods to limit access to the blasting area; and,

f. Types, patterns and duration of audible warning and all clear signals to be used before and after blasting.

3.2.4 Public Meetings

**************************************************************************
NOTE: Communicate with the project manager and stakeholders about whether specific requirements for a meeting or multiple meetings are needed. It may be necessary to advertise the meeting in a local newspaper and specify the meeting room capacity.
**************************************************************************

Fifteen calendar days prior to any blasting operations, provide the approved Seismic Specialist, Blasting Specialist and Blasting Consultant to attend a public relations meeting to be conducted on an evening to be determined by the Contracting Officer. This meeting will inform the public about the anticipated blasting operations. The Blasting Specialist, Blasting Consultant and Seismic Specialist must make a short presentation of blasting operations and answer any questions pertaining to public concerns dealing with the blasting operations, the magnitude of seismic vibrations, airblast and potential for flyrock that may impact the public. Distribute points of contact for the public and local entities in the event of concerns related to the blasting program.

3.2.5 Warnings and Signals

Establish a method of warning all employees on the job site of an impending blast following the guidance of the EM 385-1-1. The signal must consist of a five-minute warning signal to notify all in the area that a blast will be fired in five minutes. A second warning signal must be sounded one minute before the blast. After the blast is over, sound an all-clear signal, after the blast site has been inspected for misfires by the Blaster in Charge to provide notification to all personnel in the area that the blasting operation is finished. No personnel other than the Blaster in Charge must enter the blast area until it has been determined to be all clear.

3.2.6 Time Restrictions for Blasting

**************************************************************************
NOTE: Research the specific State requirements. This paragraph will need to be tailored for the
specific site conditions, for example, avoiding blasting during rush hours in the morning and afternoon. Most locations prohibit blasting on Sunday but may allow on Saturdays and some Holidays.

Blast only during daylight hours, one-half hour before sunrise and one-half hour after sunset, and between 7 AM and 7 PM, local time, on weekdays and only during the approved time periods each day and at the same time each day, in concert with the approved closure time for area roads. No blasting is allowed on Saturdays, Sundays, or official holidays recognized by the Federal Government or the State of [_____] unless consent is granted by the State Fire Marshal. Drilling activities and blasthole loading are not time restricted, except as noted in Section 01 14 00 WORK RESTRICTIONS.

3.2.7 Traffic Control During Blasting

NOTE: This section should be edited for the specific project sites traffic control issues. Communicated with stakeholders and local utilizes, DOTs, Railroads, businesses during design phase to capture any special needs the Government will need to specify for the Contractor to carry out during blasting. This Paragraph is an example.

During blasting operations traffic may need to be temporarily halted to allow safe execution of blasting and possible removal of rock fragments and debris. Traffic control, including such delays must be the sole responsibility of the Contractor. Traffic control must be in close coordination with the [_____] Department of Transportation[ and the town of [_____]]. Include the traffic control plans with the Blasting Safety Plan.

It is not anticipated that blasting activities will impact traffic due to the distance of the blasting from the road. The Contractor will need to coordinate with [_____] for blasting [______]. In addition, use protective blasting mats for all shots [______], unless otherwise directed by the Contracting Officer to minimize any fly rock near [______] may be required, if, in the opinion of the Contracting Officer, flyrock becomes an issue. If traffic stoppages are warranted, coordinate with the Contracting Officer. A sentinel boat must be stationed [______] of the work area to prevent any boaters from entering the blast area.

Recreational boats, swimmers, fisherman and the public, on land or in the water must be prohibited access within 762 meters 2500 feet of the blasting area. Station sentinel boats to prevent any boaters from entering the blast area.

3.2.8 Notification to Navigation

NOTE: Use the following paragraph when working in or near navigable waters or navigation lock.

Notify the lockmaster at [_____] Lock, the US Army Corps of Engineers, [_____] District, Navigation Branch a minimum of [14] calendar days prior to the commencement of blasting operations to allow for sufficient time to
send out navigation notices. The information to be supplied will include the dates and time window of blasting operations.

3.2.9 Lightning Detection Equipment and Safety

Furnish, maintain and operate Lightning Detection Device during the entire period of blasting operations and during the periods that explosives are used at the site. Equipment must provide real time audio and visual alarm/signal and detection based on combined detection of electromagnetic, electrostatic, light wave spectral and audio disturbances, or a commercial service based on these as a minimum as approved. Equipment must be capable of detecting lightning within 40 kilometers 25 miles as minimum of the blast area.

**************************************************************************
NOTE: Obtain technical feedback from the rest of the design team for minimum lightning detection distance.
**************************************************************************

Provide the equipment after approval of lightning detection device. When and where the lightning detection device indicates a blasting hazard potential, immediately evacuate personnel from all areas where drilling is being conducted or explosives are present. When a lightning detector indicates a blasting hazard, perform the following:

a. Clear the blasting area of all personnel. Place guards at all access points to the blast area.

b. Immediately notify the Contracting Officer of the potential hazards and precautions being taken.

c. Terminate the loading of holes and secure the unused explosives to an approved location.

d. When the hazard dissipates, inform the Contracting Officer that the drilling and loading of holes will continue.

3.2.10 Check for Misfires

The Blaster in Charge must closely inspect the entire blast area for a minimum of five minutes following a blast to guard against rock fall before commencing work in the cut. The five-minute delay between blasting and commencing work is needed to ensure that no misfires have occurred. During the five-minute delay, it is the responsibility of the Blaster in Charge to go into the shot area and check all holes to make sure that all explosives have been detonated.

3.2.11 Misfire Handling Procedures

Should a visual inspection indicate that complete detonation of all charges did not occur, only critical personnel involved in the blasting operation or excavation of the unexploded material are allowed within the established blasting area. Restrict the site until the Blaster in Charge and the Blasting Specialist indicate the site is safe. If the misfire poses problems that cannot be safely corrected by the Blaster in Charge or the Blasting Specialist, a consultant or an explosives company representative skilled in correcting misfires must be called to resolve the problem. Compliance with this or any other provision in the Contract must not
relieve the Contractor of responsibility for any damages or injuries caused
by, related to, or arising out of blasting or associated blasting
activities. Detail the misfire procedures in the Blasting Safety Plan
including the distance of the restricted area when a misfire is discovered.

3.3 BLASTING PERSONNEL

3.3.1 Blasting Consultant

**************************************************************************
NOTE: Depending on the scope of the project, it may
not be necessary to require a Blasting Consultant.
This will be determined during design, an
Agency/Service Blasting SME or Government Blasting
Consultant should be consulted to discuss this.
Projects where slope blasting, away from sensitive
structures minor and lightly used public areas may
be a consideration to not including this
requirement. One option is to still require a
blasting consultant to be engaged but only for
reviewing the Master Blasting Plan and engaged on
very serious issues with the blasting (exceedance of
vibration and/or airblast limits, misfires, flyrock,
or excessive backbreak and/or overbreak). Excessive
backbreak will need to be defined prior to issue of
the specifications. This specification is geared
towards IFB (Invitation for Bid) where there is no
mechanism to select contractors prior to award. If
another contract mechanism is used it may be
necessary to include the bracketed text requiring a
letter of commitment from the consultant.
**************************************************************************

The Blasting Consultant, Blasting Specialist, Blasting Administrator,
Blaster in Charge, and Vibration Specialist cannot be the same person.
Retain a recognized Blasting Consultant to assist in the blast design. The
Blasting Consultant must be approved by the Contracting Officer prior to
the submission of the Master Blasting Plan. Submit the Blasting Consultant
Qualifications including resume, experience, current blasting licenses,
credentials and training of the proposed Blasting Consultant[, and a formal
letter of commitment from the consultant verifying their availability on an
"as needed" basis for the duration of the Contract prior to the award of
the Contract]. The consultant must be an expert in the field of drilling
and blasting who has derived their primary source of income by providing
specialized blasting and blasting consulting services. The consultant must
not be an employee of the Contractor, explosives manufacturer, or
explosives distributor or any other sub-contractor. There must be no
additional cost to the Government for the Blasting Consultant's duties,
even when required by the Government.

**************************************************************************
NOTE: The paragraph below should be used when
controlled blasting techniques are required.
**************************************************************************

The Contractor's Blasting Consultant with the Blasting Specialist must
develop controlled blasting techniques to be utilized in the areas
specified in the drawings during the Test Blasting program. The Blaster in
Charge is responsible for the technical application of the controlled
blasting methods specified during and following the Test Blasting. The Blasting Consultant must modify controlled blasting methods, as necessary, to meet safety requirements, airblast and vibrations limits, and protect the rock foundation. Proposed controlled blasting methods must be submitted to the Contracting Officer for approval.

The Blasting Consultant must review the Master Blasting Plan and Individual Shot Reports and attend the public meeting and be available for consultation on an "as needed" basis, as determined by the Contractor, Contracting Officer, or both. The Blasting Consultant is not required to be on the job site for review of the Master Blasting Plan or Individual Shot Reports. The Blasting Consultant must submit a short, signed Blasting Consultant's Report each month stating that the Blasting Consultant has briefly reviewed the Individual Shot Reports including blast videos, and any problems, concerns or errors in the reports were addressed. This report is due within [_____] days after the end of the month.

3.3.1.1 Blasting Consultant's Qualifications

The consultant must be able to demonstrate involvement in at least 15 projects with blasting. The consultant must have as a minimum the credentials and experience outlined below:

a. The consultant must have at least 20 [_____] years of experience in construction blasting within [_____] meters [_____] feet of protected structures, [natural resource concerns and environmentally sensitive areas], final presplit slopes or walls.

******************************************************************************
NOTE: "Natural resource concerns and environmentally sensitive" areas need to be defined elsewhere in this guide specification.
******************************************************************************

b. The consultant must be able to demonstrate that he has attended at least 15 short courses, seminars, or conferences on blasting technology, or university engineering class studies on blast design during the past 20 years including a complete understanding of blasting seismology with emphasis on vibration frequency, acceleration, and displacement (ground strain).

c. For the past 10 years the consultant must have derived their primary source of income from providing specialized blasting consulting services.

d. Project list will contain a description of the projects, details of the blast plans, and any modifications made during the project.

e. The names and telephone numbers of at least three project owners with enough knowledge of the projects to verify the submitted information.

f. The Blasting Consultant must be approved by the Contracting Officer prior to the beginning of any drilling and blasting work including submission of the Master Blasting Plan.

g. Hands-on experience as a blaster for at least three years, and

h. The Blasting Consultant, Blasting Specialist, Blaster in Charge, and Vibration Specialist cannot be the same person.
3.3.1.2 Issues Requiring the Blasting Consultant

If problems with vibration, flyrock, airblast, presplitting, or production blasting, or adverse impacts on natural resources occur the Contracting Officer will require the Contractor to immediately summon the approved Blasting Consultant and have their presence on site within 10 days after the problem develops for the following:

a. To approve the blasting plans for each individual blast.

b. To be present to review the blasthole layout on the ground before drilling begins.

c. Observe blasthole loading.

d. To sign each blasting plan and each Individual Shot Report, at no additional cost to the Government. The consultant must have full authority to stop or delay any blast the Blasting Consultant considers unsafe.

e. To submit and sign a written checklist that all necessary precautions were reviewed and followed by the drilling and blasting crews. The checklist must be as defined under the section on Individual Shot Reports. The signed checklist must be attached to each blasting report.

f. Submit Blasting Consultant's Reports after each site visit.

3.3.2 Blasting Specialist

Submit the Blasting Specialist's Qualifications including resume, experience, education, training, and valid blasting licenses of the Blasting Specialist for approval, at least 60 days before drilling and blasting operations commence. Detail the experience and training, which qualifies the specialist for work under this Contract. The duties of the Blasting Specialist are to prepare all necessary paperwork, to conduct quality control and to coordinate with the Contracting Officer on all issues dealing with blasting. The Blasting Specialist must be an employee of the Contractor on the job site each day.

a. The Blasting Specialist must have at least 10 years of verifiable experience utilizing controlled blasting techniques.

b. Within the last five years, the specialist must have completed at least five days of classroom training that has familiarized the specialist with the most current drilling and controlled blasting methods.

c. In the last five years he must have been responsible for the blast design or execution of large rock excavation projects similar in scope and complexity as this project.
NOTE: Include this sentence under paragraph a. if the project requires precision presplitting:
[or projects where at least 30,500 meters 100,000 linear feet of Precision Presplitting was used].

d. Their credentials must include a list of the projects, including the location, duration, scope, description, geologic conditions, and the challenges that developed though the course of the projects and how the challenges were resolved.

e. Each project description must be accompanied with photos which exhibit the Blasting Specialist's competency and ability to create the designed cut slope configuration to the specified tolerances. The list of projects must also contain the names and phone numbers of the project owner or their representative, Contracting Officer, or project engineers who has enough knowledge to verify the submitted information. The Contracting Officer will invalidate any project submitted as reference that cannot be verified.

3.3.3 Blaster in Charge

NOTE: Some USACE projects may require an Alternate Blaster in Charge based on the frequency, size, and complexity of the blasting operations. The Alternate Blaster in Charge must meet the same qualification requirements as the Blaster in Charge.

Submit the Blaster in Charge's Qualifications including resume, experience, education, blasting licenses and training of the Blaster in Charge for approval, at least 60 days prior to the commencement of drilling and blasting. Also submit the Contractor's Federal ATF License. Detail the experience and training, which qualifies the Blaster in Charge for work under this Contract. The Blaster in Charge is responsible for preparing the Individual Shot Plans that will be approved by the Blasting Specialist. The Blaster in Charge is responsible for marking the blasthole locations for drilling, accounting for the relevant geology, loading the blastholes according to the Individual Shot Plans and firing the blast.

a. The Blaster in Charge must be a licensed blaster in the State of [_____] per that State's regulations or issuing agency.

NOTE: If presplitting, precision presplitting, or both, is included in the project, include paragraph below as an additional requirement for the Blaster in Charge.

b. Blaster in Charge will have at least [_____] years of verifiable experience utilizing controlled blasting techniques [and at least [_____] years of experience with "Precision Presplitting" to create uniform presplit faces with blasthole spacing at 61 centimeters 24 inches or less in variably weathered and fractured rock similar to the bedrock strata present at the project site].
c. Within the last five years, the Blaster in Charge must have completed at least five days of classroom training that has familiarized the Blaster in Charge with the most current controlled blasting methods.

d. Blaster in Charge must have been responsible for at least [_____] large rock excavation projects similar in scope and complexity as this project.

******************************************************************************

NOTE: Include this sentence under paragraph d. if the project requires precision presplitting: [The projects must have included experience totaling at least [_____] linear meters [_____] linear feet of drilled blastholes for "Precision Presplitting"].

******************************************************************************

e. The Blaster in Charge credentials must include a list of the projects, including the location, duration, scope, description, geologic conditions, and the challenges that developed through the course of the projects and how the challenges were resolved. Each project description must be accompanied with photos, which exhibit the Blaster in Charge's competency and ability to design the blast. [Create the designed cut slope configuration to the specified tolerances.] The list of projects must also contain the names and phone numbers of the project owner or their representative, Contracting Officer, or project engineers who have enough knowledge to verify the submitted information. The Contracting Officer will invalidate any project submitted as reference that cannot be verified.

3.3.4 Blasting Administrator

******************************************************************************

NOTE: For smaller projects this position may not be necessary. The Blasting Administrator was added for large projects to aid the Blasting Specialist with paperwork.  
******************************************************************************

The duties of the Blasting Administrator are to be the direct assistant the Blasting Specialist to prepare all necessary paperwork, and quality control on all issues dealing with blasting. The primary function is to assist the Blasting Specialist in the preparation and completion of submittals, prepare the detailed post blast report, and the individual shot videos for submittal to the Contracting Officer, and submit the drilling logs with the post blast report. The Blasting Administrator cannot sign any paperwork. The Blasting Administrator must be approved by the Contracting Officer. Submit the Blasting Administrator's Qualifications.

The Blasting Administrator will possess the following minimum qualifications and experience:

a. Hold a current Blaster's license;

******************************************************************************

NOTE: If the Blasting Administrator will not be performing blasting duties (handling explosives in the field) this requirement may be waived but will have to be evaluated on a project specific basis.

******************************************************************************
b. Have at least [5] [_____] years of credible and verifiable experience in the industry utilizing controlled drilling and blasting techniques;

**************************************************************************
NOTE: If presplitting is required in the project, include "c" below, if not, delete.
**************************************************************************

c. Have at least five years of specialized experience with presplitting techniques;

d. Must have completed at least five days of classroom training within the last five years that has equipped the Blasting Administrator with the most current knowledge in controlled blasting or perimeter control techniques.

e. Have proven proficiency with blasting software and spreadsheets.

3.3.5 Magazine Keeper

Each magazine keeper must be experienced and familiar with the laws and general practices concerning the handling, care, use, and storage of explosives and detonators. The magazine keeper is responsible for maintaining a cleared area around each magazine. The magazine keeper will not be required to perform any duties that will in any way interfere with their duties as magazine keeper. If explosives are delivered daily from the manufacturer, the driver of the truck will serve as the magazine keeper.

3.3.6 Vibration Monitoring Specialty Firm

**************************************************************************
NOTE: This is requirement is a new format from previous specifications. The firm is submitted for approval, having the appropriate experience and the firm must have on staff the Seismic Specialists and Seismograph Technicians, typically a firm is subcontracted by the Contractor and having multiple experienced people approved allows them to have flexibility on supporting the site work. The people coming to the project or responding to the work must be within the group approved but does not need to be a single person anymore.
**************************************************************************

Retain the services of a vibration monitoring specialty firm that specializes in the prediction, monitoring and control of ground vibration and airblasts. The firm must have experience conducting installation of seismographs for vibration monitoring, communicating vibration and airblast results, and developing and maintaining a site attenuation curve. The firm must have on staff at least two Seismic Specialists that specialize in vibration monitoring and analysis. The firm must have on staff at least four Seismograph Technicians that have five years or more experience with seismograph installation and vibration monitoring. Submit resumes for all personnel and for the firm for approval citing, in additional to other pertinent data, experience, training, and education, at least 60 days prior to the commencement of blasting. The Seismograph Technicians must be persons capable of setting up the seismographs at designated locations, effectively recording the blast, and appropriately interpreting results. The Seismic Specialists must interpret the seismograph records to ensure
that the seismic data must be effectively utilized in the control of the blasting operations with respect to the existing structures. The Seismograph Technicians must supervise the placement, operation and maintenance of the seismographs. The Seismic Specialists must conduct the airblast and particle velocity regression analysis as described in this Section. The Contracting Officer may require the Seismic Specialists and Seismograph Technicians to be present during the test blast program, production blasting, or both.

3.3.7 Structural Inspection/Evaluation Technician

**************************************************************************
NOTE: Five years is the minimum requirement experience, depending on the project it might be necessary to increase the minimum if there is a special concern or sensitive structures, consult with USACE SME to help determine.
**************************************************************************

Pre and Post Blast structural inspections must be performed by technicians with at least [five] years' experience in pre-blast and post blast surveys in the State of [______]. Submit a copy of the qualifications and certificates to the Contracting Officer.

3.4 PRE-CONSTRUCTION DOCUMENTS

3.4.1 Master Blasting Plan

Submit a Master Blasting Plan at least [_____] days prior to commencing drilling and blasting operations that includes a section called Blasting Safety Plan for review and approval. The Master Blasting Plan must contain the full details of the typical drilling and blasting patterns [and control for line drilling and for the presplit, buffer and production blasting, in the situation where controlled blasting is required for the project]. The Master Blasting Plan must contain the following information, at a minimum:

a. Typical plan and section views drawn to scale of proposed drill patterns including free face, burden, blasthole spacing, blasthole diameters, blasthole angles, lift height and subdrilling depth, where allowed except for the blast that will carry the excavation to foundation grade where subdrilling is restricted as specified in the article SUBDRILLING. Base the typical plan and section views on the geology and excavation plan for this project site, it cannot be a blast plan from a previous project.

b. Typical loading diagrams for each blast design being proposed showing type and amount of explosives, primers, boosters, decks, initiators and location and depth of stemming in each blasthole.

c. Typical initiator sequence of blastholes including delay times and delay system.

d. Predicted vibration and airblast amplitudes, and the mathematical equations used to calculate them. The Contractor must monitor the results of the test blasts and with the seismic data collected can determine the site-specific ground vibration equations and the site specific airblast equations for the project. After the first 10 blasts the Individual Shot Plans must use the site-specific estimates at the 95 percent confidence level.
NOTE: Some states or counties may have specific vibration amplitude and airblast equations for specific locations.

e. Manufacturer's data sheets, including Safety Data Sheet (SDS), for all explosives, primers, and initiators to be employed. Provide copies of SDS for all explosives and detonators and define specific details about hazard communication programs for employees and specify where copies of SDS will be kept.

f. The Master Blasting Plan submittal is for quality control and record keeping purposes. Approval of the Master Blasting Plan does not relieve the Contractor of responsibility for the accuracy and adequacy of the plan when implemented in the field. Retain the professional services of a Blasting Consultant to assist with the blast designs included in the Master Blasting Plan.

g. Provide the Test Blast Plan and procedures for test blasting and modifying shot plans during production blasting in the Master Blasting Plan. Also provide the expected results from each shot including, but not limited to, the likely maximum peak particle velocity and airblast levels at the nearest inhabited structures.

h. Indicate that the Individual Shot Report design and blast record documents must provide all the data of each blast in sufficient detail; for example, the exact same blast design data conduct by anyone else from the Individual Shot Plan provided with no other information would produce similar blast results and impacts.

i. Include samples of all completed submittal forms and diagrams (Pre-Blast Surveys, Individual Shot Plan, Drilling Logs, Individual Shot Reports, Individual Shot Vibration Monitoring Report, Results of Vibration and Airblast Monitoring, and Individual Shot Video).

j. Manufacturer's specifications on equipment to be used including but not limited to drills, air compressors, drill bits, drilling equipment specifications, manufacturer's literature of the drill rods, bits, casing, etc.

k. Plans for construction sequencing line drilling, presplitting, blasting, and mucking operations to complete the rock excavation with the limitations of the peak particle velocities. Describe the change in placement any of the seismographs with regards to the progressing blasting and excavation. Provide the names of individuals responsible for the instruments, data retrieval, and analyses.

l. Single Sheet plan view showing location of all seismographs. This sheet must be amended and resubmitted whenever seismographs are moved.

m. Sample checklist that the Contractor will use to ensure that all required information is included in each blasting plan.

n. Survey Control Plan: Establish survey control as approved by the Contracting Officer for horizontal and vertical control of all line drill, presplit and production blasts. Assure that all blast holes are drilled on the specified pattern and at the location and the depths as
detailed in the blast plan.

3.4.2 Blasting Safety Plan

In addition to the Master Blasting Plan, a Blasting Safety Plan must also be prepared, as specified and outlined in EM 385-1-1, Section 29. All blasting work must be conducted in accordance with the requirements specified in EM 385-1-1.

********************************************************************************
NOTE: Minimum safe distance from blast point will vary with each project. Local, state, county and federal regulations must be taken into consideration. Ensure NEPA, 408 permits, and environmental studies incorporated the blast safety radius.
********************************************************************************

The required minimum safe distance is [_____] meters [_____] feet from the blast point. All the public, including swimming and boating recreationists must be excluded from the safety zone during blasts, including pre- and post-blast operations. The safety zone must be marked with an intrusion prevention barrier and high hazard warnings. Patrol by boat before and during blasting to prevent the recreational public from entering the safety zone.

The Blasting Safety Plan must provide a complete description of the clearing and guarding procedures that must be employed to ensure personnel, staff, visitors, and all other persons are at safe locations during blasting. A Blasting Safety Plan simply stating: "all regulations will be followed" is not acceptable and will be rejected. This plan must be developed and signed by the Contractor's Blasting Specialist with input from the Contractor's Site Safety and Health Officer (SSHO) with the intent to show how the Contractor's procedures and methods meet or exceed applicable rules, regulations and standards established by the Regulatory Agencies, codes and professional societies, and specifications listed herein. The guarding procedures must also consider aircraft and water vehicles that may enter the danger zone. This information must include detailed descriptions and maps, when appropriate of traffic control, visible warning signs or flags, audible warning signals, method of determining blast areas (all areas affected by any potentially harmful blast effects), access blocking methods, guard placement and guard release procedures, primary initiation method, and the system by which the Blaster in Charge must communicate with site security guards or other appropriate site supervisory personnel. The Blasting Safety Plan must be in accordance with and include items required in the EM 385-1-1, Section 29, 29 CFR 1910.109, 29 CFR 1926-SUBPART U.

The Blasting Safety Plan must state that explosive distributor will be delivering explosives on the day of the planned operation and recovering unused explosives at the end of the day. In the event of lightning detected at 16 kilometers 10 miles or less from the project site requirements for ceasing operations must be described. Provide a plan for controlling the temporary onsite storage of explosives or of securing an area of loaded holes until the threat has passed.

The Blasting Safety Plan must contain detailed descriptions of how and from where explosives will be transported and used at the various project work areas, and a map of the transportation route. The Blasting Safety Plan
must explain how explosive transport vehicles will satisfy all applicable ATF, OSHA, Federal, State, County, and local regulations. The Blasting Safety Plan must also include the following.

a. Specific details about hazard communication programs for employees.

b. Equipment that will be used to monitor the approach of lightning or dust storms and in such event, the site evacuation and site security plans, and the criteria for determining if the site is safe to re-occupy.

c. Methods for preventing spills or losses of explosives, drilling fluids, oil, or any other pollutants onto the ground during handling and blast hole loading operations. Include details of spill containment and contingency plans for quickly and effectively cleaning up spilled materials.

d. Method of safe and approved disposal of all explosive packaging materials.

e. Detailed contingency plans for detection and disposal of misfires resulting from cutoffs or other causes, hangfires, inadvertent initiator extraction, or accidental loss of downlines. A narrative describing in detail job steps, controls, and hazards associated with but not limited to hung or bridged powder, overloaded holes, cutoffs during placement of blast mats, failure of communication system during pre and post blasting protocols, recovery protocols for unexploded objects (UXO), etc.

f. Misfire mitigation procedures, including but not limited to restrictions of entry, securing the area prior to investigating and inspection, additional safety measures, time-sequence of operations, and mitigation protocols.

g. Fire Prevention Plan details, including tobacco smoking policies, procedures and limitations for work involving open flames or sparks, description and location of firefighting equipment, and firefighting and evacuation plans.

h. Digital copies of a valid [state] blasting license for the Blaster in Charge, Blasting Specialist and all personnel required to have one.

i. State required certifications for the Contractor's explosives supplier's Federal, ATF Explosives license or permit.

j. Other required county or state permits required for explosive transportation, use and offsite storage.

k. Explosive transporters' commercial driver's licenses with HazMat endorsements.

l. A reference in Attachment II (under misfire) when a misfire is declared the Blaster in Charge must wait 1 hour before inspecting site and provide proper safeguards for excluding employees from the danger zone except those necessary to do the work.

m. Submit updates, modifications and additions to the Master Blasting Plan in an appropriate and timely manner.
n. Complete project team organization with duties, responsibilities and authorities clearly defined. This organizational outline must also include names, addresses, resumes, responsibilities, and qualifications of all personnel authorized to sign for, receive and use explosives on this Contract.

o. Traffic Control Plan.

3.4.3 Pre-Blast Surveys

 Prior to the commencement of blasting, conduct a Pre-Blast Survey of any nearby buildings, structures and utilities within [___] meters [____] feet from the blast area that may potentially be at risk of blasting damage to document pre-existing conditions. The survey extent and method used must be acceptable to both the Contractor's insurance company and the Contracting Officer. The Contractor is responsible for any damages or injuries resulting from blasting. Submit all Pre-Blast Surveys 30 calendar days before the start of blasting. There will be no blasting allowed until the Pre-Blast Survey is submitted and approved by the Contracting Officer. Provide owners of surveyed features a copy of their feature's Pre-Blast Survey results before or with the notice of blasting commencement. Notify owners and occupants of local buildings prior to the commencement of blasting. Perform the following when conducting Pre-Blast Surveys:

a. Provide methodology to be used in conducting the Pre-Blast Survey and listing of structures, determined from the survey to be sensitive, with reasons for these structures being sensitive.

b. Each structure must be documented (including high resolution photography and videotaping) as to its construction, foundation type, condition, and closest distance to excavation blasting. The general condition and all observable defects of each structure must be documented. This includes measurements of the defects.

c. The Commodity storage facilities that may be impacted by blasting must be addressed by the Contractor for safety and continued operation during the blasting program.

d. Freestanding structures (such as retaining walls) must be inspected on the exterior and on the interior as a room. All concrete walks, driveways, etc. must be inspected for cracks, level condition, holes, and defects.
e. Industrial structures, silo/elevators and special facilities, and office space must be described relative to their present conditions and tolerance to vibration. Besides the inspection of walls, columns and stairwells, the Contractor must survey the work areas and structures for distress.

f. An inspection of accessible structures must be made and a list of all structures, which could not be surveyed or refused to allow survey, must be completed. The dates of possible subsequent surveys and physical constraints prohibiting the survey must be documented. The requirement to perform Pre-Blast Surveys is not an indication of Right-of-Entry by the Contractor. Any Right-of-Entry associated with Pre-Blast Surveys, monitoring during blasting and Post-Blast surveys are the responsibility of the Contractor. In the event a property or properties identified as significant or intended to be included in the Surveys and monitoring are not included because access was denied, indicate this occurrence including the points of contact, dates contacted and any reasons provided for denial of access (if given.)

g. Certify that the survey was prepared prior to the start of any blasting under this Contract. Submit a copy of the Pre-blast survey in conjunction with the Master Blasting Plan.

3.5 RECORD KEEPING

3.5.1 Individual Shot Plan

The Blasting Plan must be consistent with the general concepts, designs and layouts shown in the approved Master Blasting Plan. The number of rows of blastholes and the number of blastholes per row can be changed from one individual shot plan to the next. Provide reasons and technical justification for all significant changes from the Master Blasting Plan.

Submit a Blasting Plan for each blast at least [24] hours prior to the planned initiation of drilling. The results of the previous blast are to be jointly evaluated by the Contractor and Contracting Officer prior to the submission of the Individual Shot Plan. The Individual Shot Plan must contain but be not limited to the following:

a. Plan view, and at least two sectional views drawn to scale, of the shot pattern showing blasthole locations, inclinations and designations;

b. Individual blasthole depths, diameters, blasthole spacings, burden, depth intervals of stemming and depth of subdrill;

c. Type of shot, i.e. test, production, pre-split, line drilling or buffer and shot number;

d. Orientation and elevation of the collar and bottom of all blast holes;

e. Total volume of blasted material in cubic meters cubic yards;

f. Description of type of blast and indication if blast is on final slopes or inverts;

g. Amount, type, diameter and depth of explosives, stemming and delay in each hole, and amount, type, and location of boosters and centering devices and the lift elevation;
h. Plan view of blasthole shot pattern showing in-hole and surface delays and firing times of each blasthole or decked charge;

i. Anticipated time and date of blast;

j. Survey coordinates using State Plane coordinate system and, if appropriate, a local coordinate system;

k. Any significant geologic features, and techniques planned for mitigating their influence upon results must be included in plan and section with appropriate elevations;

l. Estimated/anticipated peak particle velocities and maximum peak airblast predictions at seismographs located at protected structures using site specific data and regression analysis and the accurate distances from the blast to seismographs;

m. Name of Contractor;

n. Name, signature, and license number of the Blaster in Charge;

o. The maximum charge weight per delay, pattern and sequence of delays, and firing times for the blast;

p. Type of detonators, initiation and down hole lines;

q. Powder factors both in charge weight per cubic yard of material shot and in charge weight per meter per foot of total drillhole depth;

r. An elevation sketch of a typically loaded hole depicting each hole pattern, top of overburden elevation, top of rock elevation, bottom of hole elevation and diameter of hole, sub-drilling, decking charges, locations of explosives and stemming, and the locations of primers and boosters; and

s. The location of the blast area on a scale plan map of the project indicating the location of the shot, and the distance and directional relationship between all seismic equipment and the nearest structure subject to damage using a scaled distance measured in a horizontal line from the blast site to the nearest building, or structure, berthing facility.

t. A minimum of ten high resolution photos, taken with a camera with a resolution of at least eight megapixels, of the entire blast area, preferably from above, of surface and open face of the shot and surrounding rock to document conditions prior to the shot.

u. No blastholes must be drilled until the Individual Shot Plan for them is approved. Evaluate any problems or impediments of the prior shot and implement solutions for those issues with the next Individual Shot Plan. Provide the Individual Shot Plan to the Contracting Officer electronically. The Contracting Officer will review the plan and send comments to the Contractor within 24 hours of receiving the plan if the plan is submitted between Monday and not later than close of business Thursday.

v. Include a tabular listing by hole in the ascending time order of delays by the describing: row and number within the row of the shot hole,
total delay time, the total charge weight of explosive materials for
the entire hole, top of sound rock elevation, bottom hole elevation,
stemming elevations, and detonator, primer and booster elevations in
the hole; and for each seismic monitoring location the closest
approach, the square-root scaled distance, the cube-root scaled
distance, and the estimated PPV and airblast overpressure.

3.5.2 Drilling Logs

**************************************************************************
NOTE: It may be necessary on sites with complex
geology and blasting is occurring near very critical
structures or rock outside of neat lines needs
special protection, or neat line tolerances are
especially important to consider the blaster or
Contractor to have geologist(s) on staff to log
blast holes or assist in logging blast holes, and
aide the blaster in understanding the geology and
for more accurate drilling logs. For rock
excavation’s objective(s); the project truly
requires the designed tolerances and
quality/stability of the remaining rock, which
cannot be overcome at the Contractor’s cost of
dental clean-up, rock bolting, shotcrete or mass
concrete placement; and, an experienced, agency (or
third-party) geologist will be onsite for Quality
Assurance of the logging & blasting & retained rock
stability or damage. Logging may need to be in
accordance with ASTM D2487, ASTM D5434, ASTM
D6032/D6032M in some instances.
**************************************************************************

The drillers are required to keep precise drilling logs on each blasthole
to show the depth of the geological features. At minimum, each drilling
log must include:

a. Blast number;

b. Blasthole designation and location station number, bench number and
type of blast (production, presplit, buffer, etc.);

c. Blasthole depth and diameter;

d. Elevation of top and diameter of blasthole;

e. Subdrill depth as permitted in the article SUBDRILLING;

f. Depth(s) of geologic structural features, e.g., voids, gouge or mud
seams, soft weathered or altered zones, rusty intervals, changes in
rock chip color, and other features encountered in the blasthole
pertinent to loading the hole;

g. Relative penetration rates;

h. Start and end times of drilling;

i. List any blasthole misalignment; and

j. Soft seams within the rock and sudden feed pressure changes on the rig;
k. If qualitative descriptors are used (e.g., soft, moderately hard, hard, very hard, decomposed, highly weathered, moderately weathered, slightly weathered, unweathered). Ensure consistency between drill operators in logging using these terms. Blasting Specialist and Blaster in Charge must ensure drillers are using consistent terminology between drillers.

[Log soil and rock in accordance with ASTM D2487, ASTM D5434, ASTM D6032/D6032M.] Submit an example of the Drilling Logs with the Master Blasting Plan. Copies, both hard and electronic PDFs, of these drilling logs must be provided to the Contracting Officer at least 24 hours prior to loading any blastholes. The drilling logs must be used to determine the proper design and loading of blastholes and for locating the depths for use of stemming decks across intersected geological features to protect against blowout, flyrock and any unusual or hazardous blasting effects.

**************************************************************************
NOTE: The paragraph below may be necessary where preventing subdrilling and foundation damage is critical.
**************************************************************************

[Survey the elevation at the collar of each production hole in the final blast to foundation grade to ensure that the production blastholes are not subdrilled below final foundation grade, except as permitted in article SUBDRILLING. The survey must be included in the Individual Shot Plan.

3.5.3 Individual Shot Reports

As a minimum, the Individual Shot Report must be the same form used in the Individual Shot Plan but provide all "as-built" information required for the blast plan. Furthermore, the Individual Shot Report must better describe any part of the blasting operation that wasn't adequately described by the Individual Shot Plan including information on misfires, observed field conditions, and information how the Blaster in Charge compensated for compromising field conditions, such as increased stemming amounts, or stemming decks where voids, cracks, spalls or mud seams were identified and resolved. The Blasting Specialist is responsible for recording all explosives loaded in the blasthole and for accurate documentation of daily blasting activities. Submit the Individual Shot Report no later than 24 hours after the blast. No additional blast will be drilled or loaded in the immediate area of the completed blast until the previous day's Individual Shot Report is submitted to the Contracting Officer. The Contractor must plan on multiple work areas so that production can be maintained on schedule. The report must include at minimum the following information:

a. Blast number (i.e., R-L3-PS1);

b. Date and specific time the blast was initiated;

c. Blasthole designations, locations;

d. Amount, type and depth of explosives, decking, stemming, and delay in each hole;

e. Plan and section views, drawn to scale, of drill pattern including free face, burden, blasthole spacing, blasthole diameters, blasthole angles and azimuths, blasthole number, lift height, and subdrill depth. Show
in-hole and surface delays, as well as actual firing times of each blasthole or decked charge. Use different symbols to distinguish the production, buffer, presplit and line-drilled blastholes. Include a north arrow and scale on each plan view. Label the direction of the sections on the sections. Include section parallel to, and perpendicular to the blasthole rows. Show final grade and slope lines as appropriate in the sections. Show the location of the two video recorders on the plan in relation to the blast.

f. Drilling logs for presplit, line, buffer and production blastholes. Each drill hole must be logged by the driller to provide additional information to the Blaster in Charge during loading operations. Drilling Logs must contain information pertinent to the rock characteristics and blast operations. At the minimum, drill logs must contain geological information on pertinent geologic structure, soft or weathered zones, voids, penetration rate changes, and driller's notes.

g. Loading diagram showing type, diameter, amount and depth interval of explosive, primers, initiators and location, depth and type of stemming for each blasthole. Show the charge weight of each type of explosive and the total explosive load per delay and per hole.

h. Diagrams showing the delay system in the initiation sequence in each blasthole and the location and delay time of all surface delays of each blast. Indicate which blastholes are firing with a delay of less than 8 milliseconds.

i. Trade names and sizes of all explosives, primers, and initiators to be employed.

j. Daily explosives material consumption record.

k. A description of all personal injuries and property damage caused by the blast; when the measured maximum peak particle velocity or airblast exceeded by 10 percent the anticipated values from the Blasting Plan; and, all problems with the Warning System and problematic results of the blast, such as overbreak or large fragmentation, or with the shot pattern, such as misfires.

l. The vibration and airblast report described in paragraph Vibration and Airblast Monitoring. Include a comparison of predicted and actual measured values.

m. Signature of the Blasting Specialist specifying that the Blasting Specialist has reviewed the Individual Shot Report for accuracy and completeness.

n. Signature of the Blaster in Charge.

o. Note if mats are used or required by the Contracting Officer then list the type of blasting mats or other protective covering used.

p. A brief weather description at or near the time of the detonation such as cloudy, clear, partly cloudy, and foggy, with approximate wind direction and velocity, and temperature.

q. Updated or "as-built" Plan drawings depicting the borehole pattern and the delay pattern employed as well as pounds of explosives utilized, hazard incidents, and blast holes not loaded.
r. Copies of drilling records and originals of the blast monitoring data.

s. A plan view map of each bench showing the location of each completed blast.

t. Include photos, after the shot, taken from the same locations and at the same resolution as the blasting plan photos.

u. Include an updated as-built tabular listing by hole in the ascending time order of delays by the describing: row and number within the row of the shot hole, total delay time, the total charge weight of explosive materials for the entire hole, top of sound rock elevation, bottom hole elevation, stemming elevations, and detonator, primer and booster elevations in the hole, by hole in the ascending total delay time order of delays by describing: row and number within the row of the shot; and for each seismic monitoring location the closest approach, the square-root scaled distance, the cube-root scaled distance, and the estimated PPV and airblast overpressure.

Include two log-peak particle velocity versus square root scaled distance as per RI8507 diagrams for each seismograph. One diagram including all shots. The second including only data from the last 10 shots.

Include seismic records with peak displacement, velocity and accelerations at their respective frequencies. Site curve modification may be required to ensure that vibration levels at the control room remain acceptable.

If a recorded seismic value appears anomalous, the Contracting Officer may request that the vibrations monitoring specialist interpret all of the collected seismic records from the seismographs for that blast and provide an explanation of the anomalous readings. Anomalous readings include, but are not limited to, unusually high or low particle velocities, failure of a seismograph to trigger, or atypical wave forms on the paper record. No additional blasting will be allowed until the issue is resolved to the Contracting Officer's satisfaction.

Signatures of the Blasting Specialist and Blaster in Charge will be considered as proof that the shot was laid out, drilled, loaded, and wired as designed. Proof of the Blasting Specialist and Blaster-in Charge's qualification must include remaining below the allowable peak particle velocities at all structures. Inability to remain below the allowable vibration levels may be cause for dismissal of either or both parties.

The Blasting Specialist must oversee all loading operations and collect and keep accurate records of the information required for each Individual Shot Report. Submit an example of an Individual Shot Report to the Contracting Officer for approval as least 30 days before commencement of any blasting. Failure to submit satisfactory Individual Shot Reports must result in suspension of any additional drilling and blasting until the Contractor complies with this requirement. The Blasting Specialist will make sure that the drilling logs are used by the blaster when blastholes are loaded to prevent overloading in soft or weak rock in the borehole.

The Individual Shot Reports are for quality control and record keeping. Review of, and comments on, the blast reports by the Contracting Officer will not relieve the Contractor of his responsibility for the accuracy and adequacy of the blast design.
Supplement the Individual Shot Reports with the original digital copy of the printed results of vibration and airblast monitoring showing peak readings and frequencies for each blast to the Contracting Officer. This submittal must also include the distance from the blast to the seismograph in meters feet as well as the maximum kilograms pounds of explosive per delay. The seismograph locations must be clearly marked and located on a map in the blast report.

Supplement the Individual Shot Report with the original, handwritten, field notes showing any field changes on the approved blasting plan.

The Blasting Consultant must develop a checklist of tasks that must be completed and checked off by the Blasting Specialist for each blast. Complete the tasks in an orderly fashion before a blast is fired. Submit the draft checklist for approval. Submit the completed and signed daily checklist with the Individual Shot Report.

3.5.4 Individual Shot Videos

******************************************************************************
NOTE: Video size can be a point of discussion, larger files come out of the new high quality 1080 HD and 4K videos. It may be necessary to require a frames/second or use of HD/4K videos. It is likely technology will change faster than this guide specification. This paragraph can be updated by project. The use of sFTP allows for the larger files.
******************************************************************************

Record each blast with high resolution digital video cameras from two designated locations, approximately perpendicular to one another, that provide side, front and rear views of the blast and area above it. The video images must not contain any other text than the shot number. Include metadata consisting of the blast ID, date, and time of the blast. Index the two video recordings to properly identify each blast. Submit the proposed locations of the two video recorders on a map with the Individual Shot Plan for approval. Furnish electronic file copies of video recordings on the sFTP within 24 hours of a blast. If the Contracting Officer requests that a copy of the video be submitted earlier, then deliver a copy within one hour of the request. Maintain a digital video library of all blasts. All drilling and blasting activities must cease after the 24 hours from the previous blast if the video recordings of the previous blast are not furnished to the Contracting Officer.

3.5.5 Post-Blast Surveys

******************************************************************************
NOTE: Pre- and Post-Blast Inspections and the Structural Inspection/Evaluation Specialist would only be required if there are structures or facilities requiring such inspections. Eliminate the paragraphs referencing Pre- and Post-Blast Inspections and the Structural Inspection/Evaluation Specialist if the project does not have a requirement for these inspections.
******************************************************************************

Post-blast surveys must be conducted at any location, where a reasonable
notice of damage from blasting has been provided. Post-blast surveys will be conducted by, or under the supervision of, the Structural Inspection/Evaluation Specialist, who will also sign and date each survey. The survey extent and method used must be acceptable to both the Contractor's insurance company and the Contracting Officer. The post-blast surveys must be conducted within a week of the notice of damage from blasting. The Contractor is responsible for any damages or injuries resulting from blasting. Submit a copy of all post-blast surveys within two business days of the on-premises surveys to both the structure's owner and the Contracting Officer.

3.6 BLAST EFFECTS MONITORING

**************************************************************************
NOTE: Depending on the project, this section will vary and need to be tailored for the monitoring locations and thresholds specifically. The designer should engage any subject matter expert for various disciplines - Structural for concrete, Mechanical/Electrical for related equipment (powerhouses, locks, etc.).
**************************************************************************

3.6.1 Vibration and Airblast Monitoring

**************************************************************************
NOTE: Vibration monitoring is required for every blasting project. Consult with the Structural, Mechanical, and Electrical Engineers on the project in developing the vibration and airblast thresholds. The paragraph's narrative is a generic description for most projects, where the nearest structure/facility is: Standard Construction Timber Frame, Brick, and Concrete Buildings; Lock Monoliths; Powerhouse Switchyard; Highway and Railroad Bridges; Buried Utilities; and, Wells and Aquifers. The Figure below in the notes is Figure 8-19 of EM 1110-2-3800. Some projects may require assessment by a trained experienced blasting specialist or structural engineer of lower allowable vibration criteria at critical or historic or special structures or facilities or structures with continuous occupants. Vibrations can cause the occupants of structures to become physically uncomfortable at levels well below the allowable vibration levels to avoid damage to the structure itself. Projects a with a Powerhouse and Electrical Power Relay Equipment or Pipelines, besides those with continuous occupants, should be evaluated for lower allowable vibration criteria. Some projects could utilize the assessment by a trained experienced blasting specialist or structural engineer to include higher allowable vibration criteria for those projects where typical structures/facilities are more than twice the distance of the closest approach of blasting to: Steel and Reinforced-Concrete Structures; Mass Concrete Monoliths; and, Cured Shotcrete. The specification writer must include a limitation of
the allowable vibration.

Vibration monitoring must conform to current industry standards and use equipment developed for that purpose. Peak particle velocity must be used as the unit of measure. Begin seismic vibration monitoring at least four weeks prior to the commencement of any blasting to determine vibration background levels on adjacent roads, and the [____]. Permanently mount the seismograph to record seismic events for a 24-hour period daily. Submit the background vibration monitoring reports and the baseline vibrations levels determined from the data for approval at least two weeks prior to the commencement of blasting. When blasting commences, analyze all events shown on the seismograph including normal background or blast induced vibrations. Monitor all blasts for vibration. Control ground vibration levels always using properly designed delay sequences and allowable charge weights per delay. Base allowable charge weights per delay on vibration levels recorded during the test and production blasting that produced no adverse impacts. Monitor each blast with an approved seismograph located between the blast area and the closest structure(s) of interest. The seismograph used must be capable of recording particle velocities for three mutually perpendicular direction components of vibration in the range generally found with controlled, cautious blasting. The peak particle velocity of each component must not be allowed to exceed current local, State and Federal vibration limits, whichever is more stringent, and never exceed the safe limits of the nearest structure subject to vibration damage.

Report peak particle velocity, peak acceleration and peak displacement in the Individual Shot Monitoring Report. The Individual Shot Monitoring Report must include the summary report from each seismograph which will include the peak particle velocity and frequency of the peak, peak particle displacement, peak acceleration, distance from the blast, map location of each seismograph and the blast, and charge weight per delay. A single delay includes the weight of all charges fired within 8 milliseconds of each other. Compile all vibration data in an up to date database of distance, charge weight per delay and measured peak particle velocity. The Seismic Specialist must conduct a linear regression of the particle velocities to determine the equation of the 95 percent confidence level propagation. Use the equation to predict the expected vibration in the next blast. Show the time history of the particle velocity in the vibration report.

The seismograph must also record airblast. This data must also be added to the Individual Shot Monitoring Report. The report must include the airblasts measured at each seismograph. Compile all airblast data in and up to date database with the Individual Shot Monitoring Report data. The Seismic Specialist must conduct a linear regression of the airblasts to determine the equation of the 95 percent confidence level airblast propagation. The equation must be used to predict the expected airblast in the next blast. Provide the linear regression data to the Contracting Officer in digital form to become part of the Individual Shot Monitoring Report.

NOTE: The following are the limitation of the allowable vibrations:

TABLE 1 below gives standards for allowable peak particle velocities as they relate to a variety of

</table>
common construction materials. Do not exceed these vibration limits.

These vibration limits must not be incorporated in the blast design. Many projects have been constructed utilizing a fraction of these allowable values. Properly design the blasts, set allowable vibration limits, and maintain proper control throughout the duration of construction. The Contractor is responsible for all damages caused directly by, or as a result of the blasting operations. Compliance with this or any other provisions in the Contract must not relieve the Contractor of responsibility for any damages or injuries caused by, related to or arising out of blasting or associated blasting activities.

Here are two examples of vibration tables. The first is more generic and should be used the section shows for a specific project also requiring an initial peak particle velocity for test blasting ramp up.

</tbody>
</table>
Note that older deteriorated structures or utilities and structures housing computers or other sensitive equipment may require lower peak particle velocity limits than those provided in Table 1. Also, buried pipelines owned by private utility companies or bridge structures owned by other agencies may be subject to lower limiting values imposed by the owner. The safe vibration limits and charge weights per delay to achieve these vibration limits must be established by the Seismic Specialist and the Blasting Consultant. Vibration limits for all non-government owned structures must conform to the laws of the State of [____].

Blast vibrations measured 30.5 meters 100 feet or less from final walls must not exceed 12.7 cm/s 5 ips. If any damage occurs to benches or final slopes above the blast area, the blast vibration levels may be reduced at the option of the Contracting Officer. The vibration limits will be subject to approval by the Contracting Officer.

3.6.2 Blasting Near Green Concrete, Grouting, and Shotcrete

Blasting operations are typically ongoing in one section of a project while placing concrete or applying shotcrete in another.

NOTE: The following are the limitations on allowable vibration:

Some guidelines for peak particle velocities related to time intervals after placing mass concrete/shotcrete/grout curtains are given in Tables 2 and 3 should be considered when designing a blast. The specification writer must include a limitation of the allowable vibration when there is green concrete expected on the project. Table 2 has two option, one is more conservative, designer should make engineering decision which to use or adjust based on data.

3.6.3 Measuring and Recording Instruments

Submit seismographs for approval. Provide up to [_____] blasting seismographs capable of sampling rates of 15,000 samples per second or higher that meets ISEE PSBS. The 15,000 samples per second accuracy is required to acquire reproducible vibration readings. The units must be self-contained except for external geophones and microphones. The seismograph must be capable of providing a printout of each blast or downloading the data to a portable device for off-site printing. The units must be programmed with specific data for each site of seismograph placement, which includes seismograph location, geophone burial or mounting method, calibration signal, date, time and closest distance to the blast area. The seismic record must also indicate the maximum charge weight of explosives per delay in the blast. The seismographs must not be placed inside of a structure, unless required for the designated purpose and authorized by the Contracting Officer. The seismographs and geophones must be placed on and secured to sound bedrock or virgin soil, or mass concrete foundations. The seismographs should not be placed near a structure, unless the intent is to measure that structure’s specific response to the blast. Include the raw data values from the seismograph of vibration and airblast.
3.6.4 Seismograph Locations

NOTE: This paragraph will vary depending on the project, the designer should determine what structures need to be monitored. It may be necessary to require one or two extra seismographs that are placed at the Contracting Officer's direction.

Install seismographs at the following locations:

a. Closest point on the existing main dam and auxiliary dam.

b. Main dam powerhouse or as otherwise directed by the Contracting Officer.

c. Three other locations selected by the Contractor with the agreement of the Contracting Officer.

These locations are subject to change as the project progresses.

3.6.5 Individual Vibration Monitoring Report

Provide the original digital results of vibration monitoring in the form of peak readings and frequencies for each blast prior to conducting any subsequent blasts, provide the Contracting Officer with access to the online data available immediately after the shot. Submit the vibration monitoring reports with the individual shot reports. Data recorded for each shot must include the following:

a. Identification of instrument used and location.

b. Name of qualified observer and interpreter.

c. Distance and direction of recording station from blast area.

d. Maximum pounds of explosive per delay period.

e. Type of ground at recording station and material on which the instrument is sitting.

f. How the geophone is anchored, if peak acceleration is greater than 0.2 g to prevent decoupling of the sensor.

g. Maximum particle velocity in each component direction.

h. A dated and signed copy of seismic records with their supporting information.

i. Regression analysis of seismic data measured at each seismograph for each blast. The Seismic Specialist must conduct an independent regression analysis for each seismic location after each blast. The regression analysis is necessary to understand vibration transmission throughout the site and must be used to accurately predict the vibration levels generated on the next blast design.

j. Airblast results.
Take all necessary precautions to assure that the peak particle velocity
readings available from the blast record are accurate to the maximum extent
possible, as defined by the manufacturer of the equipment. The equipment
must be calibrated annually.

3.6.6 Airblast Monitoring

NOTE: The peak overpressure threshold should be 133
dB in accordance with the EM385-1-1, some state
regulations set a lower dB threshold. The designer
must research state, county or local requirements
and decide if the most stringent must be selected.

Take every precaution to minimize airblasts from all blasts. Install an
airblast monitoring system between the main blasting area and the nearest
structure subject to blast damage or annoyance. The equipment used to make
the airblast measurements must be specifically manufactured for that
purpose. Peak overpressure must be held below [133] dB (linear peak scale),
100 Pa 0.015 psi at the nearest residential or inhabited structure or
other designated location. Appropriate blasthole patterns, detonation
systems, and stemming must be used to prevent venting of blasts and to
minimize airblast and noise levels produced by the blasting operations. A
dated record of the peak overpressure measurements signed by the Seismic
Specialist must be furnished to the Blasting Specialist immediately after
each blast unless a variance is given by the Contracting Officer. Provide
the Contracting Officer with access to the online data available
immediately after the shot. Include the airblast data in the Individual
Vibration Monitoring Report.

3.6.7 Flyrock Control

NOTE: Use of blasting mats may be required in
specific areas depending on the project needs and
risks.

Before firing any blast in areas where flying rock may result in personal
injury or any damage to property or the work area, the rock to be blasted
must be covered with approved blasting mats, or other equally serviceable
material, to prevent flyrock. The Contractor must ensure that enough
blasting mats are available at the project site to cover the blast area.
If flyrock occurs all blasting must cease until the Blasting Consultant
files a report explaining the cause of the flyrock and methods that must be
employed on all subsequent blasts to prevent flyrock. Submit this report
to the Contracting Officer for review before any additional blasts are
detonated. No additional compensation will be given to the Contractor for
work stoppage after a flyrock incident.

3.6.8 Rock Damage Control

NOTE: Tailor this paragraph to the specific site
issues that may affect blasting.

The rock formations are known to contain geological features including
variable weathering, alteration, fracturing and shearing, voids, weathered joints and gouge seams. Rock cores recovered during drilling investigations disclose the site's geological conditions and are available for review by the Contractor. The Contractor is encouraged to review the [Geotechnical Data Report, Geotechnical Baseline Report, other reports provided with bid documents], the drill core, drill core photographs, cut slopes, and all geotechnical and structural information available before planning and conducting blasting operations.

Use stemming decks across weak or open geological features to confine the energy into the hard rock and minimize explosive gas penetration into these features. No rock mass damage, uplift or shifting or significant overbreak will be tolerated. Control drilling accuracy and delay timing to provide proper relief toward the free face away from final rock slopes. Any blasting damage or breakage into the excavation walls will be mitigated at the Contractor's expense. Damage is defined as the loosening of rock behind final lines and grades, opening of joints in the final wall and rock block displacement in the final wall. If any damage occurs to the final wall that requires remediation, it must be the responsibility of the Contractor to prove that the blasting method employed did not cause the damage.

3.7 TEST BLASTING

**************************************************************************
NOTE: The test blasting will be highly specific for the project site. The designer may have a way to carry out the test blasting in order to have the Contractor demonstrate satisfactory results. Typically, the main reason for test blasting is to gain understanding of how the blasting on the site causes vibrations/air blast on monitored structures, develop a site attenuation curve to design future blasts with vibration in mind. The other is to demonstrate results, line drilling and presplitting that meets the specifications and no damage to final faces and foundation grade. Typically the test blasting occurs in an area where there is room for failure, if a test presplit causes significant back break it won't be to a finished face and can be removed. The designer must also keep in mind that a poorly design shot can result in blast damage, such as induced cracks or even opening of rock joints, and can extend beyond the blast area more than 30 meters 100 feet. Typically an area that would be removed with full production blasting. Test blasting will be reviewed by the Contractor's consultant and the Government's consultant (if retained), blasting Subject Matter Expert (SME) within USACE.

The following is typical test blasting language.
**************************************************************************
Submit the Test-Blast Plan for review and approval. Allow 21 days for review after submittal. Allow 14 days for Government review after submitting the revised plan. Approval of the revised plan will not relieve the Contractor of their responsibility to produce safe and satisfactory results as set forth by these specifications.
Prior to commencing full-scale blasting operations in a different rock type, weathering grade or new bench elevation, demonstrate the adequacy and effectiveness of the proposed blasting plan by drilling, blasting, and excavating short test sections, not exceeding 15.3 meters 50 feet in length, to determine which combination of method, hole spacing, and explosive loads produces the proper split. If more than one presplit design is tested in one test blast, each presplit design section must be at least 6 meters 20 feet in length along the surface.

The first opening blast starting from a level plane that has only vertical relief (i.e. a sinking cut), must not be used as the production test blast. However, its results must be considered when designing the test blasts. The opening blast must be excavated to full depth if possible before drilling the blastholes for the test blast. The test blast must incorporate the planned methods of presplitting and must be near the center of the excavation and at least 4.5 meters 15 feet away from the final excavation walls [or invert]. The Contracting Officer has the option to adjust the location of the test blast areas to optimize for geology. Anticipate blasting up to 10 test sections with at least one test at each different geologic condition. The location of the test blast section must be approved in advance. The Contracting Officer may direct the Contractor to use test section lengths less than 15.2 meters 50 feet if field conditions warrant.

Unless otherwise directed, begin the presplit test blast with presplit holes spaced at 61 centimeters 24 inches center to center. Requirements for presplit and production blasting operations are covered elsewhere in this specification but apply to test blasts.

Do not drill ahead of the test shot area until the test section has been as fully excavated as possible and the results have been evaluated by the Contracting Officer. If the results of the test blast(s) are unsatisfactory, in the opinion of the Contracting Officer, the Contractor's Blasting Consultant must revise the blast design as necessary to achieve the specified results. Unsatisfactory test blast results include an excessive amount of fragmentation beyond the indicated lines and grade, extensive overbreak, flyrock, ground vibration, airblast or violation of other requirements or these specifications. All costs incurred by the Contractor in adopting revised blasting methods necessary to produce acceptable test blast results will be borne by the Contractor.

If at any time during the progress of the work, the methods of drilling and blasting do not produce the desired result of an undamaged rock slope within the specified tolerances, perform additional test sections by drilling, blasting and excavating short sections, not exceeding 15.2 meters 50 feet in length, until a technique is developed that produces the desired results. No additional compensation will be made for the additional test sections.

At the conclusion of the test blast program, produce a Post-Test Blast Evaluation Report which examines all reports, surveys, test data, and other pertinent information and conclusions reached. Submit a Test Blast Evaluation Report prepared by the Blasting Consultant and Blasting Specialist after testing blasting is completed.

3.8 BLASTHOLE DRILLING

Survey the elevation at the collar of each production hole in the final
blast to foundation grade to ensure that the production blastholes are not
subdrilled below final foundation grade, except as permitted in paragraph
SUBDRILLING. The survey must be included in the Individual Shot Plan and
must not be changed without prior approval from the Contracting Officer.

Drill production blastholes according to the patterns in the approved
Individual Shot Plan. Prior to commencement of drilling of any production
blasthole, all holes must be located by survey and clearly marked and
numbered. Drill the production blastholes within two blasthole diameters
of the marked collar location. The blastholes must have no more than a
plus or minus [_____] meter foot horizontal tolerance at the bottom. If
holes are drilled outside of these tolerances, except for geologic reasons,
fill these holes with crushed stone or neat grout and re-drill them at the
approved location as directed by the Contracting Officer at no additional
expense to the Government.

After drilling of blast holes, place approved, reusable plastic blasthole
markers in each hole to identify all blasthole locations and keep material
from falling into the holes. Check, measure and record the depth of all
blastholes as soon as the drill is retracted from the blasthole. If any
blasthole has become plugged or is unable to be fully loaded, re-drill or
clean out those holes with air prior to commencement of loading
operations. Check and measure the depth of all blastholes in a shot to
ensure each blasthole is open to the original drilled depth prior to
loading of any holes. If any blasthole is found not be open to the drilled
depth, re-drill the shot holes to the proper depth at the Contractor's
expense. If any holes are too deep, fill the holes to the proper depth
with crushed stone. Blasthole loading and drilling may be ongoing
concurrently in a shot area; nonetheless, drilling must be separated from
loaded holes by a distance equivalent to at least the depth of the loaded
hole but in no case less than 15.2 meters 50 feet.

The Contracting Officer may require inclined boreholes to reduce toe
burdens and backbreak.

3.9 PRODUCTION BLASTING

The Contractor must provide a detailed narrative for the proposed sequence
of production blasting for the project in the Master Blasting Plan, to be
evaluated and approved by the Contracting Officer. The proposed sequence
must be tailored primarily towards conducting a safe blasting operation and
overall responsible, prudent, and professional blast design in efforts to
keep overbreak, flyrock, vibration and airblast levels to a minimum. If in
the opinion of the Contracting Officer satisfactory results in the
production blasts are not being produced, the Contracting Officer reserves
the right to require changes in the blast design which could include
variables such as burden, spacing, bench height, timing sequence and
delays, subdrill depths, explosive loads, detonators, blast matting and the
use of air decks or stemming in borehole bottoms. Such required revisions
will be at no additional cost to the Government.

**************************************************************************
NOTE: The proposed language below can be used as
guidance when both presplit and production blasting
are used in the project. THE PRODUCTION BLASTING
SECTION WILL BE HEAVILY TAILORED FOR THE PROJECT.
THIS IS GENERAL TEXT THAT CAN BE ADJUSTED.

The drilling of presplit and production blastholes
must be done one pattern at a time. Advanced
drilling of adjacent presplit or production blastholes will not be permitted. The presplit wall conditions must be evaluated after each blast by both the Contractor and the Contracting Officer before the adjacent presplit blasting plan can be approved or drilled whenever possible.

The sequence of Production and Presplit blasting for any single blast must be as follows:

1. Submit an individual shot plan.
2. Individual shot plan approved or revisions requested before approval.
3. Conduct drilling and submit Drilling Logs to Contracting Officer and Blaster in Charge.
5. Conduct rock removal, scaling and rock reinforcement Joint Evaluation of results by Contractor and Contracting Officer.
6. Submit an Individual Shot Plan for the subsequent blast in that work area.
7. Prepare a sufficient number of planned blasting areas in advance to maintain the project schedule.

The presplit wall conditions must be evaluated by the Contractor and the Contracting Officer after the Contractor exposes a minimum of 2.4 meters 8 feet (vertical) of the wall. If 2.4 meters 8 feet of exposure is not sufficient to determine the condition of the presplit wall, reinforce the exposed wall as necessary, then expose a minimum additional 2.4 meters 8 feet (vertical) of wall. Repeat this downward to the toe of the presplit wall or until the Contracting Officer can determine if the presplit wall condition is adequate before approving the Individual Shot Plan for the adjacent presplit blast. Evaluate the effects of each production blast on the presplit and line drilled walls before submitting a blasting plan for the next blast.

The drilling tolerance must be evaluated and if drill tolerance exceeded the allowable tolerance then benches will be reduced in height to where the drilling tolerance was obtained on the subsequent blasts.

3.9.1 General Blasting Considerations and Limitations

In order to help control the effects of vibration, flyrock and airblast, maintain a burden distance that is not more than one-half the bench height and the burden must be between 25 to 35 times the diameter of the explosive charges in the blastholes. Deck loading must be placed across joints and seams that may direct energy and gases into the final walls. "Mud capping" for secondary blasting or blasting to reduce oversize rock fragments of blocks is prohibited.
NOTE: The language below is suggested example for projects requiring presplit as a controlled blasting method for a new spillway. Consult with USACE Blast Consultant or Blasting SME during design phase for suggested blasting considerations and limitations tailored to the project.

Production blasts must advance from the center of the spillway cut toward the left and right final cut slopes. The final shot for the left and right cut slopes must be a buffer shot. Blasting may be conducted on the upstream and downstream ends of the spillway at the same time.

Perform all production blasting, including that carried out in conjunction with the test blast section requirements, in accordance with the following general requirements.

Drill Production blastholes according to the patterns in the approved Individual Shot Plan. Bulk blasting agents will be permitted in specified locations. The use of cartridged explosives is required at locations described in paragraph 2.1.2 Blasting Products.

Set a buffer zone where the row of production blast holes in the row that is immediately adjacent to the presplit line are drilled on a plane approximately parallel to the plane of the presplit line. Drill the line of 3-inch diameter buffer holes no closer than one meter three feet to the design excavation line and with a hole spacing no closer than one meter three feet. The explosive loads in buffer holes must not exceed 50 percent of the full explosive load that is placed in a 3-inch production blastholes.

Detonation of the buffer holes must be on a delay sequence towards a free face and fired in sequence after the adjacent production blastholes. Detonation of production holes must be on a delay sequence toward a free face. The delay between adjacent rows parallel to the final face must be sufficiently long to minimize blast damage to the final face. Other than for sinking cuts, all blasts within 15.2 meters 50 feet of the final walls must be designed such that the open face is parallel to the excavation walls to reduce excessive pressure on the presplit final walls.

The true burden of blasts along the final walls, must be designed to be perpendicular to the final walls.

Take all necessary precautions in the production blasting so as to prevent blast damage to the
presplit or line drill face. If presplit results are not satisfactory and production or buffer blasts damage the presplit or line drill face (as evidenced by back-break or opening of joints beyond the presplit line, uplifted rock blocks at the presplit line or damage to the perimeter as determined by the Contracting Officer or Blasting Consultant), the Contractor may be directed to add another line of buffer holes on a parallel plane adjacent to the presplit holes for some or all of the successive buffer zone blasts.

Lift Height and Explosive Cartridge Diameter:
Follow this specification for explosive diameter as a function of bench height. This may require the use of mixed drilling for maximum production efficiency. Tamping of explosive cartridges or cartridge compression will not be allowed.

Lifts up to 10 Feet Deep: Production blastholes that are designed for lifts or hole depths of 10 feet or less must be loaded with explosive cartridges no larger than 1.25-inches in diameter. The final lift above the design excavation line must be 10 feet high and use these small diameter charges at the Labyrinth Weir and within 200 feet of the Labyrinth Weir. Short blastholes along final cut slopes of 0.25H:1.0V or shallower must also use 1.25-inch diameter explosives. Tamping of explosive cartridges or cartridge compression will not be allowed.

Lifts from 10 to 15 Feet Deep: Load production blastholes designed for lifts of 10 to 15 feet deep with explosive cartridges no larger than 2-inches in diameter. Tamping of explosive cartridges or cartridge compression will not be allowed.

Lifts Greater Than 15 Feet Deep or within 50 Feet of Final Walls: Load production blastholes that are designed for lifts of 15 or more feet deep or within 50 feet of final walls with explosive cartridges no larger than 2.5-inches in diameter. Tamping of explosive cartridges or cartridge compression will not be allowed.

Lifts Between 20 and 35 Feet Deep and Greater than 50 Feet from Final Walls or Farther than 200 Feet from the Labyrinth Weir: Bulk explosives may be used in the area 200 feet beyond the Labyrinth Weir, and 50 feet beyond the final excavation walls. The blastholes may be up to 3.5 inches in diameter and bulk loaded with bulk blasting agents.

In the area less than 200 feet from the Labyrinth Weir, and/or less than 50 feet from the excavation walls, tamping of explosive cartridges or cartridge compression will not be allowed.
When blasthole alignment restrictions can be met and geological conditions permit, the lift depth may be increased to a maximum of 35 feet at the option of the Contracting Officer.

3.10  PRESPLIT BLASTING

NOTE: Delete paragraph if presplit blasting is NOT to be used in the project.

Perform all presplit blasting, including presplit test blasts, in accordance with the following requirements:

Unless otherwise permitted by the Contracting Officer, completely remove all loose and decomposed rock along the top of the excavation floor for a distance of at least 9 meters 30 feet beyond the end of the production hole drilling limits or to the edge of the excavation cut slope to reduce the possibility of flyrock before drilling any presplit blastholes.

The presplit blastholes must be 7.6 centimeters 3 inches in diameter.

NOTE: Use the suggested paragraph when requiring precision presplitting methods.

Use the precision presplitting methods defined in paragraph Precision Presplitting, for all presplit blasting on this project. Presplit blasthole spacing must be 61 centimeters 24 inches on centers.

The Contracting Officer reserves the right to determine whether blasting results are satisfactory after evaluating the final rock slopes. Successful demonstration of presplit blasting including blasthole spacing and the ability to meet allowable tolerances must be completed using test blasts during the beginning of blasting operations and when there is a change in rock materials character and bench elevations as outlined in the blasting test section of the specifications.

Use proper equipment and techniques to control drilling operations and ensure that no hole deviates from the plane of the planned final face by more than 6 inches normal to the slope or 15.2 centimeters 6 inches from its planned position along the slope. Presplit blastholes deviating more than these limits will not be paid for unless, if in the Contracting Officer's opinion, satisfactory rock slopes are being obtained.

Drill presplit blastholes along a line that is within 7.6 centimeters 3 inches of the design excavation line. If the presplit holes are outside of the tolerance given in Subpart c, fill the holes with crushed stone or neat grout and re-drill at the correct location. Use electro-mechanical or electronic devices installed on all equipment for drilling the presplit holes to accurately measure the angle at which the drill steel enters the rock. Presplit blasthole drilling will not be permitted if these devices are not being used. The drill rig used must have the ability to change feed, impact, and rotation pressures on demand to adjust for the varying rock conditions and maintain presplit hole alignment. If problems
maintaining the blast hole tolerances persist, use an approved device, to
determine blasthole orientation before the holes are loaded.

******************************************************************************
NOTE: Use this subpart if specific areas need more
alignment control.
******************************************************************************

Measure the blasthole orientation of all presplit blastholes drilled at the [location(s) where this method is needed] using an approved device to check borehole alignment.

The row of presplit holes must extend 9 meters 30 feet beyond the limits of the production blast.

Measure and record the blasthole depth on the drilling log after drilling is completed. Place protection over each blasthole before moving the drill to the next blasthole location. The Blaster in Charge must also measure the blasthole depth to determine that it is free of obstructions for its entire depth before loading the blasthole. The Blasting Specialist must record the depths on the Individual Shot Report. Exercise all necessary precautions so that placing the charges does not cause caving of material from the walls of the holes. Blasthole conditions may vary from dry to partially to filled with groundwater. The depth of water in each blasthole must be recorded in the Individual Shot Report. The maximum diameter of explosives used in presplit holes must not be greater than one-half the diameter of the presplit hole. Perform presplitting before the production blast.

Line drilling along final walls may be required at corners where presplit lines meet.

Blastholes exceeding the allowable tolerances for location and alignment must be refilled with crushed stone or lean grout (at the option of the Contracting Officer) and re-drilled at the proper location and alignment.

Use only standard cartridge explosives manufactured specifically for presplitting or detonating cord in presplit holes. Do not use continuous columns of presplit explosives in the presplit holes. Use lighter loads composed of fractional cartridges affixed to detonating cord with inert spacers between charges or detonating cord in the blastholes. Firmly affix the cartridges to the detonating cord in such a manner that the cartridges will not slip down the detonating cord nor bridge across the hole.

******************************************************************************
NOTE: Add this sentence if using precision presplitting.
******************************************************************************

Use "Precision Presplitting" methods as defined in paragraph DEFINITIONS.

Spacing between the fractional cartridges along the detonating cord must not exceed 91.4 centimeters 36 inches center to center and must be adjusted to give the desired results. Fractional sticks of presplit explosive must be assembled and affixed to the detonating cord in accordance with the explosive manufacturer's instructions, a copy of which must be furnished to the Contracting Officer. The "air deck" method of presplitting is not allowed. The bottom charge of a presplit hole may be larger than the line charges but must not be greater than one pound or so large as to cause
overbreak or damage to the toe of the slope. Place the column charge of the presplit hole far enough below the collar, and reduce the upper charge(s) sufficiently to avoid overbreak and heaving of rock at the collar of the hole.

Place stemming in the upper portion of all presplit blastholes, extending from the uppermost charge to the hole collar. Stemming material must not extend more than 76.2 centimeters 30 inches below the collar of the hole. If test blasts produce unsatisfactory results adjustments must be made. Stemming material for presplit blastholes must consist of dry sand or drill cuttings supported by a stemming plug. Cover the presplit blasts as well as an adjoining production blast with blasting mats, if required to prevent flyrock.

If required to reduce ground vibrations or noise, presplit holes may be delayed, providing the hole-to-hole delay is no more than 25 milliseconds.

The presplit face must not deviate more than 15.2 centimeters 6 inches either side of a plane passing through adjacent drill holes, except where the character of the rock is such that, as determined by the Contracting Officer, irregularities are unavoidable. The geologic conditions affecting rock character include joints, shears, voids, gouge seams and variable weathering/alteration zones of various thicknesses and orientations. Design the blasts in such a manner to keep explosives gases from entering these planes and zones of weakness. Use of the Daily Drill Logs during explosive loading to identify the depth of weak zones and install stemming decks across them. The stemming decks must be filled with dry, angular, well graded crushed stone with the gradation specified in paragraph STEMMING.

**************************************************************************
NOTE: Typically cushion or trim blasting are not used on Civil Works projects. Exceptions must be decided early in the project design phase.
**************************************************************************

3.11 CUSHION OR TRIM BLASTING

Do not use cushion or trim blasting on this project.

**************************************************************************
NOTE: Note: Use the following paragraph templates if needing for precision Presplitting of specific areas of the excavation or project:

Precision Presplitting of Foundation Excavations at Service Spillway: For presplitting of excavations for concrete wall foundations at the Service Spillway, the Contractor must use a spacing between blastholes not to exceed 18 inches. The explosive load cannot exceed 0.04 pounds per square foot of face created for the column load. The bottom charge in these precision presplit blastholes cannot exceed 0.5 pounds.

Precision Presplitting at Main Dam Right Wall: Explosives must not be permitted for precision presplitting to form final cut slope surfaces at the Main Dam Right Wall. The Contractor must use
UFGS

non-explosive demolition agent to fracture bedrock. Presplit hole spacing must range from eight to 18 inches, center to center. Hole diameter, final hole spacing and grout mixing, and proportions must be in accordance with manufacturer's recommendations for bedrock conditions encountered. The Contractor must take care to assure proper temperature and other environmental considerations meet the manufacturer's recommendations prior to use. Nonexplosive demolition agent must be use in such a manner to shear the web of rock between holes without any damage to the presplit final wall.

**************************************************************************

3.12 LINE DRILLING

Perform all line drilling in accordance with the following requirements:

**************************************************************************

NOTE: Line drilling spacing is typically twice to four times the diameter of the drill hole size, it could be varied depending on the project.

**************************************************************************

a. The line drill holes must be 7.2 centimeters 3 inches in diameter and drilled with a spacing of 15.2 centimeters 6 inches on center.

b. Use proper equipment and techniques to control drilling operations and ensure that no line drill hole must deviate from the plane of the planned slope by more than 7.2 centimeters 3 inches normal to the slope or 7.2 centimeters 3 inches from its planned position along the slope plane. Line drill holes deviating more than these limits will not be paid for unless, in the Contracting Officer's opinion, satisfactory rock slopes are being obtained.

c. Drill line drill holes within [_____] centimeters [_____] inches of the marked collar location. If the line drill holes are outside of the 7.2-centimeters 3-inch tolerance, fill them with crushed stone or lean grout and re-drill at the correct location.

d. Locate line drill hole collars along a line that is within 7.2 centimeters 3 inches of the design excavation line. Line drilling will not be permitted if electro-mechanical or electronic devices are not being used to accurately determine the angle at which the drill steel enters the rock. The drill rig should have the ability to change feed, impact and rotation pressures on demand to meet the varying rock conditions and to maintain hole alignment. If problems maintaining the drill hole tolerance persist, use an approved device to determine blasthole orientation before the holes are loaded.

**************************************************************************

NOTE: Include the following paragraph if need to extend line drilling beyond lengths of cut:

**************************************************************************

Lined drill holes in those areas where located must extend a minimum of 9 meters 30 feet beyond the limits of the production holes to be detonated, or to the end of the cut, as applicable.
3.12.1 Line Drilling Locations

Line drilling must be performed at the following locations:

**************************************************************************
NOTE: Depending on the project geology and structure, it may be appropriate to lengthen the distances line drilling is to be conducted at corners, the bracketed lengths here should be considered a minimum. The orientation of the jointing/fractures/foliation may dictate this length.
**************************************************************************

a. [3][_____] meters [10][_____] feet on either side of outside corners with an angle equal to or less than 120 degrees.

b. [1.5][_____] meters [5][_____] feet on either side of inside corners with an angle equal to or less than 90 degrees.

**************************************************************************
NOTE: Use the following if project is in karst or areas of large cavities.
**************************************************************************

If cavities are encountered during presplit drilling, that section of presplit line must be lined drilled in order to prevent presplit gases from entering the cavity.

3.13 STEMMING

**************************************************************************
NOTE: Depending on the geology of the project site this paragraph should be tailored to the project, for example in places with karst a more detailed procedure should be specified or contractor required to submit a procedure for dealing with larger voids.
**************************************************************************

Variations in rock hardness, structure, and other geological conditions encountered at depth will require the Contractor to stem the blast holes through soft weak areas, shears, open joints, and voids; therefore, close attention will be taken to classify the rock while drilling the blast holes. Where necessary, holes will be stemmed with dry, angular, well-graded crushed stone from .3-cm to 1-cm 1/8-inch to 3/8-inches in diameter without fines. The Blasting Consultant may submit a written, signed request to use drill cuttings for applications such as in presplit blastholes, must be submitted to the Contracting Officer for approval. Wet holes must not be stemmed with drill cuttings. No separate payment is made for stemming.

3.14 SUBDRILLING

**************************************************************************
NOTE: Depending on the project features it may be necessary to further specify where subdrilling is allow and to what depth. Describe depth range of subdrilling in the Master Blasting Plan. There may be places where subdrilling is prohibited or limited as in the case where structures are to be
constructed on the blasted surface and anchored - as subdrilling can complicate and significantly alter planned anchorage.

Subdrilling of blastholes below the design excavation line of the foundation is restricted to limited areas of the excavation. Use precise survey control to attain accurate drill blasthole depths and locations in accordance with the approved Master Blasting Plan. The methods of controlling blasthole depths and locations are subject to approval. Describe in the Master Blasting Plan the depth range of subdrilling planned in areas where it is allowed.

If test blasts on higher benches in the same geologic material as that above foundation grade demonstrate that subdrilling with no explosive placed in the hole below grade (air or water cushion in subdrill) causes no cracking below the grade, a request to use the subdrilling procedure may be submitted for approval.

Backfill any blastholes that are not in compliance with these requirements with crushed stone to the appropriate depth at the Contractor's expense.

3.15 FRAGMENT SIZE DISTRIBUTION AND TOLERANCES

NOTE: This section should be written with direct coordination from the project designer of record, who will provide input on maximum rock size/gradation based on project (embankment fill zones, etc.). Large stones (riprap, armor stone, derrick stone) may be required in the project and the blast must be adequately designed to produce this large stone. Some projects will not need this paragraph. CAUTION: requiring stone gradation may imply that the stone may be conducive to that gradation - which may not be the case.

Produce rock fragmentation from blasts such that [_____] percent of the fragments are [_____] centimeters [_____] inches or less in diameter for placement into the rock crusher and into the rock fill zones of the embankments. Reduce oversize material from blasting to meet the size range specified above. Predictive methods involving photo comparison and image analyses such as Wipfrag or Motion Metrics are encouraged to analyze size distribution of fragmented rock. Any secondary blasts of oversize fragments must be covered with blasting mats, and use a charge diameter no greater than 3 centimeters 1.25 inches.

NOTE: Include tolerance for each proposed structure from the excavation lines. For example, "The tolerance for the perimeter walls is minus 30.5 cm/ft 12 inches/foot from the design excavation line. The tolerance for the invert in the area of the Labyrinth Weir foundation and within 61 meters 200 feet downstream from the Weir is minus 31 centimeters 12 inches from the design excavation line. Elsewhere, the tolerance for the invert is plus or minus 31 centimeters 12 inches from the design excavation line."
3.16 REQUIRED MUCKING

Muck and scale following each shot after firing for inspection of the slopes, bottom of the shot lift, or foundation. Drilling and loading for the next shot must not be allowed before the required mucking of the previous shot. This requirement may be waived temporarily when in the opinion of the Contracting Officer, the Contractor's blasting is satisfactory (i.e. no backbreak, overbreak, vibration cracking, exceedance of vibration or airblast thresholds etc.). Notwithstanding this requirement, the face must fully be dug out after every shot to a distance not less than 6 meters 20 feet prior to drilling and loading the next shot to allow inspection and evaluation of the shot face and allow for adjustments to the blast design for adjacent shots. Required mucking after each shot must be reinstated, when in the opinion of the Contracting Officer blasting is unsatisfactory. Any excavation support deemed necessary by the Contractor or Contracting Officer for the safety of personnel in the excavation will be installed as the excavation proceeds. Blasting of the next lower lift will not be permitted until the slope has been accepted by the Contracting Officer.

3.17 SCALING

NOTE: Typically a level of scaling is required for each project, an excavation spec may have more detail on this, or require bolting or other methods of stabilization before carrying down an excavation with more blasting.

Scale any loose and unstable or unsafe appearing material remaining on the rock slopes after blasting and as the excavation is carried down. Perform scaling immediately after each lift of the rock mass is removed by production blasting. The scaling must be accomplished by methods approved by the Contracting Officer. Drilling of the next lift will not be allowed until a rock slope has been properly scaled and rock reinforcement installed as determined by the Contracting Officer. No separate payment is made for scaling.

NOTE: This guide specification covers the requirements for termiticide treatment measures for subterranean termite control.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1 GENERAL

NOTE: Termite infestation exists throughout the United States and overseas areas with the exception of Alaska. Soil treatment will be specified for all types of construction where termites are likely to establish colonies and make concealed access to wood construction, including wood doors, windows, finish, and trim, or to wood-product, cloth, or cellulose storage in buildings. Soil treatment will also be required for structures constructed of or containing wood-preservative-treated items or containing electronic equipment (e.g., hydraulic digital interfaces, medical equipment) that will be damaged due to nuisance swarms of termites that may occur due to untreated soil. Soil treatment is not
required for power plants, central-heating plants, water or sewer treatment plants, incinerators, pump houses, and structures of similar nature which have neither electronic equipment that could be damaged due to nuisance swarms, wood in their construction nor wood or cellulose items stored within, and which have little chance of conversion to alternative uses.

Modification of this section, including materials, concentrations, or rates of application, which are considered necessary because of climatic conditions, porosity of soil to be treated, type of termite, or heavy infestation of termites, will be as recommended by the cognizant Pest Management Consultant. Modifications will be in accordance with the guidance contained in the installation integrated pest management plan. Army Regulation 210-50, Housing Management, paragraph SPECIAL CONDITIONS, prohibits termiticide treatment through or under concrete slabs where HVAC ducts or vents are within or beneath the slab. Information is also available from state and local agriculture agencies and from the EPA National Pesticide Telephone Network at 1-800-858-7378.

When termites are known to be present on the project site, any crawl space on the ground level needs to be designed for a concrete cover to be placed over the soil after treatment by a termiticide. Because the crawl space remains accessible to people and animals, it requires the concrete cover and signage.

For maximum termite protection, new structures should be designed and constructed using pressure treated lumber EPA registered wood preservatives, especially for foundation members. Untreated lumber in existing structures may be treated with EPA registered wood treatment chemicals which can be applied to untreated wood.

**************************************************************************
1.1 REFERENCES
**************************************************************************

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically
be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

**************************************************************************

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

U.S. DEPARTMENT OF DEFENSE (DOD)

DODI 4150.07 (2019) DOD Pest Management Program

1.2 ADMINISTRATIVE REQUIREMENTS

Coordinate work related to final grades, landscape plantings, foundations, or any other alterations to the finished construction which might alter the condition of treated soils.

1.3 SUBMITTALS

**************************************************************************

NOTE: Review Submittal Description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G". Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.

**************************************************************************

Government approval is required for submittals with a "G" or "S"
classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-01 Preconstruction Submittals
Termiticide Application Plan; G[, [_____]]

SD-03 Product Data
Termiticides

Warranty
Pest Management Report

1.4 QUALITY CONTROL

1.4.1 Regulatory Requirements

**************************************************************************
NOTE: Contact regional pest management consultant
to obtain service specific reporting requirements.
**************************************************************************

Comply with DODI 4150.07 for requirements on Contractor's licensing, certification, and record keeping. Maintain daily records using the Pest Management Report.
Management Maintenance Record, DD Form 1532-1, or a computer generated equivalent, and submit copies of records when requested by the Contracting Officer. These forms may be obtained from the main web site: https://www.esd.whs.mil/Directives/forms/fmo_poc/

1.4.2 Qualifications

For the application of pesticides, use the services of an applicator whose principal business is pest control. The applicator must be commercially certified in the state where the work is to be performed as required by DODI 4150.07. No contractor personnel may work under the supervision of a certified person even where this is permitted practice in those States or host nations in which the DOD property is located. Termiticide applicators must also be certified in the U.S. Environmental Protection Agency (EPA) pesticide applicator category which includes structural pest control. Submit a copy of the pest control business license and pesticide applicator certificates to the Contracting Officer prior to any applications.

1.4.3 Safety Requirements

Formulate, apply, and dispose of termiticides and their containers in accordance with label directions. Draw water for formulating only from sites designated by the Contracting Officer, and fit the filling hose with a backflow preventer meeting local plumbing codes or standards. Maintain an air gap between the filling hose and tank. Perform filling operations under the direct and continuous observation of a contractor's representative to prevent overflow. Secure pesticides and related materials under lock and key when unattended. Ensure that proper protective clothing and equipment are worn and used during all phases of termiticide application. Dispose of used pesticide containers off Government property.

1.5 DELIVERY, STORAGE, AND HANDLING

1.5.1 Delivery

Deliver termiticide material to the site in the original unopened containers bearing legible labels indicating the EPA registration number, manufacturer's registered uses and in new or otherwise good condition as supplied by the manufacturer or formulator.

1.5.2 Inspection

Inspect termiticides upon arrival at the job site for conformity to type and quality in accordance with paragraph TERMITICIDES. Each label must bear evidence of registration under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA), as amended or under appropriate regulations of the host county. Inspect other materials for conformance with specified requirements. Remove unacceptable materials from the job site.

1.5.3 Storage

Storage of pesticides on the installation will not be permitted unless it is written into the contract.

1.5.4 Handling

Handle and mix termiticides in accordance with the manufacturer's label and SDS, preventing contamination by dirt, water, and organic material. Protect
termiticides from weather elements as recommended by the manufacturer's label and SDS. Spill kits must be maintained on pest control vehicles and must be available at the mixing site. Conduct termiticide mixing in an area that has been approved by the Integrated Pest Management Coordinator (IPMC) or Contracting Officer, and with adequate spill containment that can contain at least 110 percent of the volume of the tank.

1.6 SITE CONDITIONS

The following site conditions determine the acceptable time of application.

1.6.1 Soil Moisture

Test soils to be treated immediately before application. Test soil moisture content to a minimum depth of 75 mm 3 inches. The soil moisture must be as recommended by the termiticide manufacturer. Application of the termiticide is not permitted when soil moisture content exceeds manufacturer's recommendations.

1.6.2 Runoff and Wind Drift

Application of termiticide will not be permitted during or immediately following heavy rains, when conditions may allow runoff, when it may create an environmental hazard or when average wind speed exceeds 16 km 10 miles per hour. Termiticide is not permitted to enter water systems, aquifers, or endanger humans or animals.

1.7 WARRANTY

**************************************************************************
For Navy projects, modifications must be approved by the cognizant NAVFAC Applied Biologist.

For Army projects, contact information can be found at https://aec.army.mil/index.php?cID=432
**************************************************************************

Provide a 5 year written warranty against infestations or reinfestations by subterranean termites of the buildings or building additions constructed under this contract. Include in the warranty annual inspections of the buildings or building additions during the warranty period. If live subterranean termite infestation or subterranean termite damage is discovered during the warranty period, and the soil and building conditions have not been altered in the interim:

a. Re-treat the site and perform other treatment as may be necessary for elimination of subterranean termite infestation;

b. Repair damage caused by termite infestation; and

c. Reinspect the building approximately 180 days after the re-treatment.

PART 2 PRODUCTS

2.1 SYSTEM DESCRIPTION

Chemical termite control uses liquid termiticide treatments applied to the soil to form a continuous chemical barrier in the soil around both sides of the foundation. The application can be surface applied or rodded and
trenched. This barrier prevents foraging termites from reaching the foundation and piers. Only the soil adjacent to these foundation elements is treated. For slab construction (including foundations, patios and garages), the entire soil (or gravel) surface is treated before the vapor barrier is installed and the slab poured over it. Soil treatment is coordinated with all building activities from foundation construction through final grading of the soil around the building’s exterior. In order for the treatment to be effective, the final phase of the application must be done after final grading and sometimes after landscaping is completed so that the treated soil is not disturbed.

2.2 MATERIALS

2.2.1 Termiticides

Provide termiticides currently registered by the EPA or host country. Termiticides must be approved by the Contracting Officer and the Pest Management Consultant prior to use. Select non-repellent termiticides (active ingredient: chlorantraniliprole, chlorfenapyr, fipronil, or imidacloprid) for maximum effectiveness and duration after application. Select a termiticide that is suitable for the soil and climatic conditions at the project site and apply at the highest labeled rate. Submit manufacturer's label and Safety Data Sheet (SDS) for termiticides proposed for use.

PART 3 EXECUTION

3.1 PREPARATION

Before termiticide application begins, remove all cellulose containing materials from the site such as wood debris from clearing and grubbing and post construction wood scraps, such as ground stakes, form boards, cardboard paper, and scrap lumber from the site.

3.1.1 Verification

Before work starts, verify that final grades are as indicated and smooth grading has been completed in accordance with Section 31 00 00 EARTHWORK. Finely grade soil and remove particles larger than 25 mm 1 inch. Compact soil particles to eliminate soil movement.

3.1.2 Foundation Exterior

If the exterior perimeter treatment is applied before major construction is completed it will be damaged or removed. The exterior foundation perimeter treatment will have to occur in phases during completion of any pads, porches, aprons, sidewalks, final grading, or landscape plantings adjacent to the building foundation. These treatment areas should be coordinated after all major construction but before any pads, porches, or other items requiring special consideration are poured adjacent to the foundation walls. Submit written verification that final grading, landscape planting, and other items adjacent to the foundation will not disturb treatment of the soil on the exterior sides of foundation walls, grade beams, and similar structures.

3.1.3 Utilities and Vents

Turn off and block HVAC ducts and vents located in the treatment area prior to application to protect people and animals from termiticide.
written verification that the HVAC ducts and vents, water and sewer lines, and plumbing have been turned off or blocked prior to applying termiticide.

3.1.4 Crawl and Plenum Air Spaces

Submit written verification that crawl and plenum air spaces have been located and identified prior to applying termiticide.

3.1.5 Application Plan

Prior to commencing application of termiticide, submit a Termiticide Application Plan addressing the following items:

a. proposed sequence of treatment work including dates and times of application
b. termiticide trade name
c. EPA registration number
d. chemical composition
e. concentration of original and diluted material
f. formulation
g. manufacturer's recommended application rates
h. regional requirements
i. application rate of active ingredients
j. method of application
k. area or volume to be treated
l. amount to be applied
m. copy of the pest control business license
n. copy of the pesticide applicator certificates

3.2 APPLICATION

For areas to be treated, establish complete and unbroken vertical and horizontal soil chemical barriers between the soil and all portions of the intended structure which may allow termite access to wood and wood related products. Make applications to crawl spaces in accordance with label directions. Applications to crawl space areas that are used as plenum air spaces will not be permitted.

3.2.1 Equipment Calibration and Tank Measurement

Submit a list of equipment to be used. Conduct calibration test on the application equipment to be used immediately prior to commencement of termiticide application. Measure the volume and contents of the application tank. Testing must confirm that the application equipment is operating within the manufacturer's specifications and meets the specified requirements. Submit written certification of the equipment calibration.
test results within one week of testing. Where results from the equipment calibration and tank measurements tests are unsatisfactory, re-treatment will be required.

3.2.2 Mixing and Application

Perform all work related to formulating, mixing, and application in the presence of the Contracting Officer, a DOD certified pesticide applicator, Pest Management Quality Assurance Evaluator (QAE)/Performance Assessment Representative (PAR), or IPMC. Applications must be made at the highest rate or concentration allowed by the label. Submit mixing formulation:

a. Quantity of pesticide used.

b. Rate of dispersion.

c. Percent of use.

d. Total amount used.

A closed system is recommended as it prevents the termiticide from coming into contact with the applicator or other persons. Only use water from designated locations. Fit filling hoses with a backflow preventer meeting local plumbing codes or standards. Maintain an air gap between filling hoses and tanks. Prevent overflow during the filling operation. Spill kits must be maintained on pest control vehicles and must be available at the mixing site. Termiticide mixing must be conducted in an area that has been designated by the IPMC or Contracting Officer and that has adequate spill containment. Inspect the application equipment prior to each day of use for leaks, clogging, wear, or damage. Immediately perform repairs on the application equipment to prevent or eliminate leaks and clogging.

3.2.2.1 Application Method

**************************************************************************
NOTE: Termiticide may be applied as a surface spray or by rodding and trenching.
**************************************************************************

[3.2.2.1.1 Surface Application

Use surface applications for establishing horizontal barriers. Apply termiticide as a coarse spray and provide uniform distribution over the soil surface. Termiticide must penetrate a minimum of 25 mm 1 inch into the soil, or as recommended by the manufacturer. If soils are treated to a depth less than specified or approved, repeat work performed to the depth specified at no additional cost to the Government.

][3.2.2.1.2 Rodding and Trenching

Use rodding and trenching for establishing vertical soil barriers. Trenching must be to the depth of the foundation footing. Width of trench must be as recommended by the manufacturer, or as indicated. Rodding or other approved method may be implemented for saturating the base of the trench with termiticide. Backfill the trench immediately after termiticide has reached maximum penetration as recommended by the manufacturer. If maximum penetration is not achieved, as recommended by the manufacturer, repeat work performed to maximum penetration as recommended by the manufacturer at no additional cost to the Government. Backfill in 150 mm 6
inch rises or layers. Treat each rise or layer with termiticide.

3.2.3 Sampling

The Contracting Officer may draw samples for analysis, at any time and without prior notice, from stocks at the job site to determine if the amount of active ingredient specified on the label is being applied. When analysis, performed by the Government, indicates samples contain less than the amount of active ingredient specified on the label, repeat work performed with pesticides conforming to this specification at no additional cost to the Government.

3.2.4 Vapor Barriers and Waterproof Membranes

Apply termiticide prior to placement of a vapor barrier or waterproof membrane.

3.2.5 Placement of Concrete

Place concrete covering treated soils after the termiticide has reached maximum penetration into the soil as recommended by the manufacturer. Cover treated areas with plastic if slab is not to be poured immediately following termiticide application.

3.2.6 Clean Up, Disposal, and Protection

Once application has been completed, proceed with clean up and protection of the site without delay.

3.2.6.1 Clean Up

Clean the site of all material associated with the treatment according to label instructions, and as indicated. Remove and dispose of excess and waste material off Government property.

3.2.6.2 Disposal of Termiticide

Dispose of residual termiticides and containers off Government property, and in accordance with label instructions and EPA criteria.

3.3 FIELD QUALITY CONTROL

3.3.1 Verification of Measurement

Once termiticide application has been completed, measure tank contents to determine the remaining volume. The total volume measurement of used contents for the application must equal the application rate established in the application plan. Submit written verification that the volume of termiticide used meets the application rate established in the application plan.

3.3.2 Inspection

3.3.2.1 Technical Representative

Provide a technical representative who is a DOD certified pesticide applicator, Pest Management QAE/PAR, or IPMC. The technical representative must be present at all meetings concerning treatment measures for subterranean termites and during treatment application. Contact the IPMC
prior to starting work.

3.4 CLOSEOUT ACTIVITIES

Upon completion of this work, submit the Pest Management Report DD Form 1532, or an equivalent computer product, to the IPMC. This form identifies the target pest, type of operation, brand name and manufacturer of pesticide, formulation, concentration or rate of application used.

3.5 PROTECTION

3.5.1 Protection of Treated Area

Immediately after the application, protect the area from other use by erecting barricades as required or directed. Provide signage in accordance with Section 10 14 00.10 EXTERIOR SIGNAGE. Place signage inside the entrances to crawl spaces and identify the space as treated with termicide and not safe for children or animals.

3.5.2 Disturbance of Treated Soils

Re-treat soil and fill material disturbed after treatment before placement of slabs or other covering structures.

3.5 PROTECTION

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for termite control barriers, including both steel mesh and basaltic sand barriers. Project requirements and local conditions will dictate which barrier system is to be used.

This section is tailored for STEEL MESH and BASALTIC SAND termite barrier systems.

Adhere to [UFC 1-300-02](https://www.dtic.mil/urml/) Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a [Criteria Change Request (CCR)](https://www.dtic.mil/urml/).

NOTE: This specification consists of furnishing and installing a complete stainless steel mesh barrier system or graded basaltic barrier sand at all penetrations, joints, and perimeter foundations as a physical barrier below the concrete slabs and foundations of a structure to prevent the entry of Formosan and other ground termites into wood components of the structure, similar to laying down a chemical barrier of soil termiticide treatments.

The use of these materials does not preclude the use
of other preventive measures, such as chemical
treatment and pressure treated lumber for
construction, to provide maximum protection to the
structure. In fact, it is recommended that these
materials be used in conjunction with chemical
treatment at all vulnerable areas, such as
penetration areas around electrical conduits and
plumbing pipes that penetrate the slab, as well as
the foundation perimeter and shoulder portions of
the barrier. These termite barriers must comply
with all codes. It is also recommended that
pressure treated lumber be used to provide maximum
protection to the structure.

**************************************************************************
**************************************************************************

NOTE: For Air Force, termite control barriers are
not recommended by the Air Force Civil Engineer
Center as a cost-effective method of termite
prevention or control for Air Force real property.
Instead use Section 31 31 16.13, CHEMICAL TERMITE
CONTROL.

**************************************************************************
**************************************************************************

NOTE: To download UFGS Forms, Graphics, and Tables,
go to: http://www.wbdg.org/ffc/dod/unified-
facilities-guide-specifications-ufgs/forms-graphics-tables

**************************************************************************
**************************************************************************

PART 1   GENERAL

**************************************************************************

NOTE: Termite infestation exists throughout the
United States and overseas areas with the exception
of Alaska. Steel mesh termite barriers or graded
basaltic sand can be prescribed for installation at
all sites where termites are likely to establish
colonies and make concealed entries to wood
construction, when it is deemed appropriate and cost
effective.

**************************************************************************

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

ASTM INTERNATIONAL (ASTM)

ASTM C128 (2022) Standard Test Method for Density, Relative Density (Specific Gravity), and Absorption of Fine Aggregate

1.2 ADMINISTRATIVE REQUIREMENTS

1.2.1 Pre-Installation Meetings

Convene a pre-installation meeting at least one week prior to beginning installation to review conditions of preparation, storage and handling, installation procedures, sequencing, protection, and coordination with other related work. The project superintendent, installer, installer's crew leader, and representatives of the trades affected by this work are required to attend. Notify the Contracting Officer at least 10 calendar days before the meeting.

1.3 SUBMITTALS

**************************************************************************
NOTE: Review Submittal Description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G". Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item if the submittal is sufficiently important or complex in context of the project.

**************************************************************************
For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.

**************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

1.4 QUALITY CONTROL

1.4.1 Qualifications

1.4.1.1 Steel Mesh Barrier System

a. Only employee system installers trained in the behavior of termites and installation techniques of the mesh barrier, and accredited by the system's manufacturer. Submit certification that system installers meet the requirements specified and for the effective time period of accreditation.

b. Only employ workers trained and accredited at the appropriate level by the system's manufacturer.

1.5 DELIVERY, STORAGE, AND HANDLING

Deliver materials to the site in original, unbroken packaging and containers, with original labels in place, to include any U.S. Environmental Protection Agency (EPA) designation. Store materials in conformance with system manufacturer's recommendations.

Store and handle the material so as to prevent contamination by dirt, water, and organic material.

1.6 SITE CONDITIONS

1.6.1 Environmental Requirements

In addition to the manufacturer's installation instructions and before placing material, ensure project site is free from standing water.

1.7 WARRANTY

**************************************************************************

NOTE: Choose the first sentence for minimum 1-year written warranty for existing building repair or renovation projects. Choose the second sentence for 5-year written warranties on new building or
addition projects.

[Provide a minimum 1-year written warranty against infestations or reinfestation by subterranean termites of existing buildings with barrier installed during repair or renovation.] [Furnish a 5-year written warranty against infestations or reinfestation by subterranean termites of the buildings or building additions constructed under this contract.] Written warranty must be jointly signed by an officer of the Contractor and the supplier. Perform annual inspections of the building[s] or building addition[s]. If live subterranean termite infestation or subterranean termite damage is discovered during the warranty period, and building conditions have not been altered in the interim, take the following actions:

a. Correct defective steel mesh basaltic sand installation and perform other treatment as may be necessary to eliminate subterranean termite infestation.

b. Repair damage caused by termite infestation.

c. Reinspect the building approximately 180 calendar days after the repair.

PART 2 PRODUCTS

NOTE: Check with local agencies to determine the local building code requirements and specifications to ensure conformance where required.

2.1 SYSTEM DESCRIPTION

2.1.1 Steel Mesh System Description

A complete termite control barrier system encompasses a fine steel mesh placed across all termite entry points to the building. Principal entry points include all cracks, joints, penetrations, and other termite entry points within the concrete slabs and cavities in walls. The steel mesh and fastening system physically prevents the termites from entering the building. The mesh is too fine for the termites to pass through, too hard to chew through, and highly corrosion resistant against future break down.

2.1.2 Basaltic Sand System Description

A complete termite control barrier system composed of a graded basaltic sand as a physical barrier below the concrete slab or foundation of a structure to prevent the entry of Formosan ground termites into wood components of the structure, similar to laying down a chemical barrier of soil termiticide. The use of this preventive measure does not preclude the use of other preventive measures such as chemical treatment, steel mesh barrier system, and pressure treated lumber to provide maximum protection to the structure. It is recommended that this material be used in conjunction with chemical treatments of vulnerable areas such as around electrical conduits, plumbing pipes that penetrate the slab, and the shoulder portions of the barrier and with pressure treated lumber to provide maximum protection to the structure.
2.2 MATERIALS

2.2.1 Asbestos Prohibition

No asbestos containing materials or equipment are permitted at the job site. Ensure materials proposed for the project are asbestos free.

2.2.2 Steel Mesh Materials

Provide stainless steel mesh that conform to ASTM A478 and ASTM A580/A580M, Type A1AA marine grade 316 stainless steel mesh of 0.18 mm 0.007 inches diameter wire with mesh openings of 0.66 by 0.465 mm 0.026 by 0.018 inches.

2.2.2.1 Steel Mesh Material Submittals

Submit statements signed by responsible officials of the manufacturer of material attesting that material meets specification requirements. These statements must be dated after award of the project contract and clearly name the project.

Submit samples of steel mesh materials. Provide 102 by 102 mm 4 by 4 inch samples of steel mesh to be used in this work.

2.2.3 Accessories

Provide parging adhesives, bonding cement, high grade stainless steel clamps, ties, and other accessories as recommended by system's manufacturer.

2.2.4 Basaltic Sand

Provide clean, dry sand material manufactured from crushed basalt rock that meets the following requirements.

a. Material gradation, ASTM C136/C136M.

<table>
<thead>
<tr>
<th>Sieve Size</th>
<th>Percent Passing</th>
</tr>
</thead>
<tbody>
<tr>
<td>4.75 mm No. 4</td>

</tr>
</tbody>
</table>

b. Specific gravity, ASTM C128, 2.80.

c. Silica (S102) content, 45 percent.

d. Abrasion loss, after 500 revolutions, 20 percent, when tested in accordance with ASTM C131/C131M.

PART 3 EXECUTION

**************************************************************************************************************************
NOTE: Provide stainless steel mesh graded basaltic
sand in a manner to provide maximum protection to the dwelling. The material provides a physical barrier against termites, thus, preventing entry. A range of techniques and material widths may be required to meet site conditions. The designer is required to determine the extent of openings to be covered to provide quantity estimates for the material installed.

**************************************************************************

NOTE: The stainless steel mesh must be installed in a manner to provide maximum protection to the dwelling. The material provides a physical barrier to the termites, thus, preventing entry. A range of techniques and material widths may be required to meet site conditions. The designer is required to determine the extent of openings to be covered to provide quantity estimates for the material installed.

**************************************************************************

3.1 EXAMINATION

Examine the substrates and conditions under which work of this section will be performed. Coordinate with this specification all work related to final grades, landscape plantings, foundations, or any other alternations to finished construction that might alter the condition of the site. Do not proceed until any unsatisfactory conditions detrimental to timely and proper completion of the work have been corrected. Submit written verification that site conditions are as required and other site work will not disturb the installation.

3.2 PREPARATION

In addition to the manufacturer's requirements and before placing material, remove any visible plant roots, construction wood scraps such as ground stakes, form boards, scrap lumber, and standing water from the excavated area. Inspect the utility trenches to ensure they are sufficiently wide to permit adequate cover under, around, and over pipes and conduit that will be encapsulated with the basaltic sand materials. In addition, inspect the foundation perimeter to ensure there is sufficient room between the sides of the excavations and the edges of the foundations to provide the required barrier depth and width.

Provide finished or temporary site grading to remove standing water from the project site (i.e., excavated areas or adjacent areas). Grading must provide positive drainage towards temporary, new or existing drainage features. Grading must not result in low spots that hold water or direct water towards new or existing facilities.

3.2.1 Surface Preparation

Perform work related to final grades, landscape plantings, foundations, or any other operations that might alter the condition of the site, in accordance with this specification. Before installing the steel mesh, ensure that the following have been completed:

a. Eliminate termite food sources by removing wood debris, such as ground
stakes, form boards, scrap lumber, and any cellulose containing material from the work area.

b. The work area has been filled with finely graded soil consisting of particle sizes no larger than 25 mm 1 inch and compacted to eliminate soil movement. Ensure the site conditions meet the manufacturer's recommendations for installing the steel mesh.

c. Footings, foundations, and outer forms are in place.

d. Penetrating pipes for communications, electrical, and plumbing are in place.

e. Submit site conditions certificate documenting that the site conditions are acceptable for the steel mesh barrier system.

3.3 INSTALLATION

Install a basaltic sand system in accordance with the manufacturer's installation instructions.

Submit basaltic sand shop drawings of the basaltic sand installation at all interior and perimeter foundations, joints, and penetration conditions to the Contracting Officer for approval before installation.

3.3.1 Steel Mesh Instructions

Strictly follow the manufacturer's instructions published in Manufacturer's Installation Instruction Manual. In addition to the system manufacturer's instructions, place the stainless steel mesh across all openings, joints, penetrations, and other termite entry points to the building (including all shrinkage cracks in concrete slabs and built penetrations in slabs and walls that termites may use for access points) and in accordance with manufacturer's recommendations. Clamp, parge adhere, bond, or embed the steel mesh to the material surrounding the opening in accordance with the manufacturer's recommendations. Install with no gaps, penetrations, or damage to the mesh system. Submit steel mesh shop drawings of the termite steel mesh installation at all perimeter foundations, joints, and penetration conditions to the Contracting Officer for approval before installation.

To avoid an electrolytic reaction, do not place dissimilar metals in contact with the steel mesh.

3.3.1.1 Installation Sequence

a. Install the steel mesh barrier in accordance with the manufacturer's recommendations. Fit and clamp the mesh around all pipe penetrations, and terminate the mesh at the perimeters, as appropriate for the building construction and as described in the manufacturer's installation manual. Lap joint the mesh 10 to 15 mm 0.39 to 0.59 inches and the joint may be strengthened by using bonding cement for a minimum distance of 500 mm 20 inches along the joint.

b. Install special fittings that are appropriate to the construction, as described in manufacturer's installation manual.

c. Following installation of mesh and vapor barrier, install reinforcing steel and concrete, as specified under other sections. Seal
penetrations and shrinkage cracks through concrete slabs in accordance with manufacturer's recommendations.

d. To maintain resistance to termites, complete the system and do not disturb, penetrate, or damage during the remaining contract time period.

3.3.1.2 Steel Mesh Integration

Where required, integrate mesh into subsequent construction, as described in manufacturer's installation manual.

3.3.2 Placement

Place the basaltic sand barrier under slabs, in utility trenches, along edges of concrete pavement, in concrete masonry unit (CMU) cells, along retaining walls, and other areas that termites may use for access points and in accordance with manufacturer's recommendations.

Place material in one lift for thicknesses of 150 mm 6 inches or less and in successive lifts of 100 to 150 mm 4 to 6 inches where the indicated thickness is greater than 150 mm 6 inches. Compact each lift prior to placing successive lifts. Use power driven, vibrating-plate type tampers for large areas and rod-and-plate type hand tampers for small areas such as utility trenches and foundation and walk edges.

3.3.2.1 Slab on Grade

**************************************************************************
NOTE: Show the required depths on the drawings.
100 mm Four inches depth is the minimum required.
For areas where capillary action is a problem, consult a soils engineer if the depth should be increased or other capillary prevention measures are required.
**************************************************************************

Provide a barrier of the depth indicated. Rake smooth and machine tamp, making at least three passes over the entire area. Hand tamp around pipe and conduit risers.

3.3.2.1.1 Utility Trenches

Place the required depth of material for bedding in the trenches prior to placing pipes and conduits and hand tamp the material. For pipes 75 mm 3 inches and larger in diameter: after placing the pipe, bring material up to the top of the pipe and carefully hand tamp the material. Then, bring the material up to the top of the trench and tamp. For pipes smaller than 75 mm 3 inches in diameter and for conduit: bring material up to the top of the trench and tamp.

3.3.2.1.2 Edges

After concrete is placed and the form is removed, remove any dirt, loose concrete, and other debris and hand place and tamp additional material to the existing grade.

3.3.2.2 CMU Block Walls

Place the material in non-grouted cells at a height of at least one course.
above grade of the wall.

3.3.2.3 Fence Posts and Utility Poles

Line the designated hole with a geotextile or similar material before proceeding with the work.

Once the geotextile is in place, put a 100 to 150 mm 4 to 6 inch layer of the basaltic sand at the bottom of the hole. Hand tamp the material. After positioning the fence post or utility pole in the middle of the hole, fill around the sides, compacting the material after successive lifts of 150 to 300 mm 6 to 12 inches until the hole is completely filled. Ensure that a 100 to 150 mm 4 to 6 inch basaltic sand barrier exists around the perimeter of the post or pole.

3.3.2.4 Retaining Walls

Place the required amount of material below the footing and up to the grade level of the wall. Place lifts of 100 to 150 mm 4 to 6 inches with compaction of each lift prior to placing successive lifts.

3.4 FIELD QUALITY CONTROL

3.4.1 Inspection

Provide Manufacturer's Guidance for performing a visual inspection of the installed mesh to ensure the steel mesh provides the designed termite physical barrier.

3.4.2 Manufacturer Field Services

Before installing the steel mesh, verify that final grades are as indicated and smooth grading has been completed. Provide written verification that the site conditions under the proposed slabs are proper for the installation of the termite barrier system in accordance with the manufacturer's recommendations.

3.5 PROTECTION

Protect the installed steel mesh system, attachments, and accessories before, during, and after the work of all trades, as required by the system manufacturer or as directed by the Contracting Officer.

In the event that subsequent trades on the site move or damage the mesh, clamps, or parging mix, immediately contact the mesh installer for a recommendation of the necessary repairs.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1 GENERAL

1.1 MEASUREMENT AND PAYMENT

NOTE: Delete this paragraph when lump sum bidding is used.

Measure the total surface area in square meters covered by geosynthetic drainage layer. Base final quantities on as-built conditions. Allowance will be made for geosynthetic drainage layer in anchor and/or drainage trenches but no allowance will be made for waste, overlap, or materials used for the convenience of the Contractor. Geosynthetic drainage layer accepted by the Contracting Officer will be paid for at the respective contract unit price in the bidding schedule.
1.2 REFERENCES

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

ASTM INTERNATIONAL (ASTM)

ASTM D1603 (2020) Carbon Black Content in Olefin Plastics

ASTM D4218 (2020) Determination of Carbon Black Content in Polyethylene Compounds by the Muffle-Furnace Technique

ASTM D4355/D4355M (2014) Deterioration of Geotextiles from Exposure to Light, Moisture and Heat in a Xenon-Arc Type Apparatus

ASTM D4632/D4632M (2015a) Grab Breaking Load and Elongation of Geotextiles

ASTM D4716/D4716M (2008; R 2013) Determining the (In-Plane) Flow Rate Per Unit Width and Hydraulic Transmissivity of a Geosynthetic Using a Constant Head

Geotextile

1.3 SUBMITTALS

**************************************************************************

NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.

**************************************************************************

Government approval is required for submittals with a "G" or "S"
classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-03 Product Data
   Sampling and Testing
   Penetrations
   Construction Quality Control (QC) Laboratory

SD-04 Samples
   Geosynthetic Drainage Layer
   Seams and Overlaps

SD-06 Test Reports
   Sampling and Testing
   Geosynthetic Drainage Layer

1.4 QUALITY ASSURANCE

Provide a construction quality control (QC) laboratory that has also performed quality assurance (QA) testing, if required, of geosynthetic drainage layers for at least five completed projects, having a total minimum area of \([186,000] \text{ square meters} = 2 \text{ million square feet}\). Submit qualifications of laboratory carrying current accreditation via the Geosynthetic Accreditation Institute's Laboratory Accreditation Program (GAI-LAP) for the tests it will be required to perform.

1.5 DELIVERY, STORAGE, AND HANDLING

The QC inspector must be present during delivery and unloading of the geosynthetic drainage layer. Ensure the drainage layer material has not been damaged during shipping, storage, or handling. Repair or replace any drainage layer material found to be damaged. Accept delivery of material only after the required submittals have been approved. Label each roll with the manufacturer's name, product identification, lot number, roll number, and roll dimensions. Wrap rolls that have attached geotextiles individually in plastic. Store the rolls in a level and dry area.

PART 2 PRODUCTS

2.1 GEOSYNTHETIC DRAINAGE LAYER

******************************************************************************
NOTE: The flow capacity required for the geosynthetic drainage layer should be determined using a procedure such as the one described in GRI Report Number 19 - The Design of Drainage Systems Over Geosynthetically Lined Slopes. Appropriate global safety factors and reduction factors should be applied to transmissivity values reported by
manufacturers. A global factor of safety of 2 is typically used. Guidance on reduction factors for intrusion, creep, chemical clogging, and biological clogging are provided in Designing with Geosynthetics by Dr. Robert Koerner and GRI Standard-GC8 Determination of the Allowable Flow Rate of a Drainage Geocomposite.

If high long term normal stresses are anticipated (e.g. 192 kPa 4000 psf or greater), requirements for maximum allowable creep strain should be included in Table 1. Creep strain requirements for geosynthetic drainage layers are determined using test method GRI GS 4 - Time Dependent (Creep) Deformation Under Normal Pressure. Typically, a normal stress of 2 to 3 times the design stress for a period of at least 10,000 hours is used for creep strain testing.

Delete paragraphs and sentences which describe geotextile material and construction requirements if geotextiles will not be attached to the geonet.

**************************************************************************

Use polyethylene polymer, which is clean and free of any foreign contaminants, to manufacture the geonet component of the geosynthetic drainage layer. Submit one properly identified 610 by 610 mm 24 by 24 inch minimum size geosynthetic drainage layer sample; fasteners proposed for use; and the method of seaming and overlapping. Submit manufacturer's quality control test results. Use regrind material which consists of edge trimmings and other scraps to manufacture the geonet; however, do not use post-consumer recycled materials. Conform the geosynthetic drainage layer to the property requirements listed in Table 1. Component criteria for the geonet alone and geotextile alone are also listed in Table 1. Cover the geonet on [one] [both] sides with nonwoven geotextile. Create geocomposite by heat bonding geotextile to the geonet. Do not bond the geotextile to the drainage net within 150 mm 6 inches of the edges of the rolls. Where applicable, Table 1 property values represent minimum average roll values (MARV). The value for AOS represents the maximum average roll value (MaxARV).

**Notes:**

1. The diameter of the presser foot must be 56 mm 2.22 inches and the pressure must be 20 kPa 2.9 psi. For other thickness options, see manufacturer's literature.

2. This is the average peak value for five equally spaced machine direction tests across the roll width.

3. Manufacturer's historical data.

4. Measure manufacturing quality control transmissivity tests using a gradient of [0.1] [_____] under a normal pressure of [10] [100] [_____] kPa [1.45] [14.5] [_____] psi. Use a minimum seating period of 15 minutes. Perform the test between rigid end platens.

5. Average of five tests across the roll width. Discounting the outer 305 mm 1 foot of each side of the roll, collect samples at the 10, 30, 50, 70, and 90 percent positions across the roll width. Test both sides for double sided geocomposites.

### 2.2 SAMPLING AND TESTING

#### 2.2.1 Manufacturing Quality Control Testing

Provide manufacturing quality control test methods and frequencies in accordance with Table 1 unless otherwise approved. Submit manufacturer's quality control manual and construction quality control test results.
2.2.2 Construction Quality Control Testing

NOTE: One or more additional performance type transmissivity tests are often required to be performed by the Contractor's quality control laboratory. These tests should be performed at gradients and normal stresses that model site conditions. The type of material in contact with the geosynthetic drainage layer affects the flow properties of the drainage layer. Performance tests should use site specific soils and geosynthetics when such materials are known.

Typically, normal loads for CQC transmissivity tests are seated on the geosynthetic drainage layer for 100 hours prior to testing to account for long-term intrusion and creep. A reduction factor for intrusion should be used if a seating period of less than 100 hours is used.

The transmissivity requirement for the construction quality control transmissivity tests will generally be lower than the value shown in Table 1 for the manufacturing quality control tests.

Perform a minimum of one construction quality control transmissivity test in accordance with the requirements of this paragraph. Measure transmissivity using a gradient of [_____] under a normal pressure of [_____] kPa psf. Attach geotextile to the geonet in the same configuration as will be used in the field. Sandwich the drainage layer between [_____] on the bottom and [_____] on the top. Use a minimum seating period of [100][_____] hours. Achieve a minimum transmissivity of [_____].

PART 3 EXECUTION

3.1 INSTALLATION

3.1.1 Surface Preparation

Prior to placement of the geosynthetic drainage layer, provide a subgrade that is smooth and free of all materials which could damage the drainage layer.

3.1.2 Placement

Do not damage the geosynthetic drainage layer during placement. Unroll the drainage layer in the direction of maximum slope, keeping the net flat against the subgrade to minimize wrinkles and folds. Do not drag the drainage layer across textured geomembrane if a geotextile is attached to the surface facing the geomembrane. Place adequate ballast (e.g. sandbags) to prevent uplift by wind prior to covering.
3.1.3 Seams and Overlaps

3.1.3.1 Geonet Side Seams

Overlap geonet side seams a minimum of 100 mm 4 inches. Space side seam fasteners a maximum of 1.5 m 5 feet. In anchor trenches, space fasteners a maximum of 305 mm 1 foot.

3.1.3.2 Geonet End Seams

NOTE: Flow capacity of the geosynthetic drainage layer must be adequate to ensure all flow remains in the drainage layer and head does not build up in the cover soils above the drainage layer. For this reason, consideration must be given to flow capacity of end seams on slopes. If end seam flow capacity is a concern, end seams can be prohibited on side slopes or they can be configured such that water can flow from one geonet to another without passing through any geotextile layers.

Overlap geonet end seams a minimum of 305 mm 1 foot. Space end seam fasteners spacing a maximum of 305 mm 1 foot. Make overlaps in the direction of flow.

3.1.3.3 Geonet Fasteners

Tie geonet rolls together with plastic fasteners. Use fasteners that are a contrasting color from the geonet and attached geotextiles. Metallic fasteners will not be allowed.

3.1.3.4 Geotextile Seams

The geotextile component of the geocomposite must be [overlapped in the direction of flow] [thermally bonded using approved methods] [sewn using approved methods].

3.1.3.5 Geotextile Cap Strips

Place geotextile cap strips over any exposed edges of geocomposite. Provide cap strips that are a minimum of 610 mm 2 feet in width and thermally bond to the geotextile component of the geocomposite.

3.1.4 Stacked Geosynthetic Drainage Layers

When geosynthetic drainage layers are to be stacked, stagger roll ends and edges so that joints do not lie above one another.

3.1.5 Corners

In the corners of landfill liner side slopes, install an extra layer of drainage layer material from the top to the bottom of the slope.

3.1.6 Penetrations

Submit penetration details. Mechanically attach a geotextile apron to pipes and other appurtenances penetrating through the drainage layer so
that soil is prevented from getting into the drainage layer. Extend the
apron of the attached geotextile out from the pipe or appurtenance a
minimum of 610 mm 2 feet. Thermally bond the apron geotextile to the
geotextile [component of the geocomposite.][overlying the geonet.]

3.2 REPAIRS

3.2.1 Geonet Damage

Make repairs by placing a patch of the geosynthetic drainage layer over the
damaged area. Extend the patch a minimum of 610 mm 2 feet beyond the edge
of the damage. Use approved fasteners, spaced every 150 mm 6 inches around
the patch, to hold the patch in place. If more than 25 percent of the roll
width is damaged, approval must be obtained to repair or replace the
damaged roll.

3.2.2 Geotextile Damage

Repair damaged geotextile by placing a patch of geotextile over the damaged
area with a minimum of 305 mm 12 inches of overlap in all directions.
Thermally bond the geotextile patch in place.

3.3 PROTECTION AND BACKFILLING

Cover the geosynthetic drainage layer with the specified materials within
[14] [_____] days of acceptance. Place cover soil from the bottom of the
slope upward and do not drop directly onto the drainage layer from a height
greater than 915 mm 3 feet. Push the cover soil out over the geosynthetic
drainage layer in an upward tumbling motion so that wrinkles in the
drainage layer do not fold over. Do not operate equipment on the top
surface of the geosynthetic drainage layer without permission from the
Contracting Officer. Provide an initial loose soil lift thickness of 305 mm
12 inches. Use equipment with ground pressures no greater than 50 kPa 7
psi to place the first lift of soil. Maintain a minimum of [460] [610]
[915] [_____] mm [18] [24] [36] [_____] inches of soil between construction
equipment with a ground pressure greater than 50 kPa 7 psi and the drainage
layer. Cover soil compaction and testing requirements are described in
Section 31 00 00 EARTHWORK.

NOTE: This guide specification covers requirements for geotextiles.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1   GENERAL

NOTE: The "Geotextile Engineering Manual" by the Federal Highway Administration and "Designing with Geosynthetics" by Robert M. Koerner provide information on design criteria and example calculations used for the design of geotextiles.

1.1 MEASUREMENT

NOTE: Delete paragraphs MEASUREMENT and PAYMENT when lump sum bidding is used.

Measure the as-built surface area, covered by geotextile, in square meters.
yards. Allowance will be made for geotextile in anchor and/or drainage trenches but no allowance will be made for waste, overlaps, damaged materials, repairs, or materials used for the convenience of the Contractor.

1.2 PAYMENT

Geotextile installed and accepted will be paid for at the respective contract unit price in the bidding schedule. This unit price will include the cost of materials, equipment, installation, testing, and other costs associated with placement of the geotextile.

1.3 REFERENCES

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

ASTM INTERNATIONAL (ASTM)

ASTM D4354 (2012; R 2020) Sampling of Geosynthetics for Testing

ASTM D4355/D4355M (2014) Deterioration of Geotextiles from Exposure to Light, Moisture and Heat in a Xenon-Arc Type Apparatus

ASTM D4632/D4632M (2015a) Grab Breaking Load and Elongation of Geotextiles

1.4 SUBMITTALS

**************************************************************************
NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.

**************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:
1.5 DELIVERY, STORAGE, AND HANDLING

Deliver, store, and handle geotextile in accordance with ASTM D4873/D4873M.

1.5.1 Delivery

Notify the Contracting Officer a minimum of 24 hours prior to delivery and unloading of geotextile rolls packaged in an opaque, waterproof, protective plastic wrapping. Do not remove the plastic wrapping until deployment. If quality assurance samples are collected, immediately rewrap rolls with the plastic wrapping. Repair or replace as directed, geotextile or plastic wrapping damaged during storage or handling. Label each roll with the manufacturer's name, geotextile type, roll number, roll dimensions (length, width, gross weight), and date manufactured.

1.5.2 Storage

Protect rolls of geotextile from construction equipment, chemicals, sparks and flames, temperatures in excess of 71 degrees C 160 degrees F, or any other environmental condition that may damage the physical properties of the geotextile. To protect geotextile from becoming saturated, either elevate rolls off the ground or place them on a sacrificial sheet of plastic in an area where water will not accumulate.

1.5.3 Handling

Handle and unload geotextile rolls with load carrying straps, a fork lift with a stinger bar, or an axial bar assembly. Do not drag rolls along the ground, lift by one end, or drop to the ground.

PART 2 PRODUCTS

2.1 RAW MATERIALS

A minimum of [7] [_____] days prior to scheduled use, submit manufacturer's certificate of compliance stating that the geotextile meets the requirements of this section. For needle punched geotextiles, certify that the geotextile has been continuously inspected using permanent on-line full-width metal detectors and does not contain any needles which could damage other geosynthetic layers. Provide the certificate of compliance attested to by a person having legal authority to bind the geotextile manufacturer.
2.1.1 Geotextile

NOTE: This note contains information from Standard Specifications for Transportation Materials and Methods of Sampling and Testing, Part I – Specifications, Copyright 1999 by the American Association of State Highway and Transportation Officials (AASHTO), Washington, D.C. AASHTO has given permission to use this information.

Values for grab strength, seam strength, tear strength, and puncture strength for various applications can be obtained from the AASHTO M 288 – Standard Specification for Geotextiles. The most recent version of M 288 should be used as a reference. The table in M 288 is divided into three geotextile classes. The severity of installation conditions for the application generally dictates the required geotextile class.

The following values for permittivity and apparent opening size (AOS) are from AASHTO M 288. Values for permittivity and maximum AOS should be compared to actual values of commonly manufactured products to assure there are a sufficient number of manufacturers who can meet specifications.

<table>
<thead>
<tr>
<th>AASHTO M288 PERMITIVITY AND AOS REQUIREMENTS</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>SOIL TO BE FILTERED</strong></td>

<tr>
<td>15 TO 50 PERCENT PASSING 75 m NO. 200</td>
</tr>
<tr>
<td>GREATER THAN 15 PERCENT PASSING 75 m NO. 200</td>
</tr>
</tbody>
</table>

The values listed above provide general guidance only. A site specific geotextile design should be performed especially if one or more of the following problematic soil environments are encountered: unstable or highly erodible soils such as non-cohesive silts; gap graded soils; alternating sand/silt laminated soils; dispersive clays; or rock flour. For cohesive soils with a plasticity index greater than 7, the geotextile maximum average roll value for AOS should be 0.30 mm No. 50 sieve.
Compatibility testing should be considered in situations where the geotextile will be exposed to chemicals which could degrade its physical properties. Refer to ASTM D5322 - Practice for Immersion Procedures for Evaluating the Chemical Resistance of Geosynthetics to Liquids for additional guidance on compatibility testing.

Geotextiles may also be used to provide puncture protection for geomembranes. Needle-punched nonwoven geotextiles are commonly used to provide puncture protection. GRI Report Number 13 - A Design Methodology for the Puncture Protection of Geomembranes provides guidance on the design of geotextile cushion layers. Typical index properties for a 350 g/square meter geotextile are shown below:

<table>

Provide geotextile that is a [woven] [nonwoven] pervious sheet of polymeric material consisting of long-chain synthetic polymers composed of at least 95 percent by weight polyolefins, polyesters, or polyamides. The use of woven slit film geotextiles (i.e. geotextiles made from yarns of a flat, tape-like character) will not be allowed. Add stabilizers and/or inhibitors to the base polymer, as needed, to make the filaments resistant to deterioration by ultraviolet light, oxidation, and heat exposure. Regrind material, which consists of edge trimmings and other scraps that have never reached the consumer, may be used to produce the geotextile. Post-consumer recycled material [may also] [must not] be used. Form geotextile into a network such that the filaments or yarns retain dimensional stability relative to each other, including the edges. Meet the requirements specified in Table 1. Where applicable, Table 1 property values represent minimum average roll values (MARV) in the weakest principal direction. Values for AOS represent maximum average roll values.

2.1.2 Thread

A minimum of [7] [_____] days prior to scheduled use, submit proposed thread type for sewn seams along with data sheets showing the physical properties of the thread. Construct sewn seams with high-strength polyester, nylon, or other approved thread type. Provide thread with ultraviolet light stability equivalent to the geotextile and color that contrasts with the geotextile.

2.2 MANUFACTURING QUALITY CONTROL SAMPLING AND TESTING

The Manufacturer is responsible for establishing and maintaining a quality control program to assure compliance with the requirements of the specification. A minimum of [7] [_____] days prior to scheduled use, submit manufacturer's quality control manual. Provide documentation describing the quality control program upon request. Perform manufacturing quality control sampling and testing in accordance with the manufacturer's approved quality control manual. As a minimum, randomly sample geotextiles for testing in accordance with ASTM D4354, Procedure A. Acceptance of geotextile must be in accordance with ASTM D4759. Tests not meeting the specified requirements will result in the rejection of applicable rolls.

PART 3 EXECUTION

3.1 QUALITY ASSURANCE SAMPLES AND TESTS

**************************************************************************
NOTE: The need for and amount of quality assurance testing should be based on site conditions and the amount of geotextile being placed. EPA/600/R-93/182 indicates that a frequency of testing of once per
10,000 square meters 100,000 square feet has been used in the past for some large waste containment facilities.

3.1.1 Quality Assurance Samples

Provide assistance to the Contracting Officer in the collection of quality assurance samples for quality assurance testing; assign [7] [____] days in the schedule to allow for testing. Collect samples upon delivery to the site [at the request of the Contracting Officer.] [in accordance with ASTM D4354, Procedure B. Consider the lot size for quality assurance sampling to be the shipment quantity of the product or a truckload of the product, whichever is smaller. The unit size is considered one roll of geotextile.]. [at a frequency of one per 10,000 square meters 100,000 square feet]. Identify samples with a waterproof marker by manufacturer's name, product identification, lot number, roll number, and machine direction. Note the date and a unique sample number on the sample. Discard the outer layer of the geotextile roll prior to sampling a roll. Collect samples by cutting the full-width of the geotextile sheet a minimum of 1 meter 3 feet long in the machine direction. Immediately reseal rolls which are sampled in their protective covering.

3.1.2 Quality Assurance Tests

[Provide] [The Contracting Officer will provide] quality assurance samples to an Independent Laboratory. Samples will be tested to verify that geotextile meets the requirements specified in Table 1. Do not perform test method ASTM D4355/D4355M on the collected samples. Base geotextile product acceptance on ASTM D4759. Tests not meeting the specified requirements will result in the rejection of applicable rolls.

3.2 INSTALLATION

3.2.1 Subgrade Preparation

NOTE: Reference the appropriate sections for compaction requirements if the geotextile will be placed on a soil subgrade.

The surface underlying the geotextile must be smooth and free of ruts or protrusions which could damage the geotextile. Provide subgrade materials and compaction requirements in accordance with Section [____].

3.2.2 Placement

NOTE: For collection ditches, geotextile placed in the direction of flow should be wide enough to cover the entire width of the ditch. If this is not possible, the geotextile should be placed perpendicular to the direction of flow and shingled in the down-gradient direction.

Notify the Contracting Officer a minimum of 24 hours prior to installation of geotextile. Repair or replace geotextile rolls which are damaged or...
contain imperfections as directed. Lay the geotextile flat and smooth so that it is in direct contact with the subgrade. The geotextile must also be free of tensile stresses, folds, and wrinkles. On slopes steeper than 10 horizontal on 1 vertical, lay the geotextile with the machine direction of the fabric parallel to the slope direction.

3.3 SEAMS

**************************************************************************
NOTE: Overlapped seams are commonly used for geotextile not placed in tension. Geotextile seams can also be produced by sewing or the application of thermal energy. Contact the geotextile manufacturer for installation instructions using thermal methods. ASTM D4886 should be referenced for heat seamed geotextiles.

For geotextile placed in tension, seams should be sewn and the stitch type should be based on the manufacturer's recommendations.
**************************************************************************

3.3.1 Overlap Seams

**************************************************************************
NOTE: Seams are typically overlapped a minimum of 300 mm 12 inches. The specified seam overlap should be greater than 300 mm 12 inches for soft subgrades or where large amounts of differential settlement are anticipated. The maximum overlap is typically 1 meter 36 inches. For soils with a CBR value of less than 1, seams are typically sewn. Refer to AASHTO M 288 for additional guidance on overlaps for soft subgrade conditions.
**************************************************************************

Continuously overlap geotextile panels a minimum of [300] [_____] mm [12] [_____] inches at all longitudinal and transverse joints. Where seams must be oriented across the slope, lap the upper panel over the lower panel. If approved, sewn seams may be used instead of overlapped seams.

3.3.2 Sewn Seams

**************************************************************************
NOTE: The plans and/or specifications should indicate which seams must be sewn.
**************************************************************************

Seam strength can be specified based on ASTM D4632/D4632M for applications where the geotextile will not be placed in tension. In this case, seam strength is typically measured in accordance with ASTM D4632/D4632M and is typically specified to be equal to or greater than 85 to 90 percent of the grab strength of the geotextile. If seam strength testing will be required, add seam strength requirements to Table 1.

The need for quality assurance testing needs to be determined on a site specific basis and should be
based on how critical the project is and the consequences of failure.

If the geotextile is designed to be in tension, strength testing should be required and ASTM D4884/D4884M should be used to determine seam strength. Quality assurance and quality control testing should be performed on all seams that are designed to be in tension.

Sew factory and field seams [on all slopes steeper than 1 vertical on [4][_____] horizontal] [at the locations shown on the drawings.] Use a 401 locking chain stitch or a stitch recommended by the manufacturer. [For field and factory seams which are sewn, provide at least a 2-meter sample of sewn seam before the geotextile is installed. For seams that are field sewn, sew the seams using the same equipment and procedures as will be used for the production seams. If seams are sewn in both the machine and cross machine direction, provide samples of seams from both directions.]

[Provide Quality Assurance seam samples to the Government at the request of the Contracting Officer]. Provide seam strength meeting the minimum requirements specified in Table 1. Tie off the thread at the end of each seam run to prevent unraveling. Sew skipped stitches or discontinuities with an extra line of stitching with a minimum of 450 mm 18 inches of overlap.

3.4 PROTECTION

NOTE: The use of staples or pins to hold geotextiles in place should not be allowed in applications where the geotextile will be located adjacent to other geosynthetic layers which could be damaged.

The purpose of limiting exposure time prior to covering geotextiles is to minimize damage due to UV radiation and to prevent direct contact by vehicles, humans, and animals. To prevent UV degradation, exposure time of polypropylene geotextile should be limited to 14 to 28 days. Polyester geotextile is more resistant to UV degradation and may be exposed to UV radiation for at least 28 days without damage.

Protect the geotextile during installation from clogging, tears, and other damage. Repair or replace damaged geotextile as directed. Use adequate ballast (e.g. sand bags) to prevent uplift by wind. Do not leave the geotextile uncovered for more than [14] [_____] days after installation.

3.5 REPAIRS

Repair torn or damaged geotextile. Remove clogged areas of geotextile. Perform repairs by placing a patch of the same type of geotextile over the damaged area. Extend the patch a minimum of 300 mm 12 inches beyond the edge of the damaged area. Continuously fasten patches using approved methods. Align the machine direction of the patch with the machine direction of the geotextile being repaired. Remove and replace geotextile rolls which cannot be repaired. Perform repairs at no additional cost to
3.6 PENETRATIONS

Construct engineered penetrations of the geotextile [as shown on the drawings] [by methods recommended by the geotextile manufacturer].

3.7 COVERING

**************************************************************************
NOTE: This paragraph should be modified if the geotextile will be covered by another geosynthetic layer.

If large stones or riprap will be placed over the geotextile, the drop height of the stones should be addressed in the specifications. At some projects, the Contractor is required to construct a small test fill to verify his placement techniques will not damage the geotextile and to determine the maximum allowable drop height.
**************************************************************************

Do not cover geotextile prior to inspection and approval by the Contracting Officer. Place cover soil in a manner that prevents soil from entering the geotextile overlap zone, prevents tensile stress from being mobilized in the geotextile, and prevents wrinkles from folding over onto themselves. On side slopes, place soil backfill from the bottom of the slope upward. Do not drop cover soil onto the geotextile from a height greater than 1 m 3 feet. Do not operate equipment directly on top of the geotextile without approval of the Contracting Officer. Use equipment with ground pressures less than 50 kPa 7 psi to place the first lift over the geotextile. Maintain a minimum of [300][_____] mm [12][_____] inches of soil between full-scale construction equipment and the geotextile. Cover soil material type, compaction, and testing requirements are described in Section 31 00 00 EARTHWORK. Do not use equipment for placing cover soil that stops abruptly, makes sharp turns, spins their wheels, or travels at speeds exceeding [2.2] [_____] m/s [5] [_____] mph.

  3.18.2 Final Project Report

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for bioengineering practices for stream bank and shoreline stabilization. This section was originally developed for USACE Civil Works projects.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1 GENERAL

NOTE: This guide specification covers bioengineering practices as related to stabilizing stream banks and shorelines using natural vegetation by itself or in conjunction with stone, rock, dead vegetation structures, or organic erosion control matting. The methods may also be applied to small tributaries, gullies, canals, and drainage channels. The use of the term bioengineering refers to soil bioengineering in this specification. Soil bioengineering is a method of stabilizing soils using living and dead plant material and biodegradable manufactured products. Bioengineered structures should not at anytime be constructed on...
embankments, levees, or flood control structures where there is a risk of failure of the project from a single event or a storm with a recurrence interval of 10 years.

This specification focuses only on stream banks and shorelines at or near the edge of water. This specification is not for coastal protection. This specification does not include requirements for hard or dead vegetation structures that are for erosion control or habitat restoration. This specification does not include the use of geosynthetic materials, metal, or requirements for traditional stone or rock hardened structures for bank protection. The designer should be cognizant that the structures described in this specification often must be augmented with the establishment or enhancement of vegetative zones on the landward portions of the banks or shores. Refer to TR-EL-97-8 Bioengineering for Stream Bank Erosion Control Report 1 Guidelines for guidance.

The designer should use caution in the selection of bioengineering methods for bank stabilization. Many bioengineering methods provide improved erosion resistance to stream banks or shorelines. However, bioengineering methods are not designed to repair inherently unstable stream banks or shorelines, which require engineering design, soil improvement, or extensive soil removal prior to vegetation efforts. Bioengineering methods will not prevent bank failures due to poor soil conditions, over steepened or undercut slopes, rapid draw down or drop of water levels, or where flow velocities exceed bioengineering established tolerances. Improved stability due to the development of root mats in the soil may take two or more years to be realized. Therefore, the desired bioengineering methods or bioengineered structures must be selected based on-site specific conditions, realistic expectations of performance, and consultation with soil, hydraulic, and structural engineers and environmental resource personnel.

The designer should compare bioengineered structures to more traditional stabilization methods, such as stone revetments or concrete channel lining, in terms of cost and performance before final selection of stabilization methods. Traditional stabilization methods may be better suited and more economical and provide greater protection at lower costs than bioengineered structures. The designer should review case histories on the performance and maintenance of existing bioengineered structures during selection and design. It is important to anticipate possible future failures of banks due to toppling of large mature vegetation, changes in vegetation species, and impact on the structure and vegetation by animal and human activities. Hard
structures may be preferred at locations where the risk of loss of life or property is apparent or where rapid changes in land use may pose such a risk in the future.

This specification is applicable to semiarid and temperate regions. The construction of bioengineered structures in arid regions requires special attention to the selection of appropriate plant species, water supply, irrigation, and maintenance for successful completion and performance. Other bank protection alternatives may be more cost effective than bioengineered structures in arid regions.

The construction of bioengineered structures in cold climates requires additional design efforts to reduce or prevent damage. Structures may be damaged by the impact of ice flows or ice blocks in the stream or river. The development of ice at the stream bank that incorporates the vegetation of the structure may result in vegetation loss or increased forces on the structure. Consult with a hydraulic engineer on methods to minimize damage to the structure. The percent of damage and mortality to vegetation may be higher due to frost or severe cold. Free draining soils should be used to reduce the amount of frost heave on structural components. Structures may not be suitable in climates with deep frost depths where surficial soil may be subject to flow when disturbed during the spring thaw. Bioengineering methods may not be suitable in cold regions where plant development and growth are stunned due to the climate and where root development, which is required for performance of the structure, may require more than 2 years. Consult with regional experts when planning bioengineered structures in these regions.

Planning of the bioengineered structure requires a multidisciplinary team approach. The designer should consult at a minimum with personnel in soil mechanics, structural design, hydraulic engineering, biological sciences, botany, regulatory, cost estimating, contracting, and construction during the initial development of conceptual designs, comparison of alternatives, and throughout project execution as required. Clear objectives for the selection, performance, and risk of the structure must be developed early in the planning phase. Sponsors and the public must be advised about the cost, performance, safety, benefits, and risks of the selected structure during the early stages of design. The designer should be aware of the need for construction oversight during installation to ensure quality.

The designer should include the long-term costs of maintenance in cost estimates and the amount of
maintenance required for adequate and safe performance of the structure. Monitoring or after care of the structure may be necessary for 2 to 10 years after the structure is completed to ensure the vegetation becomes established and the structure is meeting performance requirements. The impact of changes to site conditions should be evaluated during planning for safety and maintenance requirements. The effect of loss, damage, and change of vegetation species on structure performance should be discussed. The effect of disease, fire, harvesting, or removal related to plants in the structure and impact on performance must be elevated. Requirements for vegetation replenishment, pruning, selective cutting, and replacement should be included in maintenance planning. Repair to the soil, backfill, or hard materials in the structure must be addressed. The accretion of sediment on stream banks due to the trapping of sediment by vegetation should be evaluated for loss of stream conveyance and decreased slope stability due to the increased weight of accreted sediment. Damage due to wave action from storms, navigation, or boats should be determined.

Clear acceptance criteria should be defined for the project as well as warranty requirements. Acceptance and warranty requirements may be more stringent and require longer periods of time than traditional bank stabilization projects due to the need for vegetation to become established.

The following stream flow velocities are recommended for maximum limits on the selected methods of stream bank or channel stabilization.

- Vegetative protection 2.5 m/s 8 feet per second (fps) Structural and bioengineering
- Woody material, 2.5 m/s 8 fps
- Woody material and herbaceous species, 1.5 m/s 5 fps
- Herbaceous alone, 1 m/s 3 fps

(USDA TN Plant Materials No 23, Technical Notes, September 1993)

Flow velocities greater than 2.5 m/s 8 fps may require reinforced matting or hard structures.

Bioengineering methods require construction techniques and materials, which are described by other existing specifications. The following specifications should be included with this specification in the bid package depending on site conditions and design objectives.

Minor clearing and grubbing of vegetation is provided in this specification with an emphasis on salvaging cleared or grubbed material for the construction of the bioengineered structure. For
extensive clearing and grubbing of vegetation for site construction or access, refer to Section 31 11 00 CLEARING AND GRUBBING.

Minor earthworks may be required for the construction of the bioengineered structure. In addition, select fill or backfill materials may be needed. This specification only includes the requirements for the minimal earthworks necessary for key trench installation and surface roughening. For slope reduction, benching, and material specification, refer to Section 31 00 00 EARTHWORK.

The construction of bioengineered structures often results in the exposure of soils that require protection from erosion. This specification mentions the need for erosion control products but does not provide the specifications or installation methods for these products.

Bioengineering methods may incorporate stone or rock. For the requirements for hard armor, refer to Section 35 31 19 STONE, CHANNEL, SHORELINE/COASTAL PROTECTION FOR STRUCTURES.

Seeding is an important component for many bioengineered structures. To specify the requirements for the installation procedures for seeding, refer to Section 32 92 19 SEEDING.

Fencing may be required during and after construction to protect bioengineered structures and associated vegetation from damage due to human and animal activities. For the requirements for fencing, refer to Section 32 31 13 CHAIN LINK FENCES AND GATES or 32 31 26 WIRE FENCES AND GATES.

Bioengineered structures are commonly placed in or adjacent to bodies of water. Employ Best Management Practices for storm water pollution prevention in accordance with Section 01 57 19 TEMPORARY ENVIRONMENTAL CONTROLS.

Portions of this specification may not be consistent with sections in the construction contract. The designer will delete unnecessary paragraphs of this specification or provide full requirements to portions in this specification that may conflict with or contradict other sections in the contract. These conflicts, contradictions, or lack of requirements will be resolved between this section and other specifications and the construction contract before the design package is released for review.

For additional information concerning bioengineering practices, methods, structures, construction, and performance, see the following publications:

The publications listed above are a small sample of the numerous publications available with related guidance for bioengineering practices. The designer is encouraged to obtain and review local and State publications that are specific to the region of project work. These publications generally contain useful information on suitable plant species, soil and stream conditions, and regulations. Insert project specific references as needed. Numerous guidance and case history publications on bioengineering by the USACE may be reviewed at http://libweb.wes.army.mil.

Publications may contain drawings of proposed structures that are of value for reference and incorporation in design documents. It is strongly recommended that the designer obtain and review drawings of the various bioengineering methods and structures during the preparation of this specification. These drawings lend considerable clarity to the descriptive text about the structures. These drawings should be included in the specification package as attachments to this specification and should be modified to reflect site-specific conditions and restraints.

**************************************************************************

1.1 SUMMARY

**************************************************************************

NOTE: Provide requirements that are specific to the work and that the Contractor will be responsible for completing.

The Contractor should submit sufficient drawings to clearly define site layout, structure, details, site
conditions, extents of features, and the like to allow adequate planning and cost estimating. The designer will delete or add drawings that are necessary to meet project needs.

The work by the Contractor consists of furnishing and installing bioengineered features and structures. Submit design, details, cross sections and profiles of site engineered structures to enhance [stream bank] [and] [shoreline] stability within project limits and in areas outside the project limits where the soil surface is disturbed from work under this contract [and as noted on the drawings]. Include in this work all necessary evaluation, design, materials, labor, supervision, and equipment for installation of a complete system and after construction maintenance. Submit a list of all equipment and tools that will be used for the construction of the bioengineered structure. Include information on products used in equipment such as fuel, hydraulic fluids, and the like. Coordinate this section with the requirements of Section [31 11 00 CLEARING AND GRUBBING] [and] [31 00 00 EARTHWORK] [and] [35 31 19 STONE, CHANNEL, SHORELINE/COASTAL PROTECTION FOR STRUCTURES] [and] [32 31 13 CHAIN LINK FENCES AND GATES][32 31 26 WIRE FENCES AND GATES] [and] [32 92 19 SEEDING] [and all other specifications or requirements as necessary].

1.2 MEASUREMENT AND PAYMENT

NOTE: Add or delete products and measurement and payment as require for project specific needs.

1.2.1 Binder

Measure the standard binder by the linear meter foot placed.

1.2.2 Live or Dead Cuttings

Measure live or dead cuttings by number and type of individual cuttings. No payment will be made for cuttings not required for use in the structure, defective, or that are trimmed from cuttings. Include all harvesting, soaking, transportation, and preparation in the measurement for payment.

1.2.3 Materials

Measure soil and rock by the [cubic meter yard] [metric 2000 pound ton].

1.3 REFERENCES

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also
use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

ASTM INTERNATIONAL (ASTM)

U.S. ARMY CORPS OF ENGINEERS (USACE)

TR-EL-97-8 (1997) Bioengineering for Streambank Erosion Control; Report 1, Guidelines

1.4 SUBMITTALS

NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.
The designer should ensure adequate time is allowed for the review of submittals before the start of work. The designer will clearly note the time for submittals, where required. Insert the number of copies required as needed.

The submittals listed below are for general bioengineering projects. The designer will edit this section to tailor the submittals to the project needs and requirements and include submittals not listed below as necessary.

**************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-01 Preconstruction Submittals

Existing Site Conditions
Site Evaluation Plan
Permits and Regulations
Construction Work Sequence Schedule
Seed Establishment Period
Dewatering; G[, [_____]]

1.5 QUALITY ASSURANCE

Ensure all Contractor and subcontractor personnel are fully qualified to perform the specified work and provide the Contracting Officer with such documentation no less than [30] [____] days before the notice to proceed. Do not start work until the Contracting Office is satisfied that the Contractor meets or exceeds all required qualifications. All Contractor records, documents, and work may be inspected by the Contracting Officer or designated representative at any time. Replace or repair immediately items not meeting quality requirements at no cost to the Government.

1.5.1 Regulatory Compliance

Perform the specified work in accordance with all applicable Federal, State, and local regulations.
1.5.2 Pre-Installation Conference

Coordinate and conduct meetings with the USACE and all subcontractors prior to the start of any work to ensure all work requirements are fully understood and will be performed. All of these meetings must take place in the presence of the Contracting Officer.

1.5.3 Substitutions

Substitutions will not be allowed.

1.5.4 Qualifications

1.5.4.1 Installer's Qualification

Submit the installer's company name and address; training and experience and or certification. The installer must be certified by the manufacturer for any special training and/or experience required for installation.

1.5.4.2 Personnel Qualifications

Submit a list of personnel working on the project including name, title, and statements of their current positions and previous experiences. Use selected personnel that have been involved in bioengineering design and construction efforts similar to the proposed site work within the last 2 years.

1.6 DELIVERY, STORAGE, AND HANDLING

**************************************************************************

NOTE: Provide specific information on required delivery procedures, inspection requirements and methods, special storage needs, and specific handling methods.

Edit this section to include materials that are specific to the project work. Add or delete materials or products as required.

Sediment samples should be collected for mechanical and chemical analyses. Rock and stone should be tested for toughness, durability, chemical stability, and freeze and thaw at a minimum. Vegetation to be used in construction should be tested for health and presence of disease. All analyses must be performed by analytical laboratories that are certified by the USACE. The designer will add or delete sample and testing requirements to this section as needed. Specify the specific tests and methods adjacent to the sample or refer to the accompanying specification in which this information is contained.

**************************************************************************

Submit a list of nonvegetative materials to be used in the construction of bioengineered feature or structure. Include manufacturer's literature regarding physical characteristics, limitations, and application or installation instructions. Store materials in designated areas as
recommended by the manufacturer and that are protected from direct exposure to the elements, moisture, and any potential damage. Do not drop containers from trucks. Provide material free of defects that would void required performance or warranty. Deliver manufactured items in the manufacturer's original sealed containers and stored in a secure area.

Prior to delivery of materials, submit certificates of compliance attesting that materials meet the specified requirements. Include the following for items listed in this section:

a. Certification of recycled content or,
b. Statement of recycled content.
c. Certification of origin including the name, address and telephone number of manufacturer.
d. Certification for binders showing EPA registered uses, toxicity levels, and application hazards.

1.6.1 Erosion Control Blankets

Furnish erosion control blankets in rolls with suitable wrapping to protect against moisture and extended ultraviolet exposure prior to placement. Label erosion control blanket rolls to provide identification sufficient for inventory and quality control purposes.

1.6.2 Seed

Inspect seed upon arrival at the job site for conformity to species and quality. Reject seed that is wet, moldy, or bears a test date five months or older. Store seed in a cool dry area protected from moisture.

1.6.3 Lumber

Inspect lumber for straightness and defects. Reject warped, damaged, or used lumber. Do not store lumber directly on the ground and protect from moisture until the time of installation.

1.6.4 Vegetation

Inspect vegetation cuttings, herbaceous plants, and clump plantings for species, size, health, and preparation. Reject diseased, improperly sized, and incorrect species. Specific requirements for storage and handling are provided below.

1.6.5 Earth Materials

Provide select fill, top soil, stone, rock, aggregate, and sand meeting design specifications. Store excavated sediments and fill in well drained areas, separated from the ground by a non contaminating isolation barrier. Reject material not meeting specifications or with contained physical or chemical contaminates.

1.6.6 Logs, Trunks and Brush

Use logs, trunks, and brush of the size and quality specified. Place materials in organized manner in stock piles near the work site ensuring they were not damaged during delivery, storage, or installation. Do not rest materials directly on the ground or expose to precipitation if they are to remain at the storage site for longer than [4] week before installation. Use coverings for the logs, trunks, or brush that do not
promote mold or rotting.

1.7 PROJECT/SITE CONDITIONS

1.7.1 Environmental Requirements

**************************************************************************
NOTE: Include information on the physical and
environmental characteristics and limitations at the
work site e.g. temperature, illumination, slope,
water depth, etc.
**************************************************************************

[_____

1.7.2 Existing Site Conditions

**************************************************************************
NOTE: Include information on site conditions,
references to documents and reports about site
conditions, and requirements for the Contractor to
obtain all literary information available for site
planning and design. This paragraph should include
the need for surface mapping, subsurface
exploration, hydraulic analyses of streams or lakes,
and all other information necessary for successful
design and construction that is not provided by the
Government. Also note that lack of supply of such
information by the Government does not relieve the
Contractor of any such necessary research or studies.
**************************************************************************

Submit a detailed description of the existing site conditions prior to
construction work including but not limited to literary references, site
visits, public or private reports, studies (engineering, ecological,
environmental, etc.) and topographic or other maps. Submit [_____] copies
of this survey to the Contracting Officer [_____] days before the start of
work.

1.7.3 Site Evaluation Plan

**************************************************************************
NOTE: Consider the following items during site
evaluation and project planning to improve the
success of the bioengineered structure. The items
below are not all inclusive for every site. Other
evaluation factors may be relevant based on site
specific conditions.

Do not construct bioengineered structures:
- where soil or water is contaminated with compounds
  or elements that may damage live vegetation or where
disturbance may result in expansion of the area of
contamination,
- at locations with unstable slopes that cannot be
  mitigated as part of construction,
- where robust stabilization structures are required
  for protection of navigation structures, levees, or
embankments,
- where damage of the structure could pose a risk to loss of life or property,
- where long-term maintenance and after care of the structure and vegetation is not desired,
- where climate or hydraulic conditions may threaten establishment of vegetation,
- where the streambed is degrading and where such degradation can not be stopped by altering hydraulic conditions of the stream or by the use of hard armor,
- along stream banks or shorelines subjected to high wave action from storms or watercraft,
- in areas subject to shade from other plant species that may hinder growth of the selected plant species for the structure,
- in areas where the structure may not be secured from undesired animal or human traffic and subsequent damage.

Check with local, State, and Federal agencies to ensure all regulations are understood and followed. Do not alter wetland areas.

Know the mean, mean low, mean high, minimum, and maximum water elevations of the stream, river, or lake. The definitions of water levels may be defined in terms of hydrologic analyses or by observation of stream geomorphic features.

- The maximum water elevation should be the highest water possible at the site due to storm surges, waves, floods, or water storage. The elevation of debris associated with flood events or storm waves on the high bank may be used for recent high water elevations.
- The mean high water elevation is the average high water level over 19 years. This elevation is typically located where trees and brush are established on the high bank of the channel.
- The mean water elevation is the average height of water over 19 years. This elevation typically corresponds to the area where reeds and small shrubs are present on the low bank adjacent to the stream channel or shore.
- The mean low water elevation is the average height of the low water over 19 years. This water level is characterized by the upper extent of aquatic plants on the bank or swash zone at the toe of the bank or shore.
- The minimum water elevation may correspond to the minimal flow in the stream channel or lowest elevation of a lake due to drought or human activities such as irrigation or water storage. The minimal water elevation may be the bottom of the stream channel or lake if these water bodies may be completely drained.

The designer is advised to modify these definitions and water level elevations based on the growing and
dormant seasons for species of vegetation used in construction to ensure establishment, performance, and survivability. Determine the amount and rate of change of water elevations due to natural or human activities.

Determine the possible height of waves, direction, and frequency due to storms or navigation operations.

Determine the changes in current velocities and flow direction due to different stages, seasons, or storm events.

Known the sediment load, composition, size, and rates of deposition or erosion at the site.

Know the climate of the work area. Severe flooding, drought, or cold during construction or in the future may damage the structure.

Determine the requirements for regular monitoring and maintenance of the structure to ensure plant survival and structure performance.

Specify the need for and the role and responsibilities of a multidisciplinary team for design and planning, construction, and after care.

The site evaluation plan may require literary searches; subsurface and surface exploration, sampling, and testing; surface topographic, geological, biological mapping; hydraulic engineering studies; assessment of the site in relation to residences, commercial property, and biological communities; and impact of navigation or water storage projects on the site. The report should contain sufficient information to determine if the site is viable for the proposed structure and sufficient information for structure design and planning.

**************************************************************************

Furnish a site evaluation plan stating clear and concise project objectives and assessment criteria of the viability of the proposed structure based on the physical, chemical, biological, political, and social site conditions and aspects. Submit the contents of the plan developed by the Contracting Officer and the Contractor in [_____] copies of this plan to the Contracting Officer [_____] days before the start of work. The plan should contain supporting documentation and studies, which include but are not limited to climate, geological, geotechnical, hydraulic, botanical, geomorphic, project cost estimates, and regulatory and permitting requirements. Include a review of case histories of bank stabilization methods at other similar sites, reconnaissance report on site conditions and suitability for bioengineering structures or methods, design alternatives, potential problems, and recommendations for the types and methods of bioengineered structures if applicable to site conditions and uses. Include lists of all applicable permits and regulations and methods of compliance related to construction. Submit list and copies of all required and approved permits for site work and of all regulations that
pertain to site work to the Contracting Officer [_____] days before the start of work. Include a report identifying the species of vegetation and plants that will be used for construction. Refer to TR-EL-97-8 for site evaluation and planning guidance. The report includes but is not limited to:

Supply of vegetation,
Harvest area and procedures,
Retention of existing vegetation,
Short and long-term interaction of selected species with existing vegetation,
Interaction of species with existing structures,
Retention or elimination of nonnative or invasive species,
Performance of selected vegetation in the proposed structure,
Maintenance and replacement.

1.8 SEQUENCING AND SCHEDULING

**************************************************************************
NOTE: Most bioengineered structures must be completed during the period of dormancy of plant growth unless otherwise noted. Structures completed outside of this dormant season will not be accepted by the Government unless provided with specific information on the need for such schedule and survivability of plant species used for construction. Local requirements may limit construction periods and must be fully complied with and adhered to unless granted waiver rights by the appropriate regulatory authorities. See paragraph TIME OF PLANTING in PART 3 for additional information.
**************************************************************************

Conduct all work [during the period of plant dormancy] [as stated below] and in accordance with all Federal, State, and local requirements for in-stream or near stream construction. The construction sequence must result in successful completion of the structure. Submit a construction work sequence schedule, detailing the work tasks and order of completion, to the Contracting Officer for approval a minimum of [90] [_____] days prior to the start of construction. Do not commence work without the approval of the schedule and construction sequence by the Contracting Officer. Construction must not occur if climatic conditions threaten the survivability of plants or worker safety. Construction sequence schedule .

1.9 WARRANTY

**************************************************************************
NOTE: The designer should consult with the manufacturer to ensure proper application and installation techniques for the site specific project conditions. Warranties vary with different materials and may be void if proper technical advice is not obtained. Seed germination is not covered under the warranty.
**************************************************************************

The structure and all manufactured materials will be under Contractor warranty for a period of [2] years including vegetation and earthworks.
Stone and rock will be under warranty from decomposition for [5] years.

1.10 MAINTENANCE

**************************************************************************
NOTE: Bioengineered structures require observation and maintenance for up to 5 years after installation to ensure the vegetation becomes established. Observation should be done on a weekly basis for the first year and bimonthly thereafter for the second year at a minimum. A minimal level of acceptable survival of plants should be established. The Contractor should be required to replace plants that die above the allotted percentage and area of concentration that may adversely affect structure performance.
**************************************************************************

1.10.1 General

Include in maintenance eradicating weeds; protecting embankments and ditches from surface erosion; maintaining the performance of the erosion control materials and mulch; replacement of dead or non-viable plants; repair of soil, stone, rock, or hard structures, and protecting installed structures from human and animal activities.

1.10.2 Maintenance Instructions

Furnish written instructions containing drawings and other necessary information to the Contracting Officer, describing the care of the installed material; and including when and where maintenance should occur and the procedures for material replacement. Submit instruction for year-round care of installed products including schedule, materials, and tasks. Describe the methods for specific maintenance activities and equipment and tools required for such efforts. Include requirements on safety and regulations and permits.

PART 2 PRODUCTS

**************************************************************************
NOTE: Consult local codes and regulations for additional information that may effect the project before design work begins. The choice of methods and materials will be project specific and will be at the discretion of the designer. Edit the specification choices of products to best suit the needs of the project.
**************************************************************************

2.1 BINDERS

Submit certification for binders showing EPA registered uses, toxicity levels, and application hazards. Prior to delivery of materials, submit certificates of compliance attesting that materials meet the specified requirements and certified copies of the material certificates. Ensure all binders are biodegradable and untreated hemp or coir rope or fasteners, which are able to withstand 2 years minimum exposure to the environment of placement without significant degradation in strength or quality. Do not use steel or plastic binders or fasteners.
2.2 EROSION CONTROL ITEMS

**************************************************************************
NOTE: Several structures require the application or integration of erosion control products. These products include but are not limited to mulch, straw, hay, shredded bark, coir, mulch control netting, and erosion control mats. Products selected for use should be biodegradable and non-damaging to the environment in which they are placed. Sediment retention products may also be required as part of construction efforts. Mention the specific needs and types of products below.
**************************************************************************

Provide [erosion control products] [and] [sediment control structures or products]. Install materials and structures according to manufacturer's recommendations based on [actual site conditions] [and] [as shown in the drawings].

2.3 SEED

**************************************************************************
NOTE: State-certified seed is more stringently monitored than State-approved seed, and therefore, more expensive.
**************************************************************************

Provide seed in accordance with Section 32 92 19 SEEDING. Provide [state-certified] [state-approved] seed of the latest season's crop in original sealed packages bearing the producer's guaranteed analysis for percentages of mixture, purity, germination, hard seed, weed seed content, and inert material. Use labels in conformance with AMS Seed Act and applicable State seed laws. Provide classification, botanical name, common name, percent pure live seed, minimum percent germination and hard seed, maximum percent weed seed content, and date tested. Submit the Seed Establishment Period calendar time for seed establishment. When there is more than one seed establishment period, describe the boundaries of the seeded area specific for each period. Proportion permanent seed species and mixtures by weight as follows:

<table>
<thead>
<tr>
<th>Mixture Percent by Weight</th>
<th>Percent Pure Live Seed</th>
<th>Botanical Name</th>
<th>Common Name</th>
</tr>
</thead>
<tbody>
<tr>

2.4 PERMANENT VEGETATION SPECIES AND MIXTURES

**************************************************************************
NOTE: Live or dead cuttings from locally harvested stock should be specified in this section. Nursery stock may also be used for design purposes or in areas with limited supplies of cuttings at or near the work site. Nursery stock has a higher chance of survival due to developed root systems but may add cost to the project.
**************************************************************************
The selection of the appropriate vegetation species for the site should be made by consultation with a qualified geotechnical engineer, hydraulic engineer, biologist, and botanist based on site conditions, stability requirements, desired habitat creation, and blending ability with surrounding vegetation. The soil types, hydraulic conditions and requirements, and ability of the selected species to survive in the work area must be determined and considered in species selection. Selected species should improve or enhance slope stability and should be flexible and of low height at maturity to allow maximum conveyance of water in the channel.

At some sites, nonnative species may be more appropriate due to changed site conditions or alterations by natural or human activities. Native species may not be able to survive in such alternated settings. For restoration projects, non-native or intrusive species may need to be removed before planting native species to reduce competition for resources and to improve the survivability of the native plants. Plant species should be collected from the same watershed and near the work site to prevent the import of differing genetic stains into the project area.

Woody vegetation that matures to have trunk diameters greater than four inches should not be used. Such species when mature pose a threat of scour to the bank down stream of the trunk during high flow events. In addition, these species may develop extensive root system that may damage the structure when the tree dies and rotates into the stream or lake. In this case, the root wad typically removes a large amount of soil as it is pulled from the bank. The resulting hole may be subject to scour and result in structure damage or failure during moderate or high flow events.

Sedimentation types and depositional rates should be determined. Some streams may transport sediment that may abrade or break vegetation. Alternatively, large amounts of sediment may be deposited at the site and cover vegetation. The combined effect of the trapping of large amounts of sediment by the selected vegetation species may result in the accretion of sediment onto the bank. While this accretion of material provides additional bank protection in the short term, the long term effects may be large bank failures due to the added weight of the sediment on the bank. The structure may be damaged or destroyed if the failure plane cuts the structure. Therefore the vegetation species in such areas should allow adequate water flow through the vegetation to reduce the amount of sediment that accumulates at the site.

On banks down stream of water storage project,
selected vegetation should be able to survive or recover rapidly in the event water levels must remain at elevated levels for an extended period of time due to flood or navigation releases.

Provide specifics on quality requirements.

Submit classification, botanical name, common name, harvest location, plant heath, and date tested, (live or dead cuttings, nursery stock, plants). Provide permanent vegetation type and planting plan, species and mixtures for [live and dead cuttings] [and] [nursery stock] [and] [herbaceous plants] as follows:

<table>
<thead>
<tr>
<th>Mixture Percent by Volume</th>
<th>Percent Live and Dead</th>
<th>Botanical Name</th>
<th>Common Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>[_____]</td>
<td>[_____]</td>
<td>[_____]</td>
<td>[_____]</td>
</tr>
</tbody>
</table>

Provide weed seed or noxious plants that are a maximum of 1 percent by weight of the total seed mixture. [Undesired], [non native] [and] [or] invasive vegetation species are not allowed. Ensure all live cuttings and containerized plantings are capable of growth and rooting and free of disease or defects at the time of installation.

2.5 STAKES

Provide stakes consisting of 100 percent biodegradable materials and designed to safely and effectively secure erosion control blankets, coir logs, fascines, and other bioengineered structures for temporary or permanent applications. Ensure the biodegradable stakes are fully degradable by biological activity [within 2 years]. The stakes must exhibit ample rigidity to enable being driven into hard ground, with sufficient flexibility to resist shattering.

2.6 STAPLES

Do not use metal or plastic staples.

2.7 SYNTHETIC GRID AND SHEET SYSTEMS

Do not use synthetic grid and sheet systems.

2.8 CRUSHED ROCK, GRAVEL, SAND, STONE, RIPRAP, and BACKFILL

Provide quality of rock, gravel, sand, stone, riprap, and backfill in accordance with requirements in Section 31 00 00 EARTHWORK and Section 35 31 19 STONE, CHANNEL, SHORELINE/COASTAL PROTECTION FOR STRUCTURES. Reject materials not meeting specified requirements and immediately replace by suitable material at no cost to the Government.

2.9 WATER

Water for irrigation, soaking of plants and cuttings, and dust control is the responsibility of the Contractor. Water must be clean, free of contaminants, and have a turbidity of less than 20 NTU. Use water from [a public source of know quality] [local surface water source] [groundwater well] near the work site. [Test water obtained from non public sources for
2.10 FENCING

**************************************************************************
NOTE: Permanent or temporary fencing may be required around work sites to prevent vandalism and damage to newly planted vegetation by livestock, animal, or human activities. Fencing may be temporary or permanent. Specify temporary fencing such as plastic construction fence, snow fence, or rental fence below. Use Section 32 31 26 WIRE FENCES AND GATES or 32 31 13 CHAIN LINK FENCES AND GATES to specify permanent wire and chain link fabric fences and gates if required.
**************************************************************************

[All fencing must be in accordance with Section [32 31 26 WIRE FENCES AND GATES][32 31 13 CHAIN LINK FENCES AND GATES].] Fencing must be temporary and consist of [_____] fence. Secure fencing to [wood] [metal T-poles] that are driven 600 mm 2 feet into the ground and extend 1.2 m 4 feet above the finish grade. Install fencing [at the start of work] [after construction]. Allow fencing to remain in place [until vegetation is established] [for 3 years].

2.11 IRRIGATION

**************************************************************************
NOTE: Sites may require extended periods of irrigation to ensure vegetation establishment. Irrigation systems may be on the surface or underground. Water retention in the structure in arid regions may be aided by the use of super absorbent polymers. Edit this specification for products that may be used with open trench irrigation.

Some sites may be remote and may not have electrical or water supplies available. In this case, the designer should include products for solar power, water tanks, or methods such as daily watering by water truck.
**************************************************************************

[All underground irrigation must conform to Section 32 84 24 IRRIGATION SPRINKLER SYSTEMS or as approved by the Government.] Provide the following products and materials for irrigation.

<table>
<thead>
<tr>
<th>Product</th>
<th>Manufacturer</th>
<th>Quantity</th>
<th>Purpose</th>

2.12 FERTILIZER, PESTICIDE, HERBICIDE

**************************************************************************
NOTE: Edit this paragraph as required. Fertilizer, pesticide, and herbicide may be required for the

SECTION 31 32 39 Page 24
construction, establishment, and maintenance of bioengineered structures. The designer will consult with a qualified botanist, biologist, landscape engineer, and regulatory agencies before selecting the use of or type of fertilizer, pesticide, or herbicide for application at the site. Products, if selected for use, should not pose a threat to water quality or the environment. Pesticides and herbicides will only be used when absolutely necessary. Use of biological methods for pest or plant control is encouraged. Provide specific product names, manufacturer, method and concentration of application, and other required product information below.

**************************************************************************
Provide the following products and materials.

<table>
<thead>
<tr>
<th>Product</th>
<th>Manufacturer</th>
<th>Quantity/Application</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>

</tr>
</tbody>
</table>

2.13 MATERIAL TESTING

**************************************************************************

NOTE: Edit this section as required. Provide specific methods, procedures, sample numbers, test, and the like.

The Contractor should collect samples of select fill and site soils for physical and chemical analyses to ensure these materials are appropriate for growth of the selected plant species. Refer to specific soil requirements needed for healthy plant growth to complete this section. Imported soil or select fill must be tested to ensure the material is free of seeds or root stocks of non native or invasive species or detrimental biological organisms.

Soil samples from the surface and subsurface of the site should be collected for geotechnical and chemical analyses. Geotechnical test parameters should be at a minimum grain size with hydrometer, moisture content, density, and Atterberg limits as required. Testing of site soils and select fill for permeability, consolidation, and soil strength may also be required depending of site conditions and selected structure. Soil samples should be collected to confirm that soils at the site are not contaminated with hazardous, toxic, or radioactive compounds that would require special handling.

Samples of surface and groundwater should be collected to verify that seepage into the stream or water body at the work site is not contaminated with compounds that will endanger plant survival or pose a hazard to human health and the environment. Water
that is not obtained from a public source should be tested for biological and chemical contamantes.

Specify analytical laboratories for analyses, turn around time for samples, and holding times for chemical samples.

The soil and water samples must be collected and analyzed a minimum of 120 days before the start of construction. The analytical results must be reviewed by the Contracting Officer before work continues at the site. If hazardous compounds or chemicals are discovered, then the work will be terminated. All testing must be performed by USACE validated laboratories.

Several different types of samples and tests may be required depending on structure design, construction, and location. Soil samples should be collected for geotechnical analyses for grain size, moisture content, density, Atterberg limits, compaction, shear strength, and pH. Soil at the site and fill that may be imported should also be tested for these parameters. The chemistry of the soil should be tested to ensure the soil will support vegetation growth and is free of contamantes. Soil should be tested for deleterious microorganisms that could increase plant mortality. Surface and groundwater should be sampled for chemistry and quality.

Submit certified reports of inspections and laboratory tests, prepared by an independent testing agency, including analysis and interpretation of test results. Properly identify each report. Describe test methods used and compliance with recognized test standards. Collect samples of soil and water at and for use at the site, collected at the locations as shown in the drawings and at source locations for the materials or water. Collect these samples and test as specified below.

<table>

</tbody>
</table>

PART 3 EXECUTION

3.1 SITE VERIFICATION OF CONDITIONS

Coordinate, through the work schedule, the timing of land disturbing activities with the provision of erosion control measures. An erosion control plan will be required in accordance with applicable Federal, State, or local requirements. Perform erosion control operations under favorable weather conditions. When excessive moisture, frozen ground, or other unsatisfactory conditions prevail, stop the work as directed. When special conditions warrant a variance to earthwork operations, submit a revised construction schedule for approval. Do not apply bioengineering materials in adverse weather conditions, which could affect their performance. Complete all tasks necessary for the required submittals.
3.2 SITE PREPARATION

3.2.1 Temporary Construction Facilities

Establish access routes to the construction site prior to the start of work and show them on the drawings. Provide all temporary construction facilities in accordance with Section 01 50 00 TEMPORARY CONSTRUCTION FACILITIES AND CONTROLS. Provide access to the work site and harvest area by [temporary] [permanent] [roads] [and] [paths] designed for [motorized vehicles] [and] [pedestrian access] if acceptable and in accordance with regulations and property owner restrictions and permission. Select access methods that have the least impact on existing site conditions and that may be easily removed and restored upon the completion of work. Provide strict access control to the work and harvesting sites to prevent access by non-authorized personnel. Install [access gates] [barricades] at the entrances of temporary [roads] [paths] to the sites. [Secure these gates with a keyed lock and keep closed at all times when personnel are not present at the gates for access. Provide duplicate keys for the lock to the Contracting Office, landowner, authorized regulatory personnel, and fire and law enforcement as required.] [Place appropriate signage on the gates that clearly specify site access is restricted.]

3.2.2 Clearing and Grubbing

Clear access route and construction site of vegetation necessary for the construction of the bioengineered structure or staging area in accordance with Section 31 11 00 CLEARING AND GRUBBING. Efforts will be made to salvage vegetation suitable for use in the bioengineered structure.

3.2.3 Erosion and Sediment Control

Install erosion and sediment control measures prior to active construction efforts to prevent erosion of soil and offsite releases of sediment.

3.2.4 Earthwork

Slope and grade the [stream bank] [shoreline] [in accordance to Section

SECTION 31 32 39 Page 27
3.2.4.1 Trenches

Unless otherwise stated, make trenches to the depth, width, and line as shown on the drawings. Make side slopes, unless otherwise indicated, at the angle of repose. [Use material removed from the trench as backfill.] [Remove material that is removed from the trench from the site.] [Backfill trenches with select fill]. [Compact the floor of the trench to 90 percent maximum dry density and smooth.] Place backfill in 150 mm 6 inch lifts compacted [to 80 to 90 percent maximum dry density] [sufficiently to improve soil density but not impede vegetation root growth]. [Key trenches into the stream bank for a distance of 3 feet]. [Install shoring [if the trench exceeds 1 m 3 feet in depth] [as required by regulations]]. [The Contractor is responsible for dewatering of trenches for construction purposes.]

3.2.4.2 Finished Grade

Provide smooth finish grade and as shown on the drawings and in accordance with Section 31 00 00 EARTHWORK.

3.2.4.3 Surface Roughening

**************************************************************************
NOTE: Surface roughening should be performed on all slopes with exposed earth that are greater than 3H:1V. Surface roughening reduces surface runoff velocities and provides depressions that collect sediment, seed, and water, thereby improving vegetation establishment on the slope. Roughening may be accomplished by traversing the surface with track-mounted equipment, manual efforts such as hand raking, or terracing of the slope during excavation or the placement of fill. The method of roughening may vary depending if the slope is a new cut or fill surface or an existing or graded slope. Surface roughening should not create ridges or depression that hinder the mowing of slopes that are 3H:1V or less.
**************************************************************************

Roughen surfaces of all barren slopes related to work efforts by [equipment] [and] [manual efforts] to reduce erosion and promote trapping of seed, water, and sediment. Compact all lifts as specified in Section 31 00 00 EARTHWORK. [Cover surfaces of the lifts with loosely compacted soil to a depth of 100 mm 4 inches.] [Use track-mounted equipment to traverse the slope from the toe to the crest to place track imprints parallel to the contours of the slope.]

a. [Roughen slopes on new cut faces greater than 3H:1V by stair-step cuts installed during construction. Ensure the faces of the steps do not exceed 600 mm 2 feet in height in soft material or 900 mm 3 feet in height in hard material. Make horizontal spacing between the vertical faces no less than the vertical height of the step.]

b. [Roughen slopes on new fill greater than 3H:1V by the installation of lifts of compacted soil that does not exceed 200 mm 8 inches in thickness.]
c. [Roughen existing slope of graded areas by tilling, disking, harrowing and seeding, or other suitable method or equipment to produce ridges and depressions in the surface of the slope, which are parallel to the contours of the slope. Ensure these ridges and depressions do not exceed 25 mm 1 inch in depth or height above the grade surface and space no more than 250 mm 10 inches apart.]

d. Do not smooth the final roughened surface by blading or scraping. Break all large soil clumps into small clumps no more than 50 mm 2 inches in diameter and disperse on the immediate surface. Cut or fill mounds or depressions of soil that are greater in height or depth than those produced by the method of roughening with suitable material to grade and roughen to match the adjacent surface. Backfill depressions of depth greater than 150 mm 6 inches with compacted suitable material until reaching the design grade of the slope and roughened. Do not compact sand or silty sand to a density that may prevent vegetation planting and growth. Seed, plant, or cover roughened areas with erosion control products [immediately after roughening] [within [_____] days after completion of roughening].

3.3 FIRE PREVENTION

Take all efforts possible to prevent fire at the work site and harvest area as a direct result of work efforts. Provide fire prevention or suppression equipment to personnel at the work and harvest sites. Provide all equipment in compliance with applicable regulations and maintain in working condition at all times and within no more than 5 m 15 feet distant from the active work areas.

3.4 SANITATION

Provide adequate portable sanitation facilities for persons at the construction and harvest sites that are in compliance with all Federal, State, and local requirements.

3.5 HARVESTING OF VEGETATION

**************************************************************************

NOTE: Most plants for bioengineering structures constructed near water are wetland plants except for species used for the vegetation of high bank areas. Woody plants or herbaceous plants may be used and should be somewhat flood tolerant. Harvesting may include the collection of woody plants, herbaceous plants, or single or clump plantings. Vegetation should be harvested from local sources and native plant species near the construction site. The need to obtain vegetation from distant sources should be evaluated in terms of cost and the risk of introducing foreign genetic material into the watershed in which work occurs. Vegetation should be obtained when at all possible from the same watershed in which the work will occur. Other stabilization methods may be more appropriate for the site due to high transportation and handling costs.

Site harvesting requires the cutting of existing
vegetation for live and dead stakes, poles, or cuttings, collection of roots or tubers, or excavation of plants with root mats intact. The harvest site must not be over harvested and must be restored as much as reasonably possible after harvest work is completed. Determine the number and location of the vegetation that may be harvested before construction by a qualified botanist or forest engineer.

**************************************************************************

3.5.1 Harvesting of Woody Plants

**************************************************************************

NOTE: Woody plants consist of stem cuttings that quickly sprout roots and stems from the parent stem. These plants are typically willow and perhaps some species of dogwood and alder. Nursery stock with established roots may also be used.

The length of the harvested vegetation will vary with site conditions and structure design. In general, stakes and poles should extend at least 300 mm 1-foot above the top of structure. Cuttings should extend at least 300 mm 1-foot beyond the edge of a structure or 600 mm 2 feet above the ground surface. Base the actual lengths of the stakes or poles on the depth of soil from the surface to the mid summer capillary zone or water table. For guidance, the minimum length is three feet. The diameters for the base of cuttings and stakes may range from 19 to 38 mm 3/4 to 1.5 inches and should be of sufficient diameter to resist buckling when driven into the streambed or bank. Live poles may range from 50 to 100 mm 2 to 4 inches. Live or dead logs used for crib walls should be at least 100 mm 4 inches in diameter for gullies and 200 mm 8 inches in diameter for use in streams or rivers. To improve survivability, live stakes and poles must be of sufficient length to penetrate the soil 600 mm 2 feet below the bioengineered structure or to within the capillary zone of moisture in the soil.

**************************************************************************

Harvest [stakes] [,] [poles] [,] [and] [cuttings] from local sources of selected species. Only import species of plants foreign to the ecosystem environment at the work site if they pose minimal threat to interfering with the native vegetation, are accepted by regulatory and environmental management, and are able to survive at the specific site. Unless otherwise stated below, provide [cuttings] [and] [stakes] that are 19 to 38 mm 0.75 to 1.5 inches in diameter and at least 1 m 3 feet in length. Use [stakes] [poles] with a diameter of 50 to 75 mm 2 to 3 inches and minimum length of 1.5 m 5 feet for insertion into armored stream bank structures. Cut [stakes] [and] [cuttings] [and] [poles] as straight as possible from healthy plants. Ensure plants for harvest are a minimum of one-year-old, preferable 2 to 5 years in age. Do not use suckers or current year growth. Ensure all cuts are clean and free of splits or excessive peeling of bark. Ensure at least two bud scars are visible on the [cutting] [stake] [pole] above the surface of the ground or structure when
installed. [Stakes] [Poles] with deviations or curvatures greater than 13 mm 0.5 inch from vertical per 200 mm 1-foot of length will not be accepted. [Trim all branches emanating from the [stake] [pole] as close as possible to the surface of the stake without damage to the bark.] [Cut the bottom end of the [stake] [pole] at an angle of 60 degrees to the horizontal. Cut the top of the [stake] [pole] normal to its length.] [Harvest live cuttings from branches and include the growth tips of the branch. Cut the butt of the cutting at an angle to the vertical to aid in placing into soil.] If trunks of vegetation remain after cutting, ensure these trunks have a sufficient number of healthy branches remaining to allow survival.

3.5.2 Harvesting of Herbaceous Plants

**************************************************************************
NOTE: Edit this section as required. Consult a qualified botanist for harvesting, handling, growing, and transplanting requirements if herbaceous plants are to be used. Herbaceous plants may be emergent aquatic plants such as reeds, rushes, and sedges or may be non aquatic plants such as grasses or other forbs that require moisture during some portion of the year. Harvesting of these plants requires the collection of seeds, roots, or tubers. The roots or tubers may be transplanted directly to the site. Plants from the roots may be grown in a nursery and subsequently transplanted to the site. Plants or roots collected in the field must be placed in containers filled with water and kept cool until being transplanted to growing media at a nursery. Exposure of the harvested plants to wind or dry and hot conditions should be avoided. Consult a wetlands expert for methods for collecting and growing of wetland plants.

**************************************************************************

3.5.3 Harvesting of Reeds or Clump Plantings

**************************************************************************
NOTE: Edit this section as required. Consult a qualified botanist for harvesting and transplanting requirements of reed or clump plantings. Single plants or groups of plants may be harvested, which include the root mass in soil plugs. Large clump plantings require the removal of vegetation with the root mass and surrounding soil intact. These larger plantings may be extracted by hand and shovel methods or the use of light or heavy equipment.

**************************************************************************

3.5.4 Sealing of Harvest Cuts

Trim all harvest cuts on trunks or branches of the host vegetation of loose wood or bark and sealed with an approved sealant to prevent desiccation and disease or infestation at the end of the workday without exception.
3.5.5 **Harvest Site Restoration**

Restore the harvest site to preexisting conditions as best as possible after harvesting is completed. Restoration includes but is not limited to removal of aggregate or wood chip roads or access paths, access gates, and ruts or depression, or other items or features related to work activities.

3.5.6 **Disposal of Excess Vegetation**

Excess cut vegetation from harvesting must be [thinly distributed on site] [collected and removed from the site] [staked on-site and [burned] [left in place]] [collected and transported to the work site for incorporation in the designed structure].

3.6 **TIME OF PLANTING**

**************************************************************************

NOTE: Edit this section as needed for site specific conditions. Provide specific dates for the planting window below.

Woody plants and nursery stock should be planted in the dormant season. These plants are dormant when buds are set in the fall after the first hard freeze until the time when the buds begin to swell in the early spring. If planting can not be done during the dormant season, then the cuttings may be stored in a cold environment at -2 degrees C 28 degrees F until planting is possible.

Herbaceous plants may be planted during the dormant or non dormant seasons. If planted in the non dormant season, these plants should be placed as early as possible in the spring to allow the greatest amount of time for root development and growth. Herbaceous plants should not be planted during hot or dry weather if at all avoidable.

The time of planting is also dependent on site climatic and hydrologic conditions. The best time to plant is when the stream or lake is at mean water level. Planting should occur in the fall at sites where the water levels are expected to be low from the fall to the spring and if the plants may experience some growth and establishment before spring floods. Planting at sites where water levels fluctuate during the winter due to flooding or where frost heaving of soil occurs should be delayed until late spring. Late fall plantings may be preferable at locations subject to winter flooding and summer droughts. Fall planting is not recommended for areas where late season droughts or frost heaving occurs below the root level. The designer should consult a hydraulic engineer to determine water levels and flow velocities at the site during the planting and initial growth periods. Clump planting of shrubs or reeds should occur in the spring or early summer.
Start planting in the [spring] [fall] [summer] no earlier than [_____] and complete no later than [_____].

3.7 TRANSPORTATION OF HARVESTED VEGETATION

a. Submerge all freshly harvested and prepared live woody vegetation immediately in clean uncontaminated water and do not allow to dry out. Transport cut vegetation to the work staging area submerged in water. If site conditions prohibit direct access to storage bins filled with water, then wrap the freshly cut live vegetation in cloth, which is thoroughly saturated with water, and transport to a storage bin filled with water within no more than one hour from the time of cutting.

b. Transport live vegetation from the staging area to the work site in containers fully covered with clean water. Remove vegetation from the containers and immediately place in the ground. In the event that access to the installation site is limited, remove vegetation from the soaking tanks and wrap in bundles that are completely covered with at least three layers of saturated highly absorbent cloth or saturated biodegradable paper product with high saturated strength. Place cloth and bundles in plastic liners for greater ease in transportation to the work site.

c. Do not leave cut vegetation uninstalled at the work site and exposed to air or heat or excessive cold for any reason. Do not soak dead [cuttings] [stakes] [poles] unless the design requires this vegetation to be flexible. Cut live vegetation that is exposed to air for longer than 15 minutes during harvesting, transportation, installation, or which were not collected or transported as specified above are not acceptable. Do not accept damaged live vegetation and replace at no expense to the Government.

d. [Transport [herbaceous plants] [nursery stock] to the work site in covered vehicles. Do not subject plants to cold or excessive heat or drying during transport. Carefully unload plants at the staging area and place in a shaded area. Water plants and maintain in healthy condition until the time of installation. Transport plants to the work site [by hand] [push cart] [vehicles] and immediately install at the site. Do not accept damaged, wilted, diseased, or dead [plants] [nursery stock] and immediately replace at no expense to the Government.]

3.8 SOAKING AND PAINTING OF LIVE WOODY VEGETATION

******************************************************************************
NOTE: Make all possible efforts to prevent the harvested live vegetation from losing moisture from the time of cutting to insertion into the ground. Soaking of the live vegetation greatly improves the ability of the plants to survive transplant into the bioengineered structure.
******************************************************************************

a. Soak all harvested live vegetation in clean water for 3 to 5 days before installation into the ground. Place live vegetation in clean, leak proof, large plastic storage containers or similar, which are at least 300 mm 12 inches longer in length than the cut vegetation. Do
not use reused or new metal drums or drums used for the containment of hazardous wastes or chemicals. Place containers in organized lines in a shaded location separated by a sufficient distance to allow access of a vehicle to the containers for the placement and removal of the vegetation. Give each container a unique identification number or series of numbers and letters that is clearly visible at the end of the container that will be approached for the placement or the removal of vegetation. Record identification numbers and reference relation to the contained vegetation for quality control and construction purposes.

b. Check water levels in the containers twice daily and add water as needed to ensure the containers are filled with sufficient water to completely cover the contained vegetation with a minimum of 50 mm 2 inches of water. Rust proof weights or clean cobbles or boulders may be used to weight down the vegetation and retain it under the water surface. Do not crush or damage the vegetation. Replace water in the containers completely with fresh and clean water every 3 days without exception. Vegetation that remains in water that has not been replaced as required will be deemed defective and will not be accepted by the Government. Water replacement schedule may be adjusted to compensate for weekends and holidays with the notification and approval of the Contracting Officer.

3.8.1 Mixing of Live Vegetation

Do not comingle vegetation of a specific species with another species during cutting, soaking, or transportation.

3.8.2 Painting of Stakes and Poles

**************************************************************************
NOTE: The painting of the tops of the live stakes and poles will reduce desiccation of the cuttings, potential for disease mortality, and allow ease in locating once installed. Perform all painting after soaking. Stakes or poles made of lumber may be painted at the option of the designer to improve visibility.
**************************************************************************

Paint the top ends of the [stakes] [and] [poles] with a latex paint diluted with water at a ratio of one part paint to one part water. The tops of the [stakes] [and] [poles] must be [dipped in the dilute paint mixture to a depth of 75 mm 3 inches after soaking] [painted immediately after planting by [brush] [spray applicator]]. The color of the paint must be [caution yellow] [safety orange]. The top ends of dead [stakes] [and] [poles] must [not] be painted.

3.8.3 Harvesting and soaking records

Prepare daily logs documenting the activities of plant harvesting, transportation, and soaking. Ensure these records contain at a minimum: name, date, weather conditions, company, location of harvest area, location of soaking area, site rehabilitation, species harvested, number of cuttings harvested, number of cuttings placed in soaking tanks, damage to cuttings, problems, and solutions to problems encountered. Clearly indicate the health of the primary vegetation from which the cuttings are obtained, diameter of cuttings and primary vegetation, length of cuttings, trimming procedures, time of cutting, time of placement in transportation bins,
handling procedures, sealing of harvest cuts, time the live vegetation is delivered and transferred to soaking tanks, and identification label of the tank in which the cuttings are placed. Include the duration of soaking of the vegetation, water quality and time and amounts of water added to the tank during soaking, time of removal of the cuttings from the tanks, time of planting of the cuttings, and procedures used for removal, transportation, and planting of the vegetation at the construction site. Ensure records are signed by the lead harvest person or person in charge of soaking and planting and provide to the on-site manager at the end of each day. Provide records to the Contracting Officer within [24] [_____] hours of completion.

3.9 STAGING AREA

**************************************************************************
NOTE: A staging area for operations may be required. This staging area should be level and of sufficient size for the positioning of numerous bins for the soaking of live vegetation before installation. The staging area should also be of sufficient size to allow parking, storage of equipment, construction of bioengineering components, work trailer, sanitation, and water tanks if necessary.
**************************************************************************

Construct a staging area at the work site for the storage of equipment, work trailer, portable sanitation, water tanks, parking, and all other materials and equipment required to complete the work. The site should have a level portion for the placement of soaking tubs for the live vegetation. [Secure staging area by an eight feet high chain link security fence to prevent vandalism or unauthorized access to the staging area.] Perform adequate surface preparation to prevent excessive settlement, ponding of water, or rutting. Show location and design of the staging area in the drawings.

3.10 SITE DRAINAGE

**************************************************************************
NOTE: The designer should specify the site specific requirements for temporary and permanent drainage in this section. Work and harvest sites should be well drained at all times to prevent the ponding of water. Runoff water may need to be stored in retention or settling ponds before release to surface water bodies or channels. Remove all temporary drainage features and structures and restore to preexisting or design conditions at the end of work. Drainage may be a requirement for structure stability and for final grade of the work site. Some structure may require internal drainage of groundwater to improve stability. The requirements for internal drainage design should be stated in the requirement paragraph of the selected structure. Employ Best Management Practices in accordance with Section 01 57 19 TEMPORARY ENVIRONMENTAL CONTROLS.
**************************************************************************
3.11 DEWATERING

NOTE: Excavations may need to be dewatered to allow construction. Failure to due necessary site investigation or characterization may result in construction delays, unsafe working conditions, and cost claims.

It is important to understand the subsurface groundwater conditions, surface drainage, and precipitation in the area of the work during the selection and design of a structure. Water in excavations may delay work efforts, interfere with proper soil placement and compaction, and damage vegetation. Structures that incorporate large amounts of woody vegetation may be damaged due to buoyant forces if these excavations fill with water before sufficient material or binders have been placed to hold the vegetation in place. Water removed from excavations may require treatment before release.

Excavations adjacent to tidally influenced water bodies offer challenges in water control and drainage of excavation in terms of construction timing. Time of construction and dewatering may need to be adjusted to match tidal events and require work during time periods other than normal working hours. Similarly, work schedule and dewatering of excavations may need special attention adjacent to rivers or streams that fluctuate seasonally or daily due to water releases from water storage or hydropower projects. In areas where water levels fluctuate, precautions should be taken to ensure the structure will not be damaged by buoyant forces or by currents.

Dewatering of excavations can be expensive due to planning, equipment, labor, and disposal efforts. Alternative designs, locations, or foundations should be considered to reduce project costs if required. Groundwater should be tested for chemical contamination before the start of work. The cost of dewatering and treatment of such water may be high.

Submit overall plan for dewatering and any required diversion of water. Completely address in the plan installation and removal of the required systems and features. Dewater for construction, obtain and review all necessary information to ensure dewatering efforts are in compliance with regulations, and ensure the designed dewatering efforts are adequate based on site conditions and climate and other variables that may effect dewatering efforts. [Submit a technical memorandum detailing all dewatering requirements, locations, methods, and disposal procedures to the Contacting Officer at least [60] days before the start of work.]

Information provided by the Government regarding dewatering requirements
and site conditions in no way relieve the Contractor of full responsibility for all dewater planning, efforts, and costs. Ensure the structure will not be damaged by buoyant forces or by currents should water enter the excavation or during the removal of this water. Ensure dewatering efforts do not impact adjacent structures or property, result in instability of the excavation floor or slopes, produce unsafe working conditions, or damage to animals or the environment.

3.12 BIOENGINEERED STRUCTURES

**************************************************************************
NOTE: The most common types of bioengineered structures are described below. These structures may be categorized as common, transverse, deflector, or longitudinal. Common structures are generic bioengineered structures applicable to gullies, stream banks, and lake shores. Transverse structures are constructed across stream channels that are less than 4.5 m 15 feet wide and 3 m 10 feet deep. Deflector structures are constructed from the bank into a stream or river to deflect flow away from the bank. Longitudinal structures are constructed parallel to stream banks or lake shores. Bioengineered structures may be used separately or in combination for bank protection and stabilization depending on the geotechnical and hydraulic site conditions, physical setting, desired habitat, and supply of construction materials. Structures not pertinent to the proposed design should be deleted from this specification. Structures described below are:

Common Structures
Permanent seeding
Live Staking
Joint planting
Pole planting
Live fascine
Siltation structures
Brush mat
Clump planting

Transverse Structures (streams less than 4.5 m 15 feet wide, gullies, small tributaries)
Palisade
Brush and stone sill
Wattle fence sill
Vegetated crib wall or wood sill
Vegetated dry stone barrier
Brush works or brush packing
Live fascine sill

Deflectors (Streams wider than 9 m 30 feet, stream bank protection)
Vegetated deflector (groins, dikes, spurs)
Live brush sill
Brush transverse
Brush grid

Longitudinal Structures
Single or clump reed planting
Live stone revetment
Brush layered revetment
Longitudinal live fascine
Longitudinal brush packing
Live crib wall

The specific names for bioengineered structures have not been standardized. The names of the structures listed above are not inclusive of all structures mentioned in literary sources and only represent a general compilation of the most commonly referenced names assigned to the structures. Therefore, individuals may have a different understanding of the function and design of a structure when provided with only a name. A diagram of the proposed structure is recommended for inclusion in this specification to provide clarity in the description and intent of the requirements. The designer may obtain these drawings from numerous literary sources, private vendors, or State resource agencies. It is recommended that the designer review these drawings during the selection of the structures for use and that the designer should provide these drawings to other personnel involved in the design and planning of the project to reduce confusion in design objectives and requirements. These drawings may be edited for site specific conditions as needed and should be included in or attached to this specification.

The following paragraphs provide the general types of information that are required for the description of requirements for the structures. The designer must edit the selected requirements to meet project objectives and performance criteria based on actual site conditions.

3.12.1 Common Structures

3.12.1.1 Permanent Seeding

NOTE: Permanent seeding is a simple method of stream bank stabilization that may be used along low velocity streams or channels with peak flows less than 0.08 cubic meter per second 3 cubic feet per second. Seeding must be combined with erosion control stabilization methods to prevent or reduce soil erosion during germination and the first several years of vegetation growth. Selected species of grasses and/or plants should be native to the area, resilient, provide a dense root mat, and be able to withstand being submerged in water for extended periods. The placement of rock or woody debris may be required at the toe of the bank to reduce undercutting.

Select seed conforming to all required regulations and requirements and
perform all seeding in accordance with Section 32 92 19 SEEDING. Place seed before installation of erosion control mats or the application of other erosion control materials or products.

3.12.1.2 Live Staking

**************************************************************************
NOTE: Live staking is the insertion of living stakes of vegetation into the ground. Live staking may be used to cover large areas of stream banks and to infill areas between other bioengineered structures. Live poles may also be used in lieu of stakes if deeper ground penetration is required. In this event, the method should be referred to as live pole staking. Combining live stakes with dead stakes may be feasible where the trapping of debris on the bank is desired or where there is a limited supply of local live vegetation.
**************************************************************************

Drive live stakes into the ground in a row parallel to the stream bank with the stakes spaced 1 meter 3 feet apart. Install rows of stakes starting from the toe of the bank and progressing landward and space 1 meter 3 feet apart. Offset successive rows of stakes from the preceding row by one half the spacing distance between the stakes. Perform construction in accordance with ASTM D6765 Standard Practice for Live Staking.

3.12.1.3 Joint Planting

**************************************************************************
NOTE: Joint planting is a variation of live staking in which live stakes or poles are driven between the joints of large natural stone, rip rap, or other forms of bank armor. This method may be used to add vegetation to stretches of stream bank, which are protected by barren armor to improve habitat and add areas of shade. Vegetation will improve bank stability due to the development of root mats. The vegetation will also decrease the velocity of water adjacent to the bank during high flow events. Caution is advised to check the stability and condition of the armor before using these methods on existing protected banks. The amount of sediment that may accumulate on the back as a result of the vegetation should be considered in long term design performance since the deposition of large amounts of sediment may overload the bank and result in failure.
**************************************************************************

Install live [stakes] [poles] in rows parallel to the stream bank with the [stakes] [poles] driven into joints between the [stones] [rocks] of the bank armor. Drive [stakes] [poles] a minimum of 600 mm 2 feet into the soil behind the armor and space 1 meter 3 feet apart. Incline [stakes] [poles] at 15 to 45 degrees from horizontal. Install rows starting at the toe of the bank and progressing landward and space 1 meter 3 feet apart. Offset [stakes] [poles] in successive rows from the [stakes] [poles] in the preceding row by half the spacing distance. Extend tops of the [stakes] [poles] at least 0.5 m 1.5 feet but no more than 1 meter 3 feet above the top of the armor.
3.12.1.4 Pole Planting

**************************************************************************
NOTE: Pole planting is the placement of vertical live or dead poles in multiple rows along the toe of a stream bank. The poles may trap debris between the poles and between the poles and the bank. The accumulation of debris should reduce the flow velocity adjacent to the bank and encourage the deposition of sediment and thus promote the aggradation of the bank over time. The structures will not provide immediate erosion protection, habitat, or bank stability. Erosion protection and habitat should develop as debris is trapped and the vegetation begins to grow. The stability of the bank should improve over time as new bank is formed and vegetation and root mats become established in the new bank material. Pole planting may be used in areas with steep or vertical banks or in areas with a limited supply of the vegetation that is necessary for the construction of other types of bioengineered structures. Pole plantings may be combined with brush mats or brush grids. Pilot holes may need to be drilled to allow the installation of the poles in coarse alluvial streambeds. Pole planting is not recommended for use in stream channels that contain large boulders or where bedrock may be within a few feet of the channel bottom. The depth to scour must be known to ensure the poles will not be lost due to degradation of the stream bottom during a flood event.
**************************************************************************

Drive live poles vertically into the stream bed to a minimum depth of 1 m 3 feet. [Extend no more than one-half the length of the pole below grade above the ground.] [Drive poles to refusal.] [Drill pilot holes at the locations where the poles are installed using a steel rod or mechanized drilling machine. Place poles into the holes and compact loose sediment around the poles in place. Add additional sediment as needed to fill any space between the pole and the inner wall of the pilot hole until the hole is filled to the existing surface.]

a. Ensure poles are straight and at least 100 mm 4 inches in diameter. Shape driving tip to a point to aid in installation. Branches must [not] be stripped from the pole [where exposed above grade after installation]. Cut the top of each pole normal to its length.

b. Install poles in rows parallel to the stream bank at a nominal spacing of 1 m 3 feet. Install rows starting at the toe of the bank and progressing towards the stream channel to the mean low water level. Offset poles in successive rows from the poles in preceding rows by one half the spacing distance. Ensure tops of the poles are at a uniform elevation [of 1 m 3 feet] above the mean low water level along the bank.

3.12.1.5 Live Fascine

**************************************************************************
NOTE: Live fascines are long bundles of live or
dead branch cuttings tied together in tubular sections from 1 to 10 m 4 to 30 feet in length and up to 300 mm 1-foot in diameter. Smaller diameters and lengths of fascines are advantageous in areas where access by vehicles is not possible and materials must be provided to the site by manual labor. Fascines are recommended for sites close to large supplies of vegetation. Fascines are advantageous in stabilizing slopes of long length and for protecting the toes of banks. The structures are effective in reducing erosion on sloped banks that are subjected to bank scour or high surface runoff. The horizontal arrangement of fascines will reduce erosion and trap sediment and seed on the slope. The structures will deflect and insulate the bank from the stream current.

The stability of the bank will improve as the live vegetation develops root systems. Steep or undercut banks must be reduced in slope to provide a stable slope for construction and installation of the fascines. Banks that have experienced sloughing or rotational failures must be repaired by the removal of the failed material and the reconstruction of a stable surface before the installation of the fascine structures.

Fascines require large amounts of live vegetation for construction. Therefore, these structures are best suited for temperate regions where there is a significant supply of available and suitable vegetation near the work site. Staggered fascine structures are recommended in areas with limited supplies of vegetation or as a means to reduce project costs. Fascines are suitable to protect the toes of banks when used in combination with other bioengineering methods on the slopes. Fascines may be used at transition areas between different types of erosion or stabilization structures such as between erosion control mats and live siltation structures at the toe of a stream bank, or with brush mats or layered structures.

Fascines may be referred to as horizontal or vertical structures. Horizontal fascines are placed parallel to the stream channel. These fascines will reduce bank erosion by scour and surface runoff. The recommended spacing between horizontal fascines based on bank slope are:

<table>
<thead>
<tr>
<th>Slope</th>
<th>Slope Distance Between Trenches (mft)</th>
<th>Maximum Slope Length (mft)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1H:1V to 1.5H:1V</td>
<td>0.9-1.23-4</td>
<td>4.515</td>
</tr>
<tr>
<td>1.5H:1V to 2H:1V</td>
<td>1.2-1.54-5</td>
<td>620</td>
</tr>
<tr>
<td>Slope</td>
<td>Slope Distance Between Trenches (mft)</td>
<td>Maximum Slope Length (mft)</td>
</tr>
<tr>
<td>------------------</td>
<td>--------------------------------------</td>
<td>---------------------------</td>
</tr>
<tr>
<td>2H:1V to 2.5H:1V</td>
<td>1.5–1.85–6</td>

<td>2.7–39–10</td>
<td>18.360</td>
</tr>
</tbody>
</table>

Vertical fascines are placed normal to the stream channel. These fascines may be used to serve as drainage conduits between the key trenches of horizontal fascines and are recommended in temperate regions and banks composed of poorly drained soils. Vertical fascines may be used to protect the bank from scour. Determine the spacing of the vertical fascines by site conditions, but should be close enough to prevent scour of the bank between the vertical bundles.

The trenches for the horizontal fascines may extend the full width of the work area or may be of shorter length and staggered to reduce the amount of material and labor required for the project. Key trenches must be installed at the toes of banks for horizontal fascine structures. The key trenches may be filled with natural stone and live and/or dead fascines up to three bundles in height. The ends of all trenches should be keyed into the bank or protected with large natural stone to prevent scour.

The trenches for vertical fascines should extend from the crest to the toe of the bank if these fascines are used without other structures on the slope. The trenches for the vertical fascines may extend between the trenches of horizontal fascines if used in combination. In this case, the vertical fascine trenches should connect the lowest portions of the horizontal fascine trenches to allow drainage. Trenches for both horizontal and vertical fascines may be installed landward of the crest of the bank if additional protection is desired and sufficient room for these trenches is available.

Fascines composed of live cuttings may be placed on bank slopes to the mean high water level of the stream. Live cuttings capable of growth under saturated conditions may be placed in the stream and in key trenches to elevations below the mean water level. Dead cuttings may be used for fascines placed in saturated conditions or may be interwoven with live cuttings to provide added resiliency to live fascines. Fascines composed of dead cuttings may also be used separately at the toe or on the bank slopes where erosion and scour protection are desired and other bioengineered or hard structures
are used for bank stability. Fascines should be wrapped with erosion control matting when installed in fine-grained cohesionless soil to reduce erosion of backfill.

Fascines should not be constructed on the ground. Elevated tables or braces should be used for assembly. All fascines bundles should be constructed by laying live cuttings parallel to one another with all growth tips oriented in the same direction. The cuttings should have a minimum of 300 mm 1-foot of overlap on successive layers. The live vegetation cuttings should be secured into a bundle using biodegradable binders spaced every 450 to 600 mm 1.5 to 2 feet along the length of the bundle. The fascines should be carried to the installation site in a manner that prevents excessive bending or breakage. Fascines with broken or loose cuttings due to excessive bending or the failure of binders must be repaired or replaced at no expense to the Government.

3.12.1.5.1 Horizontal Fascines

Install all trenches parallel to the direction of the bank contours. All trenches must be 450 mm 18 inches wide and no more than 50 mm 2 inches deeper than the diameter of the fascine bundles.

a. Excavate a key trench [at the toe of the bank] [at the mean [high] water level] [at the location shown on the drawings] [to a depth of 1 m 3 feet below the mean high water level] and extend the full length of the working area. Make trenches up slope of the key trench [the same length as the key trench] [3 m 10 feet in length and separate by a spacing of 3 m 10 feet longitudinally. The midpoints of the trenches placed up slope must coincide with the midpoints of the spaces between the down slope trenches]. Space trenches 1.2 m 4 feet apart. Install a trench at the toe and at two feet below the crest of the bank regardless of spacing interval. Extend these trenches the full length of the work site. [Place at least [2] [_____] trenches landward of the crest of the slope at a spacing of 1.2 m 4 feet.] Ensure all trenches are [keyed into the bank slope] [and] [filled for a distance of 1 m 3 feet with large natural stone at the up stream and down stream ends of the trenches].

b. Place the fascine bundle in the center of the trench with at least 50 mm 2 inches of the bundle exposed above the top of the existing grade of the stream bank. The junction between the ends of adjacent fascine bundles in the same trench must be [offset side-by-side] [interwoven with each other] for a distance of 300 mm 1-foot. Anchor fascine bundle in the trench with [live] [and] [dead] [stakes] [and] [poles] that are at least 50 mm 2 inches [square] [in diameter] at the top, 700 mm 2.5 feet in length, and taper from the top to the base. Drive [stakes] [poles] vertically through the fascine until flush with the top of the bundle starting 1-foot from the end of each fascine and space every 1 m 3 feet thereafter. Drive a terminal [stake] [pole] 300 mm one-foot from the end of the fascine regardless of spacing interval. Do not drive [stakes] [poles] through or within 150 mm 6 inches of the binders. Drive live [stakes] [poles] into the slope on
the downhill side of the fascine bundle at an angle not to exceed 45
degree from vertical. Place [stakes] [poles] at the midpoint between
the anchor [stakes] [poles] and contact the underside of the fascine,
but do not penetrate the fascine. Extend at least 75 mm 3 inches of
these downhill live [stakes] [poles] above the ground surface. Place
soil and lightly tamp into place around the fascine and brush into the
voids in the fascine until only the top of the bundle is partially
exposed. Slope top of the backfill towards the back of the fascine
trench to prevent overtopping by runoff and to retain water and
sediment.

c. [Place a single fascine in the key trench.] [Stack up to [3] [_____] fascalines on top of one another in the key trench.] Drive live poles
vertically into the ground to a minimum depth of 600 mm 2 feet to
secure the [stacked] fascine bundle(s) in the key trench. Extend these
poles at least 600 mm 2 feet above the top of the upper most bundle.
Backfill key trenches with compacted [removed sediment] [select fill]
to match the [existing] [final grade of the] surface.

3.12.1.5.2 Vertical Fascines

Install trenches normal to the bank contours and space 3 m 10 feet apart
starting from the up stream end of the work site. Place a trench at the
down stream end of the work site regardless of spacing interval. Extend
trenches [from the [toe of the bank] [key trench]] to [the crest of the
bank] [3 m 10 feet landward of the crest of the bank]] [between the
horizontal fascine trenches. Offset vertical trenches by 1.5 m 5 feet
between horizontal trenches to prevent through flow of drainage]. Make all
trenches 450 mm 18 inches wide and no more than 50 mm 2 inches deeper than
the diameter of the fascine bundles. [Excavate a key trench parallel to
the bank contours at the [toe of the bank] [mean high water level] and
extend the full length of the working area. Fill key trench with
horizontal fascine bundles as specified above in paragraph HORIZONTAL
FASCINES].

a. Place fascine bundle in the center of the trench with at least 50 mm 2
inches of the bundle exposed above the top of the existing grade of the
stream bank. The junction between the ends of adjacent fascine bundles
in the same trench must be [offset side-by-side] [interwoven with each other]
for a distance of 300 mm 1-foot. Anchor fascine bundle in the
trench with [live] [and] [dead] [stakes] [and] [poles] that are least
50 mm 2 inches [square] [in diameter] at the top, 700 mm 2.5 feet in
length, and taper from the top to the base.

b. Drive [stakes] [poles] vertically through the fascine until flush with
the top of the bundle starting 300 mm 1-foot from the end of each
fascine and space every 1 m 3 feet thereafter. Drive a terminal
[stake] [pole] 300 mm one-foot from the end of the fascine regardless
of spacing interval. Do not drive [stakes] [poles] through or within
150 mm 6 inches of the binders. Drive live [stakes] [poles] into the
slope on the up stream and down stream sides of the fascine bundle at
an angle not to exceed 45 degree from vertical. Place [stakes] [poles]
at the midpoint between the anchor [stakes] [poles] and contact the
underside of the fascine, but do not penetrate the fascine. Extend at
least 75 mm 3 inches of the up stream and down stream live [stakes]
[poles] above the ground surface.

c. Place soil and compact into place around the fascine and brush into the
voids in the fascine until only the top of the bundle is partially
3.12.1.6 Siltation structures

**************************************************************************

NOTE: Siltation structures are composed of live or dead cuttings that are placed parallel to the toe of a stream bank at or below the mean high water elevation of the stream. These structures provide immediate erosion protection, fish habitat during high flow events, and trap sediment that results in bank aggradation. The structures deflect the current in the stream away from the toe of the bank to prevent scour and undercutting. The stability of the bank is improved as root systems develop.

Siltation structures are recommended for sites with low flow velocities such as the insides of meander bends, side channels, and in areas of bank scour behind obstructions. The structures are well suited for locations where the development of new bank is desired. Siltation structures should be combined with large natural stone, coir logs, root wads, or other hard structures if used in areas subject to high flow velocities and scour.

The structures may be constructed of live or dead cuttings. Live cuttings should be 1 to 2 m 3 to 6 feet in length, flexible, and from species of plants with do not mature to heights greater than 3 m 10 feet. Side branches may remain on the cuttings. Live cutting structures should be placed at the mean high water elevation of the stream to allow growth of vegetation unless the selected species is capable of root generation under saturated conditions.

Dead cuttings may be incorporated into a live structure to improve its resiliency and resistance to abrasion by sediment and debris. The dead cuttings may be from any locally available species of vegetation. Structures composed completely of dead cuttings are suitable for areas were temporary bank aggradation and erosion protection are desired. Dead cutting structures may be placed above or below the mean high water level of the stream. If the dead structure is placed below the mean high water level, it is recommended that large natural stone be placed on the cuttings to reduce floating of the cuttings. More than one row of live or dead siltation structures may be placed along a stream bank to increase the width of coverage.

Siltation structures may be placed on the stream bank normal to the toe of the bank and oriented up to 15 degrees down stream from the perpendicular to the toe. Theses structures are recommended for low slope banks to reduce erosion of low banks, improve bank stability due to root development, and for
areas where sedimentation is desired. The spacing between these structures should be determined based on actual field conditions and flow velocities to prevent scour between the structures. Live stakes or poles may be placed between the siltation structures.

**************************************************************************

a. The siltation structure must [be parallel] [normal] to the contours of the bank. Compose the structure of [live] [dead] [live and dead cuttings, comprising [80 percent] [and] [20 percent] of the structure, respectively]. Provide cuttings that are 1 to 2 m 3 to 6 feet in length [and flexible] with side branches attached.

b. Place cuttings in a trench that is excavated [at the toe of the bank] [1 m 3 feet from the toe of the bank towards the stream channel] [as shown on the drawings]. The trench must [be parallel to the bank contours and at the mean high water elevation.] [extend the entire length of the work site.] [[normal] [inclined at 15 degrees down stream to the bank contours.]] [Extend the trench from the toe of the bank to the mean water elevation of the stream.] Ensure all trenches are 600 mm 2 feet deep with a 'V' shaped cross section. [Space trenches 1 m 3 feet apart.] [Key all trenches 1 m 3 feet into the stream bank.]

c. Push ends of the cuttings vertically into the bottom of the trench along the centerline with the growth tips extending 450 mm 1.5 feet above the top of the trench. Place cuttings to form a layer that is 150 mm 6 inches thick with at least [15] [_____] cuttings per 300 mm linear foot of trench. Place large natural stone on either side of the bases of the cuttings and place backfill to infill between the stones to the top of the existing [design] grade. [Protect the stream side portion of the structure and the toe of the bank with [coir logs] [exposed dead fascines] [large natural stone with joint plantings of [live] [and] [dead] [poles] [stakes] [root wads]]. Protect the ends of the structure with large natural stone placed on the up stream side of structure where it ties into the stream bank.

3.12.1.7 Brush Mat

**************************************************************************

NOTE: A brush mat is composed of live or dead cuttings that are placed on the stream bank to form a densely packed layer of cuttings. These structures provide immediate erosion protection, habitat for fish during high flow events, and the rapid establishment of extensive root systems in the bank. Brush mats are well suited for erosion protection of banks damaged by flooding. The growth of the vegetation composing the mat structure may be improved by placing an initial lift of brush and covering it with soil and then placing a second lift of brush to the design surface. The mat is held in place by anchor stakes or poles and further secured to the slope by rope or binding products that are laced between the anchor poles. Erosion control matting may be installed beneath the brush mat to reduce erosion of slope soil, especially if this soil is poorly compacted or easily eroded.
Brush mats require large quantities of vegetation and labor for construction. If an insufficient supply of live cuttings is available, then dead cuttings may be intermixed with the live cuttings in approximately equal portions. Dead cuttings should be flexible to allow construction and interweaving with the live cuttings. The base of the mat at the toe of the bank should be secured with rock or longitudinal bioengineered structures to prevent erosion or damage of the mat. The cuttings for the mat may be placed in small trenches cut into the face of the bank or pushed directly into the slope without the excavation of trenches.

**************************************************************************

a. Provide [live] [and] [dead] cuttings that are generally straight, supple, 1.5 m 5 feet long, and with lateral branches still attached. Shape cut ends of the cuttings to sharp tips for penetration into the stream bank. Place cuttings in rows parallel to the contours of the bank starting 1 m 3 feet below the bank crest. Space rows every 600 mm 2 feet thereafter down slope to the toe of the bank. Extend all rows the full length of the work site.

b. Push cut ends of the cuttings into the bank at the same contour elevation for each row with the growth tips toward the top of the bank. Orient the cuttings [normal] [at an angle of 15 degrees down stream from normal] to the bank toe. Place at least 15 cuttings per 300 mm liner foot in each row. Use a light roller and foot pressure to push the cuttings of subsequent rows against the bank over the cuttings of preceding rows to achieve a mat thickness of 100 mm 4 inches. [Place up to 15 percent of the cuttings parallel to the slope of the bank and interwoven with the cuttings that are placed with the growth tips toward the top of the bank. Use these parallel cuttings to reinforce the brush mat. Orient the growth tips of the parallel cuttings down stream.] Continue process of placing and compressing cuttings down slope until the toe of the bank is reached. Place a row of cuttings along the toe of the bank regardless of spacing interval.

c. Protect toe of the bank by [large natural stones] [[live] [dead] fascines] [coir logs] that overlie the base of the cuttings of the row at the toe of the bank. [Install an erosion control mat on the prepared grade of the bank slope before the placement of the cuttings.] [Extend ends of the mat 1.2 m 4 feet over unprepared bank.]

d. Drive [live] [dead] anchor stakes that are 50 mm 2 inches in diameter through the mat and 600 mm 2 feet into the stream bank. Do not extend the tops of these stakes more than 300 mm 1-foot above the top of the mat. Place stakes in rows parallel to the bank contours starting at the crest of the bank with the stakes spaced 1 m 3 feet apart. Space subsequent down slope rows every 1 m 3 feet to the toe of the bank. Install a row of stakes along the toe of the bank regardless of spacing interval to anchor the base of the mat. Notch the top of each anchor stake with a 13 mm 1/2-inch deep triangular cut that is normal to the length of the stake and 25 mm 1 inch below the top of the mat when compressed by foot pressure adjacent to the stake.

e. Secure the up stream and down stream ends of the mat with anchor stakes that are placed with a spacing interval equal to one half the above
specified spacing distance of stakes in the rows. Extend the one half distance spacing of stakes for 1 m 3 feet towards the center of the structure from the up stream and down stream ends of the mat and extend from the base to the top of the mat at these locations.

f. Secure mat to the slope using binding ropes. Lace ropes across the mat in a diagonal. Secure a single length of rope to a stake in the row of stakes at the toe of the bank. Secure rope to each stake that is oriented diagonally to this stake in a single direction from the toe of the bank to the crest of the bank. Tie together ropes that cross between stakes. Secure ropes parallel and normal to the slope along the rows of stakes and to the stakes that lie in a line from the crest to the toe of the bank. Tie these ropes together where they meet between stakes. Secure all ropes to the stakes with non raveling knots. Allow no more than 150 mm 6 inches of rope to remain at the ends of the rope lengths after they are installed.

g. Brush [removed soil] [select fill] into the mat to within 50 mm 2 inches of the top of the structure.

3.12.1.8 Clump Planting

**************************************************************************

NOTE: Clump planting requires the excavation, transport, and placement of live vegetation with root wads and attached soil. This planting method is recommended for establishing vegetation on steep banks of limited height and on the upper banks or floodplains of a stream where the plants will not be subjected to long periods of inundation by water and where adequate moisture is available. Plantings should not be subjected to erosion, flooding, animal traffic or grazing, dry conditions, or high winds during the first several years after installation. Minor earthwork is recommended to reduce vertical faces or remove undercut slopes from the bank to limit the loss of plant clumps due to scour or flooding. Selected woody vegetation should not grow to large mature trees, which could induce scour and loss of the bank due to obstruction of the stream flow or the rotation of the tree into the stream channel and creation of a large hole as the root wad is pulled from the bank. Heavy equipment may be required if plant clumps or root wads are too large to be easily moved by manual efforts. The toe of the stream bank should be protected from erosion by the placement of large natural stone, erosion control matting, or construction of longitudinal bioengineered structures. Irrigation and fencing may be required to ensure the survivability of the plants.
**************************************************************************

a. Prepare stream bank for clump planting by excavating 600 mm 2 feet deep holes with floors that slope into the bank and that are at least 150 mm 6 inches longer and wider than the same dimensions of the removed clumps. Ensure the floors of these holes are not within 150 mm 6 inches of the groundwater table. The excavations must be [spaced at 2 m 6 feet and separated by 1 m 3 feet of existing bank] [1 m 3 feet in
width, continuous, and separated by 1 m 3 feet of existing bank] along the extent of the work site. Use removed soil as backfill. [Remove excess soil from the excavations from the site.] [Thinly spread excess soil from the excavations on the upper bank landward of the clump plantings.] Roughen and seed exposed surface of the backfill [and cover with erosion control products].

b. Locate suitable species for transplant in the vicinity of the work site. Do not allow plant species to mature to heights greater than 4.5 m 15 feet or trunk diameters exceeding 100 mm 4 inches. Ensure clumps of plants do not exceed the width of the removal equipment. If clumps are removed by hand, ensure these clumps do not exceed 1 m 3 feet in any dimension. Remove clumps with existing soil and as many shallow roots as possible to aid in growth and survival, and transport immediately to the work site and place.

c. Prior to placement, flood the excavation with water to moisten the soil and aid in plant survival. Place plant clumps with vegetation [standing vertically] [slightly inclined towards the stream] and firmly push into the soil at the base of the excavation to prevent rafting. Drive at least [3] [_____] [dead stakes] [or] [live poles] driven through each clump to secure it to the bank. Place biodegradable coir net with a minimal life of 2 years on top of the soil of the clump and extend 1 m 3 feet onto the bank beyond the limits of the excavation.

3.12.2 Transverse Structures

NOTE: Transverse structures consist of live vegetation or a combination of live vegetation and hard material (dead vegetation, logs, rock, and natural stone) that are constructed normal to and across small stream or river channels or narrow gullies. These structures are recommended for streams with low flow, intermittent streams, or dry gullies subject to flow after precipitation events. The harder structures may be used in narrow channels that experience infrequent or seasonally torrential flows.

The transverse structures function as weirs and drop structures, which reduce the velocity of stream flow, bed degradation, and may result in the transformation of the channel profile to a stepped profile due to the retention of sediment and debris. The reduction in flow velocity aids in reducing bank erosion. In addition, these structures may be placed at the toe and parallel to the stream bank, thus directly improving bank stability and reducing undercutting and erosion especially in areas with banks composed of low cohesive materials. Structures should be placed with key trenches into the banks to improve stability and to prevent the by pass of the structure due to lateral erosion of the bank.

Advantages of transverse structures are ease of construction at remote sites using locally available materials and the establishment of habitat with
time. A primary disadvantage of these structures is that they may obstruct fish passage and may reduce the conveyance of the channel resulting in local flooding. Therefore, the structures should be designed to allow fish passage and constructed of supple vegetation that matures to minimal height. Some transverse structures require significant amounts of manual labor and may not be economical in areas of limited vegetation supply. Periodic maintenance may be required to remove excessive amounts of trapped debris to prevent possible flooding, fire dangers, build up of decomposing plant material, or heath hazards caused by habitation of the debris by insects or vermin or trapping of dead fish or animals. These structures may be combined with other forms of live and dead bioengineered structures and hard structures such as gabions, or riprap.

Stagnant water may become present behind transverse structures depending on site conditions. These areas of stagnate water may become breeding grounds for mosquitoes or other insects and undesirable aquatic plants and animals. The designer will include adequate drainage features in the design to remove water from behind the structure, such as open channels, drainage pipes, or passive subsurface drains.

3.12.2.1 Palisade

NOTE: A live palisade is a weir composed of live poles, which develops into a transverse zone of vegetation that crosses the stream channel. These structures may be installed rapidly, are easy to construct, and provide shade to the stream channel as the vegetation matures. Palisades are best suited for small gullies or streams in low-lying areas that are less than 10 m 30 feet wide and 4 m 12 feet deep. The streambed should consist of loose sand, silt, or soft clay to allow easy installation of the poles used in the construction of the palisade. A steel rod may be required to install pilot holes for the driving of the poles in medium to hard clay, dense sand, sand with fine gravel, and medium dense silt. Palisades may be installed in coarse alluvial streams if placed in a trench excavated in the streambed. These structures in coarse alluvial systems should be viewed as temporary and expendable since they may be damaged by bed load and large debris transported during periods of high flow.

A palisade may be constructed entirely of dead poles if the project objective is the temporary stabilization of the stream channel. These structures will not become reinforced with time by
root structures and will deteriorate. However, depending on the site conditions, these structures may be adequate for the retention of sediment on which native grasses and vegetation may take root, thus resulting in the evolution of the dead structure to a live transverse brush sill. Dead palisades may be used in coarse alluvial streams since the establishment of a vegetated structure is not expected and may not be desired.

The live or dead poles should be driven a minimum of 600 mm 2 feet into the streambed for poles under 1.5 m 5 feet in length. Poles over 1.5 m 5 feet in length should be driven a minimum of 1 m 3 feet into the streambed. The poles should be harvested from local vegetation and should be a minimum of 38 mm 1.5 inches in diameter. The bottoms of the poles should be formed to sharp points to aid in the driving of the poles into the streambed.

The live or dead poles should be driven a minimum of 600 mm 2 feet into the streambed for poles under 1.5 m 5 feet in length. Poles over 1.5 m 5 feet in length should be driven a minimum of 1 m 3 feet into the streambed. The poles should be harvested from local vegetation and should be a minimum of 38 mm 1.5 inches in diameter. The bottoms of the poles should be formed to sharp points to aid in the driving of the poles into the streambed.

The strength of the palisade may be increased by attaching a cross beam to the structure. A cross beam is recommended for palisades with widely spaced or thin poles and that have a height greater than one-foot above the streambed. The cross beams should be at the same height and inclination on both sides of the palisade. The beams are attached to the palisade with binders composed of untreated coir or hemp rope that is capable of withstanding several years of exposure. The binder must be looped and tied around the cross beams and the adjacent poles in a manner that tightly secures the members together. The binders should not unravel if a portion of the binder or structure is lost or damaged. Cross beams may be composed of untreated dimensional lumber or straight poles of similar diameter as the palisade poles.

**************************************************************************

a. Provide live poles that are 1 m 3 feet long, 38 to 100 mm 1.5 to 4 inches in diameter, and cut the bottom ends of the poles to form sharp drive points. Drive poles vertically into the streambed to a minimum depth of 600 mm 2 feet and place across the channel in a [straight row] [row that is deflected down stream by 15 degrees] ['V'-shaped row pointing down stream with the apex at the center of the channel]. Space poles no less than 50 mm 2 inches but no greater than 150 mm 6 inches. [Extend center poles of the structure a maximum of [300] [600] mm [1] [2]-foot above the existing grade of the streambed.] [Use dead poles for center poles and place for a distance of 1 m 3 feet about the centerline of the structure.] [Compose central span of the structure of large natural stone keyed 600 mm 2 feet into the streambed with a top elevation 300 mm 1 foot above the existing streambed. Extend the stone 600 mm 2 feet on each side of the centerline of the structure and tightly butt with [live] [dead] poles of the palisade structure.] [The tops of the poles must increase in height outward from the center of the structure by no more than 15 mm 0.05-foot for each adjacent pole to form a notch at the center of the structure.] [The tops of the poles must be at the same elevation.] Place ends of the structure in key trenches that extend 1 m 3 feet into the stream bank.
b. Attach cross beam members of untreated [straight 25 by 100 mm 1 by 4 inch dimensional lumber] [long straight poles at least 50 mm 2 inches in diameter] to the palisade with binding products; wrap at least two times around the cross beam and adjacent pole. Install binding products to prevent raveling of the binder in the event of the loss of a portion of the binder or structure. Place [horizontal] [inclined] cross beam members at the same elevation on each side of the palisade and extend the entire width of the structure. Use beams that are 600 mm 2 feet greater in length than the structure and place the ends of the beams in key trenches in the bank. Excavate key trenches to the depth and width necessary for the placement of the ends of the cross beams and backfill with soil removed by excavation.

c. Compact sediment in the streambed around each pole using a tamping bar. [Place sediment removed from the streambed for the installation of the poles as compacted backfill around the poles.] Place dead cuttings and excess live cuttings in a criss-cross pattern on the up stream and down stream sides of the structure for a distance of 600 mm 2 feet and pack tightly against the stream bank at the ends of the structure to a thickness of 150 mm 0.5-foot for 600 mm 2 feet beyond the limits of backfill exposed at the key trenches.

3.12.2.2 Brush [and Stone] Sill

**************************************************************************
NOTE: Brush sills are transverse structures similar to palisades, but composed of live or dead cuttings. These structures reduce stream channel degradation, are easy to construct, and may be combined with natural stone to improve performance. Selected vegetation should mature to low height, remain supple with time, and be capable of good root mat development. Live or dead cuttings may be used for the structure and the cuttings may retain small branches and do not need to be straight. Sills may also be placed along the toes of stream banks separately or adjacent to the transverse brush sills. Sills do not trap large amounts of sediment or debris since the vegetation used in construction is pushed against the stream channel during high flow events and does not form an obstruction to flow. Therefore, these structures are suitable for channels where minimal changes to the stream profile are desired. Sills may be constructed in most types of alluvial material and will function in coarse alluvial streams. Backfill and the buried portions of cuttings should be wrapped in several layers of coir mat if the sill is constructed in a stream channel subject to infrequent torrential flows. The width of the construction trench may be increased up stream of the vegetation and filled with large natural stone to reduce damage to the structure by bed load in high flow channels. Live stakes may be planted between the joints of the stone.
**************************************************************************

Excavate a 600 mm 2 feet deep trench normal to and across the entire width of the stream channel. Place live cuttings in a criss cross manner with 20
cuttings per 1 meter 3 linear feet of trench on the down stream face of the trench. [Place cuttings in the same pattern and concentration as in the trench for the sill on the stream side faces of trenches excavated at the toes of the banks for a distance of 4.5 meters 15 feet up stream and down stream of the ends of the sill structure]. Push cut ends of the cuttings into the bottom of the trench to [refusal] [150 mm 6 inches] and extend the growth tips 600 mm 2 feet above the top of the existing streambed. Place large natural stone on top of the cut ends of the cuttings [to the top of the existing streambed to fill the entire trench] and tamp into the streambed to secure the stones in place. Place removed sediment in the voids between the natural stone [and place over the lower stone work to fill the entire trench]. Thinly spread excess sediment up stream of the structure. Place large natural stone at the ends of the structure against the bank [and at the upstream and down stream ends of the trenches excavated parallel to the banks]. Drive [live stakes] [and] [dead cuttings] up to 600 mm 2 feet in length into the [sediment backfill on 150 mm 6 inch centers] [between the joints in the natural stone] across the entire width of the trench and 1 m 3 feet up each bank from the toe of the bank. Space sills [15 m 50 feet apart] [as shown on the drawings].

3.12.2.3 Wattle fence sill

**************************************************************************
NOTE: Wattle fence sills are recommended for narrow and slow flowing streams, small gullies, agricultural drainage ditches, or open channel drains. These sills are best suited for streams or drainage systems with coarse-grained bed load, which will be trapped by the weaves of the fence. The sills may not trap fine-grained sediment or reduce erosion in fine-grained alluvial streams since the fine sediment may pass through the structure. These fence structures may be constructed of live or dead vegetation. The use of live poles and cuttings should result in the establishment of a row of vegetation across the stream channel with time. Cross beams are recommended for structures over two feet in height. These sills may be combined with brush sills and brush layer structures.
**************************************************************************

a. Excavate a trench 600 mm 2 feet deep and 300 mm 1 foot wide normal to and extend across the entire width of the stream channel. [Live] [Dead] poles must be 1 m 3 feet long with a minimum and maximum nominal diameters of 38 and 100 mm 1.5 and 4 inches, respectively. Cut bottom ends of the poles to form sharp drive points. Drive poles vertically into the streambed to a minimum depth of 600 mm 2 feet and place across the channel in a [straight row] ['V'-shaped row pointing down stream with the apex at the center of the channel with the poles] at a spacing of 600 mm 2 feet. Extend poles a maximum of [300] [600] mm [1] [2]-foot above the existing grade of the streambed. [Use dead poles for center poles and place for a distance of 1 m 3 feet about the centerline of the structure.]

b. Extend wattle fence from the bottom of the trench to the tops of the poles. The top of the fence must be [at the same elevation] [sloped to the center of the channel]. Construct fence of flexible [live] [and] [dead] cuttings that are 2 meters 6 feet in length and from 19 to 38 mm 3/4 to 1.5 inches in diameter. Ensure cuttings are [laced horizontally
between the poles in an alternating woven pattern with the cuttings being placed on the up stream and down stream sides of adjacent poles across the structure starting from the steam bank [placed on the up stream side of the poles and tightly packed and interwoven to form a braided vertical structure]. Overlap ends of the cuttings 300 mm 1-foot with adjacent cuttings. Secure cuttings of the fence to the poles with binding products. Install binders to prevent raveling of the binders in the event of the loss of a portion of the binders or structure.

c. [Place sediment removed from the trench in the excavation as compacted backfill around the poles and lower fence.] [Place live stakes at 300 mm 1-foot spacings in the backfill.] [Place large natural stone at the bottom of the trench along the up stream and down stream toes of the fence [and extend to the top of the existing streambed]. [Tamp stones into place and use sediment to fill voids between the stones.] [Place live stakes in the joints between the stones.]] Thinly spread excess sediment up stream of the structure.

d. Place [cross beam members of untreated [straight 25 by 100 mm 1 by 4 inch dimensional lumber] [long straight poles at least 50 mm 2 inches in diameter] on the down stream side of the poles and overlie the fence on the up stream side of the structure. Attach beams to the structure with binding products wrapped at least two times around the cross beam and adjacent pole and lace through the wattle fence cuttings.] [Place cross beams horizontal and at the same elevation on each side of the structure and extend the entire width of the structure.] [Extend both ends of the structure into a key trench that is excavated 600 mm 2 feet in the banks.] [Extend both ends of the structure to the existing stream banks and cover on both sides with large natural stone placed from the channel bottom to the top of the structure. Rest stone on the stream bank, at least 600 mm 2 feet thick, and extend 1.5 m 5 feet away from the structure in the up stream and down stream directions.]

3.12.2.4 Vegetated Crib Wall or Wood sill

**************************************************************************
NOTE: A vegetated crib wall consists of a hollow box-like structure of timber or logs filled with earth and live cuttings. A wood sill is a vertical open wall composed of timber or logs that forms the front header, which is not tied to a similar structure, or rear header, up stream by stretchers as is the case with the crib wall. The crib wall is more stable than the wood sill. These structures may last 20 to 30 years depending on the type of timber used, are quick to construct, and may use locally available materials. The live cuttings take over the function of the crib wall as the cuttings grow and mature and the timber decays. These structures should not exceed 1.5 m 5 feet in height and are well suited for gullies with fine-grained sediment bed load and narrow streams less than 4.5 m 15 feet wide with steep gradients.

Crib walls or wood sills may be combined with brush sills, brush mats, or large natural stone on the up stream or down stream sides of the structure to reduce erosion. Stability of the structure may be
improved using a double crib design composed of front and back rails. Backfill should be free draining material with less than 10 percent fines. However, if such backfill material is not readily available, removed sediment may be placed as compacted backfill. Timber used for the crib wall may be untreated manufactured 100 mm 4-inch square posts, locally harvested vegetation with trunk diameters greater than 100 mm 4-inch, or a combination of these materials. Treated lumber will not be used.

**************************************************************************

a. Excavate a trench that is 1.5 m 5 feet wide and 600 mm 2 feet deep and extends normal to and across the entire width of the stream channel. Slope the floor of the trench at 15 degrees up stream and [manually compact using a tamping bar weighing at least 18 kg 40 pounds] [compact using a small motorized tamping machine] until the bottom of the trench is dense and provides a solid base for the crib wall [wood sill]. The floor of the trench must be [as shown in the drawings] [of uniform grade across the trench width]. Fill depressions in the trench floor with compacted material to raise these areas to grade and reduce positive areas above the floor design elevation to grade. Key trench into the stream banks for a distance of 1 m 3 feet. Use material removed from the key trenches as compacted backfill in the key trenches. [Remove sediment removed from the trench in the stream channel from site and replace with select fill.] [Use sediment removed from the trench in the stream channel as compacted backfill].

b. Frame [crib wall] [wood sill] with [untreated, straight 100 mm 4-inch square by 2.5 m 8 feet long posts] [100 to 150 mm 4 to 6 inch diameter by 2.5 m 8 feet long straight logs harvested from local sources. Cut logs normal to the trunks with all branches stripped from the trunks]. Place down stream header [parallel to the bottom of the trench and extend the full width of the trench] [along the alignment shown in the drawings]. [Place up stream header parallel and 1.5 m 5 feet up stream of the down stream header.] Place splices between members end-to-end and in line. Drive wood posts that are at least 100 mm 4 inches in diameter vertically 150 mm 6 inches from the splices on the up stream and down stream sides of the headers. Drive wood post on both sides of the headers at the midpoints between the splices. Place members at the ends of the structure firmly against the faces of the key trenches. Drive wood posts on both sides of the headers at the toes of the banks and the toes of the key trenches.

c. Stretchers [for wood sills must be 1.2 m 4 feet] [for live crib walls must be 2 m 6 feet] in length. Place stretcher between the vertical splice poles and normal to the down stream header. Space stretchers every 1.2 m 4 feet between the poles and have a minimum of 100 mm 4 inches extending down stream of the header face. Place rear butt of the stretcher [firmly against the upstream face of the trench] [on top of the up stream header]. Attach stretcher to the header(s) with binding products wrapped three times around the stretcher and header in a criss cross pattern and secure with a non-raveling knot. Drill a 13 mm 1/2-inch diameter hole vertically through the stretcher and header. Drive a 16 mm diameter by 300 mm 5/8 inch diameter by 12 inch long [non-galvanized steel spike] [steel rebar] [hard wood dowel] into the hole and set flush to the top of the stretcher.
d. Backfill the open area between the down stream header and the upstream [trench face] [header and the portion of the trench upstream of the upstream header] with compacted [sediment removed from the trench excavation] [select fill] to an elevation that is at the middle of the stretchers. Place live cuttings that are 19 to 38 mm 3/4 to 1.5 inch in diameter and 2.4 m 8 feet long in a criss cross manner on top of the compacted backfill with the cut ends pushed into the up stream face of the trench. Ensure at least 600 mm 2 feet of growth tips of the cuttings extend beyond the face of the down stream header. Place backfill and lightly compact on top of the cuttings to the top of the stretchers. Place additional lifts of headers, stretchers, backfill, and cuttings until only the final lift remains. Offset centerlines of the down stream headers 50 mm 2 inches upstream of the lower headers to provide an incline to the down stream face of the structure.

e. The top down stream header must be 100 mm 4 inches larger in diameter than the headers used for wall construction to reduce sediment loss due to scour. Cut vertical poles on both sides of the headers flush with the top of the final down stream header [and the top rear header]. Place a header at the midpoint between the top down stream and up stream headers and secure with binders and [spikes] [rebar] [dowels] to the underlying stretchers. Fill the lift of backfill immediately below the completion headers with a tightly packed brush mat composed of live [and dead] cuttings that are placed in an alternating pattern perpendicular and parallel to the wall. Ensure each layer of cuttings is 100 mm 4 inches thick and cover with a thin layer of lightly compacted backfill. Place [rounded clean natural stone from 200 to 300 mm 8 to 12 inches in diameter] [excavated sediment] from the top of the packed brush to the top of the down stream header and grade up stream to match the existing slope of the stream channel up gradient of the work site. [Drive live stakes vertically on 600 mm 2 feet centers into the backfill at the top of the structure.] [Place large natural stone armor 600 mm 2 feet thick at the ends of the structure and on the slopes of the banks for a distance of 2 m 6 feet upstream and down stream from the structure. Plant live stakes in the joints between the stones.] Fill trench down stream of the structure with [large natural stone] [a brush [and stone] sill] [a brush mat].

3.12.2.5 Vegetated Dry Stone Barriers

**************************************************************************
NOTE: Vegetated dry stone barriers are constructed of large natural stone with interlayered live cuttings. These structures may be built to heights of 4.5 m 15 feet and serve as weirs or drop structures in high gradient streams with torrential flows and heavy coarse bed load. Stone barriers may also be constructed to slightly above the existing elevation of the stream channel to prevent bed degradation. The largest stones that may be moved by manual efforts should be used. Construction of barriers adjacent to existing large boulders may reduce the amount of work required.**************************************************************************

Excavate a trench that is 1.2 m 4 feet wide and 1 m 3 feet deep normal to and across the entire width of the stream channel and key 1 m 3 feet into the stream banks. Slope the bottom of the trench at 15 percent in the up stream direction and compact using a manual tamping bar weighing at least
18 kg 40 pounds. Place large stone of similar size on the entire floor of
the trench with a minimum of voids between the stones. Cover stones by
[fine sediment] [select fill] and work into the voids between the stones
until only the tops of the stones are visible. Place live cuttings that are
2 m 6 feet long and up to 38 mm 1.5 inches in diameter on top of the
stones in a criss cross pattern with the butts of the cuttings in contact
with the up stream face of the trench. Orient growth tips of the cuttings
down stream and extend 0.5 m 1.5 feet beyond the farthest down stream
placed stones. Place additional lifts of stone, fill, and cuttings on the
lower lifts until the design height of the structure is reached. Place
stones of each successive lift to interlock with the tops of the stones of
the lower lift. Place live cuttings at the top of the structure in between
the stones and incline slightly down stream. [Drive live stakes that are
600 mm 2 feet long between the joints of the stones at the top of the
structure on 600 mm 2 feet centers and for a distance of 1 m 3 feet up the
stream banks.] Cover top stones with a 100 mm 4 inch thick layer of [fine
sediment] [select fill].

3.12.2.6 Brush Work or Brush Packing

**************************************************************************
NOTE: Brush work or brush packing uses live and
dead cuttings to fill a section of a gully or stream
channel to reduce erosion of stream banks. These
structures provide erosion protection to the channel
by covering the channel with a mat of brush and are
recommended for intermittent streams with
fine-grained sediment. Brush works refers to brush
mats placed across the stream channel with growth
tips pointing up stream and which extend up the
stream banks. Construction of brush work starts at
the upstream limit of the work site and progresses
down stream with each new layer of cuttings
overlying the immediately up stream layer of
cuttings. Brush packing refers to thickly packed
layers of brush placed with the growth tips inclined
slightly down stream that fill a gully or small
stream channel. Brush packing starts at the down
stream limit of the work site and progresses
upstream with each new layer of cuttings overlying
the immediately down stream layer of cuttings. Bank
stability is improved as the vegetation grows and
develops root systems in the lower bank. The
cuttings may be anchored in the channel by cross
logs secured to vertical poles driven into the
streambed.
**************************************************************************

a. [Start brush work construction at the upstream end of the work site and
progress down stream with each down stream layer of cuttings overlying
the layer of cuttings immediately upstream.] [Start brush packing
construction at the down stream end of the work site and progress
upstream with each upstream layer of cuttings overlying the layer of
cuttings immediately down stream.]

b. Excavate trenches that are 300 mm 1-foot deep normal to and across the
entire stream channel [and extend 1.5 m 5 feet up the stream banks].
Space trenches 1.5 m 5 feet apart. Place live cuttings that are 2 m 6
feet in length in the trench in a herringbone pattern at an angle of 30

SECTION 31 32 39 Page 57
degrees from the centerline of the channel with the growth tips pointing [upstream] [inclined down stream at an angle of 45 degrees from vertical]. The cuttings must [not] extend up the stream banks. Push cut ends of the cuttings firmly into the streambed. Place [removed sediment] [select fill] and compact over the cut ends of the cuttings to the elevation of the existing channel. Repeat this procedure for the specified length of channel at the work site.

c. Place cross logs normal to the channel and on top of the cuttings every 1 meter 3 feet. Ensure logs are 100 mm 4 inches in diameter and extend the full width of the channel. [Place cross logs parallel to the slope of the bank on top of the brush [work] [pack] layers that extend up the stream banks. Shape ends of the cross logs at the toes of the banks to sharp tips and drive the logs 500 mm 1.5 feet into the streambed at the angle of the slope of the stream bank.] Drive [live] [dead] poles vertically into the streambed on the down stream sides of the cross logs. Space poles at 600 mm 2 feet intervals and ensure the tops of the poles are not greater than 150 mm 6 inches above the tops of the cross logs. Drive poles at the toes of the stream banks regardless of spacing interval. Tie poles and cross logs together using binders that are wrapped around the logs and poles in a manner to prevent raveling.

3.12.2.7 Live Fascine Sill

**************************************************************************
NOTE: Live fascine sills are more resilient and less prone to damage by scour than brush sills. However, heavy coarse bed load and large woody debris transported during high flow events may damage the fascines. Fascine sills may be used to form low drop structures to prevent streambed degradation in narrow streams with low flow velocities and minimal coarse bed load. Sills may be combined with other bioengineering methods for channel stabilization of high gradient or torrential flow streams. Fascines have the advantage of being flexible and therefore may be placed to conform to the existing profiles of the stream channel and may be easily extended up the banks of the channel. The diameter and strength of the fascine may be increased by adding dead branches and gravel or cobbles to the fascine. Fascines should be placed in trenches that are normal to the stream channel and that are at least 50 to 75 percent the diameter of the fascine in depth. Live fascines may be placed on top of one another to form step sills. Step sills are constructed by placing a down stream fascine in a trench and positioning a fascine directly up stream of the down stream fascine. The up stream fascine should rest on the upper one quarter of the exposed down stream fascine.
**************************************************************************

Each fascine must be 300 mm 12 inches in diameter and 3 m 10 feet in length and constructed of live cuttings that are from 19 to 38 mm 3/4 to 1.5 inches in diameter. Up to 35 percent dead branches [and 15 percent rounded gravel or cobbles] must be interwoven with the live cuttings. Excavate a 200 mm 8-inch deep by 0.5 m 1.5 feet wide trench normal to and across the entire width of the stream channel [and at least 1.5 m 5 feet up the faces
of the stream banks]. Place fascine in the trench. The junction between fascine bundles in the same trench must be [offset side-by-side] [interwoven] for a distance of 300 mm 1-foot. Anchor fascine in the trench with 700 mm 2.5 feet long [live] [dead] stakes that are at least 50 mm 2 inches [in diameter] [square] at the top and taper from the top to the base. Drive stakes vertically through the fascine until flush with the top of the bundle starting 300 mm 1-foot from the end of the fascine and space every 1 meter 3 feet thereafter. Drive a terminal stake 300 mm one-foot from the end of the fascine regardless of spacing interval. Drive [live] [dead] stakes at a 45-degree angle on the down stream side of the fascine but do not penetrate the bundle. Secure fascine to the stakes with binders wrapped around the fascine and secure to the stakes. Tie binders to prevent ravel in the event of damage. Use removed sediment as backfill and place and compact on the up stream and down stream sides of the fascine and brush into the fascine structure until only the top of the fascine is visible. [Space fascine sills 8 m 25 feet apart starting from the down stream end of the work site.] [Place fascine sills at the locations shown on the drawings.]

3.12.2.8 Vegetated Deflector

**************************************************************************
NOTE: Vegetated deflectors are traditional hard structures composed of rock (groins, dikes, spurs) or timber (log or pile revetments) that incorporate live vegetation and which provide excellent long-term bank protection with the added benefits of shade and habitat enhancement. These structures protect the banks of large streams and rivers, which are subjected to high velocity flows, by deflecting the energy of the current away from the banks. The incorporated vegetation improves the strength of the structure and the quality of habitat over time. A key component for the establishment of vegetation on these structures is the retention of fine-grained material and the exposure of the hardened structure above the mean water level of the stream or river. Only vegetation that matures to trees or brush of less than 2 m 6 feet in height and which remains flexible should be used. Species that may mature to tall trees with extensive root systems may not be used, since these trees may damage the hard structures.

For existing structures, fine-grained material may be placed in open voids and live posts driven into these voids in the structure. For new construction, the interior of the structure may be composed of fine-grained material capable of supporting root growth. This core should be covered with rock of suitable size to resist transport by the stream or river. The cover armor must be anchored along the perimeter of the structure in a key trench below the scour depth of the high flow events. Additional stability of the armor may be gained by inserting dead stakes between stones in areas below the mean water level. Live poles may be driven into the joints of the armor above the mean water level.
Retention of fine-grained material in the core of the structure may be improved by placing this material in untreated sand bags composed of natural fibers. The lifetime of the sand bags should be sufficient to prevent the loss of fines until the roots of the live poles lock this material in place. The surface of the sand bag core may be covered with a coir erosion mat prior to the placement of armor. To reduce the number of sand bags, the core may be constructed of compacted material overlain by a three-bag thick layer of sand bags, which is in turn overlain by the stone armor. A layer of well-graded fine gravel and coarse sand may be placed beneath the stone armor to form a filter layer and thus further reduce the loss of fines from the core. Other deflector alternatives include the use of logs or wood structures as cores surrounded by fine-grained material with exterior stone armor. These structures may be used to assist in trapping sediment behind rock groins or dikes to fill large scour areas in a stream or river banks.

a. Excavate a trench [4.5 m 15 feet wide, 1 m 3 feet in depth below the lowest elevation of expected scour, that extends from the toe of the high bank to 3 m 10 feet into the stream below the mean low water elevation. The trench must be [keyed 1.5 m 5 feet into the bank.] [as shown on the drawings]. [Place live cuttings against the face of the trench from the mean water level to the high bank. Extend these cuttings at least 450 mm 1.5 feet above grade and push the cut ends of the cuttings firmly into the bottom of the trench and cover with a thin layer of [sediment] [select fill]]. Place [natural stone] [quarry rock] at least 1 m 3 feet in the minimal dimension against the outer perimeter face of the trench and maintain as much contact with adjacent stones as possible. [Place [stone] [rock] to a height of 600 mm 2 feet above the high mean water level of the stream]. Slope the outer face of the [stone] [rock] at [2H:1V] while the face towards the center of the trench is at the angle of repose. Brush [sediment removed from the trench] [select fill] into the voids between the [stones] [rocks] until the soil is even with the tops of the [stones] [rocks]. Place live cuttings on top of the outer [stones] [rocks] with the cut ends of the cuttings firmly pushed into the bottom of the inside trench. Cover the ends of the cuttings with a thin layer of sediment that is overlain by [backfill] [sandbags]. [Drive live poles between the [stones] [rocks] to a depth of at least 1.2 m 4 feet.] Fill the core of the structure lying inside the larger outer [stones] [rocks] with [removed sediment] [select fill] [in untreated biodegradable sand bags that are placed tightly end to end and in vertical overlapping pattern] [compacted cohesive sediment removed from the trench separated from the outer [stones] [rocks] by a 600 mm 2 feet thick layer of select fill contained in untreated biodegradable sand bags].

b. Place successive lifts of armor [stone] [rock] on top of the completed lifts to the design slopes and grades of the structure. Place live cuttings on the top of each lift. Raise the core of the structure concurrently with the lifts of armor material. The final lift must consist of interlocked [stone] [rock] that extends across the entire top of the structure. Brush [removed sediment][select fill] into the voids between the [stones] [rocks]. Plant live stakes in the joints.
between the [stones] [rocks] with a spacing of 1 m 3 feet. The top of the rock structure must be 300 mm 1 foot above the top of the original elevation of the high bank.

3.12.2.9 Live Brush Sill

*********************************************************************************************************************************************
NOTE: Live brush sills are structures composed of live vegetation that extend perpendicular from the toe of the bank into the stream channel. These structures may extend landward to the high bank. The sills trap sediment and debris, reduce scour, and are useful in establishing vegetation on point bars of barren flat expanses of low bank. These structures are inexpensive, easy to construct, and may reduce the amount of rock or stone armor required for bank protection. The development of root systems and the growth of vegetation improve bank stability and develop riparian habitat. Dead cuttings may be used in these structures to improve their resistance to erosion and damage due to currents or debris. Sills composed entirely of dead cutting may be placed below the mean high water elevation separately or between harden transverse structures. These dead brush sills trap debris, sediment, and result in bank aggradation. Live sills, or other live bioengineered structures, may be placed on the new bank created by the dead sills at a future date to promote improved stability and habitat development.
*********************************************************************************************************************************************

Excavate a 600 mm 2 feet deep trench with a 'V' shaped cross section normal to the toe of the stream bank from [the mean high water level] for a distance of [3 m 10 feet into the stream channel [from the mean high water level]] [and] [6 m 20 feet landward of the toe of the bank.] [to the edge of existing vegetation] [as shown on the drawings]. Place live cuttings in the trench with the cut ends pushed firmly into the bottom of the trench with the growth tips extending at least 600 mm 2 feet above the top of the existing grade. Place at least 20 cuttings per 300 mm linear foot of trench and rest all cuttings against the down stream side of the trench. Place large stone up to 150 mm 6 inches in diameter on the bottom of the trench against the cut ends of the cuttings and cover with loosely compacted [sediment] [soil] [select fill] to the existing surface. [Mound excess material removed from the trench that is to remain on site around the base of the sill at the surface.] Space sills 1.5 m 5 feet apart.

3.12.2.10 Brush Transverse

*********************************************************************************************************************************************
NOTE: Brush transverses are stone structures augmented with live or dead brush cuttings that are easy to construct and inexpensive. These structures are useful in deflecting high velocity flows away from stream banks to prevent scour and erosion and may be used to aid in the repair of scoured or failing areas of stream banks. The live vegetation will develop root systems that will strengthen the structure and provide shade and habit. The stone
structure deflects and dissipates the stream velocity away for the bank thereby creating areas of still water down stream of the structures in which sediment may be deposited. The brush cuttings assist in sediment trapping during periods of high flow. This vegetation matures with time and will eventually completely cover the scour area. Brush transverses may be combined with brush grids to repair areas of bank scour in high flowing rivers.

Brush transverse structures are not suitable for use in streams with torrential flows and heavy clastic bed load. Installation trench depth and width must be based on hydraulic analyses of stream velocities and bed load transport. The structure may be normal to the stream bank or inclined at an acute angle to the stream bank in the down stream direction. The use of subrounded large natural stone from the immediate area of work is preferred for construction. If such material is in limited supply, then the available natural stone may be used as cover stone and the core of the structure may be constructed of angular to subangular quarry rock. In areas that lack natural stone, local durable quarry rock may be used for the entire structure.

-----------------------------------------------------------------------------------------------------------------

a. Excavate a trench 600 mm 2 feet deep by 1.5 m 5 feet wide from [the face of the high bank] [edge of the stream bank] to [3 m 10 feet beyond the low mean water elevation of the stream] [the new bank alignment as shown on the drawings]. [Key trench into the stream bank for a distance of 1 m 3 feet.] Firmly compact the base of the trench. Place live [and] [dead] cuttings that are at least 1.5 m 5 feet in length and that have side branches attached on the down stream side of the trench. Place the cuttings with a concentration of at least 20 cuttings per 300 mm linear foot of trench to form a layer with a thickness of 100 mm 4 inches. Push cut ends of the cuttings firmly into the streambed with a minimum of 1 m 3 feet of the growth tips extending above grade and incline in the down stream direction. Cover cut ends of the cuttings with a 75 mm 3 inch layer of moderately compacted [fine-grained sediment] [select fill] and extend from surface grade to the base of the trench at the angle of repose.

b. Place durable [large natural stone] [quarry rock] that is 450 mm 1.5 feet in minimal dimension along the up stream side of the trench, against the fill covering the cut ends of the cuttings, and completely fill the key trench. Place [natural stone] [quarry rock] ranging from 150 to 450 mm 0.5 to 1.5 feet in minimal diameter to cover the floor of the trench and firmly tamp into place to provide the greatest contact with adjacent [stones] [rocks]. [Brush] [Wash] [fine sediment] [select fill] into the voids between the [stones] [rocks] until only the tops of the [stones] [rocks] remain exposed. Place successive layers of [stone] [rock] on lower lifts in a pattern that allows the greatest amount of interlocking of [stones] [rocks] and fill the voids between the [stones] [rocks] with [fine sediment] [select fill] to the top of the structure. Construct the end of the structure that projects into the stream of [large stone] [rock] that is 1 m 3 feet in minimal dimension for a distance of 2 m 6 feet. [Place excess sediment removed from the trench along the up stream and down stream toes of the structure]
structure.] Place the farthest up stream structure in the work area at an angle of 30 degrees to the direction of stream flow to deflect the current towards the center of the channel. Construct subsequent down stream structures at right angles to the stream bank with a spacing of the average length of the structure.

3.12.2.11 Brush Grid

**************************************************************************

NOTE: A brush grid consists of layers of brush laid out in a rectilinear pattern with each successive lift being placed normal to the lower lift. The structures are well suited for the repair of severely scoured or sloughing areas on banks in streams with high flow velocities and large range or frequent changes in water level. These structures may be used on portions of the streambed from the toe of the high bank to the edge of the mean low water level of the stream. For large scour areas, a brush grid may be constructed at the up stream end of the scour hole between the stream bank and a brush traverse or vegetated groin or dike. The remaining portion of the scour area may be filled with widely spaced brush transverse structures. The areas between the transverses may be filled with brush sills. A brush grid requires significant manual labor and a large supply of brush. The amount of labor and materials may be reduced by combining the grid with brush sills, vegetated dikes, gabions, or by constructing a widely spaced grid work of brush instead of a complete cover of brush.

**************************************************************************

a. [Extend an excavation that is 4.5 m 15 feet wide and 1 m 3 feet deep from the edge of the high bank 6 m 20 feet into the stream channel. Slope the floor of the excavation towards the bank at 2H:1V and make smooth and compact. Extend the side slopes beyond the above specified dimensions and at the angle of repose. Key trench 1.5 m 5 feet into the stream bank.] [Excavate sediment to form a level floor at the installation area to the grades and dimensions shown on the drawings.][ Drive live] [dead] poles composed of [untreated manufactured lumber] [straight sections cut from local trees] vertically 1 m 3 feet into the streambed [along the alignment of the proposed bank] [as shown on the drawings] [in a straight row that is 4.5 m 15 feet from the edge of the high bank]. Place additional poles between the new alignment of poles and the stream bank on 1.5 m 5 feet centers. The poles must be 100 mm 4 inches in diameter. The length of the poles must be such to allow 600 mm 2 feet of pole to extend above the mean water level. Shape bottoms of the poles to sharp tips to facilitate driving them into the streambed. Cut tops of the poles normal to the lengths of the poles. The top elevations of the poles must be the same for all poles. [Drill pilot holes, slightly larger in diameter than the poles, into the streambed using a [steel punch rod] [mechanical drill] in coarse alluvial sediment]. Stand the poles erect without support after installation in the streambed. Install loose or nonvertical poles. Replace poles damaged during installation at no expense to the Government.
b. Provide base layer of the structure consisting of 150 mm 6 inch diameter by 6 m 20 feet long trunks of trees with their branches still attached. Do not attach root wads to the trunk. Pack these trunks tightly between the poles with the growth tips extending 600 mm 2 feet into the stream beyond the new bank alignment. Place trunks horizontally in the excavation with the cut ends placed [in the key trench] [firmly butted against] the stream bank.

c. Place [removed sediment] [select fill] over the trunks until only to tops of the trunks are exposed. Place live cuttings up to 50 mm 2 inches in diameter vertically in rows spaced 1 m 3 feet apart parallel to the base layer of trees with a minimum of 5 cuttings per 300 mm linear foot of row. Push cut ends of the cuttings through gaps between the base logs and into the streambed. The top of the growth tips of the cuttings must be at the same elevation as the top of the vertical poles and inclined at a slight angle down stream. Place a layer of live cuttings consisting of 1 m 3 feet wide rows that are up to 300 mm 12 inches thick horizontal on top of the first lift of trunks and pull around the upright live cuttings and poles. Extend the growth tips 600 mm 2 feet beyond the new alignment into the stream. Separate the rows from the vertical posts by a distance of 300 mm one-foot. Place sediment on top of the cuttings to fill all voids until only the top of the rows are exposed. Place a lift of cuttings normal to the first lift of cuttings with the growth tips extending 600 mm 2 feet beyond the down stream edge of the structure. Place sediment on top of this lift of cuttings the same as the lower lift. Place lifts of rows of cuttings in this alternating manner until the structure reaches a minimal height of 1 m 3 feet above the mean low water level. Place large natural stone along the outer perimeter of the structure to protect it from scour. Secure top of the structure with [a layer of natural stone] [sand bags filled with select fill] placed on top of the horizontal cuttings and around the vertical live cuttings and poles.

3.12.3 Longitudinal structures

**************************************************************************
NOTE: Longitudinal structures or plantings are placed parallel to stream banks or lake shores and may be used in conjunction with hard engineered structures to provide habitat, shade, and to obscure the hard structures from view thus allowing a more natural appearance to the protected bank.
**************************************************************************

3.12.3.1 [Single] [Clump] Reed Planting

**************************************************************************
NOTE: Reed planting involves the planting of single reeds or clumps of reeds along a stream bank or lake shore. This method is well suited for low flowing streams, lakes, canals, and stagnate areas of water that are protected from wave action or strong currents. Such sites may include exposed banks at or slightly below the mean low water level, tidal flats, or areas of low relief shoreline that extends some distance into a water body. The reeds dissipate energy of the water acting on the shore area and reduce erosion while root structures improve the strength of the bank. Planting should
begin at the wet shoreline and progress landward. This planting method is simple to implement and complete, but must be accomplished during the first months of summer to allow the plants to become established.

The method does not provide immediate erosion protection to the bank nor will the plants tolerate shade. The effect of the plantings may not be realized until two to three years after planting. Reed planting will not reduce failure of unstable banks or shorelines. Clump planting refers to the planting of a large group of reeds contained in a large soil and root mat in a hole excavated at the site.

Plant reeds during the active growing period. Deliver reeds to the site in bundles in saturated cloth. Plant [single reeds] [reed clumps] on a grid with a spacing of 600 mm (2 feet) starting at the shoreline and progressing landward [for a distance of 16 m (50 feet)] [to the existing reed line]. The stems of the reeds must be slightly above grade and vertical. Protect shoreline edge of the planting area by [a line of natural stone] [coir log] [log] [______]. [Ensure placed between stone armor at the water line are placed between the stones in narrow trenches backfilled with fine-grained sediment.]

3.12.3.2 Live stone revetment

NOTE: Live stone revetments are traditional stone or rock armor revetments placed on banks for stabilization and erosion protection with the addition of live cuttings placed in the joints between the armor stones. These structures are well suited for sites where extensive areas of bank must be protected along high flowing streams with heavy bed load or lake shore subject to wave action. Saplings may be placed between the rock joints if topsoil is placed to fill the interstitial voids between the armor stones. Construction must occur in the dormant season for live cutting revetments and in the spring or autumn for transplanted saplings. Expect 30 to 50 percent mortality rate with cuttings, particularly in drier climates. Driving cuttings or live poles deeper into the stream bank and irrigation of the site may improve plant survivability.

The designer is encouraged to review existing references on stone revetment function, performance, and construction. Also, the designer should consider the impact the construction of a hard structure may have to the surrounding banks and channel such as the shifting of erosion to adjacent or cross stream locations that are not protected.

a. Prepare bank by reducing the slope to [2H:1V] [as shown in the
3.12.3.3 Brush Layered Revetment

**************************************************************************

NOTE: Brush layer revetments are constructed of alternating layers of live brush cuttings and rock. These structures are easier to construct and of lower cost than live revetments and are suitable for protecting long stretches of stream banks or lake shores. The live brush will cover the armor rock with time and obscure it from view. Angular quarry stone or rip rap may be used with this method.

**************************************************************************

a. Prepare bank by reducing the slope to [2H:1V] [as shown in the drawings]. The surface of the bank must be smoothed and compacted. Excavate a key trench at the toe of the stream bank and extend [1 m 3 feet below the mean low water level] [600 mm 2 feet below the lowest elevation of estimated scour]. Overlay the bank by a 100 mm 4 inch thick layer of 75 mm 3-inch minus compacted fill that contains less than 5 percent fines to serve as a filter blanket between the outer armor stone and the bank soil.

b. Place live cuttings in the trench against the stream side wall of the trench. Push the cuttings into the streambed and cover the cut ends with a thin layer of [sediment] [select fill]. Place large stone with a nominal diameter of 1 m 3 feet in the key trench. Rest the large
stone on the ends of the cuttings and anchor them in place. Place armor stone up the bank from the key stones to the bank crest [and extend 1.5 m 5 feet landward of the bank crest]. Place each stone to interlock with down slope stones to form a rock mass the covers 100 percent of the exposed bank. Place the stones by [hand] [heavy equipment with a placing bucket]. Do not dump stones in mass from the top of the bank. Push stones into the bank using suitable heavy equipment once the stone is placed. [Brush] [Wash] [sediment] [select fill] into the voids between the rocks as the rocks are placed.

c. Place stone in lifts not to exceed 1 m 3 feet in height. The top of the lift must be within 150 mm 0.5-foot of the same elevation across the surface of the lift [and parallel to the water surface of the stream]. Place a layer of loosely compacted topsoil at least 150 mm 6 inches thick on the top of the rock lift. Place live cuttings in a criss cross manner with 20 cuttings per 1 m 3 linear feet on top of the topsoil layer with the cut ends pushed at least 300 mm 1-foot into the bank beneath the filter layer and with growth tips extending 150 mm 1.5 feet beyond the face of the armor rock. Cover cuttings with 100 mm 4 inches of moderately compacted topsoil. Place the next lift of rock on top of the compacted top soil and push these rocks into the topsoil until refusal due to contact with the rocks of the underlying lift. Continue process of alternating layers of rocks, cuttings, and topsoil to the [design height] [top of bank].

d. Key ends of the structure into the stream bank. Excavate key trenches 1.5 m 5 feet into the stream bank at the up stream and down stream ends of the structure. These trenches must be 1.5 m 5 feet deep and the faces of these trenches must be the same slope as the face of the prepared bank. Fill trenches with large [stone] [rock] that is pushed into the bottom and sides of the trench. Fill voids between the [stones] [rocks] with soil removed from the trench. Extend [stone] [rock] to the surface and wrap in a continuous mass into the armor [stone] [rock] on the face of the bank.

3.12.3.4 Longitudinal Live Fascine

**************************************************************************

NOTE: Longitudinal live fascines consist of live fascines combined with brush layers and possible bank toe armor stone along the length of a stream bank or lake shore. These structures provide immediate protection of the toe of the bank from current or wave erosion. These structures are inexpensive and easy to construct and suitable for low banks. The method may be used as toe protection for stable high banks if the upper portions of the banks are protected by other bioengineered or hard structures.
**************************************************************************

Compose fascines of live cuttings and construct in accordance with paragraph "Live Fascines" in PART 3. [Excavate a trench at the mean low water level of the stream with a floor that slopes at 15 degrees towards the bank.] [Excavate a key trench between the fascine trench and the mean low water line. This trench must be 600 mm 2 feet deep and 1 m 3 feet wide. Terminate the face of the key trench at the lip of the trench for the fascine. Fill trench with [quarry rock] [large natural stone] [rock and brush fascines anchored with dead stakes].] Place a layer of live
cuttings in the bottom of the fascine trench in a criss cross manner with
the cut ends of the cuttings in contact with the face of the trench and the
growth tips extending 150 mm 1.5 feet beyond the lip of the trench. Place
a minimum of 20 cuttings per linear foot. Cover cuttings with a layer of
compacted soil. Place fascine the trench and anchor in place by live
poles. The poles must be 1.2 m 4 feet in length and drive 10 mm 2.5 feet
into the bottom of the trench through the fascine. Space the poles every 1
m 3 feet along the length of the fascine. Place backfill around the
fascine to the [grade of the original bank] [design grade].

3.12.3.5 Longitudinal Brush Packing

**************************************************************************
NOTE: Longitudinal brush packing is a method suited
for the repair or protection of near vertical or
under cut banks subject to erosion. These
structures provide immediate protection to the bank
from erosion or wave action. The stability of the
bank should improve over time as vegetation becomes
established dependent on the properties of the soils
that compose the bank. The structures are suited
for low to fast flowing streams or active lake
shores. They are simple and easy to construct but
may require large amounts of fill and vegetation.
The structure consists of lifts of soil and brush
that are wrapped by erosion control products. Do
not use geosynthetic or plastic netting unless
absolutely necessary and in this case only for the
lower lifts of the structure.
**************************************************************************

a. The slope of the bank must be reduced to [2H:1V] [steps that are 300 mm
12 inches high and 600 mm 24 inches deep from the toe to the crest of
the bank] [as shown on the drawings]. Excavate a key trench at the toe
of the design slope. This slope must be of the same grade as the
adjacent undamaged stream bank. The key trench must be 1.2 m 4 feet
wide and 600 mm 2 feet deep and extend the length of the work site.
Fill trench with [large natural stone] [quarry rock] that has a nominal
diameter of 600 mm 2 feet and that is well graded with 100 percent
greater than 100 mm 4 inches. Place [stone] [rock] to form a
triangular topped dike with side slopes of 2H:1V. The [stone] [rock]
must be tamped into place.

b. Place a 100 mm 4 inch layer of [select fill] [removed sediment] on top
of the landward face of the rock dike and compact. Cover [fill]
[sediment] layer with erosion control fabric composed of [coir netting]
[____]. Extend fabric from the face of the bank to at least 1.2 m 4
feet beyond the top of the rock dike. Secure netting to the soil layer
with [staples] [stones] [stakes]. Ensure fabric is free of wrinkles
and extend the full length of the rock dike.

c. Place live cuttings [with 25 percent dead branches] on top of the
fabric layer in a herringbone pattern. Push cut ends of the cuttings
into the streambed to refusal. Place cuttings at a density of 20
cuttings per 300 mm linear foot to a thickness of 100 mm 4 inches. The
growth tips of the cuttings must extend 150 mm 1.5 feet beyond the top
of the crest of the rock dike into the stream channel. Brush [select
fill] [removed sediment] into the voids between the cuttings. Place a
100 mm 4 inch layer of [select fill] [removed sediment] on top of the
cuttings and compact. The fabric that extends over the rock dike must be [cut and removed] [tightly rolled and anchored at the base of the cuttings on top of the rock dike].

d. Cover the top of the [fill] [sediment] layer placed on top of the first layer of cuttings with a layer of erosion control fabric composed of [coir netting] [______]. The fabric must cover the top of the lower lift. At least 1.5 m 5 feet of fabric must remain above the contact of the lower lift and the slope of the bank. Stake this portion of fabric temporarily to the bank slope. At least 2 m 6 feet of fabric must extend beyond the top of the design slope. Place a 300 mm 12 inch layer of [select fill] [removed sediment] on top of the fabric and compact to 90 percent dry density. Place the ends of the fabric on top of the compacted material. Place the fabric near the face of the bank on top of the compacted material and pull free of wrinkles. Place the portion of fabric towards the stream channel across the face of the compacted material and pull tight and secure to the top of compacted material with staples. Install staples flush with the top of the lift.

e. Place live on top of the lift of compacted material in the same manner as the cuttings on the first lift. Cover these cuttings by a 100 mm 4 inch layer of compacted [select fill] [removed sediment]. Continue process of wrapping lifts of compacted soil with erosion control fabric and the placement of layers of cuttings to the [design height of the structure] [top of the bank]. Adjust the height of the soil lift nearest to the top of the structure in thickness to meet the design grade. Do not cover the top of the structure with cuttings. [Place live cuttings across the top of the structure on 600 mm 2 feet centers for a distance of 2 m 6 feet landward of the top of the bank and for 2 m 6 feet upstream and down stream of the ends of the structure on the original stream bank.]

f. Key the structure into the bank on the up stream and down stream sides of the structure. The key trenches must be 1.2 m 4 feet deep. Wrap lifts of the structure into the trenches and butt the ends of the lifts against the face of the key trench.

3.12.3.6 Live Crib Wall

**************************************************************************
NOTE: Live Crib walls are robust structures suited for stabilization and protection of banks or shores subjected to high flow or moderate wave action. These structures provide immediate erosion protection and possible habitat during high flow events dependent upon design. The structure provides a hard frame that dissipates current or wave energy. Bank stability and habitat improve as the vegetation matures and develops extensive root systems and shade along the bank. These structures typically require earthworks and large equipment for bank preparation and backfilling. Large amounts of vegetation and labor are required. Crib walls may be used to increase the width of a stream by replacing the natural sloped banks with the near vertical walls of the structure. Crib walls may be used to repair severely scoured banks by placing the structure in the stream at the new bank alignment and backfilling the void between the structure and
the existing bank.

The structure may be combined with brush sills, brush mats, or large natural stone on the up stream or down stream sides of the structure to reduce erosion. Stability of the structure may be improved using a double crib design composed of front and back headers. Backfill should be free draining material. Timber used for the crib wall may be untreated manufactured 300 mm 12-inch square posts, locally harvested vegetation with truck diameters greater than 300 mm 12 inches, or combination of these materials.

**************************************************************************

a. Reduce stream bank to the required slope and design grade. Excavate a trench that is 600 mm 2 feet deep and extends parallel to the toe of the slope. This trench must extend the full length of the work site and must extend [for a distance of 4.5 m 15 feet into the stream channel from the toe of the slope] [in the stream channel to the distance and dimensions shown on the drawings]. Slope the floor of the trench at 15 degrees towards the bank and [manually compact using a tamping bar weighing at least 18 kg 40 pounds] [compact using a small motorized tamping machine] until the bottom of the trench is dense and provides a solid base for the crib wall. Ensure the floor of the trench is [as shown in the drawings] [of uniform grade across the trench width]. Key trench into the stream bank for a distance of 2 m 6 feet. Use material removed from the key trenches as compacted backfill in the key trenches. Sediment excavated from the trench must be [removed from the site and replaced with select fill] [used as compacted backfill]. Fill depressions in the trench floor with compacted material to raise these areas to design grade and reduce areas above grade to the design grade.

b. Frame crib wall with [untreated straight 300 mm 12-inch square by 2.5 m 8 feet long beams] [200 to 300 mm 8 to 12 inch diameter by 2.5 m 8 feet long straight logs harvested from local sources. Cut these logs normal to the trunk and strip all branches from the trucks]. Place the header adjacent to the stream parallel to the toe of the slope at the design alignment of the wall and extend the full width of the trench. Place the header adjacent to the bank parallel to and 2 m 6 feet from the stream side header in the direction of the bank. Place headers end-to-end and in line at splices between the members. Drive wood posts vertically into the streambed 150 mm 6 inches from the splices on both sides of the header.

c. Provide stretchers that are 2 m 6 feet in length. Place each stretcher normal to the headers and between the vertical poles at the splices between the headers. Space stretchers [every 1.2 m 4 feet] [mid distance] between the vertical poles and extend a minimum of 100 mm 4 inches beyond the outer edge of the stream side header face. Place rear butt of the stretcher on top of the header near the bank and [extend 100 mm 4 inches beyond the outer face of the header] [firmly place against the exposed bank]. Attach stretcher to the header with binding products wrapped three times in a criss cross pattern and secure with a non-raveling knot. Drill a 13 mm 1/2-inch diameter hole vertically through the stretcher and header. Drive a 600 mm 24 inch long, 16 mm 5/8-inch diameter [non-galvanized steel spike] [steel rebar] [hard wood dowel] into the hole and set flush to the top of the
stretcher. Backfill the open area between the inner face of the stream side header and the inner face of the landward header with compacted [sediment removed from the trench excavation] [select fill] to the middle of the stretchers. Place live cuttings 19 to 38 mm 3/4 to 1.5 inches in diameter in a criss cross manner on the top of the compacted backfill with the cut ends pushed into the backfill near the landward header. The growth tips of the cuttings must extend 600 mm 2 feet beyond the face of the stream side header. Place backfill and lightly compact on top of the cuttings to the top of the stretchers. Place additional headers, stretchers, backfill, and cuttings until only the final lift remains. The centerlines of stream side headers must be off set 50 mm 2 inches towards the bank relative to the lower headers to provide an incline to the face of the structure. Place select fill in the area between the face of the landward header and the slope of the bank. Place the fill in lifts of the same thickness as the lifts on backfill in the interior of the structure. Compact each fill to at least 90 percent dry density.

d. The top stream side headers must be 100 mm 4 inches larger in diameter than the headers used for wall construction. Cut vertical poles flush with the top of the final headers. Place a header at the midpoint between the outer headers and secured with binders and [spikes] [rebar] [dowels] to the underlying stretchers. Fill the lift of backfill immediately below the completion headers with a tightly packed brush mat composed of live [and dead] cuttings that are placed in an alternating rectilinear grid pattern. Cover each layer of brush with a thin layer of lightly compacted backfill. [Rounded clean natural stone from 300 to 600 mm 12 to 24 inches in diameter] Place [excavated sediment] from the top of the packed brush to the top of the final headers [to the grade shown in the drawings]. [Drive live stakes vertically on 600 mm 2 feet centers into the backfill at the top of the structure.] [Place large natural stone armor 600 mm 2 feet thick on the banks and against the ends of the structure for a distance of 3 m 10 feet upstream and down stream from the structure. Plant live stakes in the joints between the stones.] Fill key trenches with [large natural stone] [quarry rock] to the design grade.

3.13 IRRIGATION

Start irrigation of the structure immediately after installing erosion control products and vegetation. Apply water to supplement rainfall at a sufficient rate to ensure moist soil conditions to a minimum 300 mm 12-inch depth. Prevent run-off and puddling. Do not drive watering trucks over turf areas, unless otherwise directed. Watering of other adjacent areas or plant material not related to work efforts must be [prevented] [as specified by the Contracting Officer]. Apply water to trenches immediately before placement of live vegetation. Place water on the completed structure at the end of each day, as needed to control dust and to prevent excessive drying of vegetation, and at the completion of the structure. [Irrigate the structure after installation for 3 months until the end of the first year growing season.] [Irrigate structures in arid climates for a period of 3 years.] [Daily irrigation of the structure and work site must not exceed 20 minutes [each day] [twice a day] [3 times per week] and must be sufficient to support the survival and growth of planted vegetation. Do not exceed limits of irrigation that could impair the stability of the structure and adjust irrigation to compensate for additions or deficits to soil moisture caused by precipitation or evaporation.]
3.14 FERTILIZER, PESTICIDE, HERBICIDE

**************************************************************************
NOTE: Edit this section as required. Fertilizer, pesticide, and herbicide may be required for the construction, establishment, and maintenance of bioengineered structures. Provide methods for application, frequency of use, safety precautions for humans and the environment in the section below.  
**************************************************************************

3.15 FIELD QUALITY CONTROL

The Contracting Officer will inspect the work site prior to final acceptance of work. A punch list noting deficiencies will be compiled by the Contracting Officer and provided to the Contractor. Perform, repair, adjust, align, or otherwise comply with the specified work on the punch list to the satisfaction of the Contracting Officer. Notify the Contracting Officer at least 14 days prior to the inspection that work is ready for inspection. Work will not be accepted until all punch list items are resolved and all work meets or exceeds contract requirements. Final acceptance of work will not be provided by the Contracting Officer until all defects or deficiencies are corrected. Final Acceptance will occur only after all corrective actions and supplemental viable plantings are complete and the structure meets performance standards and all contract requirements. Comply with necessary repairs to the structure and vegetation as stated in the warranty.

3.16 CLEAN-UP

Dispose of excess material, debris, and waste materials offsite at an approved landfill or recycling center. Clear adjacent paved areas. Restore the site to preexisting conditions to the extent reasonably possible and to the satisfaction of the Contracting Officer.

3.17 PROTECTION

Immediately upon the start of the installation in an area, protect the area against traffic or other use by erecting barricades and providing signage as required, or as directed. Provide signage [in accordance with Section 10 14 00.10 EXTERIOR SIGNAGE] [as shown on the drawings]. Protect the work site and vegetation from damage and vandalism and free of trash and debris until final acceptance by the Contracting Officer.

3.18 DOCUMENTATION

Establish and maintain documentation for bioengineering practices to record the desired information and to assure compliance with contract requirements, including, but not limited to, the following:

3.18.1 Maintenance Records

Visit, inspect, and document site conditions after the completion of construction every week for the first year and every two weeks thereafter until the end of the second year. Include written reports on site structure and vegetation conditions, damage, plant loss, and the like, to fully describe site conditions at the time of the visits and changes observed since previous visits. Obtain photographs of the site and areas of growth, defects, or damage and include with the records. Submit records
to the Contracting Officer within [48] [_____] hours after the completion of the site visit.

3.18.2 Final Project Report

Specify and summarize all construction activities and problems plus information included in the construction and maintenance records as submitted throughout the project. Summarize the work rather than repeat the items in the individual reports.

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for geogrid reinforcement to enhance the veneer soil stability for landfill liners and covers.

Adhere to **UFC 1-300-02** Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1   GENERAL

NOTE: Geometric requirements such as slope length, and construction limits should be shown on the drawings.

1.1 MEASUREMENT AND PAYMENT

The unit of measurement for soil slope reinforcement will be square meters (SM) yards (SY). Overlaps for splices (if allowed) and for the Contractor's convenience will not be measured for payment. Payment will be made at the respective unit price listed on the bidding schedule. Payment will be full compensation for furnishing all material, labor, equipment, supplies and incidentals to complete the work.
1.2 REFERENCES

**************************************************************************
NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.
**************************************************************************

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

ASTM INTERNATIONAL (ASTM)

ASTM D4355/D4355M (2014) Deterioration of Geotextiles from Exposure to Light, Moisture and Heat in a Xenon-Arc Type Apparatus

1.3 SUBMITTALS

**************************************************************************
NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.

**************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-02 Shop Drawings
Installation; G[, [____]]

SD-03 Product Data
Allowable Strength
Manufacturer

SD-04 Samples
Geogrid Reinforcement

SD-06 Test Reports
Geogrid Reinforcement

1.4 QUALITY ASSURANCE

Submit a summary of the manufacturer's qualifications and [_____] copies of the manufacturer's quality control (QC) manual a minimum of 7 days prior to delivery of geogrid to the site. The reinforcement manufacturer must provide a qualified and experienced representative to be available on an as-needed basis during construction. Visit the site for consultation [at least once during construction] [as requested by the Contracting Officer].

1.5 DELIVERY, STORAGE, AND HANDLING

Check products upon delivery to ensure that the proper material has been received and is dry and undamaged. Protect the materials from damage and exposure following the guidelines presented in ASTM D4873/D4873M.

1.5.1 Labeling

Label each roll with the manufacturer's name, product identification, roll dimensions, lot number, and date manufactured.

1.5.2 Handling

Handle and unload geogrid rolls by hand, or with load carrying straps, a fork lift with a stinger bar, or an axial bar assembly. Do not drag, lift by one end, lift by cables or chains, or drop geosynthetic rolls to the ground.

1.5.3 Storage

Protect geogrid from deleterious materials, chemicals, sparks and flames,
temperatures in excess of 70 degrees C (160 degrees F), and any other environmental condition that may degrade the physical properties. If stored outdoors, elevate the rolls from the ground surface. Protect geogrids, except for extruded grids, with an opaque waterproof cover.

PART 2  PRODUCTS

2.1 GEOGRID REINFORCEMENT

**************************************************************************
NOTE: Polyester is susceptible to hydrolysis in alkaline conditions. A high molecular weight and low carboxyl end group number limit the hydrolysis. Normally, a mill certificate or certification of these properties is adequate. The molecular weight of polyester geosynthetics is determined from GSI GRI GG6, "Determination of the Number Average Molecular Weight of Polyethylene Terephthalate (PET) yarns Based on a Relative Viscosity Value", and ASTM D4603, "Determining Inherent Viscosity of Poly (Ethylene Terephthalate) (PET) by Glass Capillary Viscometer." The carboxyl end group number is determined from GSI GRI GG7, "Carboxyl End Group Content of Polyethylene Terephthalate (PET) Yarns."

The geogrid sample is intended to be for visual demonstration prior to product delivery. Conformance testing samples, if required, should be obtained from material actually delivered to the job. If testing is to be performed for prequalification, the minimum sample size should be 1 meter (36 inches) in length and the full roll width. Although 1 square meter (yard) will provide enough material for testing, the full roll width should be sampled since it provides a better selection of specimen locations, it clearly shows the machine and cross directions, and the difference in waste and shipping costs is negligible.

**************************************************************************
Submit one properly identified 600 by 600 mm (24 by 24 inches) minimum size geogrid sample with the fasteners proposed for use. Provide a geogrid that is a geosynthetic manufactured for reinforcement applications and a regular network of integrally connected polymer tensile elements with aperture geometry sufficient to permit significant mechanical interlock with the surrounding soil, aggregate, or other fill materials.

a. Submit manufacturer's certified raw and roll material test reports including ultimate strength performed in accordance with ASTM D6637 or ASTM D4595 (modified). Test results not meeting the requirements in Table 1 or in the approved Manufacturer's Quality Control Manual will result in rejection of applicable rolls. Provide certified test reports a minimum of 7 days prior to delivery of geogrid to the site.

b. Provide geogrid structure that is dimensionally stable and able to retain its geometry under manufacture, transport and installation. Manufacture geogrid with 100 percent virgin resin consisting of polyethylene, polypropylene, polyester, or other approved material and with a maximum of 5 percent in-plant regrind material. Provide...
polyester resin with a minimum molecular weight of 25,000 and a carboxyl end group number less than 30. Stabilize polyethylene and polypropylene with long term antioxidants.

c. Submit **Certificates of Compliance** for the materials provided and results of conformance testing. Submit an affidavit certifying raw and roll material test results submitted are accurate and that the reinforcement meets the requirements of the project specifications. The affidavit must be signed by an official authorized to certify on behalf of the manufacturer. [If the affidavit is dated after award of the contract and/or is not specific to the project, attach a statement certifying that the affidavit addressed to the wholesale company is representative of the material supplied.] Include a statement confirming that all purchased resin used to produce reinforcement is virgin resin. Provide affidavit a minimum of 7 days prior to delivery of geogrid to the site.

### 2.1.1 Geogrid Reinforcement Properties

The reinforcement shown on the contract drawings must meet the property requirements listed in Table 1. Reinforcement strength requirements represent minimum average roll values in the machine direction.

<table>
<thead>
<tr>
<th>PROPERTY</th>
<th>REQUIREMENT</th>
<th>TEST DESIGNATION</th>
</tr>
</thead>
<tbody>

</tr>
<tr>
<td>Interface Friction at [Peak] [Residual], Degrees</td>
<td>[_____]</td>
<td>ASTM D5321/D5321M</td>
</tr>
</tbody>
</table>

*Submit the coefficient of interaction for pull-out resistance of the proposed geogrid in a soil of similar gradation and texture to the material that will be used for fill in the reinforced zone. Establish the coefficient of interaction in accordance with ASTM D6706. Provide certified test results a minimum of 7 days prior to delivery of geogrid to the site.

#### 2.1.1.1 Allowable Strength

Submit Geogrid allowable strength calculated in accordance with GSI GRI GG4a or GSI GRI GG4b. Itemize each reduction factor. Account for splice efficiency in the calculations. Provide calculations a minimum of 7 days prior to delivery of geogrid to the site. Allowable strength is based on reduction factors for installation damage, durability, and creep that are applicable to site specific conditions. Determine reduction factors in accordance with the test procedures documented in GSI GRI GG4a or GSI GRI GG4b. The minimum reduction factor for durability is 1.1 for polyethylene and polypropylene geogrids and 1.15 for coated polyester geogrids. The minimum reduction factor for installation damage is 1.1 for all polymers. Base the reduction factor for creep on testing performed in
accordance with ASTM D5262 at the strain specified in Table 1.

2.1.1.2 Interface Friction Testing

**************************************************************************
NOTE: If the geogrid will not be placed in an anchor trench, interface friction testing should be conducted to determine the runout length for the geogrid. All potential slip interfaces beneath the geogrid need to be tested in computing the required runout length. Normal stresses specified should be representative of anticipated field conditions. Selection of peak versus residual values should be based on anticipated interface displacements.
**************************************************************************

Submit certified laboratory interface friction test results including description of equipment and test method, a minimum of 7 days prior to delivery of geogrid to the site. Conduct laboratory interface friction tests on the following interfaces: [______]. The frequency of testing for each interface must be at a rate of [1] [______] per project. Conduct tests in accordance with ASTM D5321/D5321M. Use normal stresses of [______], [______], and [______] kPa [______], [______], and [______] psi along with a displacement rate of [5.0] [______] mm [0.2] [______] inches per minute. Orient geosynthetics such that the shear force is parallel to the down slope orientation of these components in the field.

2.2 SPLICES

Provide splices consisting of a standard method or device recommended by the manufacturer of the geogrid. Splices will not be allowed unless identified on the approved layout drawings. Splices must be at least 75 percent efficient. Demonstrate the splice efficiency through tests performed in accordance with GSI GRI GG4a or GSI GRI GG4b. Splicing may consist of overlaps, fusion wedge welding, sewing, or bodkin connections. Splicing methods that are dependent on installer experience and skill level, such as hot air and torch-applied open flame, are not acceptable. Construct overlap splices by placing a minimum of 50 mm 2 inches of soil between the layers of geogrid.

PART 3 EXECUTION

3.1 INSTALLATION

Submit Geogrid layout plan along with anchorage and joint details, sequencing and construction procedures, a minimum of 7 days prior to geogrid placement.

3.1.1 Subgrade Preparation

**************************************************************************
NOTE: For landfill slope reinforcement applications, geogrids are typically placed directly on the underlying geosynthetic surface.
**************************************************************************

Immediately prior to placement of the geogrid, place the geogrid on a surface that is free of rock and other material that could damage the geogrid or the underlying geosynthetics.
3.1.2 Anchor Trench

**************************************************************************
NOTE: Delete this paragraph if an anchor trench is not required. Anchor trench dimensions need to be determined on a site specific basis.

Anchor trench dimensions must be computed based on the pull-out resistance of the geogrid. However, pull-out resistance tests (ASTM D6706) are typically not performed due to the cost and complexity of this test procedure. Data bases of interaction coefficients for different geogrids, soils, and loading conditions are kept by geogrid manufacturers. Information from these data bases should be used to design the anchorage system.
**************************************************************************

Place the anchor trench a minimum of [610] [_____] mm [24] [_____] inches back from the edge of the slope to be covered. The anchor trench must be a minimum of [610] [_____] mm [24] [_____] inches deep and [610] [_____] mm [24] [_____] inches wide. Remove ponded water from the anchor trench while the trench is open. Round trench corners to avoid sharp bends in the geogrid. Remove loose soil, rocks larger than [51] [_____] mm [2] [_____] inches in diameter, and any other material which could reduce the effectiveness of the geogrid from the surfaces of the trench. Extend the geogrid down the front wall and across the bottom of the anchor trench. Perform backfilling and compaction of the anchor trench in accordance with Section 31 00 00 EARTHWORK.

3.1.3 Placement

Install the geogrid in accordance with the Manufacturer's recommendations. Unroll the geogrid in the direction of reinforcement. After a layer of geogrid has been placed, use suitable means, that do not damage the underlying geosynthetics, to hold the geogrid flat and in place until cover soil can be placed. Remove geogrid damaged during placement and covering and replace at no additional cost to the Government.

3.1.4 Overlaps and Fasteners

**************************************************************************
NOTE: Adjacent rolls of uniaxial geogrid should not be overlapped. The plastic-to-plastic contact has reduced frictional resistance.
**************************************************************************

Position adjacent rolls of geogrid edge-to-edge and loosely fasten to maintain alignment during fill placement. Do not overlap adjacent rolls. Use fastener type and spacing as recommended by the manufacturer and approved by the Contracting Officer. Metallic fasteners will not be allowed.

3.1.5 Splices

Submit test data showing splice efficiency. Provide certified test results a minimum of 7 days prior to delivery of geogrid to the site. Locate splices, if allowed, within the bottom one-third of the slope. Limit
splicing to only one splice per reinforcing strip and do not include a splice for two consecutive reinforcing strips. Do not use individual reinforcing lengths less than 3 meters 10 feet. Pull and hold splices taut in geogrid reinforcement during cover soil placement.

3.1.6 Penetrations

For small penetrations through geogrids, cut only transverse members of the geogrid. The load-carrying longitudinal (machine direction) members must be spread around the penetration. For larger penetrations, place additional geogrid on each side of the penetration and spliced to the adjacent geogrid to compensate for any longitudinal tensile members that must be cut.

3.2 COVER SOIL PLACEMENT

**************************************************************************
NOTE: The maximum acceptable particle size of cover soil is a function of the minimum aperture size of the geogrid and the acceptable maximum particle size against the underlying geosynthetic layer. The book titled "Designing with Geosynthetics" by Dr. Robert Koerner provides guidance on computing the acceptable maximum particle size of cover soil material based on the apperature size of the geogrid.
**************************************************************************

Cover geogrid with soil within [5] [_____] calendar days of acceptance. Do not drop cover soil onto the geogrid from a height greater than 1 m 3 feet. Push the soil out over the geogrid in an upward tumbling motion. Place soil from the bottom of the slope upward. The initial loose soil lift thickness must be [350] [_____] mm [12] [_____] inches. Use equipment with ground pressures less than 50 kPa 7 psi to place the first lift over the geogrid. Maintain a minimum of [460] [610] [915] [_____] mm [18] [24] [36] [_____] inches of soil between construction equipment with ground pressures greater than 50 kPa 7 psi and the geogrid. Do not use equipment placing cover soil that stops abruptly, makes sharp turns, spins their wheels, or travels at speeds exceeding [2.2] [_____] m/s [5] [_____] mph. Additional cover soil material and placement requirements are described in Section 31 00 00 EARTHWORK.

3.3 OVERSIGHT

Keep a QA Representative present at all times during geogrid installation.

3.4 CONFORMANCE TESTING

**************************************************************************
NOTE: Conformance testing is performed to verify quality control test results submitted by the manufacturer, to detect degradation during shipping and storage, and to verify the correct product is supplied. Verification of quality control by the manufacturer and detecting degradation during shipping and storage is not economically justified for small jobs. Unlike reinforcing steel for concrete, geosynthetics are difficult to identify in the field, and even experienced personnel can
sometimes mistake the product identity of unlabeled material. Testing after delivery to verify the correct product was supplied may be advisable for critical structures. The strength is usually the most critical property to verify.

Submit results of conformance testing. Conformance testing expenses are the responsibility of the Contractor. Perform testing using a commercial testing laboratory selected by the Contractor and approved by the Contracting Officer. The laboratory must be accredited via the Geosynthetic Accreditation Institute's Laboratory Accreditation Program (GAI-LAP) for the tests the laboratory will be required to perform. The Contracting Officer reserves the right to direct the location and select the material for samples. Conformance test results must equal or exceed results reported on the Manufacturer's certified roll material test reports.

<table>
<thead>

</tbody>
</table>

Modify ASTM D4595 for geogrids considering recommendations in GSI GRI GG6. Express the tensile strength on a unit length basis by substituting $n \times a$ for $W_s$, where:

- $W_s =$ specimen width, (mm inches)
- $n =$ number of ribs in the sample (must be a whole number)
- $a =$ nominal rib spacing for the product tested, (mm inches)

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for the procurement and installation of steel wire mesh gabion and mattress units used as a measure of protection against erosion forces of stream flow in water courses and slope instability. This section was originally developed for USACE Civil Works projects.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1   GENERAL

1.1 SUMMARY

The work under this specification includes furnishing, assembling, filling and tying open wire mesh rectangular compartmented gabions [and mattresses] placed on a prepared surface of [filter material] [geotextile], [geotextile and filter materials], as specified, and in accordance with the lines, grades, and dimensions shown or otherwise established in the field.

a. Gabions[ and mattresses] are wire mesh containers of variable sizes, uniformly partitioned into internal cells, interconnected with other similar units, and filled with stone at the project site to form
flexible, permeable, monolithic structures. Manufacture gabions[ and mattresses] with all components mechanically connected at the production facility with the exception of the mattress lid, which is produced separately from the base. The supply to the jobsite of unassembled individual wire mesh components (panels) forming gabions [and mattresses] will not be permitted.

b. Ensure definitions of terms specific to this specification and to all materials furnished on the jobsite, with the exception of the rock to fill the baskets and the filter material, refer to and are in compliance with ASTM A975 for double twisted wire mesh Gabions[ and Revet mattresses], or with ASTM A974 for welded wire fabric Gabions[ and Gabion Mattresses]. [For ease of reference, the term "mattress" will be used in this specification in place of Revet mattress and/or Gabion mattress, where the statement is of general nature and it is not specific to the double twisted or welded wire mesh products.]

1.2 UNIT PRICES

**************************************************************************
NOTE: For small projects, the district may opt to use lump sum payment.

Double twisted wire mesh gabions manufactured in SI (metric) units are different in size from those manufactured in English (inch-pound) units.

Sizes for double twisted wire mesh gabions and mattresses in SI (metric) units must refer to Tables 3 and 5 on ASTM A975. Sizes for double twisted wire mesh gabions and mattresses in English (inch-pound) units must refer to Tables 4 and 6 on ASTM A975. Sizes for welded wire mesh gabions and mattresses both in SI (metric) and English (inch-pound) units must refer to Table 1 on ASTM A974.

This note also applies to the subparagraphs below titled Unit of Measure.
**************************************************************************

1.2.1 Filter Material

1.2.1.1 Payment

Payment will be made for costs for filter material, including furnishing, hauling, placing, and maintenance of the filter layers until placement of the gabion [and mattress] cover is completed and accepted. No payment will be made for excess thickness of filter layers or for material required to replace material lost by rain wash, wind erosion, or otherwise, except for additional filter material ordered in writing.

1.2.1.2 Measurement

Filter material will be measured for payment based upon computations made from the theoretical filter thickness as specified or shown, and the areas acceptably placed where shown or staked in the field.
1.2.1.3 Unit of Measure

Unit of measure is cubic meter cubic yard.

1.2.2 Gabion [and Mattress] Protection

1.2.2.1 Payment

Payment will be made for costs associated with gabion [or mattress protection], including the costs of furnishing, assembling, and placing the wire baskets, the stone fill, and all other materials, labor, equipment, tools, supplies, and incidental costs in connection with completing this item of work.

1.2.2.2 Measurement

Gabions [or mattresses] meeting the requirements of these specifications and acceptably placed within the limits indicated on the drawings or otherwise established in the field, will be measured for payment by the cubic meter cubic yard of stone filled gabions [or mattresses] in place.

1.2.2.3 Unit of Measure

Unit of measure will be cubic meter cubic yard.

1.3 REFERENCES

**************************************************************************
NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.
**************************************************************************

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

ASTM INTERNATIONAL (ASTM)

Stainless Steel Spring Wire

ASTM A370 (2023) Standard Test Methods and Definitions for Mechanical Testing of Steel Products

ASTM A428/A428M (2021) Standard Test Method for Weight (Mass) of Coating on Aluminum-Coated Iron or Steel Articles

ASTM A975 (2023) Standard Specification for Double-Twisted Hexagonal Mesh Gabions and Revet Mattresses (Metallic-Coated Steel Wire or Metallic-Coated Steel Wire With Poly(Vinyl Chloride) (PVC) Coating)

ASTM C33/C33M (2023) Standard Specification for Concrete Aggregates

1.4 DEFINITIONS

1.4.1 Rate of Aggressiveness

Make the determination of the rate of aggressiveness (non-aggressive, moderately, or highly aggressive) on a project-to-project basis, due to the many variables involved and the lack of criteria of general validity. It is normally recommended for the choice to be based on all the available data and on the experience of existing gabion structures in similar environments.

1.4.2 Double Twisted Wire Mesh Gabions[ and Mattresses]

Classified according to the wire coating, which is applied prior to manufacturing the mesh. Coating styles are as follows:

1.4.2.1 Style 1

Wire mesh made from wire which is zinc coated before being double twisted into mesh. Fasteners, lacing wire, and stiffeners are produced from zinc-coated wire. Style 1 for the wire coating is normally recommended for:

1.4.2.1.1 Permanent

Gabion[ or mattress] structures, for works installed in non-aggressive or non-polluted environments, and this condition remains unaltered over time.

1.4.2.1.2 Temporary

Gabion[ or mattress] structures, for works in moderately aggressive environments, depending on the minimum design life of the structure.
1.4.2.2 Style 2
Wire mesh made from wire which is coated with Zn-5Al-MM before being double twisted into mesh. Fasteners, lacing wire, and stiffeners are also produced from Zn-5Al-MM coated wire. Style 2 for the wire coating is normally recommended for:

1.4.2.2.1 Permanent
Gabion[ or mattress] structures, for works installed in moderately aggressive environments.

1.4.2.2.2 Temporary
Gabion[ or mattress] structures, for works in aggressive environments, depending on the minimum design life of the structure.

1.4.2.3 Style 3
Wire mesh, lacing wire, and stiffeners as Style 1 and overcoated with PVC. Provide fasteners consisting of stainless steel wire. Style 3 for the wire coating is normally recommended for both permanent and temporary gabion structures, for works installed in aggressive or polluted environments, or when the aggressiveness of the site is moderately unpredictable or variable from low to high.

1.4.2.4 Style 4
Wire mesh made from wire which is aluminum-coated before being double twisted into mesh. Fasteners, lacing wire, and stiffeners are also produced from aluminum-coated wire. Style 4 for the wire coating is very seldom used in the gabion industry. Adequately document its life expectancy to guarantee its consistency and reliability.

1.4.3 Welded Wire Fabric Gabions[ and Mattresses]
Classified according to wire coating styles as follows:

1.4.3.1 Style 1
Welded wire fabric made from wire which is zinc coated before being welded into fabric. Spiral binders, lacing wire, and stiffeners are produced from zinc-coated wire. Style 1 for the wire coating is normally recommended for temporary gabion[ or mattress] structures, for works in non-aggressive or non-polluted environments.

1.4.3.2 Style 2
Welded wire fabric which is made from uncoated wire and the fabric is subsequently zinc-coated after fabrication. Spiral binders, lacing wire, and stiffeners are produced from zinc-coated wire. Style 2 for the wire coating is normally recommended for permanent gabion[ or mattress] structures, for works installed in non-aggressive or non-polluted environments, and this condition remains unchanged over time.

1.4.3.3 Style 3
Welded wire fabric made from wire which is coated with zinc-5 percent aluminum-mischmetal alloy (Zn-5Al-MM) before being welded into fabric.
Spiral binders, lacing wire, and stiffeners are also produced from zinc-5 percent aluminum-mischmetal alloy (Zn-5Al-MM) coated wire. Style 3 for the wire coating is normally recommended for:

1.4.3.3.1 Permanent

Gabion[ or mattress] structures, for works installed in moderately aggressive environments.

1.4.3.3.2 Temporary

Gabion[ or mattress] structures, for works in aggressive environments, depending on the minimum design life of the structure.

1.4.3.4 Style 4

Welded wire fabric made from wire which is aluminum-coated before being welded into fabric. Spiral binders, lacing wire, and stiffeners are also produced from aluminum-coated (aluminized) wire. Style 4 for the wire coating is very seldom used in the gabion industry. Adequately document its life expectancy to guarantee its consistency and reliability.

1.4.3.5 Style 5

Welded wire fabric, spiral binders, lacing wire, and stiffeners as Styles 1, 2, 3, or 4, and overcoated with PVC. Style 5 for the wire coating is normally recommended for both permanent and temporary gabion structures, for works installed in aggressive or polluted environments, or when the aggressiveness of the site is moderately unpredictable or variable from low to high.

1.5 SUBMITTALS

*************************************************************
NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.

SECTION 31 36 00 Page 10
The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.

**************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-04 Samples
   Gabions or Mattresses
   Alternative Wire Fasteners

SD-06 Test Reports
   Gabions or Mattresses
   Alternative Wire Fasteners; G[, [____]]

SD-07 Certificates
   Stone Fill
   Filter Material

1.6 QUALITY ASSURANCE

1.6.1 Samples

Furnish samples of materials used to fabricate the gabions or mattresses to the Contracting Officer 60 days prior to start of installation. Samples will be tested in accordance with specification and either ASTM A974 or ASTM A975 depending on which system is being furnished by the Contractor. The Government reserves the right to test additional samples to verify the submitted test records at the Government's expense. When the first test results indicate that the fasteners do not meet the specified requirements, the additional test will be at the Contractor's expense. The fasteners will be rejected after two tests failing to meet the requirements.

1.6.2 Test Report or Documents

Furnish copies of all test results to the Technical Representative of this specification, USACE District, Vicksburg, 4155 Clay St., Vicksburg, MS 39183-3435, Attn: Dale Goss (ED-GI).

1.7 DELIVERY, STORAGE, AND HANDLING

**************************************************************************
NOTE: Delivery to the jobsite of unassembled units will not be permitted, due to the increased labor and onsite supervision time, and to the fact that assembly is made on the jobsite and not in the quality-controlled manufacturer's facility.

Moreover, unassembled units delivered to the jobsite increase the likelihood to perform the construction by attaching units with a missing end panel rather than using entirely pre-assembled baskets. This will lower the structural integrity of the system, its strength at the connections and its overall resistance to the earth pressures.

It will be the responsibility of the manufacturer to guarantee that gabions are manufactured and delivered with all components mechanically attached, as required in ASTM A975 (Section 6.4) and ASTM A974 (Section 6.5).

**************************************************************************
Deliver gabions[ and mattresses] with all components mechanically connected at the production facility[ with the exception of the mattress lid, which is produced separately from the base]. All gabions[ and mattresses] are supplied in the collapsed form, either folded or bundled or rolled, for shipping. Bundles are banded together at the factory for ease of shipping and handling. [Mattress bases and lids may be packed in separate bundles].

a. Mattress lids may be supplied either as individual units (bundled) or in roll form. Ship lacing wire in coils with a diameter of the coil approximately 0.60 m 2 feet. Ship fasteners in boxes. Ship preformed stiffeners in bundles.

b. Deliver gabions[ and mattresses] to the jobsite labeled in bundles. Labels show the dimensions of the gabions[ or mattresses] included, the number of pieces and the color code.

PART 2 PRODUCTS

2.1 MATERIALS

**************************************************************************
NOTE: The use of the most appropriate Style for the wire coating in double twisted and welded wire gabions [and mattresses] is determined by the minimum required design life of the structure in relationship with the aggressiveness of the surrounding environment (air and water quality).

**************************************************************************

2.1.1 Double twisted wire mesh Gabions[ and Mattresses]

Double twisted wire mesh gabions[ and mattresses] must be [Style 1], [Style 2], [Style 3], and [Style 4] manufactured with a non-raveling mesh made by twisting continuous pairs of wires through three half turns (commonly called double twisted) to form a hexagonal-shaped opening. Ensure gabion [and mattress] sizes, wire diameters, mesh opening sizes, and tolerances comply with the requirements of ASTM A975 (Tables 1, 3, 4, 5, 6, and Sections 9). Provide gabions [and mattresses] that meet the following test
requirements:

2.1.1.1 Metallic Coating

Ensure coating weights conform to the requirements of [ASTM A641/A641M, Class 3 (Style 1)], [ASTM A856/A856M (Style 2)], [ASTM A90/A90M] or [ASTM A428/A428M] as applicable, and [ASTM A809 (Style 4)].

2.1.1.2 PVC for Coating

Provide PVC coating which shows no cracks or breaks after the wires are twisted in the fabrication of the mesh. Ensure the initial properties of PVC coating material have a demonstrated ability to conform to the following requirements:

2.1.1.2.1 Specific Gravity

In the range from 1.30 to 1.35 dN/dm³, when tested in accordance with test method ASTM D792

2.1.1.2.2 Tensile Strength

Not less than 20.6 MPa 2985 psi when tested in accordance with test method ASTM D412

2.1.1.2.3 Modulus of Elasticity

Not less than 18.6 MPa 2700 psi when tested in accordance with test method ASTM D412

2.1.1.2.4 Hardness

Shore "D" between 50 and 60, when tested in accordance with test method ASTM D2240

2.1.1.2.5 Brittleness Temperature

Not higher than -9 degrees C 15 degrees F, or lower temperature when specified by the purchaser, when tested in accordance with test method ASTM D746.

2.1.1.2.6 Resistance to Abrasion

The percentage of the weight loss must be less than 12 percent

2.1.1.2.7 Salt Spray Exposure and Ultra Violet Light Exposure

The PVC must show no effect after 3,000 h of salt spray exposure in accordance with ASTM B117. The PVC must show no effect of exposure to ultra violet light with test exposure of 3,000 h, using apparatus Spectral Irradiance of Open Flame Carbon Arc with Daylight Filters and 63 degrees C 145 degrees F, when tested in accordance with practice ASTM D1499 and ASTM G152

2.1.1.2.8 Evaluation of Coating After Salt Spray and Ultraviolet Exposure Test

After the salt spray test and exposure to ultraviolet light, the PVC coating must not show cracks nor noticeable change of color, or blisters or
splits. In addition, do not allow the specific gravity, tensile strength, hardness and resistance to abrasion to change more than 6 percent, 25 percent, and 10 percent respectively, from their initial values.

### 2.1.1.3 Wire Tensile Strength

The tensile strength of the wire used for the double twisted mesh, lacing wire, and stiffener, when tested in accordance with Test Methods and definitions ASTM A370, must be in accordance with the requirements of [ASTM A641/A641M (Style 1)], [ASTM A809 (Style 4)], and [ASTM A856/A856M (Style 2)], for soft temper wire.

### 2.1.1.4 Mesh Strength and Panel to Panel Joint Strength

Use the minimum strength requirements of the mesh, selvedge wire to mesh connection, panel to panel connection, and punch test, when tested in accordance with ASTM A975 Section 13.1, as shown in Table 1. The strength values reported in kN/m lb/ft are referred to the unitary width of the specimen. Perform the panel to panel test to demonstrate the ability of the fastening system to achieve the required strength, and indicate the number of wire revolutions for the lacing wire or the ring spacing for ring fasteners used. Use the same number of wire revolutions or ring spacing in the field installation. Pleating the based panel to obtain internal panels is prohibited.

### 2.1.2 Welded Wire Fabric Gabions[ and Mattresses]

Provide welded wire fabric gabions[ and mattresses] that are [Style 1], [Style 2], [Style 3], [Style 4], [and] [Style 5] manufactured with a welded wire mesh composed of a series of longitudinal and transverse steel wires arranged substantially at right angles to each other, and welded together at the points of intersection by electrical resistance welding to form fabricated sheets. Ensure gabion [and mattress] sizes, wire diameters, mesh opening sizes, physical properties of the PVC for coating, and tolerances comply with the requirements of ASTM A974 (Tables 1, 2, 3, and Sections 9). Provide gabions [and mattresses] that meet the following test requirements:
2.1.2.1 Metallic Coating

Ensure coating weights conform to the requirements of [ASTM A641/A641M, Class 3 (Style 1)], [ASTM A856/A856M (Style 2)], [ASTM A90/A90M] or [ASTM A428/A428M] as applicable, and [ASTM A809 (Style 4)].

2.1.2.2 PVC for Coating

PVC adhesion test must be PVC coating must show no cracks or breaks after the wires are twisted in the fabrication of the mesh. Ensure the initial properties of the PVC coating on the wire and welded wire fabric have a demonstrated ability to conform to the following requirements:

2.1.2.2.1 Adhesion

Ensure the PVC coating adheres to the wire such that the coating breaks rather than separates from the wire, in accordance with test method ASTM A974 Section 13.3;

2.1.2.2.2 Mandrel Bend

Provide PVC-coated wire that, when subjected to a single 360 bend at -18 degrees C 0 degrees F around a mandrel ten times the diameter of the wire, does not exhibit breaks or cracks in the PVC coating;

2.1.2.2.3 Specific Gravity

In the range from 1.20 to 1.40 dN/dm3, when tested in accordance with test method ASTM D792;

2.1.2.2.4 Tensile Strength

Not less than 15.7 MPa 2275 psi when tested in accordance with test method ASTM D638;

2.1.2.2.5 Modulus of Elasticity

Not less than 13.7 MPa 1980 psi at 100 percent strain, when tested in accordance with test method ASTM D638;

2.1.2.2.6 Hardness

Shore "A" not less than 75, when tested in accordance with test method ASTM D2240;

2.1.2.2.7 Brittleness Temperature

Not higher than -9 degrees C 15 degrees F, or lower temperature when specified by the purchaser, when tested in accordance with test method ASTM D746.

2.1.2.2.8 Resistance to Abrasion

The percentage of the weight loss must be less than 12 percent;

2.1.2.2.9 Salt Spray Exposure and Ultra Violet Light Exposure

The PVC must show no effect after 3,000 h of salt spray exposure in accordance with ASTM B117. The PVC must show no effect of exposure to
ultra violet light with test exposure of 3,000 h, using apparatus Spectral Irradiance of Open Flame Carbon Arc with Daylight Filters and 63 degrees C
145 degrees F, when tested in accordance with practice ASTM D1499 and
ASTM G152;

2.1.2.10 Evaluation of Coating After Salt Spray and Ultraviolet Exposure Test

After the salt spray test and exposure to ultraviolet light, ensure the PVC coating does not show cracks nor noticeable change of color, or blisters or splits. In addition, do not allow the specific gravity, tensile strength, hardness and resistance to abrasion to change more than 6 percent, 25 percent, and 10 percent respectively, from their initial values.

2.1.2.3 Wire Tensile strength

The tensile strength of the wire used for the welded wire fabric, spiral binders, lacing wire and stiffeners must be soft medium in accordance with ASTM A641/A641M (Style 1), ASTM A856/A856M (Style 3), and ASTM A809 (Style 4) or hand drawn in accordance with ASTM A853 (Style 2). Base the cross-sectional area of the test specimen on the diameter of the metallic coated wire. All the wires used in the fabrication of gabions [and mattresses] must use the same temper wire in accordance with given order.

2.1.2.4 Weld Shear Strength

2.1.2.4.1 Minimum Average Shear Value

The minimum average shear value in Newtons pounds-force must be 70 percent of the breaking strength of the wire or as indicated in the table as follows, whichever is greater, when tested in accordance with ASTM A974 Section 13.4. Typical minimum average shear strengths as specified are as follows:

<table>
<thead>
<tr>
<th>Wire diameter m/minch</th>
<th>Min. Av. Shear Strength N/lbs</th>
<th>Min. Shear Strength N/lbs</th>
</tr>
</thead>
<tbody>
<tr>
<td>2.200.087</td>
<td>1300292</td>
<td>1000225</td>
</tr>
<tr>
<td>2.700.106</td>
<td>2100472</td>
<td>1600360</td>
</tr>
<tr>
<td>3.050.120</td>
<td>2600584</td>
<td>2000450</td>
</tr>
</tbody>
</table>

Deem the material to conform with the requirements for weld shear strength if the average of the test results of the first four specimens or if the average of the test results for all welds tested comply with TABLE 2.

2.1.2.4.2 Panel to Panel Joint Strength

Use the minimum strength of the joined panels, when tested as described in ASTM A974 Section 13.5, as follows:
### TABLE 3
Panel to panel joint strength for welded gabions

<table>
<thead>
<tr>
<th>Test Description</th>
<th>Gabions, metallic coated (kN/mlb/ft)</th>
<th>Gabions, PVC coated (kN/mlb/ft)</th>
<th>[Revet mattresses (metallic and PVC)]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connection to selvedges</td>
<td>20.41400</td>
<td>17.51200</td>
<td>10.2700</td>
</tr>
<tr>
<td>Panel to panel (using lacing wire or ring)</td>
<td>20.41400</td>
<td>17.51200</td>
<td>10.2700</td>
</tr>
</tbody>
</table>

The strength values reported in kN/m lb/ft are referred to the unitary width of the specimen. Perform the panel to panel test to demonstrate the ability of the fastening system to achieve the required strength, and indicate the number of wire revolutions for the lacing wire used. Use the same number of wire revolutions in the field installation.

#### 2.1.3 Alternative Wire Fasteners for Gabions and Mattresses

**************************************************************************
NOTE: The use of steel rings is normally accepted in ASTM A975, for woven wire gabions and mattresses. Stainless steel rings will be used on PVC coated gabions or mattresses which meet the requirements of ASTM A313/A313M. Accepted alternative wire fasteners for welded wire gabions and mattresses are spiral binders, according to ASTM A974. The inclusion of rings for welded gabions is allowed only if proper guarantees over the pull apart, connection strength and long term durability (salt spray) are provided.
**************************************************************************

Subject to approval of the Contracting Officer, alternative fastening systems may be used in lieu of lacing wire. Alternative fasteners to lacing wire recommended for woven wire gabions and mattresses, according to ASTM A975, are steel ring fasteners for metallic coated gabions and mattresses, or stainless steel rings for PVC coated gabions and mattresses. For each shipment of wire gabions or mattresses delivered to the site, furnish the Contracting Officer, in duplicate, test reports or records that have been performed during the last year on all material contained within the shipment meets the composition, physical, and manufacturing requirements stated in this specification. Provide ring fasteners for woven wire gabions and mattresses in compliance with the minimum requirements indicated in paragraph Ring Fasteners below, and develop a minimum panel to panel joint strength as indicated in TABLE 1. Alternative fasteners to lacing wire for welded wire gabions and mattresses, according to ASTM A974, are spiral binders. Provide spiral binders for welded wire gabions and mattresses that comply with the minimum requirements indicated in paragraph Spiral Binders below. Ring fasteners may alternatively be used for welded wire gabions or mattresses, provided that they comply with the minimum specified requirements (salt spray and pull-apart resistance). Ensure panel to panel connections for welded gabions and mattresses with ring fasteners develop a minimum joint strength as indicated in TABLE 3. Provide a complete description of the fastener system and a description of a properly installed fastener, including drawings or photographs if necessary. Provide test results that demonstrate that the alternative-fastening system meets the requirements of the specifications, according to the following criteria:
a. That the proposed fastener system can consistently produce a panel to panel joint strength as indicated in the TABLE 1 for double twisted wire mesh gabions and TABLE 3 for welded wire mesh gabions;

b. That the proposed fastener system does not cause damage to the protective coating on the wire;

c. That the Contractor has the proper equipment and trained employees to correctly install the fasteners;

d. That proper installation can be readily verified by visual inspection.

Submit samples of wire fasteners with their certified test records at least 60 days in advance to the Contracting Officer for approval. The Government reserves the right to test additional samples to verify the submitted test records at the Government's expense. When the first test results indicate that the fasteners do not meet the specified requirements, the additional test will be at the Contractor's expense. The fasteners will be rejected after two tests failing to meet the requirements.

2.1.3.1 Ring Fasteners

The tensile strength of the zinc-coated steel wire, zinc-5 percent aluminum coated mischmetal alloy-coated steel wire and aluminum-coated steel wire used for fasteners must be in accordance with the requirements of ASTM A764, Type A, B, or C, Table 2 or Table 3. Use stainless steel wire for fasteners with tensile strength in accordance with the requirements of ASTM A313/A313M, Type 302, Table 2. Any fastener system must give the number of fasteners required to comply with TABLE 1, in accordance with ASTM A975 (Section 13.1.2) for woven wire gabions and mattresses, and TABLE 3, in accordance with ASTM A974 (Section 7.3), for welded wire gabions and mattresses. Do not install ring fasteners more than 100 mm 4 inches apart. Close each fastener type and overlap the free ends of the fastener a minimum of 25 mm 1 inch. The manufacturer or supplier must state the number of fasteners required for all vertical and horizontal connections for single and multiple basket joining. Approved ring fasteners including fasteners made of stainless steel are subject to the salt spray test and pull-apart resistance test and provide documentation of actual testing of panel to panel connections within the last year by validated laboratories.

2.1.3.1.1 Salt Spray Test

Join a set of two identical rectangular gabion panels, each with a width about 10-1/2 mesh openings along a selvedge wire, by properly installed wire fasteners along the two selvedge wires so that each fastener confines two selvedge and two mesh wires. If the fasteners are also to be used to joint two individual empty gabion baskets, include two additional selvedge wires which are each mechanically wrapped with mesh wires so that each fastener confines four selvedge and four mesh wires. The set of the jointed panels are subject to salt spray test, ASTM B117, for a period of not less than 48 hours. At the end of the test, ensure the fasteners, the selvedge, or mesh wires confined by the fasteners show no rusty spots on any part of the surface excluding the cut ends. Properly install fastener meeting the following requirements:

a. Ensure each interlocking fastener is in a locked and closed position.

b. Close each ring fastener, and overlap the free ends of the fastener a
minimum of 25 mm 1 inch.

2.1.3.1.2 Pull-Apart Resistance Test

Mount a new set of the jointed panels, which are prepared by the same method as specified in the salt spray test but without being subject to the 48-hour salt spray test, on a loading machine with grips or clamps such that the panels are uniformly secured along the full width. Design the grips or clamps to transmit only tension forces. The load will then be applied at a uniform rate of 220 N/s 50 lbs/sec until failure occurs. The failure is defined as when the maximum load is reached and a drop of strength is observed with subsequent loading or the opening between any two closest selvedge wires, applicable to a fastener confining either two or four selvedge wires, becomes greater than 50 mm 2 inches at any place along the panel width. The strength of the jointed panels at failure must have a minimum as indicated in TABLE 1 or TABLE 3.

2.1.3.2 Spiral Binders

Spiral binders are defined as a length of metallic coated steel wire or metallic coated steel wire with PVC coating preformed into a spiral, used to assemble and interconnect empty gabion and/or mattress units, and to close and secure stone-filled units. Fabricate spiral binders with the same wire and coating style as the wire mesh. Test requirements for spiral binders must refer to TABLE 3 regarding Metallic Coating, PVC for coating, Tensile Strength, and Panel to Panel Joint Strength.

2.1.4 Testing

Test records made within one year by certified laboratories and Government agencies will be used to determine the acceptability of the fastening system. Submit samples of wire fasteners and samples of material for fabricating the gabions and mattresses with their certified test records at least 60 days in advance to the Contracting Officer for approval. The Government reserves the right to test additional samples to verify the submitted test records at the Government's expense. When the first test results indicate that the fasteners do not meet the specified requirements, the additional test will be at the Contractor's expense. The fasteners will be rejected after two tests failing to meet the requirements.

2.1.5 Stone Fill

Submit a certificate or affidavit signed by a legally authorized official of the supplier of the stone fill and the supplier of the natural filter material (see next main paragraph below) that it meets the quality required and gradation limits specified.

2.1.5.1 General

*******************************************************************************
NOTE: Stones having a lower unit (not less than 2240 kg/m3 140 lb/ft3) may be approved by the Contracting Officer, provided that the design is performed on the selected unit weight and the stone has a performance record to prove its durability.

If stone sources are not listed in the bid documents, the District must ensure that these sources contain stone with required quality and
quantity. It is the Contractor's responsibility to determine that the selected source is capable of supplying the quantities and gradation needed and at the rate needed. Acceptance of a source of stone does not imply acceptance of all material from the source, when such materials are unsuitable as determined by the Contracting Officer.

For gabions[ and mattresses], the ability to function properly depends upon their stability, which is partly depending upon the rocks filling them. Rock sizes should be chosen to prevent them from falling through the mesh of the gabions [or mattresses]. The rock has also to withstand natural weathering processes during the life of the project that would cause it to breakdown to sizes smaller than the wire mesh opening dimensions. Provide durable rock to fill gabions[ and mattresses] and of suitable quality to ensure permanence in the structure and climate in which it is to be used.

2.1.5.1.1 Delivery

Deliver rock to the work site in a manner to minimize its reduction in sizes (breakdown) during the handling of the rock, and place and secure within the assembled and interconnected gabion[ or mattress].

2.1.5.1.2 Sources

Select the sources from which the Contractor proposes to obtain the material well in advance of the time when the material will be required in the work. The inclusion of more than 5 percent by weight of dirt, sand, clay, and rock fines will not be permitted. Rock may be of a natural deposit of the required sizes, or may be crushed rock produced by any suitable method and by the use of any device that yields the required size limits chosen in TABLE 4.

2.1.5.1.3 Properties

Provide hard, angular to round, durable rocks and of such quality that they do not disintegrate on exposure to water or weathering during the life of the structure. [Selected stone from the required excavation may be used if satisfying all requirements as to quality and dimensions.] [Obtain all stone from one of the [sources listed below][sources listed at the end of this section]].

2.1.5.1.4 Non-Listed Source

As an option, propose to furnish stone from one non-listed source. The Government [will][may] make such investigations and tests as necessary to determine whether acceptable stone can be produced from the proposed source. Collect suitable samples of stone fill material in the presence of a Government representative and submit to the Contracting Officer for approval prior to delivery of any such material to the work site. Unless otherwise specified, obtain and deliver all test samples at the Contractor's expense to [_____] at least 60 days in advance of the time when placing of the stone-filled gabions [or mattresses] is expected to begin. Suitable tests and/or service records will be used to determine the acceptability of the stone. In the event suitable test reports and service records are not available, as in the case of newly operated sources, the material may be subjected to petrography analysis, specific gravity, absorption, wetting and drying, freezing and thawing, and such other tests.
as may be considered necessary to demonstrate to the satisfaction of the Contracting Officer that the materials are acceptable for use in the work. All tests will be made by or under the supervision of the Government and at its expense.

2.1.5.2 Stone Quality

Provide stone fill, crushed stone, meeting the quality requirements of ASTM C33/C33M, and freezing and thawing requirements of [ASTM D5312/D5312M][COE CRD-C 144] for the region of the United States in which the structure will be constructed.

2.1.5.3 Gradation

Perform gradation of stone for gabions every 1000 tons placed under this contract in accordance with ASTM C136/C136M. Sizes of rock to fill gabions and mattresses are chosen on the basis of the mesh sizes, the structure's thickness, and within the limits shown in TABLE 4. Within each range of sizes, provide rock large enough to prevent individual pieces from passing through the mesh openings. Each range of sizes may allow for a variation of 5 percent oversize rock by weight, or 5 percent undersize rock by weight, or both.

2.1.5.3.1 Oversize Rock

In all cases, ensure the sizes of any oversize rock allow for the placement of three or more layers of rock within each gabion compartment[ and two or more layers of rock within each mattress compartment dependent upon the height of the mattress].

2.1.5.3.2 Undersize Rock

In all cases, place undersize rock within the interior of the gabion or mattress compartment and do not place on the exposed surface of the structure. There is a maximum limit of 5 percent undersize or 5 percent oversize rock, or both, within each gabion[ or mattress] compartment. The required rock gradation is reported in Table 4.

2.1.6 Filter Material

**************************************************************************

NOTE: When a filter layer is required beneath the gabion or mattress foundation, care must be taken to ensure that the minimum thickness is achieved evenly across the surface to be protected. To assure
sufficient relative permeability and drainage, to prevent the migration of slope materials into the filter layer, and for the retention of filter materials by the overlying gabion units, the particle size distribution of the filter material should conform to "Filter Design," Appendix E of EM 1110-2-1913."

Stone-filled units have a potential for becoming impermeable. For extreme cases of long protected slope distances, or any application where large volumes of seepage or captured runoff is anticipated, design consideration should be given to the carrying capacity of the filter material and the need for providing pipe drains through the gabion units.

Although the provision of a pervious filter layer beneath gabion slope protection is preferred, particularly for slopes steeper than 1V on 2H, construction economy may be achieved in some cases through the use of geotextile. The specifications for the geotextile should be in accordance with the instructions contained in Section 31 05 19.13 GEOTEXTILES FOR EARTHWORK.

**************************************************************************
Provide material meeting the quality requirements of ASTM C33/C33M for the region in which the structure is located. Perform the gradation test in accordance with ASTM C136/C136M. Provide filter material consisting of sand and gravel or crushed stone, well graded between the prescribed limits listed below.

[Provide filter fabrics meeting the provisions of Section 31 05 19.13 GEOTEXTILES FOR EARTHWORK].

PART 3   EXECUTION

3.1 FOUNDATION PREPARATION

Foundation preparation [may][must not] take place on frozen or snow-covered ground. After excavation or stripping, to the extent indicated on the drawings or as directed by the Contracting Officer, remove all remaining loose or otherwise unsuitable materials. Carefully backfill all depressions to grade. If pervious materials are encountered in the foundation depressions, backfill the areas with free-draining materials. Otherwise, backfill the depressions with suitable materials from adjacent required excavation, or other approved source, and compacted to a density at least equal to that of the adjacent foundation. Also remove any debris that will impede the proper installation and final appearance of the gabion layer, and carefully backfill and compact the voids as specified above. Immediately prior to placing the material, the Contracting Officer will inspect the prepared foundation surface, and place no material thereon until that area has been approved.
3.2 FILTER PLACEMENT

Spread filter material uniformly on the prepared foundation surface in a manner satisfactory to the Contracting Officer, and to the slopes, lines, and grades as indicated on the drawings or as directed. Placing of filter material by methods, which will tend to segregate particle sizes, will not be permitted. Repair any damage to the foundation surface during the filter placement before proceeding with the work. Compaction of the filter materials will not be required, but it must be finished to present a reasonably even surface free from mounds or windrows.

3.3 ASSEMBLY

3.3.1 Double twisted wire mesh Gabions

Open the gabions and unfold one by one on a flat, hard surface. Gabion units over 1.82 m 6 foot in length usually have an extra shipping fold, which must be removed. Lift up the sides, ends and diaphragms into a vertical position to form an open box shape. Connect the back and the front panels of the gabion to the end panels and center diaphragms. The top corner of the end panels and center diaphragms have a selvedge wire extending approximately 100 mm 4 inches out from the corner edge. Raise the end panels and the diaphragms to a vertical position and wrap the selvedge wire around the edge wire of the top and back panels.

3.3.2 Double Twisted Wire Mesh Revet Mattresses

**************************************************************************
NOTE: Remove this paragraph if not needed.
**************************************************************************

Lay the mattress on a flat, hard surface. When the units are unfolded for assembly, depending on their length, they will have one or two shipping folds, which must be removed. Fold in the double flap of the side panel and wire to the diaphragm. At the corners, fold the end flaps along the sides and lace up the joint. Assemble each Revet mattress individually, by erecting the sides, ends and diaphragms, ensuring that all creases are in the correct position and the tops of all sides are level.

3.3.3 Welded Wire Fabric Gabions[ and Gabion Mattresses]

Open the gabions[ or gabion mattresses] and unfold on a flat, hard surface. Rotate the units into position and join the edges with fasteners for assembly. Where spiral fasteners are used, crimp the ends to secure them in place. Where lacing wire is used, wrap the wire with alternating double and single loops with spacings not to exceed 150 mm 6 inches. Secure ends with two complete revolutions and finish with a one-half hitch. Use the same fastening procedures to secure interior diaphragms and end panels. When two gabions are placed side by side, the two end panels may be connected along the vertical edges with a single spiral fastener.

3.4 LACING OPERATIONS

3.4.1 Double Twisted Wire Mesh Gabions[ and Mattresses]

Either lacing wire or ring fasteners are permitted to lace double twisted wire mesh gabions[ or revet mattresses].
3.4.1.1 Lacing Wire

When using lacing wire, cut off a piece of wire 1.2 to 1.5 times the length of the edge to be laced. If the edge of the basket is 0.91 m 3 foot long, no more than 1.2 to 1.5 m 4 to 5 feet of wire should be used at a time to lace. For vertical joints, starting at the bottom end of the panel, twist the lacing wire and wrap two times around the bottom selvedge and alternate double and single loops through at intervals no bigger than 100 to 150 mm 4 to 6 inches. Finish the operation by looping around the top selvedge wire. The use of pliers to assemble the units with lacing wire is normally recommended.

3.4.1.2 Steel Wire Ring Fasteners

When steel wire ring fasteners are used, install the rings at the top and bottom connections of the end and center diaphragms. Base the ring spacing on the minimum pull apart strength as specified in TABLE 1. In any case, do not exceed maximum ring spacing along the edges of 0.15 m 6 inches. The use of either a mechanical or a pneumatic fastening tool for steel wire ring fasteners is required. Provide galvanized, stainless steel or Zn-5 percent aluminum-mischmetal alloy coated ring fasteners.

3.4.2 Welded Wire Mesh Gabions[ and Mattresses]

Either lacing wire or spiral binders are permitted to lace welded wire mesh gabions[ or gabion mattresses]. Place the empty units on the foundation and interconnect with the adjacent unit along the top, bottom and vertical edges using spiral fasteners. Lacing wire may be used in lieu of spiral binders for the interconnection of gabions[ or mattresses] as specified above. Base connection with lacing wire or spiral binders on the minimum panel to panel joint strength as specified in TABLE 3. Screw spiral binders along the connecting edges, and then crimp each end to secure the spiral in place. Interconnect each layer of gabions[ or mattresses] to the underlying layer along the front, back and sides.

3.5 INSTALLATION AND FILLING

Assemble empty gabion[ and mattress] units individually and place on the approved surface to the lines and grades as shown or as directed, with the sides, ends, and erect diaphragms in such a manner to ensure the correct position of all creases and that the tops of all sides are level. Properly stagger all gabion units [horizontally][ and vertically] as shown in the construction drawings. Finished gabion[ or mattress] structures must have no gaps along the perimeter of the contact surfaces between adjoining units. Connect all adjoining empty gabion units along the perimeter of their contact surfaces in order to obtain a monolithic structure. Securely fasten all lacing wire terminals. Make all joining through selvedge-to-selvedge or selvedge-to-edge wire connection; mesh-to-mesh or selvedge-to-mesh wire connection is prohibited except in the case where baskets are offset or stacked and selvedge-to-mesh or mesh-to-mesh wire connection would be necessary. As a minimum, install a fastener at each mesh opening at the location where mesh wire meets selvedge or edge wire.

a. Place the initial line of basket units on the prepared [filter layer surface][foundation] and adjoining empty baskets set to line and grade, and common sides with adjacent units thoroughly laced or fastened. Place them in a manner to remove any kinks from the mesh and to a uniform alignment. Then partially fill basket units to provide anchorage against deformation and displacement during the filling
operation. Place stone in the units as specified in paragraph Stone Fill, subparagraph Gradation, part b.

b. Correct undue deformation and bulging of the mesh prior to further stone filling. Take care, when placing the stone by hand or machine, to assure that the PVC coating on gabions will not be damaged. Fill all visible faces with some hand placement to ensure a neat and compact appearance and that the void ratio is kept to a minimum.

c. Uniformly overfill gabions [and mattresses] by about 25 to 50 mm 1 to 2 inches to compensate for future rock settlements. Gabions [and mattresses] can be filled by any kind of earth-filling equipment, such as a backhoe, gradall, crane, etc. The maximum height from which the stones may be dropped into the baskets is 0.91 to 1.20 m 3 to 4 feet. If PVC coated materials are used, no work is allowed to take place unless the ambient temperature is above -7 degrees C 20 degrees F.

3.5.1 Double Twisted Wire Mesh Gabions

After the foundation has been prepared, place the pre-assembled gabions in their proper location to form the structure. Connect gabions together and align before filling the baskets with rock. Carry out all connections (panel-to-panel) and basket-to-basket as described in paragraph ASSEMBLY. Provide stone fill with a gradation of 0.10 to 0.20 m 4 to 8 inches, as described in paragraph Gradation, and place in 0.30 m 1 foot lifts. Fill cells to a depth not exceeding 0.30 m 1 foot at a time. The fill layer should never be more than 0.30 m 1 foot higher than any adjoining cell. Install stiffeners or internal cross ties in all front and side of the gabions at 1/3 and 2/3 of the height for 0.91 m 3 feet or higher gabions, as the cell is being filled. Install stiffeners in the center of the cells. In 0.46 m 1.5 foot high units, stiffeners or internal crossties are not required. Loop internal cross ties, or alternatively the preformed stiffeners, around three twisted wire mesh openings at each basket face and securely twist the wire terminals to prevent their loosening. Minimize the number of voids by using a well-graded stone in order to achieve a dense, compact stone fill. Connect all corners securely to the neighboring baskets of the same layer before filling the units. When more than one layer of gabions is required, in order for the individual units to become incorporated into one continuous structure, connect the next layer of gabions to the layer underneath after this layer has been securely closed. Overfill gabions uniformly by about 25 to 50 mm 1 to 2 inches to compensate for future rock settlements.

3.5.2 Double Twisted Wire Mesh Revet Mattresses

**************************************************************************
NOTE: Remove this paragraph if not needed.
**************************************************************************

After being assembled, place the revet mattresses in their proper location and securely attach to the adjacent units. For structural integrity, connect all adjoining empty units by means of lacing wire or ring fasteners along the edges of their contact surfaces in order to form a monolithic structure. Place revet mattresses and securely connect while empty. Fill unit by unit; however, several units can be pre-assembled prior to filling the units. Fill revet mattress units with hard, durable, clean stone having a gradation as indicated in paragraph Gradation. Take care to ensure that diaphragm tops are accessible for wiring. On slopes, lay the revet mattress with the 1.83 m 6 foot dimension (width) longitudinal to
the slope and progressing up the slope, except for small ditches or where otherwise specified in the project. When the installation is performed on a slope, start the filling of the baskets from the lower side of the bank. Where Revet mattresses are to be placed on steep slopes (3H to 2V), secure the units by hardwood pegs driven into the ground just below the upper end panel, at 1.83 m 6 foot centers, or as specified in the project. When the Revet mattress is to be placed over a geotextile, take care to ensure that any projecting ends of wire are bent upward to avoid puncturing or tearing the cloth. Connect lids securely to the ends of the mattress and to the top sides and diaphragms using alternate double and single loops, or steel wire ring fasteners, as indicated in paragraph FOUNDATION PREPARATION. In case that more adjacent bases are to be covered at one time, use mesh rolls in place of unit size lids. Overfill revet mattresses uniformly by about 25 to 50 mm 1 to 2 inches to compensate for future rock settlements.

3.5.3 Welded Wire Fabric Gabions

After the foundation has been leveled, place the assembled gabions in their proper location to form the structure. Take care to ensure that the top of the diaphragms are aligned correctly. Connect the diaphragms securely by either spiral binders or lacing wire. Connect gabions together and align before filling them with 100 to 200 mm 4 to 8 inch diameter rocks. Provide rock filling material as specified in paragraph Gradation and place in 0.30 m 1 foot lifts. Hand-pack the fill layer carefully and brace to prevent bulging. Provide stiffeners every 0.30 m 12 inch levels for 0.91 m 3 foot or higher gabions. Form stiffeners from lacing wire and place across the corners at 0.30 m 12 inches from the corner, providing a diagonal bracing. Preformed hooked stiffeners can be utilized. Take care to ensure the number of voids is minimized by using a well-graded stone and avoiding large rocks in order to achieve a dense, compact compartment. After each 0.30 m 1 foot lift has been placed, level it for the next lift. Almost all gabion structures consist of more than one course of gabions; in order that the individual gabions may become incorporated into one continuous structure, wire them to neighboring gabions and the course below, before filling. Overfill gabions uniformly by about 25 to 50 mm 1 to 2 inches to compensate for future rock settlements.

3.5.4 Welded Wire Fabric Gabion Mattresses

**************************************************************************
NOTE: Remove this paragraph if not needed.
**************************************************************************

After being assembled, place the gabion mattresses in their proper location and securely attach to the adjacent units. For structural integrity, connect all adjoining empty units by means of lacing wire or spiral binders along the edges of their contact surfaces in order to form a monolithic structure. Place gabion mattresses and securely connect while empty. Fill unit by unit; however, it is recommended that several units be pre-assembled prior to filling the units. Fill gabion mattress units with hard, durable, clean stone having a gradation as indicated in paragraph Gradation. Take care to ensure that diaphragm tops are accessible for wiring.

a. On slopes, lay the Gabion mattress with the 1.83 m 6 foot dimension (width) longitudinal to the bank, with the exception of small ditches or when otherwise specified in project. When the installation is performed on a slope, start the filling of the units from the lower side of the bank. Where Gabion mattresses are to be placed on steep
slopes (3H to 2V), secure the units by galvanized pipes driven into the ground inside the upper end panel, at 1.83 m 6 foot centers, or as specified in the project.

b. When the gabion mattress is to be placed over a geotextile, take care to ensure that any projecting ends of wire are bent upward to avoid puncturing or tearing the cloth.

c. Connect lids securely to the ends of the mattress and to the sides and diaphragms using alternate double and single loops, or steel wire ring fasteners, as indicated in paragraph FOUNDATION PREPARATION. In case that more adjacent bases are to be covered at one time, mesh rolls can be used in place of unit size lids. Overfill gabion mattresses uniformly by about 25 to 50 mm 1 to 2 inches to compensate for future rock settlements.

3.5.5 Non-Rectangular Shapes

Gabion[ and mattress] units can conform to bends up to a radius of curvature of 18 to 21 m 60 to 70 feet without alterations. Securely connect units together first, and place to the required curvature, holding them in position by staking the units to the ground with hardwood pegs before filling. For other shapes, bevels and miters can be easily formed by cutting and folding the panels to the required angles.

3.6 CLOSING

Secure lids tightly along all edges, ends and diaphragms in the same manner as described for assembling. Adjacent lids may be securely attached simultaneously. Connect panel edges by pulling using the appropriate closing tools where necessary. Do not use single point leverage tools, such as crowbars, which may damage the wire mesh. Then turn in all end wires.

NOTE: This guide specification covers the requirements for metal sheet piling. This section was originally developed for USACE Civil Works projects.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1 GENERAL

NOTE: Permanent earth retaining structures made with steel sheet piling such as caissons, quay walls, and retaining walls are covered by this section. Temporary structures such as shoring and sheeting are the responsibility of the Contractor and unless required by conditions of the project, are not to be covered by this section. The extent and location of the work to be accomplished should be indicated on the project drawings.

The following information must also be shown on the project drawings:
1. Location of piles.
2. Soil data, where required.
3. Pile shape.
4. Pile size and weight.
5. Length or tip and cut-off elevations.

**************************************************************************

1.1 DESCRIPTION

Design, furnish, install and test metal sheet piles at the locations indicated on the drawings and specified herein. [Assume test pile[s] will be directed to be placed in [a] location[s] that can be incorporated into the work.]

1.2 REFERENCES

**************************************************************************

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

**************************************************************************

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

AMERICAN WELDING SOCIETY (AWS)

AWS D1.1/D1.1M (2020; Errata 1 2021) Structural Welding Code - Steel

AWS D1.5M/D1.5 (2020; Errata 1 2022) Bridge Welding Code

ASTM INTERNATIONAL (ASTM)

1.3 BASIS OF BID

**************************************************************************
NOTE: Select one of the following options.
**************************************************************************

**************************************************************************
NOTE: Use "Lump Sum" paragraph below for lump (principal) sum bidding of piles. Use this in all projects except those where exact pile lengths cannot be practically determined prior to the actual work. Clearly show number of piles, pile capacity, pile locations, and tip and cutoff elevations on the drawings.

Use "Unit Price" paragraph for unit price bidding of piles. Specify unit price bid items for piles only for projects where exact quantities cannot be practically determined prior to the actual work. Lengths of piles must be determined as accurately as possible, prior to bidding, since the unit price per meter (foot) of the piles varies as the length increases or decreases. Refer to Standard Test Method for High-Strain Dynamic Testing of Deep Foundations (ASTM D4945).

Whenever sheet piling section properties greater
than required by design are acceptable, "(Min.)" should be indicated after the applicable value shown in this specification or on the drawings.

**************************************************************************

1.3.1 Contractor's Geotechnical Consultant

Hire the services of an independent, Registered Professional Geotechnical Engineer, experienced in soil mechanics and Pile Dynamic Analysis, to observe test pile installation and production pile installation as specified herein. The Contractor's Geotechnical Consultant must be independent of the Contractor and must have no employee of employer relationship which could constitute a conflict of interest.

1.3.2 Lump Sum Payment

Base bids upon providing the number, size, capacity, and length of piles as indicated on the drawings. [following Table I:

<table>
<thead>
<tr>
<th>Location</th>
<th>Number</th>
<th>Section Modulus</th>
<th>Moment of Inertia</th>
<th>Length (tip to cut-off)</th>
</tr>
</thead>
</table>

*Section properties should be detailed per foot of wall, in$^3$ per ft.

**Section properties should be detailed per foot of wall, in$^4$ per ft.]

Include the cost of all necessary equipment, tools, material, labor, and supervision required to: deliver, handle, install, cut-off, dispose of any cut-offs, pullout, and meet the applicable contract requirements. Include mobilization, pre-drilling, and redriving heaved piles. If, in redriving, it is found that any pile is not of sufficient length to provide the requirements specified, notify the Contracting Officer, who reserves the right to increase or decrease the total length of piles to be provided and installed by changing the pile locations or elevations, requiring the installation of additional piles, or directing the omission of piles from the requirements shown and specified. If total number of piles or number of each length vary from that specified as the basis for bidding, an adjustment in the contract price or time for completion, or both, will be made in accordance with the contract documents. Payment for piles will be based on successfully installing piles to both the minimum tip elevation and satisfying the acceptance criteria identified herein. No additional payment will be made for: damaged, rejected, or misplaced piles; withdrawn piles; any portion of a pile remaining above the cut-off elevation; backdriving; cutting off piles; splicing; build-ups; any cut-off length of piles; or other excesses beyond the assumed pile length indicated for which the Contractor is responsible. [ Include payments for vibration monitoring, sound monitoring and precondition construction surveys.]

1.3.3 Unit Prices

**************************************************************************

NOTE: If Section 01 20 00 PRICE AND PAYMENT PROCEDURES is included in the project specifications, this paragraph title (UNIT PRICES) should be deleted from this section and the
1.3.3.1 Steel Sheet Piling, Type [____], Grade [_____]

1.3.3.1.1 Payment

Payment for sheet piling quantities will be made at the applicable contract price per linear meter foot for furnished and installed sheet piling. Payment will cover all cost of furnishing, handling, storing and installing piling including placing, driving, cutting holes and other materials, and work incident thereto.

1.3.3.1.2 Measurement

The length of sheet piling installed [and removed] will be measured to the nearest tenth of a linear meter foot. For installed pilings directed to be cut off before reaching the penetration depth shown, the portion cut off will be measured for payment as the difference between the total length of piling shown on the plans for that location and the length of piling installed below the point of cut-off.

1.3.3.1.3 Unit of Measure

Linear meter foot.

1.3.3.2 Steel Fabricated Sections, Type[s] [____], Grade [_____]

1.3.3.2.1 Payment

Payment for sheet piling quantities will be made at the applicable contract price per linear meter foot for furnished and installed sheet piling. Payment will cover all cost of furnishing, handling, storing and installing piling including placing, driving, cutting holes and other materials and work incident thereto [except the cost of furnishing piling will not be included in the contract price for Government furnished piling].

1.3.3.2.2 Measurement

The length of sheet piling installed [and removed] will be measured to the nearest tenth of a linear meter foot. For installed pilings directed to be cut off before reaching the penetration depth shown, the portion cut off will be measured for payment as the difference between the total length of piling shown on the plans for that location and the length of piling installed below the point of cut-off.

1.3.3.2.3 Unit of Measure

Linear meter foot.

1.3.3.3 Steel Sheet Piling - Government Furnished

1.3.3.3.1 Payment

Payment for sheet piling quantities will be made at the applicable contract price per linear meter foot for furnished and installed sheet piling. Payment will cover all cost of furnishing, handling, storing and installing piling including placing, driving, cutting holes and other materials and
work incident thereto [except the cost of furnishing piling will not be included in the contract price for Government furnished piling].

1.3.3.3.2 Measurement

The length of sheet piling installed [and removed] will be measured to the nearest tenth of a linear meter foot. For installed pilings directed to be cut off before reaching the penetration depth shown, the portion cut off will be measured for payment as the difference between the total length of piling shown on the plans for that location and the length of piling installed below the point of cut-off.

1.3.3.3.3 Unit of Measure

Linear meter foot.

1.3.4 Aluminum Sheet Piling, Type [____]

1.3.4.1 Payment

Payment for sheet piling quantities will be made at the applicable contract price per linear meter foot for furnished and installed sheet piling. Payment will cover all cost of furnishing, handling, storing and installing piling including placing, driving, cutting holes and other materials and work incident thereto [except the cost of furnishing piling will not be included in the contract price for Government furnished piling].

1.3.4.2 Measurement

The length of sheet piling installed [and removed] will be measured to the nearest tenth of a linear meter foot. For installed pilings directed to be cut off before reaching the penetration depth shown, the portion cut off will be measured for payment as the difference between the total length of piling shown on the plans for that location and the length of piling installed below the point of cut-off.

1.3.4.3 Unit of Measure

Linear meter foot.

1.3.5 Aluminum Fabricated Sections, Type[s] [____]

1.3.5.1 Payment

Payment for sheet piling quantities will be made at the applicable contract price per linear meter foot for furnished and installed sheet piling. Payment will cover all cost of furnishing, handling, storing and installing piling including placing, driving, cutting holes and other materials and work incident thereto [except the cost of furnishing piling will not be included in the contract price for Government furnished piling].

1.3.5.2 Measurement

The length of sheet piling installed [and removed] will be measured to the nearest tenth of a linear meter foot. For installed pilings directed to be cut off before reaching the penetration depth shown, the portion cut off will be measured for payment as the difference between the total length of piling shown on the plans for that location and the length of piling installed below the point of cut-off.
1.3.3.5.3 Unit of Measure

Linear \textit{meter foot}.

1.3.3.6 Aluminum Sheet Piling - Government Furnished

1.3.3.6.1 Payment

Payment for sheet piling quantities will be made at the applicable contract price per linear \textit{meter foot} for furnished and installed sheet piling. Payment will cover all cost of furnishing, handling, storing and installing piling including placing, driving, cutting holes and other materials and work incident thereto [except the cost of furnishing piling will not be included in the contract price for Government furnished piling].

1.3.3.6.2 Measurement

The length of sheet piling installed [and removed] will be measured to the nearest tenth of a linear \textit{meter foot}. For installed pilings directed to be cut off before reaching the penetration depth shown, the portion cut off will be measured for payment as the difference between the total length of piling shown on the plans for that location and the length of piling installed below the point of cut-off.

1.3.3.6.3 Unit of Measure

Linear \textit{meter foot}.

1.3.3.7 Cut-Offs

1.3.3.7.1 Payment

When pilings which have not been driven to penetration depths shown are directed to be cut off, except for cut-offs due to excessive battering, a lump sum payment will be made for cutting off each piling.

1.3.3.7.2 Measurement

An additional sum will be paid for each linear \textit{meter foot} of the portion cut off and measured for payment. For installed pilings directed to be cut off before reaching the penetration depth shown, the portion cut off will be measured for payment as the difference between the total length of piling shown on the plans for that location and the length of piling installed below the point of cut-off at the rate of 50 percent of the applicable contract unit price.[ No payment will be made for cut-off portions of Government furnished pilings.]

1.3.3.7.3 Unit of Measure

Each.

1.3.3.8 Splices

1.3.3.8.1 Payment

Payment will be made for each piling spliced at the direction of the Contracting Officer to drive the piling to a depth greater than shown and extend it up to the required top elevation. An additional sum will be paid
for each linear meter foot of the piling extension at the applicable contract unit price.

1.3.3.8.2 Measurement

Splices will be measured for payment for each piling spliced.

1.3.3.8.3 Unit of Measure

Each.

1.3.9 Pulled Pilings

1.3.9.1 Payment

The Contractor furnished pilings which have been installed and are pulled at the direction of the Contracting Officer and found to be in good condition will be paid for at the applicable contract unit price for furnishing and installing the pilings in their initial position plus the applicable contract unit price for the cost of pulling.

1.3.9.2 Measurement

When such pulled pilings are redriven, an additional amount equal to 50 percent of the applicable contract unit price for furnishing and driving the pilings will be paid for redriving the pilings. This additional price constitutes payment for redriving only. The cost of furnishing, initial driving, and pulling the pilings is to be paid for as specified.

a. Government furnished pilings which are pulled at the direction of the Contracting Officer and found to be in good condition will be paid for at the applicable contract unit price for installing the pilings in their initial position plus an equal amount for the cost of pulling. Such piling when redriven will be paid for at the applicable contract unit cost for installing the pilings.

b. When pilings are pulled and found to be damaged no payment will be made for the initial furnishing and driving or for the pulling of such pilings. Pilings replacing damaged pilings will be paid for at the applicable contract unit prices.

1.3.9.3 Unit of Measure

Each.

1.3.10 Removal of Sheet Pilings

1.3.10.1 Payment

Payment will be made for costs associated with removal of sheet pilings. Payment will cover cost of pulling, cleaning the interlock, sorting, inventorying and storing.

1.3.10.2 Measurement

Removal of sheet piling will be made at the applicable contract price per linear meter foot for the removal of sheet pilings.

SECTION 31 41 16 Page 11

Linear meter foot.

1.4 NAVY PROJECT PRICE AND PAYMENT PROCEDURES

******************************************************************************

NOTE: Select the applicable paragraph(s) from the following.
******************************************************************************

1.4.1 Basis of Bids

******************************************************************************

NOTE: Use this option for fixed-price contracts.
******************************************************************************

Base bids on pile sections and lengths as indicated. Should the total number of piles or the number of each length vary from that specified as the basis for bidding, an adjustment in the contract price and time for completion will be made. No additional payment will be made for withdrawn, damaged, rejected, or misplaced piles; for any portion of a pile remaining above the cut-off elevation; for backdriving; for cutting off piles, or for any cut off length of piles.

1.4.2 Measurement and Payment

1.4.2.1 NAVFAC PAC Projects

For unit price bid, see SF 1442, "Solicitation, Offer and Award" and "Schedule of Bid Items."

1.4.2.2 NAVFAC LANT Projects

Payment will be at the contract unit price per length, multiplied by the total length of acceptable piles actually installed. Base bids on the number of piles with pile length from tip to cutoff, as indicated, and on the total length of piling from tip to cutoff as specified in the document titled "Instructions to Bidders." Include in bid a unit price per unit length piling based on the quantity stated in the document titled "Instructions to Bidders." If the Contracting Officer requires an increase or a decrease in length of piles furnished and installed, the contract price will be adjusted in accordance with the Contract Clauses of the contract. The unit price bid will be used for upward or downward adjustment of the quantity subject to provisions of FAR 52.211-18, Variation in Estimated Quantities.

1.5 ESTIMATED QUANTITIES

The estimated quantities of sheet piling listed in the unit price schedule of the contract, as to be furnished by the Contractor, are given for bidding purposes only. Sheet piling quantities for payment will consist of the linear meters feet of piling acceptably installed [and removed]. Installed quantities will consist of all piling including fabricated sections driven between the required top and bottom elevations of pileings plus any additions thereto resulting from changes in design or alignment as provided in paragraph DRIVING. [Removed quantities will consist of the lengths of piling pulled from below the ground level.]
NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.

Interlock joint tension strength requirements should be deleted except for flat, or straight web, pilings used in radial or transverse tension applications.

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-01 Preconstruction Submittals

Installation Procedures; G[, [____]]

Contractor's Geotechnical Consultant Documentation; G[, [____]]

Testing Agency Qualifications; G[, [____]]

Instrumentation and Monitoring Program Report; G[, [____]]
1.7 DELIVERY, STORAGE, AND HANDLING

Conform all delivery, storage, and handling of materials to the requirements specified herein. Develop and submit plans for the delivery, storage, and handling of piles. Submit delivery, storage, and handling plans for piles at least 30 days prior to delivery of piles to the job site.

1.7.1 Delivery and Storage

Materials delivered to the site must be new and undamaged and must be accompanied by certified test reports. Provide the manufacturer's logo and mill identification mark on the sheet piling as required by the referenced
specifications. Store and handle sheet piling in the manner recommended by the manufacturer to prevent permanent deflection, distortion or damage to the interlocks; as a minimum, support on level blocks or racks spaced not more than 3 m 10 feet apart and not more than 0.60 m 2 feet from the ends. Storage of sheet piling should also facilitate required inspection activities and prevent damage to coatings and corrosion protection prior to installation.

1.7.2 Handling

Lift piles to ensure that the maximum permissible curvature is not exceeded. Holes may be burned above the cutoff length for lifting piles into the leads. If there is evidence of pile damage during driving due to the holes, Contracting Officer may forbid the burning of holes. Do not damage piles when dragging piles across the ground or barge deck.

Inspect piles for excessive curvature and for damage before transporting them from the storage area to the driving area and immediately prior to placement in the driving leads. Curvature in the pile must be measured with the pile laying on a flat surface and is the distance between the pile at the mid-length of the pile and the flat surface. Straightness of the sections of piles must conform to AWS D1.5M/D1.5, Section 3.5.1.1. Piles having excessive curvature will be rejected.

1.7.3 Damaged Piles

Inspect each pile for straightness and structural damage before transporting them to the project site and immediately prior to placement in the driving leads. Bring any damage to the attention of the Contracting Officer. Piles which are damaged during delivery, storage, or handling to the extent they are rendered unsuitable for the work, in the opinion of the Contracting Officer, will be rejected and removed from the project site, or may be repaired, if approved, at no cost to the Government.

Any pile damaged by reason of internal defects or by improper driving must be corrected by one of the following methods approved by the Engineer for the pile in question:

a. The pile is withdrawn, if practicable, and replaced by a new and, if necessary, longer pile.

b. One or more replacement piles are driven adjacent to the defective pile.

c. A Pile Dynamic Analysis and/or low integrity testing must be performed by the Contractor's Geotechnical Consultant to assess the structural integrity of the driven pile(s).

A pile driven below the specified butt elevation must be corrected by one of the following methods approved by the Engineer:

a. The pile is spliced (if approved).

b. A sufficient portion of the footing is extended down to properly embed the pile.

A pile driven out of its proper location or out of plumb as approved by the Engineer, must be corrected by one of the following methods approved by the engineer:
a. One or more replacement piles are driven next to the pile in question.

b. As directed by the structural engineer.

1.8 MATERIAL CERTIFICATES

For each shipment, submit certificates identified with specific lots prior to installing piling. Include in the identification data piling type, dimensions, chemical composition, mechanical properties, section properties, heat number, and mill identification mark.

1.9 INTERLOCKED JOINT TENSION TEST

**************************************************************************
NOTE: Include this paragraph only when the design utilizes straight web metal sheet piles, such as a cellular cofferdam. This should not be included for Z-type sheet piles.
**************************************************************************

Submit, for approval, the procedure for testing the tension strength of piling interlocks prior to testing sheet piling.

PART 2 PRODUCTS

2.1 METAL SHEET PILING

**************************************************************************
NOTE: ASTM A328/A328M covers one grade of steel sheet piling for general use. ASTM A572/A572M covers three grades (yield strengths of 290, 345, 414 MPa 42, 50, 55, 60 and 65 ksi) of steel available for high strength steel sheet piling, with ASTM A572/572M grade 345MPa 50ksi being the most common. ASTM A690/A690M covers one grade of steel available for high strength steel sheet piling for use where greater resistance to marine splash zone conditions is required. Availability of sheet piling sizes and grades should always be verified as part of the design. Each of the ASTM Specifications contains "Supplementary Requirements" for use when desired by the purchaser. Some of these are provided for and described in the individual ASTM specification; others are standardized, and are indicated only by number and title, with their description found in ASTM A6/A6M.

Hot-rolled straight web steel sheet piling sections are suitable for applications where interlocked joint strength in tension or section stability is a primary design requirement. Section stability (Biaxial Stress) is a consideration in highly stressed applications only. Cold-formed straight web steel sheet piles should not be used.

Hot-rolled z-type steel sheet pile sections have tighter interlocks and are suitable for applications where reduced permeability through the wall is a primary design requirement.
Cold-formed steel sheet pile sections are suitable for applications where the permeability through the wall is not a primary design requirement. Cold-formed sheet piles typically have a hook and grip interlock which typically has the highest permeability rates. Cold formed sheet piling will not be used in I-walls that act as a flood barrier. This is due to the much greater permeability of the lapped connections between the sheets compared to the ball-and-socket interlock connections in hot rolled sheet piling.

Higher section modulus and stiffness (moment of inertia) of a z-type steel sheet pile improves integrity during driving and allows forces to be redistributed laterally along the wall at changes in wall alignment, in weak soil zones or when the I-wall undergoes wave loadings that vary along the length of the wall. The additional strength also provides some redundancy to sections that must bridge across localized weak zones in the foundation material.

For applications in salt or brackish water use the most economical of a ASTM A690/A690M steel sheet piling which offers greater corrosion resistance or a ASTM A328/A328M steel sheet piling with a protective coating in the splash zone. A protective coating should be applied to a ASTM A690/A690M sheet piling in the splash zone of waterway bulkheads located in salt or brackish water.

Corrosion protection should be provided where piling is exposed to an adverse environment. Choose system(s) based on economics and potential hazards due to sheet piling system failure; more than one system may be necessary depending on conditions above and below the splash zone. While ASTM A690/A690M is suggested for marine environments, its use alone without protective measures may not be effective enough.

Aluminum sheet piling sections are suitable for use in applications requiring moderate bending resistance and minimal design interlocked joint strength in tension. Non-draining, clay-muck soils and soils and water with a ph outside the range of 4.5 to 8.5 and containing chlorides, sulfates or heavy metals (copper, lead, tin, mercury and cobalt) are corrosive to aluminum and should be avoided. Protective coatings or cathodic protection can be used to provide longer service life to aluminum piling in corrosive environments.

**************************************************************************
Submit detail drawings for sheet piling, including fabricated sections, showing complete piling dimensions and details, driving sequence and location of installed piling.

SECTION 31 41 16  Page 17
a. Include in the drawings details of top protection, special reinforcing tips, tip protection, lagging, splices, fabricated additions to plain piles, cut-off method, corrosion protection, and dimensions of templates and other temporary guide structures for installing piling. Provide details of the method for handling piling to prevent permanent deflection, distortion or damage to piling interlocks.

b. Metal sheet piling must be [hot-rolled steel sections conforming to [ASTM A328/A328M] [ASTM A572/A572M, Grade [_____], [Type [_____]] [, interlocked joint strength in tension as shown]] [ASTM A690/A690M [, interlocked joint strength in tension as shown (for flat web sheet piles)]]] [hot-rolled, light-duty steel sections conforming to ASTM A572/A572M, Grade [42, ][55, ][60, ][or 65].] [cold-formed steel sections formed from hot-rolled steel meeting the chemical and mechanical requirements of [ASTM A328/A328M] [ASTM A572/A572M, Grade [_____], Type [_____]] [ASTM A690/A690M]] [cold-formed steel sections conforming to ASTM A857/A857M, Grade [_____]][ extruded aluminum sections fabricated from aluminum conforming to [ASTM B221M ASTM B221,] [ASTM B308/B308M,] Alloy 6061, Temper T6.]

c. For protection of sheet piling, coat it in accordance with Section [09 97 02 PAINTING: HYDRAULIC STRUCTURES] [and] [provide cathodic protection in accordance with Section [26 42 13 GALVANIC (SACRIFICIAL) ANODE CATHODIC PROTECTION (GACP) SYSTEM] [26 42 17 IMPRESSED CURRENT CATHODIC PROTECTION (ICCP) SYSTEM] [_____]].

2.1.1 Interlocks

The interlocks of sheet piling must be free-sliding, provide a swing angle suitable for the intended installation but not less than 5 degrees when interlocked, and maintain continuous interlocking when installed.

2.1.2 General Requirements

**************************************************************************

NOTE: Designers should contact suppliers to verify current availabilities and lead times. Based upon the design requirements for each piling section select the most suitable corresponding section from manufacturer's product specification tables or other commercial sources and place the pertinent section properties of this section on the drawings as minimum requirements.

Z-type sheet pile develop a maximum resistance to bending per unit weight and are particularly adapted to cantilever and anchored type retaining walls.

Straight-Web (S) sections have their interlocks designed for maximum flexibility and tensile strength and are particularly adapted to cellular retaining walls and cellular cofferdam construction.

Take consideration of which section properties are crucial to the design of the wall. Properties such as section modulus, moment of inertia, and minimum thickness can be listed.
Interlock types for z-type sheet piles, such as Larssen or ball and socket, can also be specified if it is crucial to the performance of the design of the wall. Cold formed sheet piles generally have the highest permeability rates with their hook and grip interlocks.

Provide sheet piles with minimum section modulus, moment of inertia, shape, and size as specified in the [drawings] [plans] [contract document][design]. Sheet piling [including special fabricated sections] must be [full-length] sections of the dimensions shown. [Provide fabricated sections conforming to the requirement and the piling manufacturer's recommendations for fabricated sections.] [Fabricated sections connecting cofferdam cells and adjacent arcs composed of pilings from different manufacturers must be Y-sections fabricated from the respective manufacturer's pilings.] [Fabricated tees, wyes and cross pieces must be fabricated of piling sections with a minimum web thickness of 13 mm 1/2 inch.] [Straight web sheet piling to be placed in a circular cell or a connecting arc must be of the same manufacture.] Provide sheet piling with standard lifting holes. Metalwork fabrication for sheet piling must be as specified and in Section 05 50 14 STRUCTURAL METAL FABRICATIONS.

2.2 APPURTEONANT METAL MATERIALS

Provide metal plates, shapes, bolts, nuts, rivets and other appurtenant fabrication and installation materials conforming to manufacturer's standards and to the requirements specified in the respective sheet piling standards and in Section 05 50 15 CIVIL WORKS FABRICATIONS.

2.3 TESTS, INSPECTIONS, AND VERIFICATIONS

Requirements for material tests, workmanship and other measures for quality assurance must be as specified and in Section 05 50 14 STRUCTURAL METAL FABRICATIONS. Provide manufacturer's steel plant certificate for Government review and approval.

2.3.1 Materials Tests

Submit certified materials tests reports showing that sheet piling and appurtenant metal materials meet the specified requirements, for each shipment and identified with specific lots prior to installing materials. Material test reports must meet the requirements of ASTM A6/A6M. Perform materials tests conforming to the following requirements. Sheet piling and appurtenant materials must be tested and certified by the manufacturer to meet the specified chemical, mechanical and section property requirements prior to delivery to the site. Testing of sheet piling for mechanical properties must be performed after the completion of all rolling and forming operations. Testing of sheet piling must meet the requirements of ASTM A6/A6M.

2.3.2 Interlocked Joint Strength in Tension Test

NOTE: This is for straight web sheet pile only.
This is not be included for z-type sheet pile.

Submit the procedure for testing sheet piling interlocked joint strength in...
tension, prior to testing piling. [The interlocked joint strength in tension test must conform to the piling manufacturer's standard test, include testing at least two 75 mm 3 inch long coupons taken randomly from different as-produced pilings of each heat and must be approved.] Submit a certified report showing results based on approved testing procedures.

2.4 PILE DRIVING EQUIPMENT

Submit complete descriptions of sheet piling driving equipment including hammers, [jetting equipment,] extractors, protection caps and other installation appurtenances, prior to commencement of work. Descriptive information includes manufacturer's name, model numbers, capacity, rated energy, hammer details, cushion material, helmet, and templates. Provide pile driving equipment conforming to the following requirements. Submit descriptions of pile driving equipment, including hammers, power packs, driving helmets, hammer cushions, pile cushions, leads, extractors, jetting equipment, and preboring equipment at least 30 days prior to commencement of work.

2.4.1 Driving Hammers

**************************************************************************

NOTE: Insert desired energy ratings in this paragraph. Hammers with energy ratings between 11,860 and 21,700 J 8,750 and 16,000 foot pounds are recommended.

**************************************************************************

Hammers must be steam, air, or diesel drop, single-acting, double-acting, differential-acting[, or vibratory][or press-in] type. The driving energy of the hammers must be between [_____] and [_____] J foot-pounds as recommended by the manufacturer for the piling weights and subsurface materials to be encountered. Repair damage to piling caused by use of a pile hammer with excess delivered force or energy.

2.4.2 Jetting Equipment

Jetting [may be used at no additional cost to the Government] [will not be permitted]. [Jetting equipment must have not less than two removable or fixed jets of the water or combination air-water type. Water jets must be designed so that the discharge volume and pressure are sufficient to freely erode the material under and adjacent to the piling.]

PART 3 EXECUTION

3.1 PRELIMINARY WORK

3.1.1 Pile Length Markings

Mark each pile prior to driving with horizontal lines at 305 mm one foot intervals. Mark the interval number on pile every 1.52 m 5 feet from pile tip.

3.2 EARTHWORK

Perform in accordance with Section 31 00 00 EARTHWORK. Pre-excavation [will] [will not] [be permitted.] [permitted to a maximum depth [of [_____] meters feet below [______]] [as indicated]]. Backfill as indicated.
3.3 INSTALLATION

3.3.1 Placing and Driving

3.3.1.1 Placing

**************************************************************************
NOTE: When long piles are being driven, templates are of value. Long piles are very flexible and damage easily. Use templates to keep piles vertical.
**************************************************************************

Submit a written description of the site specific pile installation procedures for Government review and approval. Pile placement installation drawings and details must also be provided.

Any excavation required within the area where sheet pilings are to be installed must be completed prior to placing sheet pilings. Pilings properly placed and driven must be interlocked throughout their length with adjacent pilings to form a continuous diaphragm throughout the length or run of piling wall.

[ a. Pilings to be placed in cofferdam cells and connecting arcs must be picked up and completely threaded to demonstrate that they slide freely in interlock.]

[a.] [b.] Pilings must be carefully located as [indicated] [or]
directed. Pilings must be placed plumb with out-of-plumbness not exceeding [10] [22] mm per meter [1/8] [1/4] inch per foot of length and true to line. Place the pile so the face will not be more than 150 mm 6 inches from vertical alignment at any point. Top of pile at elevation of cut-off must be within 13 mm 1/2 inch horizontally and 50 mm 2 inches vertically of the location indicated. Manipulation of piles to force them into position will not be permitted. Check all piles for heave. Re-drive all heaved piles to the required tip elevation.

[b.] [c.] Provide temporary wales, templates, [master pilings] [current deflectors] or guide structures to ensure that the pilings are placed and driven to the correct alignment. Use a system of structural framing sufficiently rigid to resist lateral and driving forces and to adequately support the sheet piling until design tip elevation is achieved. Use two templates, at least, when placing each piling [at third points] [not less than 6 m 20 feet apart]. Templates must not move when supporting sheet piling. Fit templates with wood blocking to bear against the web of each alternate sheet pile and hold the sheet pile at the design location alignment. Provide outer template straps or other restraints as necessary to prevent the sheets from warping or wandering from the alignment. Mark template for the location of the leading edge of each alternate sheet pile. If in view, also mark the second level to assure that the piles are vertical and in position. If two guide marks cannot be seen, other means must be used to keep the sheet pile vertical along its leading edge.

[c.] [d.] Master pilings must be used to maintain plumbness and proper configuration in placing cofferdam cells over 27 m 90 feet in height in water flowing at a velocity of more than 1.2 m/s 4 feet per second.]
3.3.1.2 Driving

**************************************************************************
NOTE: When hard driving or driving through rocky soil or debris is anticipated, require addition of tip protection to prevent damage to sheet piling.

Jetting should generally not be permitted for:

1. Piles dependent on side friction in fine-grained low permeability soils (high clay or silt content) where considerable time is required for the soil to reconsolidate around the piles.

2. Piles subject to uplift.

3. Piles adjacent to existing structures.

4. Piles in closely spaced clusters unless the load capacity is confirmed by tests and unless all jetting is done before final driving of any pile in the cluster.

Pre-augering or spudding should generally not be permitted for piles dependent on side friction in fine-grained, low permeability soils (high clay or silt content) where considerable time is required for the soil to reconsolidate around the piles.

The press-in pile driving method can be used for reduction of noise and/or vibration associated with sheet pile driving; however, site and soil conditions will need to be considered.

**************************************************************************
Submit records of the completed sheet piling driving operations, including a system of identification which shows the disposition of approved piling in the work, driving equipment performance data, piling penetration rate data, piling dimensions and top and bottom elevations of installed piling. [The format for driving records must be as directed.] [Prior to driving pilings in water, paint a horizontal line on both sides of each piling at a fixed distance from the bottom so that it will be visible above the water line after installation. This line must indicate the profile of the bottom elevation of installed pilings and potential problem areas can be identified by abrupt changes in its elevation.] Drive pilings with the proper size hammer and by approved methods so as not to subject the pilings to damage and to ensure proper interlocking throughout their lengths.

a. Maintain driving hammers in proper alignment during driving operations by use of leads or guides attached to the hammer. [Caution must be taken in the sustained use of vibratory hammers when a hard driving condition is encountered to avoid interlock-melt or damages. Discontinue the use of vibratory hammers and impact hammers employed when the penetration rate due to vibratory loading is \(300 \text{ mm one foot or less per minute.}\)]

b. Employ a protecting cap in driving when using impact hammers to prevent damage to the tops of pilings. [Use cast steel shoe to prevent damage to the tip of the sheet piling. Submit pile shoe installation details]
and material data for Government review and approval prior to use in the field. Remove and replace pilings damaged during driving or driven out of interlock at the Contractor's expense. [Store Government furnished pilings, damaged during driving, at the site as directed.]

c. Drive pilings without the aid of a water jet [unless otherwise authorized]. [Perform authorized jetting on both sides of the pilings simultaneously; discontinue it when the pile tip is approximately 1.5 m 5 feet above the ["calculated"] [indicated] pile tip elevation and make the final 1.5 m 5 feet of penetration by driving. Before commencing the driving of the final 1.5 m 5 feet, firmly seat the pile in place by the application of a number of reduced energy hammer blows.]

d. Take adequate precautions to ensure that pilings are driven plumb. Where possible, drive Z-pile with the ball end leading. If an open socket is leading, a bolt or similar object placed in the bottom of the interlock will minimize packing material into it and ease driving for the next sheet. If at any time the forward or leading edge of the piling wall is found to be out-of-plumb in the plane of the wall the piling being driven must be driven to the required depth and tapered pilings must be provided and driven to interlock with the out-of-plumb leading edge or other approved corrective measures must be taken to insure the plumbness of succeeding pilings. The maximum permissible taper for any tapered piling must be 10 mm per meter 1/8 inch per foot of length.

e. Pilings in each run or continuous length of piling wall must be driven alternately in increments of depth to the required depth or elevation. No piling will be driven to a lower elevation than those behind it in the same run except when the pilings behind it cannot be driven deeper. Incrementally sequence driving of individual piles such that the tip of any sheet pile must not be more than 1.2 m 4 feet below that of any adjacent sheet pile. When the penetration resistance exceeds five blows per 25 mm inch, the tip of any sheet pile must not be more than 0.6 m 2 feet below any adjacent sheet pile. [For cofferdam cells the driving increments must be such that no piling leads the adjacent piling by more than [_____] mm feet and the direction of advancing the driving hammer must be reversed after each pass around the cell.] If the piling next to the one being driven tends to follow below final elevation it may be pinned to the next adjacent piling.

f. If obstructions restrict driving a piling to the specified penetration, the obstructions must be removed or penetrated with a chisel beam. If the Contractor demonstrates that removal or penetration is impractical, make changes in the design alignment of the piling structure as directed to ensure the adequacy and stability of the structure. Pilings must be driven to depths shown and must extend up to the elevation indicated for the top of pilings. [Piling driven to rock must be seated individually on the rock.] A tolerance of [_____] mm inches above the indicated top elevation will be permitted. [At least the first two sheets of the connecting arcs adjacent to the main cells must be driven in the cofferdam cells prior to filling the cells.] Pilings must not be driven within 30 m 100 feet of concrete less than 7 days old.

g. Pre-augering or spudding of piles [may be used at no additional cost to the Government] [will not be permitted]. [Discontinue pre-augering or spudding approximately [_____] meters feet above the [calculated] [indicated] pile tip elevation. Drive the pile the final [_____] meters
3.3.2 Cutting-Off and Splicing

Pilings driven to refusal or to the point where additional penetration cannot be attained and are extending above the required top elevation in excess of the specified tolerance must be cut off to the required elevation. Pilings driven below the required top elevation and pilings damaged by driving and cut off to permit further driving must be extended as required to reach the top elevation by splicing when directed at no additional cost to the Government. Submit procedure for insufficient pile length. Provide pile splicing information and details for Government review and approval prior to installation in the field. [If directed, pilings must be spliced as required to drive them to depths greater than shown and extend them up to the required top elevation.]

a. Pilings adjoining spliced pilings must be full length unless otherwise approved. [If splices are allowed in adjoining pilings, the splices must be spaced at least [_____] m feet apart in elevation.] Splicing of pilings must be as indicated. Ends of pilings to be spliced must be squared before splicing to eliminate dips or camber. Pilings must be spliced together with concentric alignment of the interlocks so that there are no discontinuities, dips or camber at the abutting interlocks. Spliced pilings must be free sliding and able to obtain the maximum swing with contiguous pilings. Welding of splices must conform to the requirements of Section 05 50 14 STRUCTURAL METAL FABRICATIONS. Shop and field welding, qualification of welding procedures, welders, and welding operators must be in accordance with AWS D1.1/D1.1M. Submit welding certifications for all welders and welding operators for Government review and approval.

b. The tops of pilings excessively battered during driving must be trimmed when directed, at no cost to the Government. Piling cut-offs [except for Government furnished pilings] will become the property of the Contractor and must be removed from the site.

c. Cut holes in pilings for bolts, rods, drains or utilities in a neat and workmanlike manner, as shown or as directed. Use a straight edge in cuts made by burning to avoid abrupt nicks. Bolt holes in steel piling must be drilled or may be burned and reamed by approved methods which will not damage the surrounding metal. [Bolt holes in aluminum pilings must be drilled.] Holes other than bolt holes must be reasonably smooth and the proper size for rods and other items to be inserted. [All holes in steel pilings on the wet side of cofferdams must be made watertight by welding steel plates over the holes after the piling installation is completed.] Do not use explosives for cutting.

3.3.3 Inspection of Driven Piling

Perform continuous inspection during pile driving. Inspect all piles for compliance with tolerance requirements. Bring any unusual problems which may occur to the attention of the Contracting Officer. Inspect the interlocked joints of driven pilings extending above ground. Pilings found to be out of interlock must be removed and replaced at the Contractor's expense. [Use divers to inspect underwater interlocked joints of cofferdam sheet piling. Government divers may also inspect the interlocked joints. The inspection of cofferdams must be performed after driving is completed, prior to filling each cell and connecting arc, and within 48 hours after filling each cell and arc.]
3.3.4 Pulling and Redriving

Submit the proposed method of pulling sheet piling, prior to pulling any piling. Pull, as directed, selected pilings after driving to determine the condition of the underground portions of pilings. Any piling so pulled and found to be damaged, to the extent that its usefulness in the structure is impaired, must be removed and replaced at the Contractor's expense. Pilings pulled and found to be in satisfactory condition must be redriven when directed. [Government furnished pilings pulled and not redriven must be stored as directed.]

3.3.5 Testing Agency Qualifications

Engage an independent testing agency qualified according to ASTM E329 for testing indicated, as documented according to ASTM D4945, and approved by the Contracting Officer.

3.3.6 Survey Data

After the driving of each pile group is complete and before superimposed concrete is placed, provide the Contracting Officer with an as-driven survey showing actual location and top elevation of each pile. Submit an as-driven survey showing actual location and top elevation of each [production pile] [test pile] within [7][_____] calendar days of completing the pile installation. Do not proceed with placing concrete until the Contracting Officer has reviewed the survey and verified the safe load for the pile group driven. Present a survey in such form that it gives deviation from plan location in two perpendicular directions and elevations of each pile to nearest 13 mm half inch. Survey must be prepared and certified by a land surveyor licensed in [____].

3.4 DRAINAGE

**************************************************************************
NOTE: Include this paragraph in cases where sheet pile walls are not designed to retain saturated soils and drainage behind the sheet pile wall is required.
**************************************************************************

Backfill material behind the sheet piling must be free draining and in accordance with Section 31 00 00 EARTHWORK.[ Install drainage system and weep holes as shown in the [contract documents] [plans].]

3.5 ANCHORS

**************************************************************************
NOTE: Include this paragraph only when tiebacks (anchors) are required to support sheet pile wall.
**************************************************************************

Conform to Section 31 68 13 SOIL AND ROCK ANCHORS.

3.6 REMOVAL

The removal of sheet pilings must consist of pulling, sorting, cleaning the interlocks, inventorying and storing previously installed sheet pilings as shown and directed.
3.6.1 Pulling

The method of pulling piling must be approved. Provide pulling holes in pilings, as required. Extractors must be of suitable type and size. Exercise care during pulling of pilings to avoid damaging piling interlocks and adjacent construction. If the Contracting Officer determines that adjacent permanent construction has been damaged during pulling, the Contractor will be required to repair this construction at no cost to the Government. Pull pilings one sheet at a time. Pilings fused together must be separated prior to pulling, unless the Contractor demonstrates, to the satisfaction of the Contracting Officer, that the pilings cannot be separated. The Contractor will not be paid for the removal of pilings damaged beyond structural use due to proper care not being exercised during pulling.

3.6.2 Sorting, Cleaning, Inventorizing and Storing

Pulled pilings must be sorted, cleaned, inventoried and stored by type into groups as:

a. Piling usable without reconditioning.

b. Piling requiring reconditioning.

c. Piling damaged beyond structural use.

3.7 INSTALLATION RECORDS

Maintain a pile driving record for each sheet pile driven. Indicate on the installation record: installation dates and times, type and size of hammer, rate of operation, total driving time, dimensions of driving helmet and cap used, blows required per meter foot for each meter foot of penetration, final driving resistance in blows for final 150 mm 6 inches, pile locations, tip elevations, ground elevations, cut-off elevations, and any reheading or cutting of piles. Record any unusual pile driving problems during driving. Submit complete records to the Contracting Officer.

3.8 VIBRATION CONTROL

**************************************************************************
NOTE: Include this paragraph when vibration monitoring is required. Add any additional criteria or requirements as necessary to the particular project.
**************************************************************************

Perform vibration monitoring at the locations [shown in the plan] [decided by the Contracting Officer] during the pile driving operations. Perform vibration monitoring [using] [seismographs] and geophones within a distance of 61 meters 200 feet from the pile driving activity. [Engage the services of a qualified, independent vibration consultant, acceptable to the Government, to conduct the vibration monitoring. The vibration consultant must have minimum of [five] years of experience in vibration monitoring. A minimum of [28] days before the installation of vibration monitors, submit to the Government the name of the vibration consultant and a list of at least [three] previously completed projects of similar scope and purpose.]

SECTION 31 41 16 Page 26
Prior to the pile driving activities, obtain baseline readings of ambient vibrations. The vibration during the pile driving activities must be limited to [a peak particle velocity of not more than 5 cm 2 inches per second] [the limits mentioned in the [contract documents]]. [Determine appropriate vibration limits as per [US Bureau of Mines] [American Association of State Highway and Transportation Officials (AASHTO)] guidelines. ]During pile driving activities, monitor the vibrations to ensure the limits are not exceeded. If the limits are exceeded, cease the pile driving activity causing the vibration until [the Vibration consultant and the Contracting Officer] are on site to observe the structures nearest to the vibration monitor which has exceeded the limits.

The Contractor must be responsible for all damages resulting from the pile driving operations and must take whatever measures necessary to maintain peak particle velocity within the specified limit. After completion of the project, remove the vibration monitors off the site and off Government property and restore the monitoring locations back to their original condition.

3.9 NOISE CONTROL

**************************************************************************
NOTE: Include this paragraph when noise monitoring is required. Add any additional criteria, references or requirements as necessary to the particular project.
**************************************************************************

Perform noise monitoring at the locations [shown in the plan] [decided by the Contracting Officer] [at noise sensitive public areas] during the pile driving operations. [Perform noise monitoring using [noise meters][, and][____]]. [Engage the services of a qualified, independent noise consultant, accept able to the Government, to conduct the noise monitoring. The noise consultant must have minimum of [five] years of experience in noise monitoring. A minimum of [28] days before the installation of noise monitors, submit to the Government the name of the noise consultant and a list of at least [three] previously completed projects of similar scope and purpose.]

Prior to the pile driving activities, obtain baseline readings of ambient noise levels. [The noise limits are mentioned in the [plan] [contract documents]]. [Determine appropriate noise limits as per [local agency] [Occupation Safety and Health Administration] guidelines]. During pile driving activities, monitor the noise to ensure the limits are not exceeded. If the limits are exceeded, cease the pile driving activity and install noise mitigation measures.

The Contractor must be responsible for all damages resulting from the pile driving operations and must take whatever measures necessary to maintain noise within the specified limit. After completion of the project, remove the noise monitors off the site and off Government property and restore the monitoring locations back to their original condition.

3.10 PRECONSTRUCTION CONDITION SURVEY

**************************************************************************
NOTE: Add any additional criteria, references or requirements as necessary to the particular project.
**************************************************************************
Perform preconstruction condition survey of [structures] [and utilities] [within 61 meters 200 feet of the pile driving activity] [specified in the plans] [decided by the Contracting Officer]. Perform outreach to the owner of the structures [28] days before performing the preconstruction condition survey. The Contractor must obtain written permission from the owner of the structure prior to accessing the structure. The preconstruction condition survey must include video and photographic documentation of the exterior and interior of above ground structures and of the interior of underground structures. Video documentation must be in high definition, and show existing conditions and highlight, where possible, existing cracks, deteriorated concrete, exposed and corroded reinforcement, cracked or broken brick or mortar, and other signs of distress. For utilities, perform the survey when the greatest extent of the interior is exposed. Provide supplementary artificial lighting as needed. The video must include annotation with location and structure nomenclature which describes any areas of distress over the video and time code superimposed on the video. Photographs must be accompanied by sketches or descriptions that indicate the location and direction of each photograph. For each structure surveyed, provide a Pre-Construction Condition Survey Report following completion of the survey. The report must contain all documentation associated with the survey including DVD copies. In the report, include notes, sketches, photographs, and videos. Provide general information, such as location details and structure type, as well as particular information on materials, condition, existing damage, aperture and persistence of cracks, and disrepair observed during visual survey. Provide a graphical depiction of locations of damage or other features of concern. Submit the Preconstruction Condition Survey Reports no later than [28] days before the commencement of pile driving activity. Accept responsibility for damages to existing adjacent or adjoining structures created by pile driving work, and repair any damages to these structures without cost to the Government.

3.11 CONSTRUCTION INSTRUMENTATION AND MONITORING PROGRAM

**************************************************************************
NOTE: Include this section if instrumentation is to be installed due to concerns about vibration, settlement, lateral movement, etc. during pile driving activities. Instrumentation should be specified and included in the specification. This section can be deleted if there are no instrumentation requirements. Add any additional criteria or requirements as necessary for the particular project.
**************************************************************************

Prepare a geotechnical instrumentation program to monitor settlement [and lateral movement] of temporary and permanent structures, utilities, [embankments] [and excavations] during pile driving. The design and distribution of instrumentation must demonstrate an understanding of the need, purpose and application of each proposed type.[ Perform noise and vibration monitoring in accordance with NOISE CONTROL and VIBRATION CONTROL sections.]

Monitoring must extend before, during and for a period after completion of construction activities related to pile driving when long-term performance issues are a concern. The monitoring plan must be designed to protect adjacent structures and utilities against damage due to the pile driving
activities. Establish limiting values of vertical [and horizontal] movement [and angular distortion] [and vibration] for each structure and utility within the zone of influence, subject to review by the Government.

Prepare a report detailing the proposed program of instrumentation and monitoring, establishing threshold values of monitored parameters, and describing the response plans that will be implemented when threshold parameters are exceeded. The report must include details about instrumentation consultant's experience, appropriate types, quantities, locations and monitoring frequencies of the instruments.

Upon acceptance of the instrumentation and monitoring program, provide, install and monitor the instrumentation and interpret the data. Submit instrumentation data reports not less than every [_____] days after the monitoring program has begun. Take corrective actions, as necessary, based on the field instrumentation data and as defined in the instrumentation and monitoring program.

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for synthetic sheet piling. This section was originally developed for USACE Civil Works projects.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1 GENERAL

NOTE: Permanent earth retaining structures made with PVC or FRP sheet piling such as bulkheads, quay walls, flood walls, cutoff walls, and retaining walls are covered by this section. Temporary structures such as shoring and sheeting are the responsibility of the Contractor and unless required by conditions of the project, are not to be covered by this section. The extent and location of the work to be accomplished should be indicated on the project drawings.

The following information must also be shown on the project drawings:
1. Location of piles.
2. Soil data, where required.
3. Pile shape.
4. Allowable moment.
5. Length or tip and cut-off elevations.
6. Waler types, sizes, and locations, where required.
7. Tie-rod or soil anchor size, spacing and material, where required.
8. Anchorage type, size, and location, where required.

NOTE: This specification is intended for the use of NEW synthetic sheet piling. Synthetic structural design is often deflection-controlled instead of strength-controlled. Be sure to check or require deflection limits for serviceability. An example of a maximum deflection limit is less than 2 percent of the span; such as the distance from the lowest wale support to the ground line. Typically, it is more economical to design PVC sheet pile walls as an anchored wall system. For background information on synthetic piling and considerations, see: USACE EM 1110-2-2502, USACE ERDC/CRREL LR-03-19 A Study of the Long-term Applications of Vinyl Sheet Piles, USACE Interim Report - General Design Guide: PVC Sheet Pile, ASCE Pre-Standard for Load & Resistance Factor Design (LRFD) of Pultruded Fiber Reinforced Polymer (FRP) Structures.

1.1 REFERENCES

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.
1.2 UNIT PRICES

**************************************************************************
NOTE: If Section 01 20 00 PRICE AND PAYMENT PROCEDURES is included in the project
specifications, this paragraph title (UNIT PRICES) should be deleted from this section and the remaining appropriately edited subparagraphs below should be inserted into Section 01 20 00.

1.2.1 [PVC Sheet Piling, Type [_____]][FRP Sheet Piling, Type [_____]]

1.2.1.1 Payment

Payment for sheet piling quantities will be made at the applicable contract price per linear foot for furnished and installed sheet piling. Payment will cover all cost of furnishing, handling, storing, and installing piling including placing, driving, cutting holes and other materials and work incident thereto.

1.2.1.2 Measurement

The length of sheet piling installed [and removed] will be measured to the nearest tenth of a linear foot. For installed pilings directed to be cut off before reaching the penetration depth indicated, the portion cut off will be measured for payment as the difference between the total length of piling indicated for that location and the length of piling installed below the point of cut-off.

1.2.1.3 Unit of Measure

Unit of measure: linear meter foot.

1.2.2 [PVC Sheet Piling – Government Furnished] [FRP Sheet Piling – Government Furnished]

1.2.2.1 Payment

Payment for sheet piling quantities will be made at the applicable contract price per linear foot for furnished and installed sheet piling. Payment will cover all cost of furnishing, handling, storing, and installing piling including placing, driving, cutting holes and other materials and work incident thereto [except the cost of furnishing piling will not be included in the contract price for Government furnished piling].

1.2.2.2 Measurement

The length of sheet piling installed [and removed] will be measured to the nearest tenth of a linear foot. For installed pilings directed to be cut off before reaching the penetration depth indicated, the portion cut off will be measured for payment as the difference between the total length of piling indicated for that location and the length of piling installed below the point of cut-off.

1.2.2.3 Unit of Measure

Unit of measure: linear meter foot.

1.2.3 Cut-Offs

1.2.3.1 Payment

When pilings which have not been driven to penetration depths indicated are
directed to be cut off, except for cut-offs due to excessive battering, a lump sum payment will be made for cutting off each piling.

1.2.3.2 Measurement

An additional sum will be paid for each linear meter foot of the portion cut off and measured for payment. For installed pilings directed to be cut off before reaching the penetration depth indicated, the portion cut off will be measured for payment as the difference between the total length of piling indicated for that location and the length of piling installed below the point of cut-off at the rate of 50 percent of the applicable contract unit price. [No payment will be made for cut-off portions of Government furnished pilings.]

1.2.3.3 Unit of Measure

Unit of measure: linear meter foot.

1.2.4 Splices

Splicing of [PVC] [FRP] sheet piling is prohibited.

1.2.5 Pulled Pilings

1.2.5.1 Payment

The Contractor furnished pilings which have been installed and are pulled at the direction of the Contracting Officer and found to be in good condition will be paid for at the applicable contract unit price for furnishing and installing the pilings in their initial position plus an equal amount for the cost of pulling.

1.2.5.2 Measurement

When such pulled pilings are redriven, an additional amount equal to 50 percent of the applicable contract unit price for furnishing and driving the pilings will be paid for redriving the pilings. This additional price constitutes payment for redriving only. The cost of furnishing, initial driving, and pulling the pilings is to be paid for as specified.

a. Government furnished pilings which are pulled at the direction of the Contracting Officer and found to be in good condition will be paid for at the applicable contract unit price for installing the pilings in their initial position plus an equal amount for the cost of pulling. Such piling when redriven will be paid for at the applicable contract unit cost for installing the pilings.

b. When pilings are pulled and found to be damaged no payment will be made for the initial furnishing and driving or for the pulling of such pilings. Pilings replacing damaged pilings will be paid for at the applicable contract unit prices.

1.2.5.3 Unit of Measure

Unit of measure: each.
1.2.6 Removal of Sheet Pilings

1.2.6.1 Payment

Payment will be made for costs associated with removal of sheet pilings which have been installed and are removed at the direction of the Contracting Officer. Payment will cover the cost of pulling, cleaning the interlock, sorting, inventorying, and storing. No payment will be made if the pulled pilings are found to be defective or damaged due to Contractor negligence.

1.2.6.2 Measurement

Removal of sheet piling will be made at the applicable contract price per linear meter.

1.2.6.3 Unit of Measure

Unit of measure: linear meter.

1.3 NAVY REQUIREMENTS

**************************************************************************
NOTE: Select the applicable paragraph(s) from the following.
**************************************************************************

1.3.1 Basis of Bids

**************************************************************************
NOTE: Use this option for fixed-price contracts.
**************************************************************************

Base bids on pile sections and lengths as indicated. Should the total number of piles or the number of each length vary from that specified as the basis for bidding, an adjustment in the contract price and time for completion will be made. No additional payment will be made for withdrawn, damaged, rejected, or misplaced piles; for any portion of a pile remaining above the cut-off elevation; for backdriving; for cutting off piles, or for any cut off length of piles.

1.3.2 Measurement and Payment

1.3.2.1 NAVFAC PAC Projects

For unit price bid, see SF 1442, "Solicitation, Offer and Award" and "Schedule of Bid Items."

1.3.2.2 NAVFAC LANT Projects

Payment will be at the contract unit price per length, multiplied by the total length of acceptable piles actually installed. Base bids on the number of piles with pile length from tip to cutoff, as indicated, and on the total length of piling from tip to cutoff as specified in the document titled "Instructions to Bidders." Include in bid a unit price per unit length piling based on the quantity stated in the document titled "Instructions to Bidders." If the Contracting Officer requires an increase or a decrease in length of piles furnished and installed, the contract price will be adjusted in accordance with the Contract Clauses of the
Contract. The unit price bid will be used for upward or downward adjustment of the quantity subject to provisions of FAR 52.211-18, VARIATION IN ESTIMATED QUANTITIES.

1.4 ESTIMATED QUANTITIES

The estimated quantities of sheet piling listed in the unit price schedule of the contract, as to be furnished by the Contractor, are given for bidding purposes only. Sheet piling quantities for payment will consist of the linear meters feet of piling acceptably installed [and removed]. Installed quantities will consist of all piling including fabricated sections driven between the required top and bottom elevations of pilings plus any additions thereto resulting from changes in design or alignment as provided in paragraph DRIVING. [Removed quantities will consist of the lengths of piling pulled from below the ground level.]

1.5 SUBMITTALS

**************************************************************************
NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list to reflect only the submittals required for the project.

The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item if the submittal is sufficiently important or complex in context of the project.

For submittals requiring Government approval on Army projects, a code of up to three characters within the submittal tags may be used to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.

**************************************************************************

Government approval is required for submittals with a "G" designation; submittals not having a "G" designation are for [Contractor Quality Control approval.] [information only. When used, a designation following the "G" designation identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-01 Preconstruction Submittals

SECTION 31 41 16.16 Page 9
1.6 DELIVERY, STORAGE, AND HANDLING

Materials delivered to the site must be new and undamaged and must be accompanied by certified test reports. Provide the manufacturer's name and mill identification mark on the sheet piling. Store and handle sheet piling in the manner recommended by the manufacturer to prevent permanent deflection, distortion, or damage to the interlocks; as a minimum, support on level blocks or racks spaced not more than 3 m 4 to 5 feet apart and not more than 0.60 m 2 feet from the ends. Storage of sheet piling should also facilitate required inspection activities and prevent damage to coatings and corrosion protection prior to installation. [Handle sheet piling over 80 feet long using a minimum of two pickup points.]

1.7 QUALITY ASSURANCE – MATERIAL CERTIFICATES

For each shipment, submit certificates provided by the sheet pile manufacturer prior to installing piling. Include in the identification data piling type, section depth, section width, sheet thickness, [cell classification of PVC virgin resin used in co-extrusion or mono-extrusion process], and section modulus. The allowable bending stress must not exceed [3,200 psi for the PVC sheet.] [10,000 psi for the FRP sheet.]
[a. The PVC sheet piling certifications must consist of the following:

   (1) Certificate of analysis from an ISO certified compounder indicating that virgin material is of Class 1-4244-33 or superior in accordance with ASTM D4216.

   (2) Certificate showing compliance with the requirements of ASTM D8427.

   (3) Material certification indicating that the material being received by the Contractor is in accordance with the geometric and material requirements outlined in the specifications.

   (4) 50 year manufacturer's warranty. Reseller or outsourcer warranties are not sufficient.]

[b. The FRP sheet piling certifications must consist of the following:

   (1) Certification that the material was produced in accordance with the manufacturer's Quality Control Plan in an ISO 9001 compliant manufacturing facility.

   (2) Material certification indicating that all material properties have been characterized in accordance with ASTM D7290.

   (3) Material certification indicating that the material being received by the Contractor is in accordance with the geometric and material requirements outlined in the Contract Documents.

   (4) 20 year manufacturer's warranty.]

1.8 CONTRACTOR QUALIFICATIONS

The Contractor must have prior experience with driving [PVC] [FRP] sheeting and must provide a list or previous job(s) that demonstrate a satisfactory installation method. Coordinate with the sheet pile manufacturer and vibratory equipment supplier regarding their recommendations concerning the proper vibratory plates or hammer / equipment and tools.

PART 2 PRODUCTS

2.1 SYSTEM DESCRIPTION

Submit [to the Contracting Officer for approval] descriptions of pile driving equipment to be used in the work. Descriptive information includes manufacturer's name, model numbers, capacity, rated energy, hammer details, cushion material, helmet, templates, and jetting equipment.

2.2 [PVC] [FRP] SHEET PILING

**************************************************************************
NOTE: PVC/FRP sheeting is ideally suited for applications where corrosion is a design concern and when exposed wall heights are under 20-feet. PVC/FRP should also be considered in cutoff applications and lower height and risk floodwall applications in accordance with EM 1110-2-2502, "Floodwalls and Other Hydraulic Retaining Walls."
**************************************************************************
Submit detailed shop drawings for sheet piling showing complete piling dimensions and details, sheet pile section properties, pieces used to turn all required corners as indicated, driving sequence, and location of installed piling.

Include in the drawings details of top protection, special reinforcing tips, tip protection, and dimensions of templates and other temporary guide structures for installing piling. Provide details and description of the method for handling piling to prevent permanent deflection, distortion or damage to piling interlocks, plus the type of transportation vehicle for bringing piles to the point of installation.

2.2.1 Interlocks

The interlocks of sheet piling must be free-sliding when sheets are plumb/level.

2.2.2 General Requirements

-----------------------------------------------------------------------------------------------------------------------------

NOTE: Designers should contact suppliers to verify current availabilities and lead times. Based upon the design requirements for each piling section select the most suitable corresponding section from the available suppliers. Designers should place the pertinent section properties of this section on the drawings as minimum requirements.

-----------------------------------------------------------------------------------------------------------------------------

[PVC sheet piling must be manufactured entirely from a rigid, high impact, UV-inhibited, weatherable vinyl compound. Provide PVC sheet piling in accordance with ASTM D8427. All exposed surfaces of the sheet piling must be UV resistant and comprised of virgin material with a minimum ASTM D4216 Cell Classification of 1-42443-33 to ensure reliable performance and color consistency. If mono-extrusion technology is used, the entire sheet pile must be comprised of virgin material with a minimum ASTM D4216 Cell Classification of 1-42443-33.]

[FRP sheet piling must be [polyester][vinyl ester] resin thermoset pultruded shapes manufactured entirely from a rigid, high impact, UV-inhibited, weatherable fiberglass reinforced polymer. All exposed surfaces of the sheet piling must be UV resistant.]

a. Determine lengthwise and transverse tensile modulus and strength in accordance with ASTM D638.

b. Determine by testing the lengthwise and transverse compression modulus and strength in accordance with ASTM D6641/D6641M.

c. Determine by testing the in-plane shear strength and modulus in accordance with ASTM D5379/D5379M.

d. Fiber reinforcements must meet the minimum tensile strength of 290 ksi in accordance with ASTM D2343.

e. Calculate and submit the moment capacities in accordance with the ASCE
Pre-Standard for Load and Resistance Factor Design (LRFD) of Pultruded Fiber Reinforced Polymer (FRP) Structures including the local compression flange buckling limit state. If using Allowable Stress Design, use safety factors of 2.5 for flexural stresses and 3.0 for shear and connection stresses.

f. Meet the durability and environmental effects material requirements of the ASCE Pre-Standard for Load and Resistance Factor Design (LRFD) of Pultruded Fiber Reinforced Polymer (FRP) Structures.

g. Visual requirements must be in accordance with ASTM D4385.

h. Sheet pile section must contain UV light absorbers and stabilizers. Include a minimum 3 mil polyester or nylon veil.

i. Dimensional requirements must be in accordance with ASTM D3917.

2.3 SHEET PROPERTIES

Sheet piling must be full-length sections of the dimensions indicated. Provide fabricated sections in accordance with the requirement and the piling manufacturer's recommendations for fabricated sections. Sheet piling must meet the following minimum properties:

<table>
<thead>
<tr>
<th>Sheet Pile Location</th>
<th>Allowable Moment (ft-lbs./ft.)</th>
<th>Section Modulus (in^3/ft.)</th>
<th>Moment of Inertia (in^4/ft.)</th>
<th>Thickness (in.)</th>
<th>Depth (in.)</th>
<th>Coverage (in.)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>

</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

[Color of the PVC sheet pile must be [_____]]. [Color of the FRP sheet pile must be [_____]]. Final color selection will be by the Engineer based on color samples submitted. Caps may be manufactured from [PVC] [FRP] [6063-T6 extruded aluminum] profiles suitable for covering the top surface of the sheet piles. Aluminum caps may be mill finish or anodized. Caps may also be reinforced concrete or wood. Wood caps must be coated with a UV resistant polymer. Sheet pile corners and caps may be PVC or 6061-T6 aluminum.

2.4 APPURTENANT METAL MATERIALS

Provide metal plates, shapes, bolts, nuts, rivets and other appurtenant fabrication and installation materials conforming to manufacturer's standards and to the requirements specified in Section 05 50 15 CIVIL WORKS FABRICATIONS.

2.5 PILE DRIVING EQUIPMENT

**************************************************************************
NOTE: Typical driving aids may include the use of a mandrel, an auger, or a pre-punch tool such as an I-beam or steel sheet pile.
**************************************************************************

Submit complete descriptions of sheet piling driving and installation
equipment including hammers, [jetting equipment,] extractors, protection caps and other installation appurtenances including driving aids, prior to commencement of work. Provide pile driving equipment conforming to the following requirements.

2.5.1 Driving Hammers

Hammers must be single-acting, gravity drop, or vibratory type. The weight of the hammers must be determined jointly by the manufacturer and the Contractor for the piling products and subsurface materials to be encountered.

2.5.2 Jetting Equipment

Jetting [may be used at no additional cost to the Government] [is prohibited]. [Jetting equipment must have not less than two removable or fixed jets of the water or combination air-water type. Water jets must be designed so that the discharge volume and pressure are sufficient to freely erode the material under and adjacent to the piling.]

2.6 TESTS, INSPECTIONS, AND VERIFICATIONS

Requirements for material tests, workmanship, and other measures for quality assurance are as specified in this Section.

2.6.1 Materials Tests

Submit certifications from the suppliers of appurtenant metal materials showing that materials meet the specified requirements for each shipment. Certifications required for [PVC] [FRP] sheeting are referenced in paragraph QUALITY ASSURANCE - MATERIAL CERTIFICATES.

PART 3 EXECUTION

3.1 EARTHWORK

Perform in accordance with Section 31 00 00 EARTHWORK. Pre-excavation is [permitted] [prohibited] [permitted to a maximum depth [of [_____] meters feet below [_____]]] [as indicated]]. Backfill as indicated.

3.2 INSTALLATION

3.2.1 Placing

**************************************************************************
NOTE: When long piles are being driven, templates are of value. Long piles are very flexible and damage easily. Use templates to keep piles vertical.
**************************************************************************

Submit a written description of the site specific pile installation procedures for Government review and approval.

Excavation that is required within the area where sheet pilings are to be installed must be completed prior to placing sheet pilings. Pilings properly placed and driven must be interlocked throughout their length with adjacent pilings to form a continuous diaphragm throughout the length or run of piling wall.
a. Pilings must be carefully located as [indicated] [or] [directed.]
   Pilings must be placed plumb with out-of-plumbness not exceeding [10]
   [22] mm per meter [1/8] [1/4] inch per foot of length and true to
   line. Place the pile so the face will not be more than 150 mm 6 inches
   from vertical alignment at any point. Top of pile at elevation of
   cut-off must be within 13 mm 1/2 inch horizontally and 50 mm 2 inches
   vertically of the location indicated. Manipulation of piles to force
   them into position is prohibited. Check all piles for heave. Re-drive
   all heaved piles to the required tip elevation.

b. Provide temporary wales, templates, [master pilings] [current
   deflectors] or guide structures to ensure that the pilings are placed
   and driven to the correct alignment. Use a system of structural
   framing sufficiently rigid to resist lateral and driving forces and to
   adequately support the sheet piling until design tip elevation is
   achieved. Use a minimum of two templates when placing each piling [at
   third points] [not less than 6 m 20 feet apart]. Templates must not
   move when supporting sheet piling. Fit templates with wood blocking to
   bear against the web of each alternate sheet pile and hold the sheet
   pile at the design location alignment. Provide outer template straps
   or other restraints as necessary to prevent the sheets from warping or
   wandering from the alignment. Mark the template for the location of
   the leading edge of each alternate sheet pile. If in view, also mark
   the second level to assure that the piles are vertical and in
   position. If two guide marks cannot be seen, other means must be used
   to keep the sheet pile vertical along its leading edge.

3.2.2 Driving

**************************************************************************

NOTE: When hard driving or driving through rocky
soil or debris is anticipated, require addition of
tip protection or a steel mandrel to prevent damage
to sheet piling.

Jetting should generally not be permitted for:

1. Piles dependent on side friction in fine-grained
   low permeability soils (high clay or silt content)
   where considerable time is required for the soil to
   reconsolidate around the piles.

2. Piles subject to uplift.

3. Piles adjacent to existing structures.

4. Piles in closely spaced clusters unless the load
   capacity is confirmed by tests and unless all
   jetting is done before final driving of any pile in
   the cluster.

Pre-augering or spudding should generally not be
permitted for piles dependent on side friction in
fine-grained, low permeability soils (high clay or
silt content) where considerable time is required
for the soil to reconsolidate around the piles.

**************************************************************************
Submit records of the completed sheet piling driving operations, including a system of identification that shows the disposition of approved piling in the work, driving equipment performance data, piling penetration rate data, piling dimensions and top and bottom elevations of installed piling. [The format for driving records is as directed.] [Prior to driving pilings in water, paint a horizontal line on both sides of each piling at a fixed distance from the bottom so that it will be visible above the water line after installation. This line must indicate the profile of the bottom elevation of installed pilings and potential problem areas can be identified by abrupt changes in its elevation.] Drive pilings with the proper sized hammer and by approved methods to prevent damage to the pilings and to ensure proper interlocking throughout their lengths.

a. Maintain driving hammers in proper alignment during driving operations by use of leads or guides attached to the hammer. [Caution must be taken in the sustained use of vibratory hammers when a hard driving condition is encountered to avoid interlock-melt or damage. Stop using vibratory hammers and impact hammers when the penetration rate due to vibratory loading is \(300 \text{ mm} \lt \text{ one foot} \) per minute.]

b. Use a protecting cap when using impact hammers to prevent damage to the tops of pilings. [Use cast steel shoe to prevent damage to the tip of the sheet piling. Submit pile shoe installation details and material data for Government review and approval prior to use in the field.] Remove and replace pilings damaged during driving or driven out of interlock at no additional cost to the Government. [Store Government furnished pilings, damaged during driving, as directed.]

c. Drive pilings without the aid of a water jet [unless otherwise authorized]. [Perform authorized jetting on both sides of the pilings simultaneously; discontinue jetting when the pile tip is approximately \(1.5 \text{ m 5 feet} \) above the ["calculated"] [indicated] pile tip elevation and make the final \(1.5 \text{ m 5 feet} \) of penetration by driving. Before commencing the driving of the final \(1.5 \text{ m 5 feet} \), firmly seat the pile in place with reduced energy hammer blows.]

d. Take adequate precautions to ensure that pilings are driven plumb. Where possible, drive Z-pile with the ball end leading. If an open socket is leading, a bolt or similar object placed in the bottom of the interlock will minimize packing material into it and ease driving for the next sheet. If the forward or leading edge of the piling wall is found to be out-of-plumb, in the plane of the wall, the piling being driven must be driven to the required depth and tapered pilings must be provided and driven to interlock with the out-of-plumb leading edge or other approved corrective measures taken to ensure the plumbness of succeeding pilings. The maximum permissible taper for any tapered piling is \(10 \text{ mm per meter 1/8 inch per foot} \) of length.

e. Pilings in each run or continuous length of piling wall must be driven alternately in increments of depth to the required depth or elevation. Do not drive piling to a lower elevation than those behind it in the same run except when the pilings behind it cannot be driven deeper. Incrementally sequence driving of individual piles so that the tip of any sheet pile is not more than \(1.2 \text{ m 4 feet} \) below that of any adjacent sheet pile. When the penetration resistance exceeds five blows per \(25 \text{ mm inch} \), the tip of any sheet pile must not be more than \(0.6 \text{ m 2 feet} \) below any adjacent sheet pile.
f. If obstructions restrict driving a piling to the specified penetration, the obstructions must be removed or penetrated with a chisel beam. If the Contractor demonstrates that removal or penetration is impractical, make changes in the design alignment of the piling structure as directed to ensure the adequacy and stability of the structure. Pilings must be driven to depths indicated and must extend up to the elevation indicated for the top of pilings. [Piling driven to rock must be seated individually on the rock.] A tolerance of [_____] mm inches above the indicated top elevation will be permitted.

g. Pre-augering or spudding of piles [may be used at no additional cost to the Government] [is prohibited]. [Discontinue pre-augering or spudding approximately [_____] meters feet above the [calculated] [indicated] pile tip elevation. Drive the pile the final [_____] meters feet of penetration].

h. If a void is left in stiff clay type soils, the void must be filled appropriately. The functional requirements of the wall and the soil conditions will determine if the backfill method will be bentonite slurry mix, sand, or earthen material to close the small void.

3.2.3 Cutting-Off

Pilings driven to refusal or to the point where additional penetration cannot be attained and are extending above the required top elevation in excess of the specified tolerance must be cut off in a manner recommended by the manufacturer to the required elevation. Do not drive pilings below the required top elevation.

a. The tops of pilings excessively battered during driving must be trimmed when directed, at no additional cost to the Government. Piling cut-offs [except for Government furnished pilings] will become the property of the Contractor and must be removed from the site.

b. Cut holes in pilings for bolts, rods, drains or utilities neatly, as indicated or as directed. Bolt holes in piling must be drilled by approved methods which will not damage the pile. Holes other than bolt holes must be reasonably smooth and the proper size for rods and other items to be inserted.

3.2.4 Inspection of Driven Piling

Perform continuous inspection during pile driving. Inspect all piles for compliance with tolerance requirements. Bring unusual problems which may occur to the attention of the Contracting Officer. Inspect the interlocked joints of driven pilings extending above ground. Pilings found to be out of interlock must be removed and replaced at no additional cost to the Government. [Use divers to inspect underwater interlocked joints of cofferdam sheet piling. Government divers may also inspect the interlocked joints. The inspection of cofferdams must be performed after driving is completed, prior to filling each cell and connecting arc, and within 48 hours after filling each cell and arc.]

3.2.5 Pulling and Redriving

*****************************************************************************
NOTE: In general pulling of [PVC] [FRP] sheet piles is discouraged.
*****************************************************************************
Submit a **pulling and redriving plan**, a proposed method of pulling sheet piling, prior to construction. Pull, as directed, selected pilings after driving to determine the condition of the underground portions of pilings. Any piling so pulled and found to be damaged, to the extent that its usefulness in the structure is impaired, must be removed and replaced at no additional cost to the Government. Pilings pulled and found to be in satisfactory condition by the Contracting Officer must be redriven when directed. [Government furnished pilings pulled and not redriven must be stored as directed.]

When used for seepage cutoff, piles must maintain mechanical interlock throughout their alignment. When out-of-interlock piles cannot be pulled to reestablish interlocks, repair methods such as overlapping of piles and grout columns must be designed to provide an equivalent barrier. Remedial measures such as this must be designed by a Professional Engineer and submitted for approval.

**3.2.6 Testing Agency Qualifications**

Engage an independent testing agency qualified in accordance with ASTM C1077 and ASTM E329 for the testing indicated, as documented according to ASTM E548, and approved by the Contracting Officer.

**3.2.7 Survey Data**

After the driving of each pile group is complete and before superimposed concrete is placed, provide the Contracting Officer with an **as-driven survey** showing the actual location and top elevation of each pile. Submit an as-driven survey showing actual location and top elevation of each [production pile] [test pile] within [7][_____] calendar days of completing the pile installation. Do not proceed with placing concrete until the Contracting Officer has reviewed the survey and verified the safe load for the pile group driven. Present a survey in such form that it gives deviation from plan location in two perpendicular directions and elevations of each pile to the nearest 13 mm half inch. The survey must be prepared and certified by a professional registered land surveyor licensed in the State of [____].

**3.3 DRAINAGE**

**NOTE:** Include this paragraph in cases where sheet pile walls are not designed to retain saturated soils and drainage behind the sheet pile wall is required.

Backfill material behind the sheet piling must be free-draining and in accordance with Section 31 00 00 EARTHWORK.[ Install drainage system and weep holes as indicated.]

**3.4 REMOVAL**

The removal of sheet pilings consists of pulling, sorting, cleaning the interlocks, inventorying, and storing previously installed sheet pilings as indicated and directed.
3.4.1 Pulling

******************************************************************************
NOTE: In general pulling of [PVC] [FRP] sheet piles is discouraged as it is likely that the pile will break. Generally the best way to safely remove [PVC] [FRP] is to trench to the bottom and remove the sheet; however, consideration should be given to other proposed methods as well.
******************************************************************************
The method of pulling piling must be approved. Provide pulling holes in pilings, as required. Extractors must be of suitable type and size. Exercise care during pulling of pilings to avoid damaging piling interlocks and adjacent construction. If the Contracting Officer determines that adjacent permanent construction has been damaged during pulling, then repair the damaged construction at no additional cost to the Government. Pull pilings one sheet at a time. Pilings fused together must be separated prior to pulling, unless the Contractor demonstrates, to the satisfaction of the Contracting Officer, that the pilings cannot be separated. The Contractor will not be paid for the removal of pilings damaged beyond structural use due to proper care not being exercised during pulling.

3.4.2 Sorting, Cleaning, Inventoring, and Storing

Pulled pilings must be sorted, cleaned, inventoried, and stored by type into groups as:

a. Piling usable without reconditioning.

b. Piling requiring reconditioning.

c. Piling damaged beyond structural use.

3.5 INSTALLATION RECORDS

Maintain a pile driving record for each sheet pile driven. Indicate on the installation record: installation dates and times, type and size of hammer, rate of operation, total driving time, dimensions of driving helmet and cap used, blows required per meter foot for each meter foot of penetration, final driving resistance in blows for the final 150 mm 6 inches, pile locations, tip elevations, ground elevations, cut-off elevations, and reheading or cutting of piles. Record unusual pile driving problems during driving. Submit complete records to the Contracting Officer.

3.6 VIBRATION CONTROL

******************************************************************************
NOTE: Include this paragraph when vibration monitoring is required. Add any additional criteria or requirements as necessary to the particular project.
******************************************************************************
Perform vibration monitoring at the locations [indicated] [decided by the Contracting Officer] during the pile driving operations. Perform vibration monitoring [using] [seismographs][ and geophones] within a distance of 61 meters 200 feet from the pile driving activity. [Engage the services of a qualified, independent Vibration Consultant, acceptable to the Government,
The Vibration Consultant must have a minimum of [five] years of experience in vibration monitoring. A minimum of [28] days before the installation of vibration monitors, submit to the Government the name of the Vibration Consultant and a list of at least [three] previously completed projects of similar scope and purpose.

3.6.1 Monitoring

Prior to the pile driving activities, obtain baseline readings of ambient vibrations. The vibration during the pile driving activities must be limited to [a peak particle velocity of not more than 5 cm 2 inches per second] [the limits mentioned in the [Contract Documents]]. Determine appropriate vibration limits in accordance with [U.S. Bureau of Mines] [American Association of State Highway and Transportation Officials (AASHTO)] guidelines. During pile driving activities, monitor the vibrations to ensure the limits are not exceeded. If the limits are exceeded, cease the pile driving activity causing the vibration until [the Vibration Consultant and the Contracting Officer] are on-site to observe the structures nearest to the vibration monitor that has exceeded the limits.

3.6.2 Damage Responsibility

The Contractor is responsible for damage resulting from the pile driving operations and must take the measures necessary to maintain peak particle velocity within the specified limit. After completion of the project, remove the vibration monitors from the site and from Government property and restore the monitoring locations back to their original condition.

3.7 NOISE CONTROL

Perform noise monitoring at the locations [indicated] [decided by the Contracting Officer] [at noise-sensitive public areas] during the pile driving operations. Perform noise monitoring using [noise meters][, and][______). Engage the services of a qualified, independent Noise Consultant, acceptable to the Government, to conduct the noise monitoring. The Noise Consultant must have a minimum of [five] years of experience in noise monitoring. A minimum of [28] days before the installation of noise monitors, submit to the Government the name of the Noise Consultant and a list of at least [three] previously completed projects of similar scope and purpose.

Prior to the pile driving activities, obtain baseline readings of ambient noise levels. The noise limits are mentioned in the [Contract Documents]. Determine appropriate noise limits in accordance with [local agency] [U.S. Occupation Safety and Health Administration] guidelines.

3.7.1 Monitoring

During pile driving activities, monitor the noise to ensure the limits are not exceeded. If the limits are exceeded, cease the pile driving activity and install noise mitigation measures.
3.7.2 Damage Responsibility

The Contractor is responsible for damage resulting from the pile driving operations and must take the measures necessary to maintain noise within the specified limit. After completion of the project, remove the noise monitors from the site and from Government property, and restore the monitoring locations back to their original condition.

3.8 CONSTRUCTION INSTRUMENTATION AND MONITORING PROGRAM REPORT

**************************************************************************
NOTE: Include this section if instrumentation is to be installed due to concerns about vibration, settlement, lateral movement, etc. during pile driving activities. Instrumentation should be specified and included in the specification. This section can be deleted if there are no instrumentation requirements. Add any additional criteria or requirements as necessary for the particular project.
**************************************************************************

Prepare a Geotechnical Instrumentation Program to monitor settlement [and lateral movement] of temporary and permanent structures, utilities, [embankments] [and excavations] during pile driving. The design and distribution of instrumentation must demonstrate an understanding of the need, purpose, and application of each proposed type. Perform noise and vibration monitoring in accordance with paragraphs NOISE CONTROL and VIBRATION CONTROL.

Monitoring must extend before, during, and for a period after completion of construction activities related to pile driving when long-term performance issues are a concern. The Monitoring Plan must be designed to protect adjacent structures and utilities against damage due to pile driving activities. Establish limiting values of vertical [and horizontal] movement [and angular distortion] [and vibration] for each structure and utility within the zone of influence, subject to review by the Government.

3.8.1 Reporting Requirements

Prepare a report detailing the proposed program of instrumentation and monitoring, establishing threshold values of monitored parameters, and describing the response plans that will be implemented when threshold parameters are exceeded. The report must include details about the Instrumentation Consultant’s experience, appropriate types, quantities, locations, and monitoring frequencies of the instruments.

Upon acceptance of the Instrumentation and Monitoring Program, provide, install, and monitor the instrumentation and interpret the data. Submit instrumentation data reports at least [_____] days after the monitoring program has begun. Take corrective actions, as necessary, based on the field instrumentation data and as defined in the Instrumentation and Monitoring Program.

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for drilling exploratory holes; drilling drain holes; drilling, washing and pressure testing grout holes; making grout connections; furnishing, handling, transporting, storing, mixing and injecting the grouting materials; patching the finished grout holes; care and disposal of drill cuttings, waste water and waste grout; clean-up grout galleries and shafts and areas upon completion of the work and all such other operations as are incidental to the drilling and the grouting. This section was originally developed for USACE Civil Works projects.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).
foundation treatment, such as under power plants, locks, cutoff trenches, tunnels, and others.

Methods for listing subdivided items are described in Paragraph 52.2/9109(g) "Variations in Estimated Quantities - Subdivided Items" of Engineer Federal Acquisition Regulation Supplement (EFARS). However, effectiveness of the use of subdivided items in grouting has been questioned as being more hazardous than helpful and that FAR 52.211-16 Variation in Quantity should be used.

Provisions are made for the use of a sanded grout but should generally be limited to those formations where quantities in excess of one cubic foot of grout per linear foot of hole are anticipated. The information contained in EM 1110-2-3506, "Grouting Technology" and EM 1110-2-1302, "Cost Estimates - Government Estimate of Fair and Reasonable Cost to Contractor" should be used as a guide in estimating quantities.

Computer Application of Geotechnical Engineering (CAGE):

a. The CAGE Grouting Task Group has developed a microcomputer program for documentation of grouting operations and graphics for rapid display of data for better field control. Some of the highlights of the program include optional data entry by a laptop or hand held computer in the field, technical review and quality control, preparation of Contractors pay schedules, and preparation of foundation reports. The User's Guide "Microcomputer Grouting Data Package (Multiple Zone and Stage Version for PC and Hand Held Computer)" is available from the U.S. Army Engineer Waterways Experiment Station (USACE-WES-GL). Use of this CAGE package will not require contractual or technical additions to the contract specifications unless the computer equipment, other facilities, or personnel for data entry are to be Contractor supplied. In such case the proper provisions should be included. This program is also an attractive tool for use in grouting operations by Corps of Engineers personnel. Use of this program should be strongly considered for any grouting operation.

b. Computer-aided control and monitoring of the grout injection has recently been used by the U.S. Bureau of Reclamation (USBR) on several of their projects. Their system is appropriate for use on large grouting projects. Use of their system will necessitate certain contractual and technical additions to the specifications which are not included in this guide specification. If interested in this type system for a large grout program more information can be obtained by contacting the CAGE grout task group and the USBR.
Chemical or other specialty grouting applications have not been specifically addressed in this guide specification as most of the CE grouting in rock foundations for concrete structures, cutoff trenches, locks and powerhouses use cement grout. However, the specification may be used as a general outline for chemical or other specialty grouting applications by insertion of the proper equipment, materials, and procedures in the appropriate paragraphs and by modification and deletion of other paragraphs. Engineer Manuals 1110-2-3504, "Chemical Grouting", and 1110-2-3506, "Grouting Technology", should be used as guides when the use of chemical grouts and other specialty grouting applications are being considered. The manufacturer of those systems that meet the potential job requirements should be contacted for verification. Also, consideration should be given to conducting laboratory and field tests and evaluations of the system or systems being considered for a given applications. There may be occasions when the engagement of a consultant would be appropriate and advantageous to assist in the planning, selecting, and evaluating of a system under consideration. Engineer Manual 1110-2-2901, "Tunnels and Shafts in Rock", should be referred to when planning tunnel grouting and the guide specification for Tunnel and Shaft Grouting should be used in the preparation of project specifications.

If grouting is anticipated during extreme temperatures, alteration of certain field procedures may be necessary and should be included in the specifications. Generally, for cold weather grouting, the grout should be maintained at temperatures above 10 degrees C (50 degrees F) until injected, and storage of the grouting materials should be at temperatures above freezing. Temperature controls for grouting surface rocks should be specified based on specific site conditions anticipated. Insulation, heated enclosures, water heaters or other equipment or procedures may be required. Grouting in extremely hot weather may also require extra precautions.

1.1 SUMMARY

**************************************************************************

1.1 SUMMARY

********************************************************************************

NOTE: If no separate section on "CONCRETE" is used, the appropriate paragraphs applicable to sampling and testing in SECTION 03 70 00 MASS CONCRETE should be inserted in the following paragraphs in lieu of the section reference given below. If a "CONCRETE" section, other than SECTION 03 70 00 MASS CONCRETE is used, the Designer should ensure that the applicable sampling and testing is included in that section.

********************************************************************************

SECTION 31 43 13.13 Page 6
a. This section covers drilling exploratory holes; drilling drain holes; drilling, washing and pressure testing grout holes; making grout connections; furnishing, handling, transporting, storing, mixing and injecting the grouting materials; backfilling holes; patching the finished grout holes; care and disposal of drill cuttings, waste water and waste grout; clean up of grout galleries and shafts upon completion of the work and all other such operations as are incidental to the drilling and grouting. The work contemplated consists of constructing a grout curtain and a drainage curtain, the approximate locations, limits, and details which are indicated. Perform Government preconstruction sampling and testing as specified below:

b. Perform sampling and testing of sand, cementitious materials, and admixtures in accordance with Section [03 70 00 MASS CONCRETE][03 30 00 CAST-IN-PLACE CONCRETE].

c. Perform sampling and testing of grout materials in accordance with Section [03 70 00 MASS CONCRETE][03 30 00 CAST-IN-PLACE CONCRETE].

1.2 UNIT PRICES

**************************************************************************

NOTE: If Section 01 20 00 PRICE AND PAYMENT PROCEDURES is included in the project specifications, this paragraph title (UNIT PRICES) should be deleted from this section and the remaining appropriately edited subparagraphs below should be inserted into Section 01 20 00.

**************************************************************************

1.2.1 Mobilization and Demobilization

1.2.1.1 Payment

Payment will be made for costs for assembling all plant and equipment at the site, preparatory to initiating the work and for removing it therefrom when the drilling and grouting program has been completed. Sixty (60) percent of the contract lump sum price for mobilization and demobilization will be paid following completion of moving onto the site, including complete assembly, in working order, of all equipment necessary to perform the required drilling and grouting operations. The remaining forty (40) percent of the contract lump sum price will be paid when all equipment has been removed from the site.

1.2.1.2 Unit of Measure

Unit of measure: lump sum.

1.2.2 Drilling Grout Holes

**************************************************************************

NOTE: Delete the bracketed phrase if pay item "Pressure Washing and Pressure Testing" is retained as a pay item.

**************************************************************************
1.2.2.1 Payment

Payment will be made for costs associated with drilling and redrilling grout holes; [washing and pressure testing of grout holes;] care and disposal of waste water and waste grout; clean-up of the site; furnishing, handling, transporting and storing of grout materials; and for furnishing all labor and supplies incidental to the work. This price is subject to the cost limitation imposed by[ Section 31 43 13.13 CONCRETE PRESSURE GROUTING,] paragraph PIPE FOR FOUNDATION GROUTING AND DRAINAGE, but only in those locations where pipe is specified. No payment will be made for grout, or the material constituents thereof, wasted due to improper anchorage of grout pipe or connections, or which is wasted due to negligence on the part of the Contractor, nor for grout which is rejected by the Contracting Officer because of improper mixing. Payment will be made at the applicable contract unit prices for materials contained in grout which are wasted, where the wasting is not due to negligence on the part of the Contractor.

1.2.2.2 Measurement

Drilling of grout holes will be measured for payment on the basis of the linear feet of holes actually drilled in concrete or rock, as shown or as directed, including all intermediate holes at locations where pipe was not installed.

1.2.2.3 Unit of Measure

Unit of measure: linear meter foot.

1.2.3 Drilling Drain Holes

1.2.3.1 Payment

Payment will be made for costs associated with drilling of drain holes actually drilled in concrete or rock, as shown or as directed. This price is subject to the cost limitation imposed by[ Section 31 43 13.13 CONCRETE PRESSURE GROUTING,] paragraph PIPE FOR FOUNDATION GROUTING AND DRAINAGE.

1.2.3.2 Measurement

Drilling of drain holes will be measured for payment on the basis of the linear meter feet of holes actually drilled in concrete or rock, as shown or as directed.

1.2.3.3 Unit of Measure

Unit of measure: linear meter foot.

1.2.4 Drilling Exploratory Holes

**************************************************************************
NOTE: If a portion of exploratory drilling is to be done through overburden, a separate pay item should be included for this portion.
**************************************************************************

1.2.4.1 Payment

Payment will be made for costs associated with drilling of exploratory
1.2.4.2 Measurement

Drilling of exploratory holes will be measured for payment on the basis of the linear meters feet of holes actually drilled in concrete or rock, as directed by the Contracting Officer.

1.2.4.3 Unit of Measure

Unit of measure: linear meter foot.

1.2.5 Pressure Washing and Pressure Testing

1.2.5.1 Payment

Payment will be made for pressure washing and pressure testing of grout holes, which includes the cost of making and breaking connections incidental to the work. Payment will be based upon the total amount of time required for pressure washing and pressure testing, determined by reducing the total number of minutes of operation to the nearest whole hour. No payment will be made for time lost due to fault or negligence of the Contractor, or due to defective equipment furnished by the Contractor. Time will be measured cumulatively to the next whole minute of operations.

1.2.5.2 Measurement

Pressure washing and pressure testing will be measured for payment on the basis of the actual time water pumps are operating. Pressure washing and pressure testing will be measured from the time pumping is begun on a hole or section of a hole until the time pumping is completed on the hole or section of the hole as determined by the Contracting Officer. Operation time will be determined by rounding 30 or more minutes of operation up to the nearest whole hour, and rounding 29 or less minutes of operation down to the nearest whole hour. Fractional time will be measured cumulatively to the next whole minute of operation.

1.2.5.3 Unit of Measure

Unit of measure: nearest whole hour.

1.2.6 Steel Pipe and Fittings

1.2.6.1 Payment

Payment will be made for costs associated with grout and drain hole pipe and fittings remaining in the permanent work.

1.2.6.2 Measurement

Pipe and fittings will be measured for payment on the basis of the actual weight of satisfactorily installed pipe and fittings left in place as shown. No additional allowance will be made because of differences in pipe size or length, or the number of pipes required.

1.2.6.3 Unit of Measure

Unit of measure: kilogram pound.
1.2.7 Portland Cement in Grout

1.2.7.1 Payment

Payment will be made for costs associated with Portland cement in grout.

1.2.7.2 Measurement

Portland cement in grout will be measured for payment on the basis of the number of cubic meters (42.6 kilograms) feet (94 pounds) of cement used in the grout satisfactorily placed in grout holes and in exploratory holes, or wasted when such wasting is not due to the Contractor's negligence.

1.2.7.3 Unit of Measure

Unit of measure: cubic meter (42.6 kilograms) foot (94 pounds).

1.2.8 Pozzolans (Fly Ash) in Grout

1.2.8.1 Payment

Payment will be made for costs associated with fly ash in grout.

1.2.8.2 Measurement

Fly ash in grout will be measured for payment on the basis of the number of cubic meters (33.6 kilograms) feet (74 pounds) of fly ash used in the grout satisfactorily placed in grout holes.

1.2.8.3 Unit of Measure

Unit of measure: cubic meter foot.

1.2.9 Sand in Grout

1.2.9.1 Payment

Payment will be made for costs associated with sand in grout.

1.2.9.2 Measurement

Sand in grout will be measured for payment on the basis of the number of cubic meters feet of sand[, dry rodded measurement,] used in the grout satisfactorily placed in grout holes or in exploratory holes.

1.2.9.3 Unit of Measure

Unit of measure: cubic meter foot.

1.2.10 Fluidifier in Grout

1.2.10.1 Payment

Payment will be made for costs associated with fluidifier in grout, including full allowance for the payment by the Contractor of all required royalties.
1.2.10.2 Measurement

Fluidifier in grout will be measured for payment on the basis of the number of kilograms pounds of fluidifier used in the grout satisfactorily placed in grout holes.

1.2.10.3 Unit of Measure

Unit of measure: kilogram pound.

1.2.11 Bentonite in Grout

1.2.11.1 Payment

Payment will be made for costs associated with bentonite in grout.

1.2.11.2 Measurement

Bentonite in grout will be measured for payment on the basis of the number of kilograms pounds of bentonite actually used in grout mixtures satisfactorily placed in grout holes.

1.2.11.3 Unit of Measure

Unit of measure: kilogram pound.

1.2.12 Placing Grout

**************************************************************************
NOTES: Select appropriate Alternative.
Under certain conditions it may be desirable to include a pay item for standby time for Government directed suspension of drilling or grouting operations.
**************************************************************************

1.2.12.1 Payment

Payment will be made for costs associated with satisfactorily placing grout in grout holes[, which includes full compensation for proportioning the mix as directed and mixing and injecting the grout as specified[ in Section 31 43 13.13 CONCRETE PRESSURE GROUTING]. Separate payment will be made for all materials used in grout as provided in unit price pay item(s) "Portland Cement in Grout", "Pozzolans (Fly Ash) in Grout", "Sand in Grout", "Fluidifier in Grout", and "Bentonite in Grout".][. No payment will be made for time lost due to fault or negligence of the Contractor or due to defective equipment furnished by the Contractor.]

1.2.12.2 Measurement

Placing grout will be measured for payment on the basis of [the number of cubic meters feet of materials, satisfactorily placed, exclusive of water [and fluidifier] and regardless of the proportions of the mixes, measured individually as specified in unit price pay items "Portland Cement in Grout", "Pozzolans (Fly Ash) in Grout", and "Sand in Grout".][the actual time grout pumps begin pumping on a hole or portion of hole and continuing until the time pumping is completed on that hole or portion of hole, as determined by the Contracting Officer. Time for satisfactory placement of
grout will be determined by rounding 30 or more minutes of placement time up to nearest whole hour, and rounding 29 or less minutes of placement time down to the nearest whole hour. Fractional placement time will be measured cumulatively to the next whole minute of operation.]

1.2.12.3 Unit of Measure

Unit of measure: [cubic meter foot.] [nearest whole hour.]

1.2.13 Connections to Grout Holes

**************************************************************************

NOTE: The price to be inserted in this paragraph should be determined on the basis of the estimated cost to the Contractor for the operation of moving the grout supply line onto the hole. This price should not include any allowance for pipe or other materials used in making the connections. This unit price pay item may be optional for grout payment on an hourly basis.

**************************************************************************

1.2.13.1 Payment

Payment will be made for costs associated with connections to grout holes at a rate of [_____] dollars per connection. Where stop grouting method is used [payment for at least one connection will be made for each packer setting in a hole]. [Payment for only one connection will be made for each hole regardless of the number of settings.]

1.2.13.2 Measurement

Connections to grout holes will be measured for payment per connection for each time the grout supply line is connected to a grout hole for the purpose of injecting grout regardless of the number of times connections are made per hole or the amount of grout actually injected.

1.2.13.3 Unit of Measure

Unit of measure: each.

1.3 REFERENCES

**************************************************************************

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically
The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

**AMERICAN SOCIETY OF MECHANICAL ENGINEERS (ASME)**

**ASME B16.3** (2021) Malleable Iron Threaded Fittings, Classes 150 and 300

**ASTM INTERNATIONAL (ASTM)**

**ASTM C618** (2023; E 2023) Standard Specification for Coal Fly Ash and Raw or Calcined Natural Pozzolan for Use in Concrete

**ASTM C937** (2023) Grout Fluidifier for Preplaced-Aggregate Concrete

**U.S. ARMY CORPS OF ENGINEERS (USACE)**

**COE CRD-C 100** (1975) Method of Sampling Concrete Aggregate and Aggregate Sources, and Selection of Material for Testing

**1.4 DEFINITIONS**

**1.4.1 Zone**

A zone is a predetermined partial depth of curtain. The first zone extends [_____] m feet downward from [the contact between the concrete and the rock] [the bottom of the cutoff trench] [overburden and the top of rock] overburden and elevation [______]. The second zone extends [_____] m feet downward from the bottom of the first zone. The third zone extends [_____] m feet downward from the bottom of the second zone. [Define additional zones as needed]. Finish all grouting in a given zone and section before work is started in the next [higher] [lower] zone.
1.4.2 Section

A section is a reach along the grout curtain, not more than [_____] feet in length in which grouting operations will not be permitted at the same time that drilling is in progress. Insofar as practicable, the grout curtain will be subdivided into sections in a manner which will facilitate the Contractor's operations.

1.4.3 Stage

A stage is one complete operational cycle of drilling, cleaning, pressure washing, pressure testing, pressure grouting, and grout cleanout within a zone. The actual depth of a stage depends upon geologic conditions encountered in drilling. It may vary from a fraction to the full depth of the zone, and is marked by the loss or gain of drill water in appreciable amounts.

1.4.4 Stop

A stop is a predetermined depth at which the expanding plug or packer is positioned.

1.4.5 Split Spacing

Split spacing is the procedure of locating an additional grout hole midway between two previously drilled and grouted holes.

1.5 SUBMITTALS

**************************************************************************
NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL

********************************************************************************
UFGS

PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-03 Product Data

Drilling Equipment

Grouting Equipment

Grout Plant; G[, [___]]

1.6 DELIVERY, STORAGE, AND HANDLING

NOTE: If no separate section on "CONCRETE" is used, the appropriate paragraphs applicable to material delivery, storage, and handling in SECTION 03 70 00 MASS CONCRETE should be inserted in this paragraph in lieu of the section reference given below. If a "CONCRETE" section, other than SECTION 03 70 00 is used, the Designer should ensure that the applicable material delivery, storage, and handling paragraphs are included in that section.

Furnish transportation and storage of materials in accordance with section [03 70 00 MASS CONCRETE][03 30 00 CAST-IN-PLACE CONCRETE]. Store a sufficient quantity of cement at or near the site of the work to insure that grouting operations will not be delayed by shortage of cement. In the event the cement is found to contain lumps or foreign matter of a nature and in amounts which, in the opinion of the Contracting Officer, may be deleterious to the grouting operations, screening through a standard 100 mesh screen may be required. No payment will be made for such screening.

1.7 PROJECT/SITE CONDITIONS

The program shown and described is based on currently available information. Conditions encountered during construction may require additions or deletions. Do not modify or curtail the grouting program as a construction expediency. It is a required part of design and is not secondary to any time or scheduling restrictions. Determine grouting mixes, pressures, injection rate and the sequence in which the holes are drilled and grouted in the field and as directed.
PART 2   PRODUCTS

2.1  GROUTING MATERIAL

Provide grout composed of water and cement, [pozzolans, admixtures, and fillers]. The grout mixes will be designed by the Contracting Officer and will be varied to meet the characteristics of each hole as determined by conditions encountered. Furnish various materials conforming to the specifications listed in paragraphs below.

2.1.1  Water

[Furnish the water used in the grout. Provide fresh, clean water that is free from injurious amounts of sewage, oil, acid, alkali, salts, or organic matter.] [Water suitable for use in the work will be furnished by the Government. It is the responsibility of the Contractor to provide any necessary connections and extensions to the Government supply line shown.]

2.1.2  Cement

**************************************************************************
NOTE: Avoid specifying the use of air entrained cement, except on rare occasions when grout may be exposed to severe freezing and thawing conditions.
**************************************************************************

Provide cement used in grout conforming to the requirements of ASTM C91/C91M and ASTM C150/C150M. The use of bulk cement will be permitted provided the Contractor employs methods of handling, transporting, and storage that are satisfactory to the Contracting Officer, otherwise only cement furnished in cloth or paper bags will be accepted to use in the work. Store cement in accordance with paragraph DELIVERY, STORAGE, AND HANDLING.

2.1.3  Pozzolans

Provide fly ash pozzolans [or other raw or calcined natural pozzolans] conforming to ASTM C618. Sampling will be done by an authorized representative of the Government. All tests will be made by and at the expense of the Government. Pozzolans may be furnished in paper sacks or in bulk. Transport, handle, and store it so as to avoid damage, waste, or absorption of moisture.

2.1.4  Admixtures

**************************************************************************
NOTE: Refer to EM 1110-2-3506, "Grouting Technology", for discussions of properties, characteristics and limitations for principal admixture and filler materials. Only the more commonly used are included here.
**************************************************************************

Add admixtures to the grout immediately before or during its mixing that consist of [accelerators, retarders, water reducers, aluminum powder, and fluidifiers].

2.1.5  Fluidifier

Furnish fluidifier that is a compound possessing characteristics which will
increase the flowability of the mixture, assist in dispersal of the cement grains, and neutralize the setting shrinkage of the grout. The quality of the material must meet the requirements specified in ASTM C937. Sample fluidifier by an authorized representative of the Contracting Officer. Trial mixtures should be tested prior to using the materials in field work. All tests will be made by and at the expense of the Government. Furnish fluidifier in moisture-resistant paper sacks shipped in sealed containers and handle and store so as to avoid absorption of moisture, damage or waste. Material which has become caked due to moisture absorption will be rejected.

2.1.6 Bentonite

Provide sodium (Na) cation, powdered montmorillonite bentonite. Add 2 percent to 5 percent by weight of cement to the cement grout. Adjust the percentage as directed by the Contracting Officer. A separate colloidal bentonite mixer is required to mix the bentonite and water to ensure fully dispensing and hydrating the bentonite before adding to the grout mixer. Handle and store the bentonite so as to avoid absorption of moisture, damage, or waste. Bentonite which has become caked due to moisture absorption will be rejected. Store a sufficient quantity of bentonite at or near the site of the work to insure that grouting operations will not be delayed by shortage of bentonite.

2.1.7 Sand

a. Provide clean sand for grout consisting of hard, tough, durable, uncoated particles with no more than [_____] percent passing the No. 200 sieve. Provide generally rounded or cubical shaped particles [containing no more than [_____] percent of flat or elongated pieces having a maximum dimension in excess of five times the minimum dimension]. Provide sand that is generally well graded from fine to coarse in accordance with ASTM C136/C136M with 100 percent passing the [No. 8][_____] sieve.

b. Subject the sand to such tests as are necessary to determine its acceptability. Perform sampling of sand in accordance with the applicable sampling provisions contained in COE CRD-C 100 or as directed. Unless otherwise directed, take all test samples under the supervision of the Contracting Officer and deliver to a designated point, at the expense of the Contractor, at least [_____] days in advance of the time when sand will be required at the site of work. All tests will be made by the Government at its expense. The tests to which the sand will be subjected will include specific gravity, absorption, soundness in magnesium sulfate, petrographic analyses, and any other tests that are necessary to demonstrate that grout of adequate durability can be produced.

c. The percentage of surface moisture in terms of the saturated surface-dried sand will be determined in accordance with ASTM C70, or other method giving comparable results.

d. Store sand in such a manner as to avoid the inclusion of any foreign materials in the grout. Maintain all sand in free draining storage for at least 72 hours prior to use.

2.2 METAL PIPE AND FITTINGS

Furnish, cut, thread, and fabricate pipe and fittings required for
constructing grout, drainage and exploratory holes.

2.2.1 Pipe

Pipe will be black steel of the diameter and in the location indicated. Furnish pipe conforming to ASTM A53/A53M.

2.2.2 Fittings

Provide black, malleable iron fittings in accordance with ASME B16.3.

PART 3 EXECUTION

3.1 EQUIPMENT

**************************************************************************
NOTE: For jobs where the estimated quantity of solids is between zero and 30 cubic meters 1,000 cubic feet, a pumping capacity of 950 cm$^3$/s 15 gpm is recommended; from 30 to 1400 cubic meters 1,000 to 50,000 cubic feet, a 1900 cm$^3$/s 30 gpm pump; and for jobs greater than 1400 cubic meters 50,000 cubic feet, a 3800 cm$^3$/s 60 gpm pump. Also, for jobs where large grout quantities are anticipated it may be desirable to specify an automated batching plant with batch tickets for all items in the mix.
**************************************************************************

The use of internal combustion engines within dam galleries for operation of drilling and grouting equipment will not be permitted. Submit details and data on the drilling and grouting equipment.

3.1.1 General

Use drilling [including exploratory hole drilling] and grouting equipment of a type, capacity and mechanical condition suitable for performing the work, as determined by the Contracting Officer. Provide power and equipment and the layout thereof meeting all applicable requirements of local, State, and Federal regulations and codes, both safety and otherwise.

3.1.2 Drilling Equipment

Use standard drilling equipment of the rotary [or percussion] type to perform the drilling as specified in paragraphs GROUT HOLE DRILLING, DRAIN HOLE DRILLING, COMPLETION OF GROUTING AND DRAIN HOLE DRILLING, and EXPLORATORY HOLE DRILLING. Use [water] [air] for removing cuttings from the hole during drilling operations. Equip air driven drills used in galleries with suitable mufflers. Supplies include all bits, drill rods, tools, casing, piping, pumps, water, and power to accomplish the required drilling. All drilling rigs and pumps will be equipped with pressure gages.

3.1.3 Grouting Equipment

Furnish grout plant capable of supplying, mixing, stirring and pumping the grout and additives, to the satisfaction of the Contracting Officer. Submit a detailed plan showing equipment and grout plant layout proposed for mixing and placing grout. Furnish plant with a minimum capacity of [[_____] mL/s] [[_____] cm$^3$/s] [[_____] gpm] [[_____] cfm] of grout
injected at a pressure not greater than [_____] kPa psi. Maintain it at all times and replace any grout hole that is lost or damaged due to mechanical failure of equipment or inadequacy of grout supply by another hole, drilled by the Contractor, at its expense. Provide the amount of grouting equipment as necessary to perform the work specified herein. Include the following:

a. A progressive cavity pump capable of passing particles up to a top size of [_____] mm inches, generating pressures up to [_____] kPa psi and pumping a maximum of [_____] mL/s [_____] cm³/s [_____] gpm [_____] cfm. In no case will the pump be separated by more than [_____] meters feet of grout line from the header of a hole being grouted. Where grout lines are more than [_____] meters feet long, place an additional pump in the line within [_____] meters feet of the header.

b. A [colloidal] [paddle] type grout mixer having a minimum drum capacity of approximately [_____] cubic meters feet with a mix batch of [_____] cubic meters feet. Provide mixing time of approximately [_____] seconds per batch.

c. A separate colloidal mixer for mixing and hydrating bentonite.

d. A mechanically agitated sump having a minimum capacity of [_____] cubic meters feet.

e. A circulating grout header with control valves and a pressure gage with protector as shown on the plans. Connect control valves to the return line and header. Join the header directly to the riser pipe at the hole by means of a quick connector union.

f. A water storage tank or suitable source of clean auxiliary water for use in washing, pressure testing and flushing operations.

g. A water meter graduated in cubic meters feet and tenths having a direct reading totalizer and capable of conveniently being set back to zero.

h. Such valves, packers, pressure gages, pressure hose, supply lines, and small tools as may be necessary to provide a continuous supply of grout at accurately controlled pressures as specified. The inside diameter of the pressure hose and grout supply line less than [_____] mm inches is not permitted. Use an accurately calibrated, high precision pressure gage to check the accuracy of all gages used in the grouting. Check gages at least every 24 hours, or more frequently if the Contracting Officer so determines. When defects are found, grouting operations will be stopped until calibration of gages has been obtained.

3.2 GROUT, DRAINAGE AND EXPLORATORY HOLES

Drill all holes for grouting, drainage or exploration at the locations, in the direction, angle, and to the depths indicated or as directed by the Contracting Officer.[ Provide a maximum tolerance for deviation in angle and direction of [_____] .] Drill and grout the first series of holes at [_____] meter foot intervals and hereinafter are referred to as primary holes. Determine the location of secondary and succeeding series (intermediate) holes by the split spacing method as defined in paragraph SPLIT SPACING. Increase the number of grout holes progressively by the split spacing method as defined in paragraph SPLIT SPACING. Increase the number of grout holes progressively by the split spacing method as deemed
necessary by the Contracting Officer until the amount of grout used indicates that the foundation is tight. Protect each hole drilled from becoming clogged or obstructed by means of a cap or other suitable device on the collar and clean out any hole that becomes clogged or obstructed due to fault of the Contractor before completion of operations in a manner satisfactory to the Contracting Officer or provide another hole at the expense of the Contractor. That portion of holes which penetrates concrete of the dam must be [formed by embedding pipes in the concrete at the time of its placement] [drilled] as specified in paragraph PIPE FOR FOUNDATION GROUTING AND DRAINAGE. Payment will be made for such partial depth of holes at the unit contract price for [Item No. [_____] "Steel Pipe and Fittings"], [Item No. [_____] "Drilling Grout Holes"], [Item No. [_____] "Drilling Drain Holes"], [Item No. [_____] "Drilling Exploratory Holes"].

3.2.1 Pipe for Foundation Grouting and Drainage

Embed all metal pipe and fittings required for constructing grout, drainage and exploratory holes. Thoroughly clean pipe and fittings of all dirt, grease, oil, grout and mortar immediately before embedment. Make all joints snug and hold the assembly firmly in position and protect from damage or displacement while the concrete is being placed. Take all necessary precautions to prevent any pipe from becoming clogged or obstructed from any cause and clean out any pipe which becomes clogged in a manner satisfactory to the Contracting Officer at the Contractor's expense. Consider the presence of tramp metal such as nails, wire, bolts, nuts and other foreign material in the pipes through which diamond drilled holes are to be drilled as obstructions. As an option, substitute percussion or diamond drilled holes through the concrete in lieu of pipe, provided that the method proposed meets with the approval of the Contracting Officer and provided further that such substitution does not result in any increased cost to the Government.

3.2.2 Grout Hole Drilling

a. Drill grout holes with standard rotary [or percussion] drilling equipment. No core recovery will be required and the type bit used will be optional with the Contractor. [Provide hole of sufficient diameter to allow use of an expansion plug or packer with an effective inside diameter of not less than 13 mm 1/2 inch]. The minimum diameter of hole must be [35] [_____] mm [1 3/8] [_____] inches at the point of maximum penetration. No grout hole will be drilled at an angle greater than [_____] degrees measured from the vertical nor to a depth greater than [_____] meters feet measured from the collar of the hole. If, as the work progresses, it is determined that holes to depths greater than indicated are necessary, drilling to such greater depth will be ordered in writing, and the drilling to depths in excess of [_____] meters feet will be paid for at a negotiated unit price.

b. Perform drilling in accordance with the applicable grouting method hereinafter described. Whenever as much as [_____] percent of the drill water is lost or the cumulative total of successive water losses is estimated to amount to [_____] percent loss, or artesian flow is encountered, stop the drilling operations, wash the hole, pressure test and grout before drilling operations are resumed in such hole. Remove injected grout from a partially completed hole by washing or other methods before it has set sufficiently to require redrilling. Redrilling required because of the Contractor's failure to clean out a hole before the grout has set must be performed at the Contractor's expense except that where the grout has been allowed to set by
direction of the Contracting Officer, the redrilling will be paid for at the contract price for drilling the grout hole. Upon completion of drilling of any hole and prior to pressure testing, remove all drill cuttings and slurry by applying water to the bottom of the hole [through open end rods] and returning the wash water through the hole to the surfaces until the return water is clear. No separate payment will be made for this washing.

3.2.3 Drain Hole Drilling

Drill drain holes with standard diamond drilling equipment, but no core recovery will be required and the Contractor may elect to use coring or noncoring bits. The minimum diameter of hole must be [72] [_____] mm [2 7/8] [_____] inches, measured at the point of maximum penetration. No drain hole will be drilled at an angle greater than [_____] degrees from the vertical nor to a depth greater than [_____] meters feet, measured from the collar of the hole. Do not drill drainage holes in any location until all adjacent grout holes within a minimum distance of 50 meters 150 feet have been drilled and grouted to full depth.

3.2.4 Completion of Grouting and Drain Hole Drilling

Complete all grouting operations and all drain hole drilling in proper working condition prior to the time of impounding water. At that time complete all work in the [grouting and drainage galleries] [tunnels], uncover and unobstruct all drain holes, and make [galleries and their gutters] [tunnels] free of all construction debris. Nipples for grout hole drilling will be removed from the [gallery] [cutoff trench] and disposed of and the finished grout holes will be patched.

3.2.5 Exploratory Hole Drilling

a. Perform such exploratory drilling as may be required to determine the condition of the rock prior to grouting or the effectiveness of the grouting operations during or after grouting. Perform all exploratory drilling with rotary drilling equipment using coring type bits. Since the maximum recovery of unpredictable soft or friable materials is of prime importance, make every effort to recover 100 percent of the core by use of the appropriate equipment and drilling procedures.

b. The holes may be required to be drilled to varying depths, with a maximum depth of [_____] meters feet. No exploratory hole will be drilled at an angle greater than [_____] degrees measured from the vertical.

c. Special care should be exercised to obtain cores in as good condition as possible. Keep, in a manner satisfactory to the Contracting Officer, an accurate Driller's Log of all exploratory holes drilled. Include a nontechnical description of all materials encountered in the drilling, their location in the holes and the location of special features such as seams, open cracks, soft or broken rock, points where abnormal loss or gain of drill water occurred, and any other items of interest in connection with the purpose for which the exploratory drilling is required.

d. Wooden or other approved core boxes will be furnished by [the Government] [the Contractor], and place the cores in the boxes in the correct sequence and separated accurately by wooden blocks, according to the measured distances in the hole. Do not contain cores from more
than one hole. Fasten the covers securely to the core boxes and deliver in the vicinity of the work as directed.

e. Grout exploratory holes under pressure, if conditions so indicate, by [stop grouting] [grouting to full depth in one operation] and backfilled in accordance with paragraph BACKFILLING OF HOLES.

3.3 PROCEDURES FOR DRILLING AND GROUTING

3.3.1 General

Accomplish drilling and grouting in single or multiple lines as shown. Drill and grout by [zones, using the split spacing, stage grouting method] [split spacing, stop grouting method] as described herein.

3.3.2 Stage Grouting

Perform stage grouting of progressively deeper zones in stages with the placement of a grout curtain by drilling and grouting in successive operations in accordance with the following general procedure.

3.3.2.1 Primary Holes

Drill primary holes for foundation grouting to their first stage of depth within the first zone. The depths will be governed by the foundation conditions.

a. Wash and pressure test the holes thus drilled and then grout, except that when pressure testing indicates a relatively tight hole, the Contracting Officer may direct that the grouting of that hole be omitted for that stage and the hole be left open for drilling and grouting of the next stage.

b. After the grouting of any hole, [remove the grout within the hole by washing or by other methods before it has set sufficiently to require redrilling][allow the grout within the hole to set and subsequently redrill the holes].

c. After the interval of time as specified in paragraph SECOND STAGE, drill the primary holes not already drilled to the limit of the first zone as directed to additional depths not exceeding the zone limit.

d. Wash the primary holes thus deepened again and pressure test and then grout at higher pressures as directed. Again, remove the grout within the hole as described above.

e. Repeat the process of successively drilling primary holes to additional depths and grouting at higher and higher pressures in stages, as directed, until all of the primary holes on the maximum spacing (see paragraph GROUT, DRAINAGE AND EXPLORATORY HOLES) have been completely drilled and grouted to the depth of the first zone in that section of the grout curtain.

3.3.2.2 Successive Holes

After the primary holes in the first zone have been completed in any section as specified above, drill and grout the second and succeeding series of holes, as determined by the "split spacing method," to the depth of the first zone in like manner until the first zone of that section is
completely grouted as directed.

3.3.2.3 Completion of Section

Repeat the process of successively drilling to additional depths and grouting at higher and higher pressures in stages for the first series of holes and then for succeeding series of holes for the second and subsequent zones of that section. Grout other sections along the grout curtain in like manner until grouting of the foundation is completed to the satisfaction of the Contracting Officer. As the drilling and grouting work progresses, it may develop that conditions are such that all or parts of the foundation already grouted require additional grouting. In such event, return the equipment and drill and grout additional holes as directed.

3.3.3 Stop Grouting

Stop grouting is a method whereby each hole is drilled to a final depth and grouted by stops through an expansion plug or packer which is set at successively shallower depths. It involves the placement of a grout curtain by drilling and grouting in accordance with the following general procedure:

a. Drill hole to the full depth and wash as specified in paragraph GROUT HOLE DRILLING.

b. Pressure test holes thus drilled and washed, and pressure washd as specified in paragraph PRESSURE WASHING AND PRESSURE TESTING.

c. Place the expansion plug, or packer, in the hole at the top of the interval to be grouted blocking off the higher portion of the holes, and the interval is grouted. The lowest zone is grouted first. In no case will the Contractor be required to set the packer deeper than [_____] meters feet.

d. After placing the grout at the pressure and mix directed by the Contracting Officer, leave the expansion plug, or packer, in place until the grout pressure drops to that pressure required for the next higher stop or as directed by the Contracting Officer.

e. Move the expansion plug, or packer, to the next higher stop and place grout at the lower pressure as directed by the Contracting Officer.

f. Repeat the procedures described in subparagraphs "d" and "e" above until grouting of the hole is complete.

g. After the primary holes in the first zone have been completed in any section as specified above, grout the second and succeeding series of holes, as determined by the "split spacing method" in like manner until all zones of that section are completely grouted as directed.

h. Grout other sections along the grout curtain in like manner until grouting of the foundation is completed to the satisfaction of the Contracting Officer.

i. As the drilling and grouting work progresses, it may develop that conditions are such that all or parts of the foundation already grouted require additional grouting. In such event, return the equipment and drill and grout additional holes as directed and no allowance above contract unit prices will be made for drilling and grouting such holes.
or for the expense of any movement of equipment necessary to the performance of such work.

3.3.4 Pressure Washing and Pressure Testing

Immediately before the pressure grouting operation, thoroughly wash the hole under pressure and pressure test. Wash all intersected rock seams and crevices containing clay or other washable materials with water [and air] under pressure to remove as much of these materials as possible. If practicable, as determined by the Contracting Officer, eject such material from one or more holes by introducing water [and air] under pressure into an adjacent hole. Do not exceed the maximum grouting pressure as directed. Test all grout holes with clean water under continuous pressure up to the maximum grouting pressure as directed. Wash all holes sufficiently tight to build up the maximum required pressure and continue washing as long as there is any increase in the rate at which water is taken, such increase indicating the fractures are being opened by the washing operation. Wash open holes in which no pressure can be built up for a period of 5 minutes, with the pump operating at full capacity, or for such period of time as fracture-filling is being removed, as evidenced by the escape of muddy water through surface openings or other grout holes.

3.3.5 Stage Grouting Procedures

3.3.5.1 First Stage

Perform the first stage, or low-pressure, shallow-curtain grouting by washing and grouting holes at locations indicated or as directed, using the "split spacing" method described in paragraph SPLIT SPACING. Similar stages of drilling and grouting are repeated as necessary to reach the bottom of the first zone. Before grouting is begun in any hole of a given series in any section, completely drill at least the nearest two holes in advance of each such hole in that series for the same stage and completely wash the adjacent hole to facilitate washing and flushing out of any intervening clay-filled seams, fractures, or solution channels. Do not grout hole beneath any portion of the dam until all concrete within [35] [_____] meters [100] [_____] feet has been placed to [full height] [_____] unless otherwise directed.

3.3.5.2 Second Stage

After all first stage grouting in any section has been completed, as specified above, proceed, when so directed, with second stage drilling and grouting in accordance with the procedure outlined herein but in no case commence the deepening of any hole preparatory to grouting before the previously placed grout has set nor conduct second stage grouting within a distance of approximately 35 meters 100 feet of any hole in which a previous stage of grouting has been completed until the grout in such previous stage hole has [taken its set] [set for a period of 24-hours]. Perform grouting at subsequent stages conforming to the same requirements as to minimum time and distance. Upon completion of all holes to the bottom of the first zone, and after the waiting period the primary holes are drilled to the next stage in the second zone and grouted at higher pressures. The process of drilling, washing, pressure testing, pressure washing, and grouting at progressively higher pressures are continued until the ground is satisfactorily tight to the required depth.
3.3.6 Stop Grouting Procedures

3.3.6.1 Stop Grouting of Grout Holes

Perform the grouting by washing and grouting holes at locations indicated or as directed. Before grouting is begun in any hole of a given series in any section, completely drill at least the nearest two holes in the advance of each such hole in that series and completely wash the adjacent hole to facilitate washing and flushing out of any intervening clay-filled seams, fractures, or solution channels.

3.3.6.2 Grouting of Existing Exploratory Holes

Clean [pressure-test], and [pressure grout] [gravity grout] existing exploratory holes or portions of holes more than five feet deep after excavation as specified for grout holes. Backfill holes less than 1.5 meters five feet deep with grout mixed in proportions directed by the Contracting Officer. Gravity grout or backfill in accordance with paragraph BACKFILLING OF HOLES.

3.3.7 Grouting Pressures

**************************************************************************
NOTE: Refer to EM 1110-2-3506, "Grouting Technology" for discussions of grouting pressures as an aid in selecting allowable pressures under different conditions.
**************************************************************************

Grouting pressures to be used in the work will vary with conditions encountered in the respective holes and use pressures as directed. It is anticipated that pressures will range from [_____] kPa psi to [_____] kPa psi but in no event will pressures in excess of [_____] kPa psi be required or allowed.

3.3.8 Grouting

Perform all pressure grouting operations in the presence of the [Contracting Officer][Government Inspector], and in accordance with the following general procedures.

3.3.8.1 Grout Mixes

**************************************************************************
NOTE: Appropriate additives will be used for specific cases.
**************************************************************************

Provide mixese in the proportions directed by the Contracting Officer who will, from time to time, direct changes to suit the conditions found to exist in the particular grout hole. [The cement grout will include 2 percent to 5 percent (by weight of cement) of sodium bentonite]. The water/cement ratio by volume will be varied to meet the characteristics of each hole as revealed by the grouting operation and will range between [_____] and [_____]. Provide the types of grout as follows:

[a. Cement Grout consisting of cement, (bentonite) and water.]

[b. Mortar Grout consisting of cement, (bentonite), sand, and water.]
3.3.8.2 Grout Injection

a. In general, if pressure tests indicate a tight hole, start grouting with a thin mix. If an open hole condition exists, as determined by loss of drill water or inability to build up pressure during washing operations, then start grouting with a thicker mix and with a grout pump operating as nearly as practicable at constant speed at all times; decrease the ratio, if necessary, until the required pressure has been reached. [If this procedure does not produce the desired pressure, use mortar grout and vary the mix as necessary to produce the desired results.]

b. When the pressure tends to rise too high, increase the water/cement ratio [and/or change or discontinue the mix of mortar grout] as may be required to produce the desired results. If necessary to relieve premature stoppage, make periodic applications of water under pressure. Do not suddenly increase the pressure or rate of pumping as either may produce a water-hammer effect which may promote stoppage.

c. Do not consider the grouting of any hole complete until [that hole refuses to take any grout whatever at three-fourths of the maximum pressures required for that stage] [that hole takes grout at the rate of one cubic foot of grout or less in ten minutes measured over at least a five minute period at the pressure required for that portion of the hole being grouted].

d. Should grout leaks develop, caulk such leaks when and as directed, the cost thereof being included in the contract price for unit price pay item "Placing Grout", in accordance with Section 01 20 00 PRICE AND PAYMENT PROCEDURES.

e. If, due to size and continuity of fracture, it is found impossible to reach the required pressure after pumping a reasonable volume of grout at the minimum workable water/cement ratio [or mortar grout with the maximum volume of sand at the minimum water/cementing materials ratio] reduce the speed of the pumping or stop pumping temporarily and perform intermittent grouting, allowing sufficient time between grout injections for the grout to stiffen. Following such reduction in pumping speed, if the desired result is not obtained, discontinue grouting in the hole when directed. In such event, clean the hole, allow the grout to set, and perform additional drilling and grouting in this hole or in the adjacent areas as directed, until the desired resistance is built up.

f. After the grouting of any [stage] [stop] of a hole is finished, maintain the pressure by means of a stop-cock or other suitable device until the grout has set to the extent that it will be retained in the hole.

g. Grout that cannot be placed, for any reason, within two hours after mixing must be wasted. If such grout is mixed at the direction of the Contracting Officer or with his knowledge and consent, such wasted grout, except as specified in Section 01 20 00 PRICE AND PAYMENT PROCEDURES, must be paid for at the contract unit prices for the materials contained therein.
3.3.8.3 Backfilling of Holes

Backfill holes with grout proportioned as directed by the Contracting Officer and generally having a water/cement ratio less than 1.0. Accomplish backfilling by injection of grout through a tremie pipe or hose inserted to full depth of hole. When grout vents at the surface, gradually withdraw the tremie, maintaining grout in pipe or hose until completely removed. Do not backfill holes containing freshly injected grout until the injected grout has set. No separate payment will be made for backfilling holes; however, grout will be paid for at the contract unit price for the Portland cement therein.

3.3.8.4 Equipment Arrangement and Operation

Arrange the grouting equipment to provide a continuous circulation of grout throughout the system and to permit accurate pressure control by operation of a valve on the grout return line, regardless of how small the grout take may be. Prevent the equipment and lines from becoming fouled by the constant circulation of grout and by the periodic flushing out of the system with water. Flush with the grout intake valve closed, the water supply valve open, and the pump running at full speed.

3.3.8.5 Protection to Work and Cleanup

[Except as otherwise specified, no grouting will be permitted within [_____] meters feet of installed perforated pipe or gravel filters for foundation drains. Where permitted in such locations, maintain a flow of water through the drains likely to be affected, to serve as tell-tales. In case leakage of grout into drains does occur immediately stop the grouting operations and remove all grout from the drains affected by washing to the satisfaction of the Contracting Officer. Payment for washing will be in accordance with unit price pay item "Pressure Washing and Pressure Testing" in [this Section][Section 01 20 00 PRICE AND PAYMENT PROCEDURES]. Repeat such stopping of grouting operations and washing of drains as often as required to complete the curtain grouting.] During grouting operations take such precautions as may be necessary to prevent drill cuttings, equipment exhaust oil, wash water, and grout, from defacing or damaging the permanent structure. Daily maintenance may be required along grout lines, in order to offer better inspection of interconnected holes and breakouts. The Contractor will be required to furnish such pumps as may be necessary to care for waste water and grout from his operations. Upon completion of these operations, clean up all waste resulting from his operations that is unsightly or would interfere with the efficient operation of the project as anticipated by the original design.

3.3.9 Records

The Contracting Officer will keep records of all grouting operations, such as a log of the grout holes, results of washing and pressure testing operations, time of each change of grouting operation, pressure, rate of pumping, amount of cement for each change in water/cement ratio, and other data as deemed by him to be necessary. Furnish all necessary assistance and cooperation to this end.

3.3.10 Communications

When, for its own convenience, the Contractor has the individual elements of the plant so located that communication by normal voice between these elements is not satisfactory, the Contracting Officer may require him to
install a satisfactory mechanical means of communications, such as a telephone or other suitable device.

NOTE: This guide specification covers the requirements for constructing a soil-bentonite slurry trench at both conventional and hazardous waste projects.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1 GENERAL

NOTE: In using this guide specification, the designer should realize that the requirements for the bentonite, backfill, and construction procedure are highly dependent on the intended purpose of the slurry trench and the environment in which it is to be used.

The primary considerations for S-B slurry trenches are blowout requirements, permeability, strength, and compressibility.

The S-B backfill should be designed to prevent possible blowout or piping of the S-B backfill into...
the surrounding foundation material due to the hydraulic gradient acting across the slurry trench. Design criteria are presented in Chapter 9, Corps of Engineers (COE) EM 1110-2-1901.

The permeability for S-B slurry trenches is usually in the order of 10^-6 to 10^-8 cm/sec. The actual permeability of the slurry trench is dependent on both the filter cake, which forms on the sides of the trench and the S-B backfill. The contributions of both are dependent on the relative permeability and thickness of the two materials. For design purposes, however, it is recommended that the permeability of the slurry trench be based only on the S-B backfill. For permanent or critical temporary projects, laboratory permeability tests should be utilized in establishing the mix design.

When design requirements dictate, both shear strength and compressibility of the S-B backfill should be analyzed by conducting laboratory testing.

Since chemical contaminants commonly associated with hazardous waste sites may increase the permeability of S-B backfill, a compatibility testing program must be undertaken prior to constructing a slurry trench. If the trench is to be excavated through contaminated material, consider performing compatibility testing using two potential backfill materials; soils to be excavated from the trench and an uncontaminated borrow source. It should be noted that compatibility testing can take from 2 to 6 months to complete. For this reason, it is generally recommended that compatibility testing be completed during the design phase of the project.

A recommended compatibility testing program consists of:

1. Free swell (ASTM D5890) and filter cake permeability tests of several bentonites using contaminated site ground water and site mixing water that will be used during construction to determine acceptable bentonites for use on the project.

2. Mix design optimization tests to determine the most economical mix of soils, dry bentonite, and bentonite slurry to produce the required permeability. This consists of short-duration (48-72 hours) permeability tests varying the amount of dry bentonite added (0, 2, and 4 percent) and if necessary the amount of additional fines added (0, 10, 20 percent) using site mixing water as the permeant.

3. Long-term flexible wall permeameter testing of at least 3 S-B backfill samples: the optimum mix design with site mixing water only as the permeant (control); the optimum mix design with contaminated
site ground water as the permeant (after 1 pore volume of site mixing water permeant to ensure a good test setup); and a bentonite content 2 percent greater than the optimum determined in step 2 with contaminated site ground water as the permeant (after 1 pore volume of site mixing water permeant). It is recommended that 3 pore volumes of ground water permeant pass through the S-B backfill samples. This typically takes at least 2 months.

To approximate field conditions in the lab, it is important to obtain contaminated ground water and mixing water from the site. The site mixing water used during compatibility testing must be the water used to make the bentonite slurry during construction.

For laboratory testing, consider requiring a permeability of one-half an order of magnitude less than the required field permeability (for example, 5x10^-8 cm/sec in the lab for 1x10^-7 cm/sec in the field).

1.1 MEASUREMENT AND PAYMENT

NOTE: Delete this paragraph when work is covered by lump sum contract price.

1.1.1 Measurement

Base measurement for S-B Slurry Trench on the area in square meters or feet of completed slurry trench measured in a vertical plane through the centerline of the slurry trench, from the top of the working surface to the bottom of the excavated trench, and vertical lines at each corner of the full depth of the excavated trench. Base measurements on surveys and soundings taken at the site as directed and approved.

1.1.2 Payment

Payment for S-B Slurry Trench will be made at the contract unit price per square meter or foot. Such price will include costs incurred for the construction and completion of the slurry trench. No separate payment will be made for material, equipment, handling and cleaning the slurry, quality control testing, record keeping, and site preparation including construction of the working surface.

1.2 DEFINITIONS

NOTE: Remove items not required in the project.

The terms used in this Section are defined as follows:
1.2.1 Slurry Trench

The slurry trench is a [_____] [900] mm [3] feet minimum width trench excavated through the existing ground or prepared working surface using the slurry method of excavation and backfilled with S-B backfill material, to form a low permeability cutoff wall.

1.2.2 Slurry Method of Excavation

The slurry method of excavation consists of excavating a vertical walled trench and at the same time keeping the trench filled with a bentonite slurry mixture. The purpose of the slurry is to support the walls of the trench and prevent movement of ground water.

1.2.3 Bentonite

Bentonite is an ultrafine natural clay whose principal mineral constituent is sodium cation montmorillonite.

1.2.4 Slurry

Slurry is a colloidal mixture of bentonite and water.

1.2.5 Soil Bentonite (S-B) Backfill

S-B backfill is a homogeneous mixture of material produced by mixing soil with bentonite slurry [and additional dry bentonite], which is placed into the excavated trench to complete the soil-bentonite slurry trench.

1.2.6 Ground Water Level

The ground water level is the piezometric level of the ground water as determined from piezometers and wells.

1.2.7 Working Surface

The working surface is the top of the [stripped and/or prepared natural ground] [or] [the surface of previously compacted fill] from which the slurry trench is constructed.

1.2.8 Confining Stratum

The confining stratum is the soil stratum or rock unit to or into which the bottom of the slurry trench is excavated.

1.3 REFERENCES

**************************************************************************
NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also
use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

**************************************************************************

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

SECTION 31 56 13.13 Page 7
NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-01 Preconstruction Submittals

Preconstruction Testing Plan; G[, [_____]]

Slurry Trench Implementation Plan; G[, [_____]]

Blasting Plan; G[, [_____]]

SD-02 Shop Drawings

As-Built Profile

SD-04 Samples
1.5 OTHER SUBMITTAL REQUIREMENTS

Submit the following:

a. Plan describing the general work sequence and layout of operations. Include scale drawings, which depict slurry and S-B backfill preparation and storage areas. Describe Contractor qualifications, equipment, method of trench excavation, [blasting,] use or disposal of excavated material, bottom cleaning, slurry preparation and maintenance, S-B backfill preparation and placement, and site clean-up.

b. Plan describing quality control equipment and test procedures, sample test forms for reporting test results, and the offsite laboratory proposed for use.

c. Data on the equipment to be used in the construction of the slurry trench; equipment to be used to obtain [bedrock] [impervious stratum] samples; [equipment to be used to obtain record control samples of the completed slurry trench;] and equipment to be used in the Contractor's quality control testing.

d. A copy of the test results from the bentonite manufacturer for each lot shipped to the site and a certificate of compliance stating that the bentonite complies with applicable standards.

1.6 QUALITY ASSURANCE

The Government may perform quality assurance testing on representative samples obtained by the [Contractor] [Government] of the bentonite slurry and S-B backfill using the laboratory and equipment furnished by the Contractor. The Government testing will in no way relieve the Contractor of the responsibility of performing tests necessary to meet the Construction Quality Control (CQC) requirements. Provide the equipment and laboratory space to government personnel on demand and these services will be considered a subsidiary obligation of the soil bentonite slurry trench construction. Make all routine testing procedures available for inspection.
by the Contracting Officer at any time.

1.6.1 Qualifications

**************************************************************************

NOTE: Remove subparagraphs not required in the project.
**************************************************************************

1.6.1.1 Contractor

Successfully installed a minimum area of [_____] 100,000 square meters
1,000,000 square feet. Provide qualifications and experience of personnel
who is responsible for conducting the operations including references (name
and telephone number) of the owners of the Contractor's previous slurry
trench construction projects.

1.6.1.2 Slurry Trench Specialist

An individual who has had experience with at least [_____] [5] projects in
all aspects of slurry trench construction which includes, but is not
limited to:

a. The use, testing, and control of bentonite slurries,
b. The mixing methods required to properly mix the slurry and backfill
   materials as required,
c. Trench excavation and backfilling procedures, and
d. A thorough knowledge of construction equipment and material testing
   required for slurry trench construction.

1.6.1.3 Slurry Trench Excavation Equipment Operator

The slurry trench excavation equipment operator must have experience using
similar slurry trench excavation equipment to be used for this contract in
a minimum of [_____] [2] projects of similar or greater magnitude (depth).

1.7 DELIVERY, STORAGE, AND HANDLING

Protect materials delivered and placed in storage from the weather, dirt,
dust or other contaminants.

1.8 GEOTECHNICAL SITE CONDITIONS

1.8.1 Exploratory Borings

**************************************************************************

NOTE: In most cases, the exploratory borings along the alignment should be obtained during design. However, in some cases, it may be necessary to have the Contractor obtain exploratory borings to determine or verify the depth or characteristics of the key stratum. This should be performed well in advance of slurry trench installation to prevent delays. If additional drilling is required, it is recommended that a separate specification be prepared for that work.
Subsurface exploratory borings have been obtained by the Government to determine the character of materials to be excavated. Locations of the borings are shown on the drawings and the logs of those borings, which fall within the area of this contract, are included in [_____] for the convenience of the Contractor. The Government assumes no responsibility for interpretation or deductions made from the logs and borings. Local minor variations may exist in the subsurface materials between boring locations and, if encountered, will not be considered as being materially different within the purview of this contract [_____] . Soils classifications shown on the logs are the result of [field visual classifications] [laboratory classifications] in accordance with the Unified Soil Classifications System. [The results of all laboratory testing, including rock and soil, are available for review by the Contractor in the [_____] .] [Attention is invited to FAR 52.236-4 Physical Data in the Special Contract [Clauses] [Requirements] for availability of core borings and soil samples for inspection.]

1.8.2 Subsurface Conditions

NOTE: A general description of the conditions to be encountered during the excavation should be provided. Also, provide a description of the stratum or formation into which the slurry trench will be keyed.

[_____] .

1.8.3 Ground Water

NOTE: Provide a discussion of the ground water that could affect the slurry trench construction.

[_____] .

1.8.4 [Embankment Conditions]

NOTE: When a slurry trench is installed through an existing embankment, a description of the embankment materials to be excavated should be provided.

[_____] .

PART 2 PRODUCTS

2.1 MATERIALS

2.1.1 Bentonite

NOTE: Bentonites for use may conform to either Section 4 or Section 5 of API Spec 13A, provided the
desired permeability is obtained during pre-construction mix design and compatibility testing. Bentonites, which conform to Section 4 of API Spec 13A, have typically been treated with small amounts of polymers. Bentonites, which conform to Section 5 of API Spec 13A, have not been chemically treated. For this specification, the values shown in Table 1 for bentonite, reflect the requirements of API Spec 13A, Section 5. Values in Table 1 should be modified accordingly for Section 4 bentonites.

In the event no bentonites conforming to either Section 4 or 5 of API Spec 13A can produce the desired permeability due to contaminants in ground water, bentonites or other materials with substantial chemical alterations or additives may be used. Use of these materials will depend upon the successful completion of a compatibility testing program and the concurrence of all appropriate State and Federal regulatory agencies. These materials should be used with caution due to the general lack of long-term performance data. These materials may be proprietary products. Modify appropriate sections of this guide specification according to manufacturer's recommendations.

**************************************************************************

Provide bentonite consisting of sodium cation base montmorillonite powder that conforms to API Spec 13A, Section [4][5], and Table 1, located at the end of this section. [Chemically treated bentonite will not be allowed.] [Other chemically treated bentonites may be considered provided the required permeability values can not be obtained with bentonites conforming with Section 4 or Section 5 of API Spec 13A.] Do not use bentonite from the bentonite manufacturer prior to acceptance by the Contracting Officer. Remove bentonite not meeting specifications promptly from the site at the Contractor’s expense. Protect bentonite from moisture during transit and storage. Submit a minimum of 4.5 kg 10 pounds of the proposed bentonite at least [1] [_____] month prior to use.

2.1.2 Water

The [Contractor must] [Government will] supply [and condition] water required for mixing with bentonite to produce slurry. Provide clean, fresh water in compliance with the standards specified in Table 1. Submit water quality test results for water used for mixing the bentonite slurry to assure conformance to these standards. Submit a record of the water source and associated chemical analysis.

2.1.3 Backfill Material

**************************************************************************

NOTE: For backfill materials with a low percentage of fines (less than 20 percent), it may be necessary to add supplemental fines from an additional borrow area to achieve the desired permeability.

If offsite borrow material is selected for use as the backfill material, it should be tested to ensure
that it is uncontaminated. It may be possible to use material excavated from the trench as backfill material, even if it is slightly contaminated. If contaminated material is being considered for use, it must be verified that the material can be safely handled in the field.

The gradation requirements below should be modified to fit the chosen backfill material. In general, no particles greater than 76 mm 3 inches should be in the mix, and a minimum fines content of 20 percent is always recommended.

Obtain backfill material from [material excavated from the slurry trench] [a Government furnished borrow area] [an offsite borrow area]. Thirty days prior to utilization of any off-site borrow, identify the site and submit a minimum of 22.5 kg 50 pounds of each type of proposed borrow soil, at least [1] [_____] month prior to use of each type of material, to the Contracting Officer for QA testing. Furnish backfill that is free of [contamination] [_____] root, debris, brush, sod, organic or frozen material. Material passing the 75 micrometer No. 200 sieve must have a liquid limit greater than [30] [_____] and a plasticity index greater than [10] [_____]. Blend materials thoroughly prior to mixing with bentonite slurry and conform to the following gradation requirements:

<table>
<thead>
<tr>
<th>Screen Size or Number (U.S. Standard)</th>
<th>Percent Passing by Dry Weight</th>
</tr>
</thead>
<tbody>
<tr>
<td>[75 mm 3 inch] [_____]</td>
<td>100 [_____]</td>
</tr>
<tr>
<td>[4.76 mm No. 4] [_____]</td>
<td>40-80 [_____]</td>
</tr>
<tr>
<td>[0.42 mm No. 40] [_____]</td>
<td>25-60 [_____]</td>
</tr>
<tr>
<td>[75 micrometer No. 200] [_____]</td>
<td>20-40 [_____]</td>
</tr>
</tbody>
</table>

2.2 EQUIPMENT

Furnish all necessary plant and equipment for use on this project.

2.2.1 Trench Excavation Equipment

Provide equipment for excavating the slurry trench of any type or combination of excavating equipment capable of performing the work as specified and shown on the drawings. [Provide equipment capable of excavating the required minimum width of trench in a single pass of the excavating equipment.] The buckets utilized with such equipment may be perforated, tapered and equipped with bottom-side cutter teeth protruding no more than 150 mm 6 inches. Design the bucket to maintain the width of the trench and to minimize raveling of the trench sides during use. The equipment must be able to reach at least [_____] 1500 mm 5 feet deeper than the maximum depth shown on the drawings.

2.2.2 Slurry Mixing and Cleaning Equipment

Equip the slurry mixing plant with a high-speed/high-shear, colloidal mixer or a high-velocity/high pressure venturi jet mixer used in conjunction with
a high-speed/high-shear centrifugal pump. Equip the plant with a mechanically or hydraulically agitated sump and include pumps, valves, hoses, supply lines, tools, and other equipment and materials required to prepare the slurry and deliver it in a continuous supply from the hydration pond [or tanks] to the slurry trench. Provide mixers capable of achieving complete dispersion of bentonite and additives, and capable of continually mixing the slurry to provide and maintain a uniform blended slurry. Provide sufficient ponds [or tanks] for storage of hydrated bentonite slurry. [Slurry cleaning equipment must be available to reduce sand, sediment, or other solids as necessary to maintain the sand content or density requirements of the slurry in the trench. Slurry cleaning equipment may include but not be limited to vibratory shaker screens, centrifugal sand separators, or stilling ponds.]

2.2.3 Field Laboratory Equipment

The field laboratory must contain as a minimum the following equipment:

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Mold and rod for slump test</td>

</tbody>
</table>

2.3 BENTONITE SLURRY MIXES

2.3.1 Initial Bentonite Slurry Mixture

**************************************************************************
NOTE: For most bentonites, 4 to 6 percent by weight should produce a slurry that will meet all the specified requirements. Other mixtures may be determined to be acceptable during pre-construction tests. S-B backfill mix designs should be determined during pre-construction testing. Results from the tests should be used in Table 1.
**************************************************************************
Conform to the standards specified in Table 1.

2.3.2 Trench Bentonite Slurry Mixture

Conform to the standards specified in Table 1.

2.3.3 Additional Bentonite

If directed by the Contracting Officer, thicken the slurry to a more viscous condition than the limits specified above. Use additional bentonite, as directed.

2.3.4 Additives

Do not mix peptizing agents and bulking agents with the slurry. Approved thinners or dispersants and flocculants of the types used in the control of oil field drilling muds, may be used to control standard properties of the slurry such as apparent viscosity, pH and filtration characteristics.

2.3.5 S-B Backfill

Mix the S-B backfill, consisting of [backfill material and bentonite slurry] [backfill material, bentonite slurry, and a minimum of [2] [_____] percent dry bentonite] thoroughly and conform to the standards specified in Table 1 just prior to placement in the trench.

PART 3 EXECUTION

3.1 GENERAL REQUIREMENTS

Construct the slurry trench to the elevations, lines, grades, and cross-sections shown and in accordance with these specifications, unless otherwise directed. The Government may modify the dimensions and quantities of the work as determined necessary. Submit a Slurry Trench Implementation Plan for approval, a minimum of [_____] weeks prior to the start of construction.

3.2 WORKING SURFACE

*****************************************************************************

NOTE: The maximum slurry trench surface slope along the slurry trench alignment during construction should be 1 percent. For sites with grades greater than 1 percent, the working surface should be designed to achieve the 1 percent slope. If contaminated, it is common practice to remove the top 300 mm 12 inches of the working surface after completion of the slurry trench. Most excavation equipment requires 6 meters 20 feet of clearance to swing around; therefore, a minimum working surface width of 12 meters 40 feet is recommended. Some equipment may require wider work platforms in order to negotiate trench corners. At sites where S-B backfill will be mixed beside the trench, instead of at a central mixing area, a wider working surface may be required. The slurry trench alignment is not required to be in the centerline of the working surface.

*****************************************************************************
Accomplish slurry trench construction from the working surface, as shown on the drawings. If the Contractor's operations require a wider working surface, submit the reason for the change. If approved, a wider working surface may be constructed at no additional cost to the Government. Working surface material and compaction requirements are described in Section [______]. In the event that the static ground water table is encountered at a depth of [______] 1 m 3.0 foot or less below the designated working surface, at the direction of the Contracting Officer, raise the working surface to a height of [______] [1] m [3] feet above the measured static ground water level with approved fill material. Utilize the constructed working surface as a basis for measurement for payment.

3.3 SLURRY TRENCH EXCAVATION

**************************************************************************
NOTE: For shallow (less than 15 m 50 feet) slurry walls, most excavation equipment can round trench corners with a 30 m 100 foot turning radius. For trenches deeper than 15 m 50 feet, consult with Contractors about the required turning radius.
**************************************************************************

Begin excavation from the working surface and provide a vertical (within 2 percent) continuous [______] 900 mm 3 foot minimum width trench to the required depth along the centerline of the excavation. [Key the slurry trench [______] 600 mm 2 feet into the [______] stratum.] The Contracting Officer may direct the Contractor to modify the trench depth based on examination of bucket cuttings or drive samples. The toe of the slope of the trench excavation must not precede the toe of the S-B backfill slope by less than [______] 9 meters 30 feet or more than [______] 30 meters 100 feet. At the intersection of 2 straight line segments, extend the trench excavation a minimum of [______] 1500 mm 5 feet beyond the outside of the intersection at all depths. If trench excavation overlaps into previously completed slurry trench, extend the excavation a minimum of [______] 3 meters 10 feet into the previously placed S-B backfill at all depths. Refill any removed section of completed slurry trench with S-B backfill at no additional expense to the Government.

3.3.1 Confining Stratum Excavation

**************************************************************************
NOTE: If the confining stratum is a competent low permeability bedrock, a very small penetration into the bedrock may be satisfactory. High costs may result by requiring a 600 mm 2 foot key into competent bedrock. Remove this paragraph if not required in the project.
**************************************************************************

Excavate the confining stratum the full trench width to the depths shown [or to the depth of refusal] [or as otherwise directed]. [Remove any [sandstone] [______] lenses encountered at the minimum excavation depth for the full width of the trench and into the underlying confining stratum.] Then sample the confining stratum in accordance with paragraph SAMPLES OF CONFINING STRATUM. Termination of excavation will be approved by the Contracting Officer.
3.3.2 BLASTING PLAN

NOTE: Blasting, if necessary, may cause unanticipated adverse effects in the subsurface. The designer should carefully evaluate the need for blasting to remove or loosen subsurface materials. Other methods such as chiseling or modification of slurry trench alignment or depths should be considered prior to implementation of any blasting. Remove this paragraph if not required in the project.

Any blasting must be approved. Conduct blasting in accordance with an approved blasting plan. Include hole spacing and depths, loading, delay sequence, type of explosives, safety program, and any other pertinent information that will be necessary for the Contracting Officer's evaluation. [Store] [Do not store] explosive materials on the site. [Furnish on site storage at [_____.]] Submit a drawing showing the top and bottom elevations of the [sandstone] [_____]. Submit a blasting plan, as specified, for approval.

3.4 SLURRY PLACEMENT AND TESTING

NOTE: Sand content of the in-trench slurry is highly dependent upon the soils through which the trench is excavated. In many cases, typical values for sand content can be as high as 30 percent without impacting the quality of the installation. It should be noted that higher sand contents also lead to a higher density slurry. Adjustments should be made in Table 1 regarding slurry density and sand content limits according to site conditions. The main concern is to ensure that sand is not dropping out of the in trench slurry to the bottom of the trench in amounts so as to affect performance of the slurry trench.

3.4.1 Slurry Placement

Introduce slurry into the trench at the time excavation begins. Maintain the level of the slurry in open trenches a minimum of 900 mm 3 feet above ground water level and no more than 600 mm 2 feet below the top of the working surface until the placement of S-B backfill is complete. [If the density or sand content of the slurry in the trench does not conform to the standards specified in Table 1, remove the excess solids from the slurry using approved methods or replace the slurry with fresh slurry.] Do not dilute slurry by surface water. Conditioning of the slurry may require recirculation through a shaker screen or the addition of approved additives. Provide sufficient personnel, equipment, slurry storage areas, and prepared slurry materials ready to raise the slurry level at any time in the excavated trench, weekends and holidays included.

3.4.2 Slurry Testing

Sample the bentonite slurry in the trench a minimum of 2 times each [_____] [8] hour shift (near the beginning and end of each shift), at two depths;
approximately 600 mm 2 feet below the slurry surface and approximately 600 mm 2 feet above the bottom of the trench. Take samples within 1500 mm 5 feet of the toe of the S-B backfill slope. Obtain additional samples at the request of the Contracting Officer.

3.5 EXCAVATED MATERIAL

[Use] [Do not use] materials excavated from the trench as backfill. [Stockpile material to be used as backfill for subsequent processing in approved areas.] [Place excavated trench material not used as backfill [in the waste disposal area] [as directed].]

3.6 STABILITY

**************************************************************************
NOTE: A stability analysis should be performed during design to determine required minimum slurry densities or levels, and to determine if any restrictions will be required regarding stockpile placement or other loading situations. Any site specific restrictions should be described below.
**************************************************************************

The Contractor is responsible for ensuring and maintaining the stability of the excavated trench at all times, for its full length and depth, and for maintaining slurry densities and levels within specified limits. Control surcharges from all excavation and backfilling equipment, waste, berm construction, backfill stockpiles, and any other loading situations that may affect trench stability. It is the Contractor's sole responsibility to ensure that the mixing of S-B backfill and any stockpiles do not affect the open trench stability. In the event of failure of the trench walls prior to completion of backfilling, re-excavate the trench, remove all material displaced into the trench, and take corrective action to prevent further deterioration, at the Contractor's expense.

3.7 TRENCH CLEANING

**************************************************************************
NOTE: The initial cleaning of the trench bottom can be accomplished with an excavator bucket. This method of trench cleaning will generally be sufficient for final cleaning of most projects. It is generally recommended to limit the distance between the excavated face and the toe of the S-B backfill, as required in Paragraph SLURRY TRENCH EXCAVATION, in order to assure trench stability. In some cases, the air-lift pump method may be the only way to clean certain reaches of the trench. However, the air-lift pump method can slow production, is somewhat difficult to maneuver in the trench, and may not clean the trench bottom effectively in many cases.

Cleaning of the S-B backfill face can be difficult since the materials are very soft and may require the excavator to track over portions of the trench that are not yet backfilled. This procedure should only be specified when required to meet project needs.
At a minimum, unless otherwise approved, clean the trench bottom at the start of each [_____] [day]. [If S-B backfill placement operations have ceased for longer than [24] [_____] hours, clean the face of the S-B backfill slope prior to the placement of additional S-B backfill.] Probe the trench bottom for any deposits or sloughed materials prior to cleaning. Clean the trench bottom by using an [excavator bucket,] [air lift pump] or other approved equipment to ensure removal of sand, gravel, sediment, and other material left in the trench during excavation or which has settled out of the slurry. Do not remove material from the walls of the trench using cleaning equipment. The Contracting Officer may require more frequent cleaning. [After the trench bottom has been cleaned, sample the trench bottom with a [drive tube] [split tube] [_____] sampler approved by the Contracting Officer. Rock surfaces that cannot be penetrated by a [drive tube] [split spoon] sampler are not required to be sampled. After examining the samples, the Contracting Officer will either approve the excavation at the points checked or require additional cleaning. If additional cleaning is required, then furnish additional samples as specified above.]

3.8 S-B BACKFILL MIXING AND PLACEMENT

3.8.1 Mixing

**NOTE: It may be preferable to mix the S-B backfill in a separate mixing area rather than along the side of the trench, particularly in contaminated areas, or where off-site borrow is used for backfill materials. Other mixing methods may include the utilization of a batch plant or pugmill operation to blend materials. Although more expensive, these procedures may minimize operations in a contaminated area.**

Thoroughly mix S-B backfill via disk ing, harrowing, bulldoz ing, blading, or other approved methods into a homogeneous mass, free from large lumps or clods of soil or pockets of fines, sand, or gravel. Occasional lumps of up to [_____] [75] mm [3] inches in their largest dimension will be permitted. Coat all particles with slurry. The S-B backfill may be sluiced with slurry during the mixing operations. Sluicing with water is not permitted. Mix the S-B backfill [in a separate mixing location as shown on the drawings] [along the side of the trench]. [When mixing the S-B backfill along the side of the trench, do not operate heavy equipment such as bulldozers in a back and forth fashion, paralleling the open trench, closer than 5 meters 15 feet from the lip of the trench. Excess slurry may be allowed to flow back into the trench].

3.8.2 Placement

Place initial S-B backfill by one of the following methods: (1) Placement by lowering S-B slurry to the bottom of the trench with crane and clamshell bucket, or tremie methods until the surface of the S-B backfill rises above the surface of the slurry trench at the end of the trench; (2) Construct a lead-in trench [1H:1V] [_____] or flatter at a point outside of the limits of work to allow a S-B backfill face to form prior to reaching the full depth of the required slurry trench. No payments will be made for the
portions of trenches which lie outside of the limits of work. Proceed with placement operations in such a manner that the slope of the initially placed S-B backfill is maintained. Free dropping of S-B backfill through the slurry is not permitted. Place the S-B backfill so that it will slide down the forward face of the S-B backfill slope. Place the S-B backfill in the excavated trench so that no pockets of slurry are trapped and that a constant slope is maintained. Make placement continuous from the beginning of the trench in the direction of the excavation to the end of the trench.

3.8.3 Mixing and Placing During Cold Weather

Do not mix or place the S-B backfill when the air temperature is below -7 degrees C 20 degrees F. Do not place frozen S-B backfill in the trench and do not use backfill material containing frozen lumps to mix S-B backfill.

3.8.4 Testing

When required, take additional samples for permeability testing at [____] intervals for the [____] [full depth] of the completed slurry trench using 75 mm 3 inch thin wall (Shelby) tubes. [If test results do not meet the requirements listed in Table 1, take corrective action as determined by the Contracting Officer.]

3.9 SOUNDINGS

Take excavation and S-B backfill soundings every [____] 6 meters 20 feet along the trench centerline using a weighted tape, cable, or other approved device. Submit a record of soundings and measurements taken during construction of the slurry trench. Measure soundings to the nearest 30 mm 0.1 ft. Measure the following:

3.9.1 Elevation of Top of Confining Stratum

Determine the top of the confining stratum based on examination of samples taken as described under paragraph SAMPLES OF CONFINING STRATUM. This elevation is subject to approval.

3.9.2 Elevation of Trench Bottom Prior to Backfilling

Determine the elevation of the trench bottom after the trench has been cleaned and approved as described under paragraph Trench Cleaning. Do not precede the toe of the S-B backfill slope more than [____] 15 meters 50 feet. This elevation is subject to approval by the Contracting Officer.

3.9.3 Profile of S-B Backfill Slope and Trench Bottom

Sound the S-B backfill slope and trench bottom at the beginning and end of each shift, and at additional times as directed, at intervals of [____] meters feet.

3.10 AS-BUILT PROFILE

Continuously maintain an as-built profile of the trench bottom and S-B backfill slopes, including descriptions of materials encountered in the trench bottom. Indicate extent of excavation and the S-B backfill profile at the end of each work day [and after each S-B backfill batch is placed in the trench as determined from soundings]. [Indicate the S-B backfill batch numbers on the profile with the limits of each batch of material delineated as placed.] Submit a scale drawing providing a log of the subsurface...
materials excavated from the trench, and a profile of the completed slurry trench.  [Delineate as placed the limits of each batch of S-B backfill.]

3.11 TREATMENT OF TOP OF SLURRY TRENCH

**************************************************************************
NOTE: For heavy equipment crossings, it is recommended the upper portion of the S-B backfill be excavated and a clay plug be placed under the compacted trench cover. Additional support may be necessary to support the anticipated loads.
**************************************************************************

Prior to placement of the compacted trench cover, place a temporary [non-compacted soil] [plastic sheeting] cover over the trench to prevent desiccation. Place the temporary cover material within [2] [_____] days after S-B backfill placement is completed over each 30 meter 100 foot reach. If any depression develops within the completed slurry trench area, repair it by placing and compacting additional trench cover soil. After a minimum [two] [_____] weeks, remove the temporary trench cover and replace by a final compacted trench cover. Place a final compacted trench cover [_____] mm feet wide and [_____] mm ft deep [as specified in Section [_____]] [to a dry density of [_____] [90] percent of maximum density at optimum moisture to plus 3 percent in accordance with ASTM D698]. Only drive heavy construction equipment and machinery over the slurry trench at approved heavy equipment crossing points.

3.12 QUALITY CONTROL TESTING

Provide Quality Control Inspectors as necessary for bentonite slurry preparation and maintenance, trench excavation, and S-B backfill preparation and placement. Submit all test results.

3.12.1 Bentonite Tests

Perform a minimum of 1 test for each specified requirement for each truck or rail car shipment delivered to the site.

3.12.2 Water Tests

**************************************************************************
NOTE: Acceptable slurries can generally be made from most water sources; however, any suspect water should be tested during pre-construction tests.
Water with high hardness
**************************************************************************

Perform a minimum of [_____] [1] test[s] for each specified requirement for each water source used. Perform testing as specified in Table 1.

3.12.3 Backfill Material Tests

Perform one set of backfill material tests, as specified in Table 1, for every [_____] 500 cubic meters yards used.

3.12.4 Slurry Properties

**************************************************************************
NOTE: It is generally recommended that after high

SECTION 31 56 13.13  Page 21
shear mixing, the slurry be allowed to hydrate for 8 hours before use in the trench. This process assures that the bentonite is fully hydrated and is uniform throughout. Shorter hydration times may be allowed if it can be shown that the prepared slurry meets or exceeds project requirements.

[Allow slurry to hydrate a minimum of [8] [_____] hours prior to use.] Test the initial bentonite slurry prior to placing in the trench and a minimum of 2 times each [_____] [8] hour shift per mixing plant. Submit a record of bentonite slurry mix quantities, proportions of additives utilized, and adjustments for each batch.

3.12.5 S-B Backfill Tests

NOTE: The confining pressure used to perform permeability testing should be representative of site conditions. To simulate site conditions, the confining pressure specified should be representative of the upper quarter to one-half of the wall depth.

Shelby tube, split spoon, or other sampling devices may be pushed into the completed slurry trench to obtain samples for quality control testing; however, it can be difficult to obtain quality samples of many S-B backfills, especially if there are coarse materials in the S-B backfill. As a result, samples of S-B backfill obtained just prior to placement in the trench are used for QA/QC, and samples of the S-B backfill from the completed wall, if taken, may be used for QA or for information only. The designer should determine what samples are necessary to meet project requirements. It should be noted that permeability tests may take several days before results are known.

Perform sampling and testing, in accordance with the approved Preconstruction Testing Plan, just prior to placing S-B backfill in the trench as shown in Table 1. [Calculate the density of the S-B backfill using a 101.6 mm 4 inch cylindrical mold as described in Paragraph 6 of ASTM D698. Place S-B backfill in the mold and rod 10 times. Then add additional S-B backfill to fill the mold. Use the weight and volume of the molded S-B backfill to determine the density.] [Determine the density of the S-B backfill using a mud balance.] Determine density at a rate of 1 test for every [_____] [1000] cubic meters yards. Take a sample of S-B backfill for permeability testing just prior to placement in the trench for every [1000] [_____] cubic meters yards. Submit a Plan providing a list of test equipment, procedures, and materials to be used to [verify] [develop] the mix design for the S-B backfill and an S-B Backfill Test Report containing the results of the tests performed, a report summarizing the procedures and results of the Pre-construction S-B backfill mix tests. Include a description of mix proportions, gradations, slumps, densities, permeabilities, and moisture contents of [_____] 3 samples of the final S-B backfill mix using the bentonite and backfill materials proposed for use. Submit a minimum of 22.5 kg 50 pounds of each type of proposed borrow soil
at least [1] [_____] month prior to use.

[3.12.6  Samples of Confining Stratum]

**************************************************************************
NOTE: This paragraph is to be used if the slurry trench is to be keyed into a confining stratum. Samples of the confining stratum can be based on examination of samples taken from bucket cuttings or drive tube samplers. In many cases, examination of bucket cuttings alone will be sufficient to determine when the confining stratum has been reached. If required, samples can be obtained with drive tube samples. Drive tubes can be pushed with the excavator bucket or a drill rig. Remove this paragraph if not needed in the project.
**************************************************************************

Take samples of the confining stratum at [_____] meter foot horizontal intervals and at additional intervals or depths as directed. Obtain samples from [either] [excavator bucket cuttings] [drive tube samples]. [The sampler must be a [_____] mm inch I.D., or larger, [drive tube sampler] with a minimum length of [_____] m feet. Obtain samples by advancing the sampler a minimum of [_____] mm inches into the confining stratum. The samples must have a minimum length [recover] of [_____] mm inches.] After examining these samples, the Contracting Officer will either approve the termination of excavation at the sample points or require additional excavation. If additional excavation is required, then furnish additional samples as specified above. Properly identify and label all samples, place in sealed plastic containers and store in a location designated by the Contracting Officer.

}3.13  CLEAN-UP

Remove excavation spoil, unused S-B backfill, and excess slurry following completion of S-B backfill placement. Dispose of these materials [in the waste disposal area] [at the direction of the Contracting Officer] [_____]

NOTE: This guide specification covers the requirements for procurement, installation, and testing of cast-in-place concrete piles, steel casing.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

NOTE: Requirements for materials and procedures for special or unusual design should be added as necessary to fit specific projects. It is expected that cast-in-place concrete will be used elsewhere on the project and therefore Section 03 30 00 CAST-IN-PLACE CONCRETE will be a part of the specification.

NOTE: Show the following information on the project drawings:

1. Locations, dimensions, shape, length, and design strength of piles.
2. Locations and lengths of test piles and load tests, if either is required.

3. Soil data, where required.

PART 1   GENERAL

1.1 REFERENCES

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

AMERICAN WELDING SOCIETY (AWS)

AWS D1.1/D1.1M (2020; Errata 1 2021) Structural Welding Code - Steel

ASTM INTERNATIONAL (ASTM)

1.2 REQUIREMENTS

NOTE: Select the applicable paragraph(s) from the following:

[1.2.1 Pile Lengths and Quantity]

NOTE: Use this option for lump-sum contracts. This
method should be used in all but special cases. Fill in Table 1 as required selecting columns applicable to project. Generally, pile capacity, location, and tip elevation are shown on the plans.

Base bids upon the number, size, capacity, and length of piles as indicated.

<table>
<thead>
<tr>
<th>Location</th>
<th>Number</th>
<th>Size</th>
<th>[Capacity]</th>
<th>Length</th>
</tr>
</thead>
</table>

When the total number of piles or the number of each length vary from that specified as the basis for bidding, an adjustment in the contract price or time for completion will be made in accordance with Contract Clause, "changes." Adjustments in the contract will not be made for pile splices; cutting off piles; for a portion of a pile remaining above the cut-off elevation; or for broken, damaged, or rejected piles.

1.2.2 Measurement and Payment

See SF 1442, "Solicitation, Offer and Award" and "Schedule of Bid Items."

NOTE: For NAVFAC LANT projects, use the following.

Payment will be for the total length of completed and accepted piling, measuring from tip elevation to cutoff elevation. Payment will be by the contract unit price for furnishing labor, materials, tools, equipment, and incidentals, and for doing the work involved in furnishing and driving piling. Driving piling includes furnishing and driving piling including test piles, jetting or drilling, pile splices, excavation and backfill around piling, pile cutoff, redriving, and replacement of broken, or rejected piles. Payment will be separate contract unit price for furnishing labor, materials, tools, equipment, and incidentals for doing the work involved in performing load tests on piles.

1.3 SUBMITTALS

NOTE: Review Submittal Description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G". Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the
Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-02 Shop Drawings

Piles and pile cap

Show placement of steel. Show casing details, closures, and splices.[ Show placement of and calculations for reinforcement.]

SD-04 Samples

Test Piles

SD-06 Test Reports

Test Pile Data

[ Load Tests ]

NOTE: Delete sentence in brackets when test piles are not driven.

For load tests, submit test data and results.[ Submit test pile data from steel cased cast-in-place concrete test piles, from which the Government will determine and list the "calculated" tip elevations and the driving resistances for all piles. Use this list as the basis for ordering piles. Do not order piles until list is provided by the Government.]

SD-07 Certificates

NOTE: Mill certificates are generally required only
when casings are used as structural members. Use bracketed sentence only when steel shell casing is used as a structural member.

Pipe Piles

Concrete Testing results

[Steel shell] Casings

Show name and location of steel mill and fabricating plant for pipe piles.

Data on Pile Driving Equipment

Include in data for driving equipment, make, model, and type of pile hammer; manufacturer's specification sheet on pile hammer; and detail drawings of driving helmets, hammer cushion or capblock with records of successful use.

SD-11 Closeout Submittals

Pile Driving Records

1.4 QUALITY ASSURANCE

1.4.1 Welding

Shop and field welding, qualification of welders, and inspection of welds must be in accordance with AWS D1.1/D1.1M.

1.5 EQUIPMENT

1.5.1 Pile Hammers

NOTE: Insert driving energy of hammer. Select hammer based on results of wave equation analysis such that hammer is compatible with pile type and capacity and hammer/cushion/pile system are capable of obtaining required capacity.

Furnish a hammer having a capacity at least equal to the hammer manufacturer's recommendation for the total weight of pile and character of subsurface material to be encountered. Obtain required driving energy of hammer, except for diesel hammers, by use of a heavy ram and a short stroke with low impact velocity.[ For driving use the same type pile hammer, operated at same rate and in same manner, as that used for driving testing piles.]

1.5.2 Driving Helmets (Caps) and Cushion (Capblocks)

Use a hammer cushion or capblock between the helmet, driving cap or driving head and hammer ram. Driving cap and hammer cushion combination must be capable of protecting head of pile, minimizing energy absorption and dissipation, and transmitting hammer energy uniformly to top of pile. When driving helmet or cap is used, it must fit loosely around top of pile so
that the pile may rotate slightly without binding within helmet or cap. [During test pile period demonstrate to satisfaction of the Contracting Officer that equipment to be used on the project performs the above function.] Hammer cushion or capblock may be a solid hardwood block at least 150 mm 6 inches thick with grain parallel to pile axis and enclosed in a close-fitting steel housing or may consist of aluminum and micarta (or equal) discs stacked alternately in a steel housing. Use steel plates at the top and bottom of the capblock assembly. Under no circumstances will use of wood blocks, wood chips, rope or other material permitting excessive loss of hammer energy be permitted.

PART 2 PRODUCTS

2.1 PILING

2.1.1 Casings

**************************************************************************

NOTE: There are generally three types of casing or pipe used. Open-end and closed-end structural casings (usually steel pipe) and a closed-end non-structural casing (usually light gage shells). Non-structural casings must be driven with a mandrel. Specify the minimum thickness for any structural casing. Thickness of non-structural casings (light gage shells) is the responsibility of the Contractor as the shell is simply a form for the concrete. Ensure minimum nominal diameter at tip and two-third points above tip are indicated on drawings. In general, use closed-end casings except in the following conditions where open-end structural casings should be considered:

1. It is important to avoid soil displacement as in piles driven adjacent to existing structures.

2. Soil condition indicate a dense or clayey soil, or extremely coarse granular soil is present, such as gravel.

**************************************************************************

Provide a circular cross section throughout casing length whether or not modified by helical corrugations or flutings. Leave casing permanently in place. Provide casing with closed tips[, except for steel pipe casings conforming to ASTM A252 that may be open-end driven]. Provide watertight joint and tip connections.[ Provide non-mandrel driven casings of steel with a wall thickness of [___] mm inches.] Provide any one of the following types or combination of types of casings[, but provide only one type or combination of casing throughout the project].

2.1.1.1 Uniform Taper

Increase diameter from tip to cut-off at a uniform rate. Provide minimum nominal diameter at tip and two-third points above tip as indicated.

2.1.1.2 Step-Taper

Increase section increments in diameter uniformly. Provide minimum nominal diameter at tip and two-third points above tip as indicated.
2.1.1.3 Constant Section

Provide constant diameter from tip to cut-off. Steel pipe piles, conforming to ASTM A252, Grade 2, may be used in lieu of casings of constant-diameter section. Provide minimum nominal diameter as indicated.

2.1.1.4 Combination Type

Combination type cast-in-place concrete piles, steel casing, may be any of the following combinations.

a. Steel pipe lower section with metal casing taper or constant-diameter upper section.

b. Constant-diameter or tapered lower section with tapered upper section.

c. Tapered lower section with constant-diameter upper section.

2.1.2 Piling

Provide steel cased cast-in-place concrete piles.

2.1.3 Reinforcement

**************************************************************************

NOTE: Ensure that reinforcing steel size is always indicated. Indicate length if less than full pile length.

**************************************************************************

Conform to the requirements of Section 03 30 00 CAST-IN-PLACE CONCRETE.

2.1.4 Concrete

**************************************************************************

NOTE: Normal usage would reference all concrete work to Section 03 30 00 CAST-IN-PLACE CONCRETE. If a mix design for this piling section is not or will not be specified in one of these sections, add the optional sentence to provide the required mix design. Insert the ultimate compressive strength required by the design. Fill in blank for slump if different values are required by mix design or pile diameter.

**************************************************************************

Conform to the requirements of Section 03 30 00 CAST-IN-PLACE CONCRETE. Provide concrete with a minimum compressive strength of [_____] MPa psi at 28 days, a slump of [from 100 to 150 mm] [4 to 6 inches] [____], and a maximum aggregate size of 19 mm 3/4 inch].

PART 3 EXECUTION

3.1 DRIVING

3.1.1 Driving Casing

**************************************************************************
NOTE: Delete items in brackets when test piles or load tests are not used.

Drive casing to or below the "calculated" tip elevation to reach a driving resistance in accordance with the schedule which the Government will prepare from the test-pile driving data. When a pile fails to reach the "calculated" tip elevation, or when a pile reaches the "calculated" tip elevation without reaching the required driving resistance, notify the Government and perform corrective measures as directed by the Contracting Officer.

3.1.2 Tolerance in Driving

NOTE: Pile butt tolerance may be increased if the design allows. Location within 100 mm 4 inches of indicated position is a strict tolerance.

Drive casing with a variation of not more than 21 mm per meter 0.25 inch per foot of pile length from the required axial alignment. Locate butts within [100] [_____] mm [4] [_____] inches of position indicated. Do not force casings into position. Check casings for heave after all piles are driven in a cluster within a 4.50 meters 15 foot radius. Redrive to required tip elevation or penetration resistance those casings found to have heaved. Maintain center of gravity of each group of footing piles with templates or other approved means. Where casings are damaged, mislocated, or driven out of alignment, replace or drive additional casing as directed.

3.1.3 Jetting or Predrilling of Casings

NOTE: Drilling may be used, providing the drill diameter is at least 50 mm 2 inches in diameter smaller than the pile, and the Contractor can demonstrate a procedure that will not detract from the carrying capacity of the pile. Jetting or predrilling should generally not be permitted in the following conditions:

1. For piles dependent on side friction in fine-grained, low-permeability soils (high clay or silt content) where considerable time is required for soil to reconsolidate around the piles;

2. For piles subject to uplift;

3. For piles adjacent to existing structures;

4. For piles in closely spaced clusters unless the load capacity is confirmed by test and unless all jetting is done before final driving of any pile in the cluster.

Jetting or predrilling of pile casing will be permitted. Discontinue jetting or predrilling approximately 1.5 meters 5 feet above
the bearing stratum[ calculated][ pile tip elevation]. Drive casing[ the final 1.5 meters 5 feet of penetration][ to calculated pile tip elevation]. Before starting[ final] driving, firmly seat casing in place by application of a number of reduced energy hammer blows.

3.2 SPLICING AND CUTTING

3.2.1 Splicing of Load Bearing Casings

**************************************************************************

NOTE: Restrict number of splices where design indicates splicing will cause structural weakness. In general uplift piles using a structural casing should have as few splices as possible.

**************************************************************************

Splices may be used when approved by the Contracting Officer. Do not use more than two splices per full length of casing. Splices must be able to transmit vertical and lateral forces, and in addition, develop 100 percent of the flexural capacity of the ordinary pile casing cross section. Make lateral joints with a full penetration groove weld in a butt joint in accordance with AWS D1.1/D1.1M or as approved by the Contracting Officer.

3.2.2 Cut-Off

Cut-off casings by oxyfuel cutting, sawing or other means approved by the Contracting Officer, to within 25 mm one inch of the designated cut-off elevation.

3.3 CONCRETING

Cast-in-place concrete is included in Section 03 30 00 CAST-IN-PLACE CONCRETE.

3.3.1 Preparation

**************************************************************************

NOTE: Insert the radius distance 3 to 6 meters 10 to 20 feet. Where open end casings are required, do not place concrete until all soil, water, and foreign material is removed.

**************************************************************************

Do not place concrete in a pile casing until all other casings within a radius of [_____] meters feet or within heave range have been driven and inspected. Clean inside of casing by removing soil and other foreign material. Remove free water until the maximum depth of water in the casing is 100 mm 4 inches. Inspect each casing after installation and before placing[ reinforcement and] concrete. Verify the integrity of the casing throughout its length. Verify the absence of distortion and that any reduction of area does not exceed 10 percent.

3.3.2 Reinforcement

Reinforce unsupported sections of piles, uplift or tension piles[ throughout their entire length][ as indicated], piles exposed to high bending stresses not resisted by batter piles, and between top of pile and pile cap or slab. Assemble and place reinforcement in casing as a preassembled unit. Secure reinforcement prior to placement of concrete.
3.3.3 Concrete

Deposit concrete in casing in a continuous operation by means of a funnel or hopper.

3.4 FIELD QUALITY CONTROL

3.4.1 Test Piles

**************************************************************************

NOTE: Indicate location of test piles on plans or insert the numbers of appropriate soil boring test holes.

**************************************************************************

**************************************************************************

NOTE: Drilling may be used, providing the drill diameter is at least \(50 \text{ mm} \) or 2 inches in diameter smaller than the pile, and the Contractor can demonstrate a procedure that will not detract from the carrying capacity of the pile. Jetting or predrilling should generally not be permitted in the following conditions:

1. For piles dependent on side friction in fine-grained, low-permeability soils (high clay or silt content) where considerable time is required for soil to reconsolidate around the piles;

2. For piles subject to uplift;

3. For piles adjacent to existing structures;

4. For piles in closely spaced clusters unless the load capacity is confirmed by test and unless all jetting is done before final driving of any pile in the cluster.

**************************************************************************

Use test piles of the type, and drive in the manner specified for all piling elsewhere in this section. The Government will use test pile data to determine the "calculated" pile tip elevation and required driving resistance. Drive test piles[ at the locations indicated][ in the vicinity of soil boring test holes Nos. [____], [____], and [____]]. Drive test piles to[ indicated tip elevation][ indicated bidding lengths]. Drive piles driven one day an additional \(150 \text{ mm} \) or 6 inches using full rated driving energy hammer on the next work day, unless refusal is encountered. Record an increase or decrease in driving resistance. When there is a decrease in driving resistance, a load test, at the expense of the Government, may be required by the Contracting Officer. Use test piles, when located properly and offering adequate driving resistance in the finished work.[ Jetting is permitted when test piles clearly establish the validity of its use, as directed by the Contracting Officer.]

[3.4.2 Load Tests

**************************************************************************

NOTE: If pile load tests are required, specify

SECTION 31 62 13.13 Page 12
number of piles. Select method of load test. Permit methods using anchor piles, see ASTM D1143, only if approved by EFD Code 411, Geotechnical Branch or in EFD’s with no Code 411, EFD Code 402, Structural Branch or EFD Code 405, Civil Branch. Insert figures (tons) corresponding to 200 percent of the design load. Select the appropriate acceptance criterion. The first method (offset) is generally recommended for normal size piles. The second method (slope) and the third method (net-settlement) can be combined into one criterion.

Perform load tests on [_____] piles in accordance with ASTM D1143/D1143M as modified herein. [The use of anchor piles is not permitted.] Provide apparatus for applying the vertical loads as required by the method, either for load supported directly by the pile or load from weighted box or platform [or reaction frame attached to sufficient uplift piles to take safely the required load] applied to the pile by hydraulic jack. Increase the load in increments until rapid progressive settlement takes place or until a total load of [_____] metric tons tons has been applied. Consider the load test satisfactory when after one hour at full test load the gross settlement of the pile butt is not greater than the gross elastic pile compression plus 4 mm 0.15 inches plus one percent of the pile tip diameter or width in millimeters inches.[ The slope of the gross load-settlement curve under the full test load does not exceed 1.4 mm per metric ton 0.05 inches per ton.][ The net settlement after removal of test loads does not exceed 19 mm 3/4 inches. ] Make load tests at locations shown on driven test piles. Additional load tests, at the expense of the Government, may be required by the Contracting Officer.[ Loading, testing, and recording and analysis of data must be under the direct supervision of a registered professional engineer provided and paid for by the Contractor.]

3.4.3 Concrete Testing

NOTE: The following table is recommended for use in determining the number of test cylinders required in relation to the size of each lot of piles to be tested.

<table>
<thead>
<tr>
<th>Pile Lot</th>
<th>Number of Test Cylinders</th>
</tr>
</thead>
<tbody>
<tr>
<td>25</td>
<td>2</td>
</tr>
<tr>
<td>100</td>
<td>48</td>
</tr>
<tr>
<td>1,000</td>
<td>20*</td>
</tr>
<tr>
<td>5,000</td>
<td>50*</td>
</tr>
<tr>
<td>1,000</td>
<td>100*</td>
</tr>
</tbody>
</table>

* Samples taken from random batches of concrete.
Sample and test concrete in accordance with Section 03 30 00 CAST-IN-PLACE CONCRETE. Take specimens for every [_____] piles with at least 4 specimens for any one day's operation. Take specimens from a batch chosen at random.

3.4.4 Pile Records

NOTE: Omit reference to load test when not required in project.

For each pile, keep a record of the number of blows required for each meter foot of penetration and number of blows for the last 150 mm 6 inches of penetration or fraction thereof for test piles, penetration in blows per meter foot for job piles [as required for the "calculated" driving resistance]. Include in record the beginning and ending times of each operation during driving of each pile, type and size of hammer used, rate of operation, stroke or equivalent stroke for diesel hammers, type of driving helmet, and type and dimensions of hammer cushion (capblock) and pile cushion used. Record retap data and any unusual occurrence during pile driving. Notify Contracting Officer 10 days prior to driving of [test] piles[ and load test].

NOTE: This guide specification covers the requirements for precast, prestressed piles.

Adhere to **UFC 1-300-02** Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a **Criteria Change Request (CCR)**.

NOTE: The extent and location of the work to be accomplished should be indicated on the project drawings or included in the project specification.

NOTE: Show the following information on the drawings:

1. Locations and design loads of piles. If both tension and compression piles are contained in
design, identify by type.

2. Size, shape, and length of piles.

3. Locations, sizes, and number of prestressing steel strands. Unit stresses for prestressing strands.

4. Details of reinforcement.

5. Details of splices, if required.

6. Locations of test piles, if required.

7. Soil data, where required.

8. Identify piles as vertical or battered.

PART 1 GENERAL

NOTE: Structural engineer must confirm the structural capacity of piles and provide specific bending moments, lateral loads and other design requirements for pile design.

1.1 DESCRIPTION

Design, furnish, install and test precast prestressed concrete piles at the locations indicated on the drawings and specified herein. [Assume test pile[s] will be directed to be placed in [a] location[s] that can be incorporated into the work.] [Test piles that meet performance requirements can be incorporated into the permanent work.]

1.2 REFERENCES

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.
The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

[1.3] SUBSURFACE DATA

Subsurface soil data logs are [indicated][appended to the special contract requirements][provided on the project drawings]. [The subsoil investigation report may be examined at [____].]

[1.4] BASIS OF BID

******************************************************************************
NOTE: Select one of the following options:
******************************************************************************

U.S. DEPARTMENT OF DEFENSE (DOD)

UFC 3-220-01 (2012; with Change 1, 2021) Geotechnical Engineering
1.4.1 Production Pile Acceptance Criteria

Safe design capacity for piles is [_____] KN [_____] kips. Drive piles to [minimum tip elevation][a minimum depth of [_____] m [_____] feet below cut-off elevation], and to such additional depth as required to obtain a bearing capacity of not less than [_____] KN [_____] kips. The Contractor's Geotechnical Consultant will determine the terminal driving criteria based on results of [dynamic pile driving tests at end of drive or restrike][static load tests][wave equation analysis].

The following formulas can be used in cases where allowable pile loads are less than 355 kN 80 kips (determined using a factor of safety of 3 for individual piles and 4 for pile groups) and are presented only as a guide to aid in establishing the controlling penetration per blow, which, together with the minimum depth of penetration will serve to determine the required minimum depth of penetration of each individual pile:

\[
R = \frac{2E}{S + 0.1} \quad \text{For double acting hammers}
\]

\[
R = \frac{2WH}{S + 0.1} \quad \text{For single acting hammers}
\]

Where \( R \) is the approximate allowable pile load in kips; \( E \) equals the energy in foot-kips per blow based on an acceptable certified statement from the manufacturer of the hammer; \( W \) equals the weight of the hammer or ram in kips; \( H \) equals the height of fall of the hammer of ram in feet; and \( S \) equals the average inches of penetration per blow for the last three blows. An allowance will be made for reduced penetration caused by shock absorption of the cushion or cap blocks.
applicability of use prior to selection. This paragraph will be typically used when there are 1) relatively small quantity of piles, 2) allowable pile loading is less than 355 kN (80 kips), and 3) the subsurface conditions are well defined. Fill in Table I as required selecting columns applicable to project. Generally, pile capacity, location, and minimum tip elevation are shown on plans. Test piles and load tests are not incorporated on lump sum contracts. Delete this paragraph for unit-price contracts.

Base bids upon providing the number, size, capacity, and length of piles as indicated on the [drawings.] [following Table I:

<table>
<thead>
<tr>
<th>Location</th>
<th>Number</th>
<th>Size</th>
<th>Capacity</th>
<th>Length (tip to cut-off)</th>
<th>Maximum Bending Moment</th>
<th>Maximum Shear Force</th>
</tr>
</thead>
</table>

Include the cost of all necessary equipment, tools, material, labor, and supervision required to: deliver, handle, install, cut-off, dispose of any cut-offs, and meet the applicable contract requirements. Include mobilization, pre-drilling, and redriving heaved piles. If, in redriving, it is found that any pile is not of sufficient length to provide the capacity specified, notify the Contracting Officer, who reserves the right to increase or decrease the total length of piles to be provided and installed by changing the pile locations or elevations, requiring the installation of additional piles, or directing the omission of piles from the requirements shown and specified. If total number of piles or number of each length vary from that specified as the basis for bidding, an adjustment in the contract price or time for completion, or both, will be made in accordance with the contract documents. Payment for piles will be based on successfully installing piles to both the minimum tip elevation and satisfying the acceptance criteria identified herein. No additional payment will be made for: damaged, rejected, or misplaced piles; withdrawn piles; any portion of a pile remaining above the cut-off elevation; backdriving; cutting off piles; splicing; build-ups; any cut-off length of piles; or other excesses beyond the assumed pile length indicated for which the Contractor is responsible.[ Include payments for vibration monitoring, sound monitoring and precondition construction surveys.]

][1.6 UNIT PRICE

**********************************************************************************************

NOTE: This paragraph is tailored for Navy.

Delete this paragraph for lump-sum contracts.

For NAVFAC PAC projects: Where there is unit pricing for piles, use this paragraph and edit applicable attachments for inclusion in Standard Form 1442, "Solicitation, Offer and Award" and "Schedule of Bid Items." Select first bracketed text.
For NAVFAC Southeast projects, where there is a need for unit pricing of piles, include this paragraph. Refer to NAVFAC SE Instruction 00010, "Instructions for Preparing Basis of Bid Statement With Unit-Priced Items," for method of specifying unit price bid items. Select first bracketed text.

**************************************************************************

[ For unit price bid, see SF 1442, "Solicitation, Offer and Award" and "Schedule of Bid Items." ]

**************************************************************************

NOTE: For NAVFAC LANT projects, use the following paragraph for measurement and payment and subsequent sub-parts.

**************************************************************************

Requirements of FAR 52.211-18 Variation in Estimated Quantity do not apply to payment for piling. Each pile and test pile acceptably provided will be paid for at the bid unit price per unit length, which will include items incidental to furnishing and driving the piles including mobilization and demobilization, [jetting][predrilling][probing], redriving uplifted piles, [an additional 1.5 m 5 feet in furnished length for any test pile not driven beyond estimated pile length,] and cutting off piles at the cut-off elevation. [Include the cost for additional length for the test piles in the total unit price cost for the job.] Payment will be made for production [and test piles] at the bid unit price for the length of pile, from tip to final cut-off, actually provided, excluding buildups and splices directed by the Contracting Officer to be made. If the actual cumulative pile length driven (tip to cut-off) vary more than 25 percent from the total pile length specified as a basis for bidding, at the direction of the Contracting Officer, the unit price per unit length will be adjusted in accordance with provisions of FAR 52.236-2 Differing Site Conditions. [Payments will be made per each at the respective bid unit price for pile cut-offs, pile build-ups, pile loads tests and pile splices.] [Include payments for vibration monitoring, sound monitoring, construction instrumentation and monitoring, and precondition construction surveys.]

][1.7 PAYMENT

**************************************************************************

NOTE: This paragraph is tailored for Army.

Delete this paragraph for lump-sum contracts.

If Section 01 20 00 PRICE AND PAYMENT PROCEDURES is included in the project specifications, this paragraph title (PAYMENT) should be deleted from this section and the remaining appropriately edited subparagraphs below should be inserted into Section 01 20 00 PRICE AND PAYMENT PROCEDURES.

**************************************************************************
1.7.1 Furnishing and Delivering Prestressed Concrete Piles

1.7.1.1 Payment

Payment will be made for costs associated with furnishing and delivering the required lengths of permanent prestressed concrete piles, including H-pile extensions, which includes costs of furnishing and delivering piles to the work site. No payment will be made for the driving head or lengths of piles exceeding required lengths. No payment will be made for piles damaged during delivery, storage, or handling to the extent that they are rendered unsuitable for the work, in the opinion of the Contracting Officer.

1.7.1.2 Measurement

Furnishing and delivering permanent prestressed concrete piles will be measured for payment by the linear meter foot of piles required below the cut-off elevation as determined by the Contracting Officer and furnished to the Contractor.

1.7.1.3 Unit of Measure

Unit of measure: linear meter foot.

1.7.2 Driving Prestressed Concrete Piles

1.7.2.1 Payment

Payment will be made for costs associated with driving permanent prestressed concrete piles, which includes costs of handling, driving, splicing of piles, performing dynamic testing, interpreting data and submitting reports, measuring heave, redriving heaved piles, removal of build-ups driving heads or cutting off piles at the cut-off elevation and removing from the work site, compiling and submitting pile driving records, backfilling voids around piles, and any other items incidental to driving piles to the required elevation.

1.7.2.2 Measurement

Permanent prestressed concrete piles will be measured for payment for driving on the basis of lengths, to the nearest hundredth tenth of a linear meter foot, along the axis of each pile acceptably in place below the cut-off elevation shown.

1.7.2.3 Unit of Measure

Unit of measure: linear meter foot.

1.7.3 Pulled Prestressed Concrete Piles

1.7.3.1 Payment

Payment will be made for costs associated with piles pulled at the direction of the Contracting Officer and found to be undamaged. The cost of furnishing and delivering pulled and undamaged piles will be paid for at the applicable contract unit price for payment item "Furnishing and Delivering Prestressed Concrete Piles". The cost of driving pulled and undamaged piles will be paid for at the applicable contract unit price for payment item "Driving Prestressed Concrete Piles". The cost of pulling undamaged piles will be paid for at twice the applicable contract unit price.
price for payment item "Driving Prestressed Concrete Piles", which includes backfilling any remaining void. The cost of redriving pulled and undamaged piles will be paid for at the applicable contract unit price for payment item "Driving Prestressed Concrete Piles". No payment will be made for furnishing, delivering, driving, pulling, and disposing of piles, including pile driving points, pulled and found to be damaged and backfilling voids. New piles replacing damaged piles will be paid for at the applicable contract unit price for payment items "Furnishing and Delivering Prestressed Concrete Piles" and "Driving Prestressed Concrete Piles".

1.7.3.2 Measurement

Furnishing and delivering pulled and undamaged permanent prestressed concrete piles will be measured for payment as specified in paragraph PAYMENT, subparagraph FURNISH AND DELIVER PRESTRESSED CONCRETE PILES. Pulling undamaged prestressed concrete piles will be measured for payment as specified in paragraph PAYMENT, subparagraph DRIVING PRESTRESSED CONCRETE PILES. Redriving pulled undamaged prestressed concrete piles will be measured for payment as specified in paragraph PAYMENT, subparagraph DRIVING PRESTRESSED CONCRETE PILES. New piles replacing damaged piles will be measured for payment as specified in paragraph PAYMENT, subparagraphs FURNISH AND DELIVER PRESTRESSED CONCRETE PILES and DRIVING PRESTRESSED CONCRETE PILES.

1.7.3.3 Unit of Measure

Unit of measure: linear meter foot.

[1.7.4 Prestressed Concrete Pile Driving Tests

1.7.4.1 Payment

Payment will be made for costs associated with furnishing, delivering, driving, pulling, and disposing of driven test piles, including [pile driving points] [and] [splices]; conducting pile driving tests; backfilling voids around piles; compiling pile driving test records; performing dynamic testing; interpreting data; and submitting reports.

1.7.4.2 Measurement

Prestressed concrete pile driving tests will be measured for payment on the basis of the applicable contract unit price per pile driving test.

1.7.4.3 Unit of Measure

Unit of measure: each.

][1.7.5 Prestressed Concrete Piles for Load Tests

1.7.5.1 Payment

Payment will be made for costs associated with furnishing, delivering, driving, pulling, and disposing of load test piles, including [pile driving points] [and] [splices]; backfilling voids around piles; compiling pile driving records; furnishing, fabricating, and mounting of strain rods and protective assembly; furnishing, fabricating, and mounting of inclinometer and inclinometer protective assembly; performing dynamic testing; interpreting data; and submitting reports. No additional payment will be made for load test piles incorporated in the permanent work other
1.7.5.2 Measurement

Prestressed concrete piles for load tests will be measured for payment on the basis of the applicable contract unit price per load test pile.

1.7.5.3 Unit of Measure

Unit of measure: each.

1.7.6 Prestressed Concrete Pile Static Axial Compressive Load Tests

1.7.6.1 Payment

Payment will be made for costs associated with prestressed concrete pile static axial compressive load tests in accordance with ASTM D1143/D1143M, including material and labor for fabricating and furnishing load frames; calibrating load cells and hydraulic jacks; furnishing specified test equipment; installing strain rods; placing and removing test loads and test equipment; recording, reducing, and submitting test data; and compiling and submitting pile static axial load test reports. No payment will be made for rejected pile compressive load tests.

1.7.6.2 Measurement

Prestressed concrete pile static axial compressive load tests will be measured for payment on the basis of the applicable contract unit price per load test.

1.7.6.3 Unit of Measure

Unit of measure: each.

1.7.7 Prestressed Concrete Pile Static Tensile Load Tests

1.7.7.1 Payment

Payment will be made for costs associated with prestressed concrete pile static tensile load tests in accordance with ASTM D3689/D3689M, including material and labor for fabricating and furnishing load frames; calibrating load cells and hydraulic jacks; furnishing specified test equipment; installing strain rods; placing and removing test loads and test equipment; recording, reducing, and submitting test data; and compiling and submitting pile load test reports. No payment will be made for rejected pile static tensile load tests.

1.7.7.2 Measurement

Prestressed concrete pile tensile load tests will be measured for payment on the basis of the applicable contract unit price per number of tensile load test.

1.7.7.3 Unit of Measure

Unit of measure: each.
1.7.8 Prestressed Concrete Pile Lateral Load Tests

1.7.8.1 Payment

Payment will be made for costs associated with prestressed concrete pile lateral load tests in accordance with ASTM D3966/D3966M, including material and labor for fabricating and furnishing load frames; calibrating load cells and hydraulic jacks; furnishing specified test equipment; installing inclinometers; placing and removing test loads and test equipment; recording, reducing, and submitting test data; and compiling and submitting pile load test reports. No payment will be made for rejected pile lateral load tests.

1.7.8.2 Measurement

Prestressed concrete pile lateral load tests will be measured for payment on the basis of the applicable contract unit price per lateral load test.

1.7.8.3 Unit of Measure

Unit of measure: each.

1.7.9 Pulled Load Test Prestressed Concrete Piles

1.7.9.1 Payment

Payment will be made for costs associated with load test prestressed concrete piles pulled prior to load testing at the direction of the Contracting Officer and found to be undamaged. The cost of furnishing, delivering, driving, and pulling undamaged load test piles will be paid for at the applicable contract unit price for payment item "Prestressed Concrete Piles for Load Tests". The cost of pulling undamaged load test piles the second time after redriving and testing will be paid for at twice the applicable contract unit price for payment item "Driving Prestressed Concrete Piles". The cost of redriving pulled undamaged load test piles will be paid for at the applicable contract unit price for payment item "Driving Prestressed Concrete Piles". No payment will be made for furnishing, delivering, driving, pulling, and disposing of load test piles pulled at the direction of the Contracting Officer and found to be damaged. New load test piles replacing damaged piles will be paid for at the applicable contract unit price for payment item "Prestressed Concrete Piles for Load Tests".

1.7.9.2 Measurement

Pulled undamaged load test prestressed concrete piles will be measured for payment as specified in paragraph PAYMENT, subparagraph PRESTRESSED CONCRETE PILES FOR LOAD TESTS. Pulling undamaged load test prestressed concrete piles the second time after redriving and testing will be measured for payment as specified in paragraph PAYMENT, subparagraph DRIVING PRESTRESSED CONCRETE PILES. Redriving pulled undamaged prestressed concrete piles will be measured for payment as specified in paragraph PAYMENT, subparagraph DRIVING PRESTRESSED CONCRETE PILES. New load test prestressed concrete piles replacing damaged piles will be measured for payment as specified in paragraph PAYMENT, subparagraph PRESTRESSED CONCRETE PILES FOR LOAD TESTS.
1.7.9.3 Unit of Measure

Unit of measure: as specified in paragraph PAYMENT, subparagraphs DRIVING PRESTRESSED CONCRETE PILES and PRESTRESSED CONCRETE PILES FOR LOAD TESTS, respectfully.

1.7.10 Pile Driving Shoes

1.7.10.1 Payment

Payment will be made for costs associated with pile driving shoes, including furnishing, delivering, and installing.

1.7.10.2 Measurement

Pile driving shoes will be measured for payment on the basis of the number of pile driving shoes required.

1.7.10.3 Unit of Measure

Unit of measure: each.

1.7.11 Prestressed Concrete Pile Splices

1.7.11.1 Payment

Payment will be made for costs associated with prestressed concrete pile splices, including all plant, labor, and material required to make the splice.

1.7.11.2 Measurement

Prestressed concrete pile splices will be measured for payment on the basis of the applicable contract unit price per pile splice.

1.7.11.3 Unit of Measure

Unit of measure: each.

1.7.12 Vibration Monitoring

1.7.12.1 Payment

Payment will be made for costs associated with vibration monitoring.

1.7.12.2 Measurement

Vibration monitoring will be measured for payment on the basis of the applicable contract unit price per vibration monitoring point.

1.7.12.3 Unit of Measure

Unit of measure: each.

1.7.13 Sound Monitoring

1.7.13.1 Payment

Payment will be made for costs associated with sound monitoring.
1.7.13.2 Measurement
Sound monitoring will be measured for payment on the basis of the applicable contract unit price per vibration monitoring point.

1.7.13.3 Unit of Measure
Unit of measure: each.

1.7.14 Preconstruction Condition Survey

1.7.14.1 Payment
Payment will be made for costs associated with preconstruction condition surveys.

1.7.14.2 Measurement
Preconstruction condition survey will be measured for payment on the basis of the applicable contract unit price per structure to be surveyed.

1.7.14.3 Unit of Measure
Unit of measure: each.

1.7.15 Construction Instrumentation and Monitoring

1.7.15.1 Payment
Payment will be made for costs associated with construction instrumentation and monitoring.

1.7.15.2 Measurement
Construction instrumentation and monitoring will be measured as a single pay item.

1.7.15.3 Unit of Measure
Unit of measure: one.

1.8 SUBMITTALS

NOTE: Review Submittal Description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets.
following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.

**************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

**SD-01 Preconstruction Submittals**

Installation Procedures; G[, [_____]]

Contractor's Geotechnical Consultant Documentation; G[, [_____]]

Wave Equation Analysis; G[, [_____]]

Precasting Manufacturer's Quality Control Procedures; G[, [_____]]

Instrumentation and Monitoring Program Report; G[, [_____]]

Testing Agency Qualifications; G[, [_____]]

**SD-02 Shop Drawings**

**************************************************************************

NOTE: When the size and complexity of project warrants certification by a registered engineer, insert requirements; otherwise delete.

**************************************************************************

Piles; G[, [_____]]

Pile Splices; G[, [_____]]

Pile Placement; G[, [_____]]

As-Driven Survey; G[, [_____]]

SECTION 31 62 13.20  Page 19
1.9 DELIVERY, STORAGE, AND HANDLING

Store, handle, and transport piles in accordance with PCI MNL-116 except as follows. Use methods for handling and storage of piles such that the piles are not subjected to excessive bending stress, cracking, spalling, or other damage. Follow the lifting instructions of the precaster.
1.9.1 Damaged Piles

Inspect each pile for sweep and structural damage such as cracking and spalling before transporting them to the project site and immediately prior to placement in the driving leads. Bring any cracks (cracks other than crazing, surface drying, shrinkage cracks and end cracks) to the attention of the Contracting Officer. Piles which are damaged during delivery, storage, or handling to the extent they are rendered unsuitable for the work, in the opinion of the Contracting Officer, will be rejected and removed from the project site, or may be repaired, if approved, at no cost to the Government.

Any pile damaged by reason of internal defects or by improper driving must be corrected by one of the following methods approved by the Engineer for the pile in question and the project Structural Engineer:

The pile is withdrawn, if practicable, and replaced by a new and, if necessary, longer pile.

One or more replacement piles are driven adjacent to the defective pile.

A Pile Dynamic Analysis and low integrity testing must be performed by the Contractor's Geotechnical Consultant to assess the structural integrity of the driven pile(s).

A pile driven below the specified butt elevation must be corrected by one of the following methods approved by the Engineer:

The pile is spliced (if approved).

A sufficient portion of the footing is extended down to properly embed the pile.

A pile driven out of its proper location or out of plumb as approved by the Engineer, must be corrected by one of the following methods approved by the engineer:

One or more replacement piles are driven next to the pile in question.

As directed by the structural engineer.

1.9.2 Repairable Cracks

Reject or repair piles with cracks equal to or greater than 0.15 mm 0.006 inches but less than 1.5 mm 0.06 inches. As an alternate to pile rejection, the Contractor may submit a proposal to repair deficient piles, which must be restored prior to driving to provide its required design capacity, perform its intended function in the structure, and take into consideration long term durability in corrosive environment.

1.9.3 Non-Repairable Cracks

Piles with cracks equal to or greater than 1.5 mm 0.06 inches will be rejected.

**************************************************************************
NOTE: Sweep and camber typically apply to steel piles. In special cases, this paragraph may apply to precast/pre-stressed concrete piles.
1.9.4  Pile Sweep

Limit sweep to 3 mm per 3 M 1/8 inch per 10 feet over the length of the pile. Piles having excessive sweep will be rejected.

1.10  QUALITY CONTROL

1.10.1  Piles

Prepare in accordance with ACI SP-66. Indicate placement of reinforcement including tendons. Indicate location of special embedded or attached lifting devices, employment of pick-up points, support points other than pick-up points, and any other methods of pick-up. Provide certification of a Professional Engineer registered in any jurisdiction of the U.S. or its territories, that layout and details of reinforcement and tendons conform with that shown on the structural design drawings.

1.10.2  Quality Control Procedures

Submit the precasting manufacturer's quality control procedures and inspection records established in accordance with PCI MNL-116.

1.10.3  Installation Procedures

a. Submit information on the type of equipment proposed to be used, proposed methods of operation, pile driving plan including proposed sequence of driving, and details of all pile driving equipment and accessories.

b. Provide details of pile driving equipment and a Wave Equation Analysis of pile drivability for selection of the hammer along with a statement of driving procedures. The Wave Equation Analysis is to be completed by the Contractor's Geotechnical Consultant for each test pile location where different subsurface conditions exist and is to include the following information pertaining to the proposed pile driving equipment:

   (2) Copies of computer input and output sheets and graphs showing soil resistance versus blow count as well as maximum tension and compression stresses versus blow count. Analysis must be run at the estimated tip elevation as well as other required elevations to define maximum stress levels in the pile during driving.

c. Provide detailed procedures for conducting the dynamic pile load test and equipment to be used for conducting the load test. The detailed description must explain how specific information of pile performance will be evaluated.

1.10.4  Contractor's Geotechnical Consultant Documentation

Hire the services of an independent, Registered Professional Geotechnical Engineer, experienced in soil mechanics and Pile Dynamic Analysis, to observe test pile installation and production pile installation as
specified herein. The Contractor's Geotechnical Consultant must be independent of the Contractor and must have no employee of employer relationship which could constitute a conflict of interest.

Provide instructions and procedures on how the Contractor will assist the Government in the processes of Dynamic Pile Testing, Inspection and Monitoring of piles during installation and testing.

1.10.5 Concrete Mix Design

Certify, using a Government-approved independent commercial testing laboratory, that proportioning of mix is in accordance with ACI 211.1 or ACI 318M ACI 318 for specified strength and is based on aggregate data which has been determined by laboratory tests during last 12 months. Submit a complete list of materials including type; brand; source and amount of cement, fly ash, pozzolan, ground slag, and admixtures; and applicable reference specifications. Submit additional data regarding concrete aggregates if the source of aggregate changes. Submittal must clearly indicate where each mix design will be used when more than one mix design is submitted. Submit a concrete mix design before concrete is placed, for each type of concrete used for the piles. Submit concrete cylinder compressive strength test results.

1.10.6 Load Test Supporting Data

Submit Jack calibration records, a testing arrangement description and diagram, and the proposed loading sequence.

1.10.7 Silica Fume Manufacturer's Representative

Provide statement that the manufacturer's representative will be present at plant to ensure proper mix, including high range water reducer (HRWR), and batching methods.

PART 2 PRODUCTS

2.1 PILE REQUIREMENTS

******************************************************************************
NOTE: Delete sentence in brackets when test piles are not required. Government requires the Contractor to employ a Geotechnical Consultant to determine the calculated tip elevation and provide oversight of piling installation and testing.
******************************************************************************

Provide precast prestressed concrete piles per PCI Journal Volume 38, Number 2 (PCI JR-382). Production of piles must be in accordance with PCI MNL-116. Order test piles [3] [_____] meters [10] [_____] feet longer in length than production piles. Drive the additional test pile length only when based upon the recommendation of the Contractor's Geotechnical Consultant and approved by the Contracting Officer. The Contractor's Geotechnical Consultant will use test pile data to determine "calculated" pile tip elevation and necessary driving resistance. This information will be given to the Contractor no later than 7 days from receipt of complete test data. Use this list as the basis for ordering the piles. Do not order piles until list is provided by the Contractor's Geotechnical Consultant. Provide test piles [1.5] [_____] meter [5] [_____] feet longer than the bid length.
2.2 MATERIALS

2.2.1 Cementitious Materials

Cementitious materials must be portland cement, [blended cement] or portland cement in combination with natural pozzolan or fly ash[ or ground granulated blast furnace slag] and conforms to appropriate specifications listed below.

2.2.1.1 Cement

**************************************************************************
NOTE: Insert type of cement required. Generally, Types II, or I/II, is preferred. Type I, or Type III with 8 percent maximum C3A and "low alkali", may be used. Do not use Type III in conjunction with silica fume. In very special cases, Type V, "low alkali," which has limited availability, may be used.
**************************************************************************
**************************************************************************
NOTE: Cement type and quantity of cement required in mix design is dependent upon the environment, soil conditions, need for corrosion protection, and location of piling:

(a) CHLORIDE PROTECTION:

Normal Use. In fresh water or air environment, specify Type I or Type II cement. Type III may be permitted provided tricalcium aluminate (C3A) content is limited to 8 percent and it is low alkali.

Marine Use. In soil or water environments, subject to chlorides above 1,000 ppm, within about 300 m 1000 feet of the ocean or tidal water, specify Type II or Type III (with a maximum tricalcium aluminate (C3A) content of 8 percent and low alkali) cement, a minimum cementitious materials content of 335 kilograms per cubic meter 564 pounds per cubic yard and a maximum water to cementitious materials ratio of 0.40.

Seawater Exposure. In direct contact with ocean water, specify Type II or Type III (with a maximum tricalcium aluminate (C3A) content of 8 percent and low alkali) cement, a minimum cementitious materials content of 390 kilograms per cubic meter 658 pounds per cubic yard and a maximum water to cementitious materials ratio of 0.40.

(b) SULFATE RESISTANCE minimum cementitious materials content of 335 kilograms per cubic meter 564 pounds per cubic yard is recommended.

Normal Use. In soils with negligible amount of sulfate, specify Type I or Type II cement. Type III cement may be permitted provided tricalcium
aluminate (C3A) content is limited to 8 percent and it is low alkali.

Moderate Sulfate Exposure. In exposures with moderate sulfate content (between 0.10 and 0.20 percent in soil and less than 1500 ppm in water), specify Type II or Type III (with a maximum tricalcium aluminate (C3A) content of 8 percent and low alkali) cement and a maximum water to cementitious materials ratio of 0.40. Do not use Class C fly ash, blast furnace slag, or silica fume for cement replacement.

Severe Sulfate Exposure. In exposures with high sulfate content (exceeds 0.20 percent in soil or 1500 ppm in water), specify Type V or Type II (with a maximum tricalcium aluminate content of 5 percent) cement, and a maximum water to cementitious materials ratio of 0.40. Do not use Class C fly ash, blast furnace slag, or silica fume for cement replacement.

Alkali-Silica Reactivity. When alkali-silica reactivity is a concern, it is recommended to limit the maximum alkali content of cement to 0.40 or 0.50, when it is locally available, otherwise use 0.60.

**************************************************************************

ASTM C150/C150M, [Type I, II, or III [_____] with a maximum alkali content of [0.40] [0.60] percent][; or] [ASTM C595/C595M, Type [IP(MS) or IS(MS)] [_____] ] blended cement except as modified herein. The blended cement must consist of a mixture of ASTM C150/C150M cement (with alkali content not exceeding [0.40] [0.60] percent) and one of the following materials: ASTM C618 pozzolan or fly ash, or ASTM C989/C989M ground iron blast-furnace slag, or ASTM C1240 silica fume. Use cement with a maximum of 0.60 percent alkali if no satisfactory test results are available (made within the past 6 months) to prove that the cement alkali content is less than 0.40 percent. Cement certificates must include test results in accordance with ASTM C150/C150M, including equivalent alkalies indicated in the optional chemical requirements.[ Use cement with a tricalcium aluminate (C3A) content of less than [8] [5] percent.] Do not use Type III cement in conjunction with silica fume.

**************************************************************************

NOTE: Fly ash, pozzolan, and ground iron blast-furnace slag increase durability. They may produce uneven discoloration of the concrete during the early stages of construction, depending upon the type of curing provided. Use Fly ash/pozzolan (loss on ignition not exceeding 3 percent) for frost areas to reduce carbon interference with air entraining admixture. Straight replacement with fly ash or natural pozzolan beyond 15 percent may decrease the concrete's strength gain rate. The following options can help mitigate this slower gain rate: (1) a lower water/cement ratio may be used, (2) partial cement replacement can be completed, e.g., one sack of cement can be replaced by 1.5 sacks of fly ash,
as long as the final replacement ratio meets the requirements, and (3) very fine fly ashes or pozzolans (e.g. with average particle sizes below 5 microns) can be used.

2.2.1.2 Fly Ash and Pozzolan

NOTE: Loss on ignition greater than 3 percent may result in significant variations in air content. The air entrainment admixture content may need to be varied often to maintain the same level of entrained air.

ASTM C618, Class N, or F except that the maximum total alkali contents must be 3.0 percent, and the maximum allowable loss on ignition must be 3 percent. If the aggregates are reactive, the maximum calcium oxide content must be 13.0 percent. Do not use Class C.

2.2.1.3 Ground Iron Blast-Furnace Slag

ASTM C989/C989M, Grade 120.

2.2.1.4 Silica Fume

NOTE: Use silica fume concrete for marine structures where low permeability and enhanced durability are necessary. The silica fume and HRWR additive should be from the same manufacturer. The Contractor and batch plant may need help from the manufacturer. Select weight percentage based on performance required. If used, a replacement of 7 percent is recommended.

NOTE: Use for high durability and low permeability. The initial cost of the concrete will increase, and supervision at the batch plant, finishing, and curing is necessary. A HRWR must be used with silica fume. The slump can be increased 50 to 125 mm (2 to 5 inches) without reducing strength. Finishing may be more difficult. Proper curing is essential because there is a tendency for plastic shrinkage cracking.

ASTM C1240, provide silica fume that is a by-product of silicon or ferrosilicon production. Provide percent by weight of the total cementitious materials as indicated in the table below.

2.2.1.5 Supplemental Cementitious Materials (SCM) Content

The concrete mix must contain one of the SCMs listed below, or a linear combination thereof.
### SUPPLEMENTARY CEMENTITIOUS MATERIALS CONTENT

### 2.2.2 Water

Water must be fresh, clean, and potable; free from injurious amounts of oils, acids, alkalis, salts, organic materials, or other substances deleterious to concrete or steel.

### 2.2.3 Aggregates

***NOTE:*** For exposed piles in areas where reactive aggregates are likely to be supplied, provide for additional tests and certification to insure that reactive aggregates will not be used. While not wholly conclusive, petrographic examination (ASTM C295/C295M), chemical test (ASTM C289/C289M), and mortar bar method (ASTM C227) are valuable indicators.

While more reliable, the concrete prism test (ASTM C1293) takes 1 to 2 years to complete and is not practical. The accelerated mortar bar method (ASTM C1260) is similarly reliable and takes only 16 days to yield results. In areas where reactive aggregates can not be avoided, specify use of low alkali cement, and cements modified to mitigate alkali-silica reactivity. Service records of concrete made with these materials along with tests should be used in evaluating these materials.

***NOTE:*** Include modification to ASTM C33/C33M when reactive aggregates could be encountered. More modifications may be required. Additional tests and certifications may be required in the submittal paragraphs.
ASTM C33/C33M[, except as modified herein. Provide aggregate free from any substance which may be deleteriously reactive with alkalis in cement in an amount sufficient to cause excessive expansion of concrete]. Do not mix, store in same stockpile, or use fine aggregates from different sources of supply in same concrete mix or same structure without approval. The fineness modulus of fine aggregate must be not less than 2.40 or greater than 3.0. For piles that will be exposed to freezing and thawing, fine and coarse aggregate subjected to five cycles of the sodium sulfate soundness test must show a loss not greater than 10 percent. If the selected aggregates fail the soundness test, the Contractor may use the aggregate source, provided concrete specimens made with the aggregates to be used for the piles must have a durability factor of not less than 80 based on 300 cycles of freezing and thawing when tested in accordance with ASTM C666/C666M. Prior to pile fabrication, submit certified test reports for the following tests specified in ASTM C33/C33M[, in addition, test the gradation of each size of aggregate in accordance with ASTM C136/C136M], [twice] [_____] during each shift when the concrete plant is operating:

a. Grading
b. Amount of material finer than 75 micrometers No. 200 sieve
c. Organic impurities
d. Soundness
e. Clay lumps and friable particles
f. Coal and lignite
g. Weight of slag
h. Abrasion of coarse aggregate
i. Fineness modulus
j. Reactive aggregates
k. Freezing and thawing

2.2.3.1 Alkali-Silica Reactivity (ASR)

Evaluate and test fine and coarse aggregates to be used in all concrete for alkali-aggregate activity.

Separately evaluate the fine and coarse aggregates using ASTM C1260. Test results of the individual aggregates must have a measured expansion equal to or less than 0.08 percent at 14 days after casting per ASTM C1260. If the test data indicates an expansion of greater than 0.08 percent, reject the aggregate(s) or perform additional testing, using ASTM C1567, as follows: utilize the Contractor's proposed low alkali portland cement [blended cement] and SCM in combination with the proposed aggregate for the test portioning. Determine the SCM quantity that will meet all the requirements of these specifications and that will lower the ASTM C1567 expansion to equal or less than 0.08 percent at 14 days after casting.

If the above option does not lower the expansion to less than 0.08 percent at 14 days after casting, reject the aggregate(s) and submit new aggregate
sources for retesting. Submit the results of testing to the Contracting Officer for evaluation and acceptance.

2.2.4 Admixtures

******************************************************************************************
NOTE: For guidance in use of either water-reducing admixtures, set retarding admixtures, or combination of admixtures, see ACI 543R-74, "Recommendations for Design, Manufacture, and Installation of Concrete Piles."
******************************************************************************************

Chemical admixtures must conform to ASTM C494/C494M, [Type A] [Type B]. Air-entraining admixture must conform to ASTM C260/C260M.] Do not use admixtures containing chlorides.

2.2.5 Prestressing Steel

Use seven-wire stress-relieved or low-relaxation strand conforming to ASTM A416/A416M, Grade 270. Use prestressing steel free of grease, oil, wax, paint, soil, dirt, and loose rust. Do not use prestressing strands or wire having kinks, bends, or other defects.

2.2.6 Reinforcing Steel

******************************************************************************************
NOTE: Minimum cover for reinforcing steel in concrete structures is dependent upon the environment, soil conditions, need for corrosion protection, and location of piling. For normal exposure minimum cover is 50 mm 2 inches. For piles exposed to marine conditions (chloride content above 1000 ppm) in or within about 300 m 1000 feet of the ocean or tidal water, use 75 mm 3 inches minimum cover, including the chamfered corners. For additional detailed guidance, see following publications: ACI 543R, "Recommendations for Design, Manufacture and Installation of Concrete Piles" (ACI Manual, Part 3); State of California, Department of Public Works, Design Specifications, Volume 1, Bridge Planning and Design Manual, Chapter 6. Piles to be used in a marine environment may receive a protective coating, particularly if the piles are steam cured. The protective coating should be applied to that portion of pile which remains aboveground or water line. Show areas to be protected on drawings.
******************************************************************************************

******************************************************************************************
NOTE: Insert grade of reinforcement. Specify ASTM A706/A706M reinforcing where welding or bending of reinforcement bars is important. In addition, ASTM A934/A934M may be specified where extra reinforcement protection is required.
******************************************************************************************

ASTM A615/A615M, Grade [300][420] [40][60]; [ASTM A706/A706M, Grade [420]
2.2.7 Ties and Spirals

******************************************************************************
NOTE: If project has been designed for epoxy rebar, add ASTM A934/A934M, "Epoxy-Coated Prefabricated Steel Reinforcing Bars" in this paragraph and in the paragraph REFERENCES.
******************************************************************************
Steel, ASTM A1064/A1064M for spirals and ASTM A615/A615M [ASTM A706/A706M] for ties.

2.2.8 Anchorages and End Fittings

ACI 318M ACI 318.

2.2.9 Grout

Provide cement grout for prestressed piles using materials conforming to requirements stipulated herein for concrete mixes. Use admixtures, if required, known to have no injurious effects on steel or concrete. Do not use calcium chloride.

[2.2.10 Epoxy Coating

[EP-3][_____] conforming to Section [____], "Epoxy-Resin Systems" of [_____]DOT RBS. Coat the top 7500 mm 25 feet of piles.

][2.2.11 H-Pile Extensions

Use H-pile extensions for composite prestressed concrete-steel piles of steel conforming to the requirements of [ASTM A36/A36M] [ASTM A572/A572M].

][2.2.12 Pile Driving Points

Use pile driving points of steel conforming to the requirements of ASTM A27/A27M or [ASTM A36/A36M] [ASTM A572/A572M], of the [type] [details] indicated.

]2.3 CONCRETE MIX DESIGN

******************************************************************************
NOTE: Insert the minimum 28 day compressive strength required by the design. A minimum of 35 MPa 5000 psi is generally required. Insert aggregate size, either 19 mm 3/4 inch or 25 mm one inch is generally maximum. For marine exposure, (or moderate and severe sulfate exposure) include last bracketed sentence, which limits the water-cement ratio to a maximum of 0.40.
******************************************************************************
******************************************************************************
NOTE: Air-entrainment may be considered optional only in regions that do not experience freezing temperatures.
ACI 211.1 or ACI 318M ACI 318, Chapter 4. Concrete must have a minimum compressive strength of \([35 \text{ [_____] MPa [5000 [_____] psi at 28 days and a maximum size aggregate of [_____] mm inches. Concrete must be air entrained with a minimum of 4.5 percent and a maximum of 7.5 percent. Mix must contain fly ash, ground iron blast furnace slag or silica fume to meet the requirements specified herein to mitigate Alkali-Silica Reactivity (ASR).\[ For marine exposure, ensure a dense concrete free of shrinkage cracks, with a minimum degree of permeability. The maximum water cement ratio must be 0.40.\]

2.4 FABRICATION

2.4.1 Formwork

Formwork and dimensional tolerances must be in accordance with PCI MNL-116, PCI MNL-135, and as specified herein. Provide forms of metal, braced and stiffened against deformation, accurately constructed, watertight, and supported on unyielding casting beds. Forms must permit movement of pile without damage during release of prestressing force. Form precast dowel holes with galvanized flexible metal conduit.\[ Inside forms or void tubes not to be grouted may be treated cardboard, plywood, or other material.\]

2.4.2 Pretensioning

Perform pretensioning in accordance with PCI MNL-116, and as specified herein. Use gage calibrated within last \([6 \text{ months}[_____] by a laboratory approved by Contracting Officer. Provide means for measuring elongation of steel to nearest \(3 \text{ mm 1/8 inch. Give tensioning steel a uniform prestress prior to being brought to design prestress. Induce same initial prestress in each unit when several units of prestressing steel in a pile are stretched simultaneously.\

2.4.3 Casting

2.4.3.1 Conveying

Convey concrete to formwork in accordance with PCI MNL-116, and as specified herein. Clean conveying equipment thoroughly before each run. During placing, make any free vertical drop of the concrete less than \(0.91 \text{ m 3 feet. Remove concrete which has segregated in conveying or placing.}\

2.4.3.2 Placing and Casting

NOTE: Select the size of chamfer required. Consult with local producers. Where project requires a large quantity of piling a specific value may be specified, otherwise, use a minimum or a range of values.

Perform concrete casting within 3 days after pretensioning steel; however, do not deposit concrete in forms until placement of reinforcement and anchorages has been inspected and approved by pile manufacturer's quality control representative. Produce each pile of dense concrete straight with smooth surfaces with reinforcement retained in its proper position during fabrication. Use vibrator with heads smaller than the minimum distance
between steel for pretensioning. Make surface of pile ends perpendicular to axis of pile. Chamfer, [a minimum of 19 mm 3/4 inch], [_____] mm [_____] inch, [between 19 mm and 31 mm 3/4 inch and 1 1/4 inch,] ends of piles and corners of square piles.

2.4.4 Curing of Piles

Cure piles using moist or accelerated curing in accordance with the PCI MNL-116 except as follows. [____]

2.4.4.1 Moist Curing

Moist cure using moist burlap coverings, plastic sheeting, or membrane curing compound until minimum strength to detension is achieved.

2.4.4.2 Accelerated Curing

After placement of concrete, moist cure for a period of 4 hours. Follow by accelerated curing until concrete has reached specified release strength. Enclose casting bed for accelerated curing with a suitable enclosure. During application of steam or heat, increase the air temperature at a rate not to exceed 22 degrees C 40 degrees F per hour. Cure at a maximum temperature of 65 degrees C 150 degrees F until concrete has reached specified release strength. Reduce temperature at a rate not to exceed 11 degrees C 20 degrees F per hour until a temperature of 11 degrees C 20 degrees F above ambient air temperature is reached. After accelerated curing, moist cure using either water or membrane curing until a total accelerated and moist curing time of 72 hours is achieved.

2.4.5 Detensioning

**************************************************************************
NOTE: Specify "release strength." Release strength of 30 MPa 4000 psi (Design strength) of 35 MPa 5000 psi or 0.8 of the 28 day design strength is desirable; however, some regions use 0.7 of the design strength 25 MPa 3500 psi for design strength of 35 MPa 5000 psi. A minimum release strength of 0.6 of the design strength is required. Check with local pile manufacturers.
**************************************************************************

Perform detensioning in accordance with PCI MNL-116, and as specified herein. Gradually release tension in strands from anchorage. Detension after approval by pile manufacturer’s quality control representative. Perform transfer of prestressing force when concrete has reached a minimum compressive strength of [_____] MPa psi.

2.5 PRODUCT QUALITY CONTROL

Where piling is manufactured in a plant with an established quality control program as attested to by a current certification in the PCI "Certification Program for Quality Control" perform product quality control in accordance with PCI MNL-116. Where piling is manufactured by specialists or in plants not currently enrolled in the PCI "Certification Program for Quality Control," set-up a product quality control system in accordance with PCI MNL-116 and perform concrete and aggregate quality control testing using an independent commercial testing laboratory approved by the Contracting Officer in accordance with the following.
2.5.1 Piles

Prepare shop drawings in accordance with ACI SP-66. Indicate placement of reinforcement including tendons. Indicate location of special embedded or attached lifting devices, employment of pick-up points, support points other than pick-up points, and any other methods of pick-up. [Provide certification of a Professional Engineer registered in any jurisdiction of the U.S. or its territories, that layout and details of reinforcement and tendons conform with that shown on the structural design drawings.]

[2.5.2 Silica Fume Manufacturer's Representative

Provide statement that the manufacturer's representative will be present at plant to ensure proper mix, including high range water reducer (HRWR), and batching methods.

2.5.3 Aggregate Tests

Take samples of fine and coarse aggregate at concrete batch plant and test. Perform mechanical analysis (one test for each aggregate size) in accordance with ASTM C136/C136M. Tabulate results of tests in accordance with ASTM C33/C33M.

2.5.4 Slump and Strength Tests

Sample concrete in accordance with ASTM C172/C172M at time concrete is deposited for each production line. Perform slump tests in accordance with ASTM C143/C143M. Mold cylinders in accordance with ASTM C31/C31M. Mold at least six cylinders per day or one for every [15] [45] cubic meter [20] [60] cubic yards of concrete placed, whichever is greater. Cure cylinders in same manner as piles and for accelerated curing, place at coolest point in casting bed. Perform strength tests in accordance with ASTM C39/C39M. Test two cylinders of each set at 7 days or 14 days, or at a time for establishing transfer of prestressing force (release strength) and removal of pile from forms. Test remaining cylinders of each set 28 days after molding.

2.5.5 Changes in Proportions

If, after evaluation of strength test results, compressive strength is less than specified compressive strength, make adjustments in proportions and water content and changes in temperature, moisture, and curing procedures as necessary to secure specified strength. Submit changes in mix design to Contracting Officer in writing.

2.5.6 Compressive Strength Test Results

Evaluate compressive strength test results at 28 days in accordance with ACI 214R using a coefficient of variation of 10 percent. Evaluate strength of concrete by averaging test results of each set of standard cylinders tested at 28 days. Not more than 10 percent of individual cylinders tested must have a compressive strength less than specified design strength.

[2.5.7 Chloride Ion Concentration

Sampling and determination of water soluble chloride ion content in accordance with ASTM C1218/C1218M. Maximum water soluble chloride ion concentrations in hardened concrete at ages from 28 to 42 days contributed
from the ingredients including water, aggregates, cementitious materials, and admixtures must not exceed 0.06 percent by weight of cement.

2.5.8 Chloride Ion Penetration

Proportion concrete to have the chloride ion penetration test in accordance with ASTM C1202 to ensure the durability of concrete in marine environment, and be below 3000 coulombs for concrete specimens tested at 56 days.

2.5.9 Precasting Manufacturer's Quality Control Procedures

Submit the precasting manufacturer's quality control procedures and inspection records established in accordance with PCI MNL-116.

2.6 MATERIAL SUSTAINABILITY CRITERIA

For materials used, where applicable and to extent allowed by performance criteria, provide and document the following in accordance with Section 01 33 29 SUSTAINABILITY REQUIREMENTS AND REPORTING:

a. Recycled content for fly ash and pozzolan.

b. Recycled content for Ground Iron Blast-Furnace Slag.

c. Recycled content for Silica Fume.

d. Minimum [75 percent] [_____] recycled content for steel used for stressed tendon reinforcing.

2.7 PILE DRIVING EQUIPMENT

Submit descriptions of pile driving equipment, including hammers, power packs, driving helmets, hammer cushions, pile cushions, leads, extractors, jetting equipment, and preboring equipment at least 30 days prior to commencement of work.

Provide Pile Driving Equipment as mentioned in this section.

2.7.1 Pile Hammers

Provide a hammer capable of developing the indicated ultimate pile capacity at blow count less than 100 per 300 mm foot considering hammer impact velocity; ram weight; stiffness of hammer and pile cushions; cross section, length, and total weight of pile; and character of subsurface material to be encountered. [Use the same pile hammer, operating at the same rate and in the same manner, as that used for driving test piles.] Use wave equation analysis to verify that the hammer will develop stresses within acceptable limits in the piles. At final driving, operate pile hammer in accordance with manufacturer's recommendation. Provide the plant and equipment for air hammers that have sufficient capacity to maintain, under working conditions, the pressure at the hammer specified by the manufacturer. The hose connecting the compressor with the hammer must be at least the minimum size recommended by the Manufacturer. Evaluate hammer performance at the end of driving by measuring blows per minute and comparing with the manufacturer's recommendations. Measure impact velocity of open-end (single acting) diesel hammers at all times during pile driving operations with a device for this purpose. If such a device is not available, obtain the stroke by measuring the speed of operation either manually or with a device that makes the measurement automatically. Equip
closed-end (double acting) diesel hammers with a bounce chamber pressure gauge in good working order, mounted near ground level so as to be easily read by the Contracting Officer. Provide a correlation chart of bounce chamber pressure and potential energy. Equip hydraulic hammers with a system for measurement of ram energy. The system must be in good working order and the results must be easily and immediately available to the Engineer.

2.7.2 Driving Helmets and Cushion Blocks

2.7.2.1 Driving Helmets or Caps and Pile Cushions

Use a steel driving helmet or cap including a pile cushion between top of pile and driving helmet or cap to prevent impact damage to pile. Use a driving helmet or cap and pile cushion combination capable of protecting pile head, minimizing energy absorption and dissipation, and transmitting hammer energy uniformly over top of pile. Provide driving helmet or cap that fits sufficiently loose around top of pile so that pile may be free to rotate without binding within driving helmet. During test pile installation, demonstrate to satisfaction of Contracting Officer that equipment to be used on project performs specified function. Use pile cushion of solid wood or of laminated construction using plywood, softwood or hardwood boards with grain parallel to end of pile. Select the pile cushion thickness placed on the pile head prior to driving by wave equation analysis so that the limiting driving stresses are not exceeded. Replace pile cushion at the start of driving of each pile and when it becomes highly compressed, charred or burned, or has become spongy or deteriorated in any manner. Show details of driving helmets, capblocks (hammer cushions), and pile cushions. Submit 2 weeks prior to [test] pile installation.

2.7.2.2 Hammer Cushion or Capblock

**************************************************************************
NOTE: Select either wood or aluminum/micarta capblock. Delete inappropriate sentences. An aluminum/micarta capblock is recommended because of its consistent elastic properties and long life. If final pile penetration resistance is based on a Wave Equation analysis, the type of capblock used should be the same as that used in the analysis.
**************************************************************************

Use a hammer cushion or capblock between driving helmet or cap and hammer ram consisting of a solid hardwood block with grain parallel to the pile axis and enclosed in a close-fitting steel housing. aluminum and micarta (or equal) discs stacked alternately in a steel housing or a suitable polymer designed for this specific purpose as indicated by the hammer manufacturer. Use steel plates at top and bottom of capblock (hammer cushion). Replace wood capblock (hammer cushion) when it becomes highly compressed, charred or burned or becomes spongy or deteriorated in any manner. Replace aluminum, micarta or polymer discs that have become damaged, split or deteriorated in any manner. Do not replace wood capblock (hammer cushion) during final driving of any pile. Do not use small wood blocks, wood chips, rope or other materials that permit excessive loss of hammer energy.
PART 3 EXECUTION

3.1 PRELIMINARY WORK

[3.1.1 Wave Equation Analysis of Pile Drivability]

a. Prior to driving any pile, submit a pile Wave Equation Analysis, performed by Contractor's Geotechnical Consultant, for each size pile and distinct subsurface profile condition. These analyses must take into account the proposed hammer assembly, pile cap block and cushion characteristics, the pile properties and estimated lengths and the soil properties anticipated to be encountered throughout the installed pile length based on static capacity analysis with consideration of driving gain/loss factors. Only one specific model of pile hammer may be used for each pile type and capacity.

b. Demonstrate using the Wave Equation Analysis that the piles will not be damaged during driving, must indicate that the driving stresses will be maintained within the limits below and indicate the blow count necessary to achieve the required ultimate static pile capacities.

**Allowable Driving Stresses**

Concrete

<table>
<thead>
<tr>
<th></th>
<th>Formula</th>

</thead>
<tbody>
<tr>
<td>Compression</td>
<td>0.85 ( f'c ) minus UPL</td>
</tr>
<tr>
<td>Tension</td>
<td>( (3 \times (\text{the square root of } f'c)) ) plus UPL</td>
</tr>
</tbody>
</table>

\( f'c \) is compressive strength of concrete

UPL = Unit Prestress after Losses

(Obtain values from pile manufacturer)

c. Perform a refined Wave Equation Analysis upon completion of the dynamic and static testing programs outlined in this specification section, taking into consideration the evaluated capacities, gain/loss factors and recommended production pile lengths.[ Develop production pile driving criteria based on the results of the refined Wave Equation Evaluations.]

d. All pile driving equipment provided by the Contractor will be subject to the approval of the Contractor's Geotechnical Consultant. Complete the attached pile and driving equipment data form, including hammer information, in full as part of the submittal of the results of the Wave Equation Analyses.

e. Pay for the cost of performing the Wave Equation Analyses and include in the base bid.

]3.1.2 Pile Length Markings

Mark each pile prior to driving with horizontal lines at 305 mm one foot intervals. Mark the interval number on pile every 1.5 2m 5 feet from pile tip.

3.2 PILE DRIVING

3.2.1 Driving Piles

**************************************************************************
NOTE: Delete bracketed option for foundation excavation when not required. Delete items in brackets dealing with tip elevation and driving resistance when test piles or load tests are not used. Delete item in brackets regarding predrilling or jetting when procedure is not used. If needed, insert maximum hammer energy for no tip resistance. This can be determined by comparing tensile stresses in pile resulting from a Wave Equation Analysis with effective prestress in pile.

Notify Contracting Officer 10 days prior to driving of [test] piles[ and load test].[ Stop foundation excavation at 300 mm one foot above foundation grade before piles are driven. Do not drive piles within 30 meter 100 feet of concrete less than 7 days old. Complete excavation to lines and grades shown when pile driving is completed.] Piles may be driven when the specified 28-day concrete strength has been achieved but not less than 7 days after casting.[ The Contractor's Geotechnical Consultant will determine the terminal driving criteria based on results of [dynamic pile driving tests at the end of drive or restrike] [static load tests] [wave equation analysis].] Drive piles to [the terminal driving criteria ] [or below "calculated"] [indicated tip elevation] [to reach a driving resistance established by the [dynamic pile driving tests at the end of drive or restrike] [static load tests] [wave equation analyses (WEAP)] in accordance with the schedule which the [Contractor's Geotechnical Consultant] [Contracting Officer] will prepare from the test-pile driving data. During initial driving and until pile tip has penetrated beyond layers of very soft soil[ or below bottom of predrilled or prejetted holes], use a reduced driving energy of the hammer as required to prevent pile damage. Refusal criteria will be established by the Contracting Officer. If a pile fails to reach ["calculated"] [indicated] tip elevation,[ or if a pile reaches ["calculated"] tip elevation without reaching required driving resistance,] notify Contracting Officer and perform corrective measures as directed. Provide hearing protection when noise levels exceed 140 dB. Do not handle or move piles or pile sections in any manner that would result in cracking or permanent damage to the concrete or to the grout surrounding the prestressing cables. Piles may be driven without pile guides or leads providing a hammer guide frame is used to keep the pile and hammer in alignment.

3.2.2 Protection of Piles

NOTE: Delete references to batter piles when not applicable to the project. Use more stringent criteria as necessary based on the application. Confirm with the structural engineer.

Take care to avoid damage to piles during handling, placing pile in leads, and during pile driving operations. Support piles laterally during driving, but allow rotation in leads.[ Where pile or projecting reinforcement orientation is essential, take precautionary measures to maintain the orientation during driving.][ Take special care in supporting battered piles to prevent excessive bending stresses in pile.] Square top of pile to longitudinal axis of pile. Maintain axial alignment of pile hammer with that of the pile. If the Contractor elects to use a pile head with projecting strands or mild steel reinforcement, prevent direct impact
forces from being transmitted through the reinforcement, by using a special driving head.

3.2.3 Pile Placement and Tolerances in Driving

**************************************************************************
NOTE: Omit references to batter piles when not applicable to the project. Select appropriate tolerances for type of pile.
**************************************************************************
Submit pile placement plans at least 30 days prior to delivery of piles to the job site.

Drive piles with a variation of not more than 2 percent from vertical for plumb piles or more than 4 percent from required angle for batter piles. Maintain and check axial alignment of pile and leads at all times. If subsurface conditions cause pile drifting beyond allowable axial alignment tolerance, notify Contracting Officer and perform corrective measures as directed. Place butts within 100 mm 4 inches of location indicated. Manipulation of piles within specified tolerances will not be permitted. Will be permitted, to a maximum of 1 1/2-percent of their exposed length above ground surface or mudline. In addition to specified tolerances, maintain a location to provide a clear distance of at least 125 mm 5 inches from butt to edge of pile cap. If clear distance can not be maintained, then notify Contracting Officer. Check each pile for heave. Redrive heaved piles to required point elevation.

3.2.4 Rejected Piles

Withdraw piles damaged or impaired for use during handling or driving, mislocated, or driven out of alignment beyond the maximum tolerance. Replace with new piles or cut-off and abandon damaged or impaired piles and drive new piles as directed. Remove excess cut-off from piles and unacceptable piles from the work site. Perform all work in connection with withdrawing and removing rejected piles from the site at no additional cost to the Government.

3.2.5 Jetting of Piles

**************************************************************************
NOTE: Jetting should generally not be permitted for piles:

1. Dependent on side friction in fine-grained low permeability soils (high clay or silt content) where considerable time is required for the soil to reconsolidate around the piles.

2. Subject to uplift or lateral forces.

3. Adjacent to existing structures.

4. In closely spaced clusters unless the load capacity is confirmed by test.
**************************************************************************
Water jets will not be permitted. Use jetting to assist driving piles through strata that cannot be penetrated practicably by use of the hammer
Predrilling of Piles

NOTE: Predrilling should generally not be permitted for piles:

1. Dependent on side friction in fine-grained low permeability soils (high clay or silt content) where considerable time is required for the soil to reconsolidate around the piles.

2. Subject to uplift or lateral forces.

3. Located in cohesionless soils.

4. In closely spaced clusters unless the load capacity is confirmed by test.

Predrilling to remove soil or other material representing the bulk of the volume of the pile to be driven[ will[ not] be permitted][ must be provided].[ The diameter of the hole must not exceed two-thirds the width of the pile].[ Predrill only to a depth of [_____] meters feet below cut-off elevation prior to setting piles].[ Discontinue drilling when the pile tip is approximately 1.5 m 5 feet above the [calculated] [indicated] pile tip elevation. Drive pile the final 1.5 m 5 feet of penetration or more to meet the required driving criteria.]

Pile Splices

NOTE: Splicing of piles normally should not be permitted except where extremely long or heavy piles are required. If splices are permitted, drawings should indicate splice details. (See PCI standard drawings for typical splice details).

[Splicing of piles is not permitted.] [Make splices as indicated. Splices must be capable of developing the full strength of the member in compression, tension, shear, and bending. Submit detail drawings of splices and design calculations demonstrating the strength of the splice for approval. Submit information for shop and field pile splices prior to fabrication.]
3.2.8 Build-Ups

**************************************************************************
NOTE: Insert compressive strength required by design, usually a minimum of 35 MPa 5,000 psi. Insert maximum percent of build-ups permitted for project. The percent will depend on criticality of pile failure at build-up; whether the top of the pile is designed as a moment connection; exposure of piles to external physical or corrosive damage. Normally, for piles supporting piers exposed to seawater, limit percentage of build-ups to 10 percent.
**************************************************************************

Where required, pile section may be extended to cut-off elevation by means of a cast-in-place reinforced concrete build-up. Make build-up in accordance with PCI BDM. Construct build-ups made after completion of driving in accordance with detail "Build-Up Without Driving." Make build-ups to be driven in accordance with detail "Build-Up With Driving." Have details of means for protecting joints by a suitable mortar or epoxy approved by Contracting Officer. Where build-ups are exposed to water, protect cast-in-place section from water during curing period. Concrete in build-up must have a minimum compressive strength of [_____] MPa psi. Build-ups will not be permitted on more than [_____] percent of total number of piles. If this percent figure is exceeded, or if in the judgment of the Contracting Officer, the clustered location of build-ups is undesirable, withdraw piles of insufficient length and replace with longer piles. Payment for such withdrawal and replacement will be made as an adjustment to the contract price.

3.2.9 Pile Cut-Off

Cut-off piles with a smooth level cut using pneumatic tools, sawing, or other suitable methods approved by Contracting Officer. Use of explosives for cutting is not permitted. Remove cut-off sections of piles from the site and off government property upon completion of the work.

3.2.10 Patching

Provide a 25 mm one inch minimum conical depression around embedded lifting loops. Where indicated or directed, cut off lifting loops at bottom of depression and patch depression with epoxy mortar.

3.2.11 As-Driven Survey

After the driving of each pile group is complete and before concrete is placed, provide the Contracting Officer with an as-driven survey showing actual location and top elevation of each pile. Do not proceed with placing concrete until the Contracting Officer has reviewed the survey and verified the safe load for the pile group driven. Present a survey in such form that it gives deviation from plan location in two perpendicular directions and elevations of each pile to nearest 13 mm half inch. Survey must be prepared and certified by a licensed land surveyor.

3.2.12 Protection of Existing Structures

**************************************************************************
NOTE: Include this paragraph only when protection is required.
**************************************************************************
of existing structures from pile driving activities is required.

The designer must indicate on the drawings all structures and facilities for which protection is required. The designer must also provide a project specific document that details design criteria, requirements for preconstruction condition surveys, post construction condition surveys, geotechnical instrumentation to measure ground movements and any other requirements.

Add any additional requirements as necessary.

Mitigate impact on existing facilities due to pile driving activities in accordance with the [project specific document] [______].

3.2.13 Pile Shoe

Submit details about pile shoe used, if any. Where indicated or directed, securely attach pile shoes of an approved design to the piles in a manner described in the detail drawings.

3.3 FIELD QUALITY CONTROL

3.3.1 Test Piles

NOTE: Select the second bracketed option when soil conditions dictate the use of a test pile longer than production piles. The ordered pile length for test piles should be 1.5 m 5 feet longer than ordered length for production piles to allow additional penetration if driving conditions dictate. Indicate location and number (if required) of test piles on plans, or list appropriate soil boring test hole numbers.

[Use test piles of type, and drive as specified for piling elsewhere in this section.] [Order test piles [____] meters feet longer in length than production piles. Drive the additional test pile length only at the direction of the Contracting Officer. ]The [Contractor's Geotechnical Consultant][Contracting Officer] will use test pile data to determine "calculated" pile tip elevation or necessary driving criteria. Drive test piles [at the locations indicated] [in vicinity of soil boring test holes Nos. [____], [____], and [____]]. Drive test piles to [indicated tip elevation] [indicated bidding lengths] [required driving criteria]. Use test piles, if located properly and offering adequate driving resistance in finished work.[ Pre-drilling or jetting is permitted only when test piles clearly establish validity of its use, or as directed by the Contracting Officer.][ Provide and operate a pile driving analyzer as specified in paragraph DYNAMIC PILE ANALYSIS during the driving of each test pile. Modify driving as required based upon recommendation of [Contracting Officer] [Contractor's Geotechnical Consultant and approval of the Contracting Officer].]
[3.3.2 Dynamic Pile Analysis]

Submit a performance report summarizing dynamic test results for test piles within [7] calendar days of completing field work. For production piles, submit a performance report within one day of testing. Submit a typed report summarizing the results of dynamic testing of production piles on a monthly basis.

Dynamic testing provides supplemental information for evaluating pile integrity, hammer and drive system performance, assess pile installation driving stresses, and pile capacities. Perform dynamic testing on [_____] percent of the piles during the full length of the pile driving and during restrike a minimum of [_____] days after initial driving. Dynamic pile testing must also be performed on [_____] production piles as chosen by the Contracting Officer. Use piles of type as specified elsewhere in this section. Provide equipment to obtain dynamic measurements, record, reduce and display its data that meet the requirement of ASTM D4945. The equipment must have been calibrated within [6] months prior to the start of the testing operations and thereafter throughout the contract duration. Drive piles at the locations indicated or at the locations selected by the Contracting Officer. Employ an independent inspection firm, hereinafter referred to as the "Contractor's Geotechnical Consultant", experienced in the pile driving process, [monitoring of test pile installation,] and in the use of the Pile Driving Analyzer and its related equipment. Perform dynamic pile analysis as follows:

3.3.2.1 Pile Analysis

[_____] working days prior to driving the piles, submit the pile and complete driving equipment data to the Contracting Officer. The Contractor's Geotechnical Consultant must use the submitted information to perform wave equation analyses and must prepare a summary report of the wave equation results. The wave equation analysis using GRLWEAP software by Pile Dynamics, Inc. or equivalent must be used to assess the ability of the proposed driving system to install the pile to the required capacity and desired penetration depth within the allowable driving stresses. Approval of the proposed driving system by the Contracting Officer must be based upon the wave equation analyses indicating that the proposed driving system can develop a pile capacity of [_____] KN kips at a driving resistance not greater than [_____] mm/blow blows per inch within allowable driving stress limits. The hammer must also be sized or adjustable such that the penetration per blow at the required ultimate capacity does not exceed 12 mm 0.5 inches.

3.3.2.2 Pile Drivability

Perform each dynamic pile analysis in two steps. The first step is to check the hammer, pile and soil performance, and to determine the suitability of the proposed hammer for the size, length and type of pile being installed for the soil types encountered as the piles are driven. This initial monitoring must determine whether pre-augering or jetting is appropriate, efficiency of the hammer relative to specified efficiency, effectiveness of cushion, level of compressive and tensile stress in pile and extent/location of any pile damage caused by the initial driving. With each blow of the pile, record the information listed below electronically and analyze the information using the Pile Driving Analyzer:

(1) Blow number
(2) Blow rate per minute and stroke.

(3) Input and reflected values of force and velocity.

(4) Value of upward and downward traveling force wave with time.

(5) Maximum and final transferred energy to pile, hammer system efficiency.

(6) Maximum compressive stress, velocity, acceleration and displacement.

(7) Maximum tensile stress in pile.

(8) Pile structural integrity, damage detection, extent and location.

(9) Bearing capacity of pile by Case method.

If the pile, hammer and soil performance evaluation recommends changes to the hammer stroke, pile cushioning, augering or any other aspect for the pile driving operation, incorporate these changes into production pile driving in an effort to control excessive stresses and pile damage. Replace test piles damaged or broken during installation incorporating driving modifications as determined by the Contractor's Geotechnical Consultant and reviewed and approved by the Contracting Officer. Repeat this procedure until allowable tensile and compressive stresses are achieved in the pile and/or pile damage is minimized. Subject selected initial driving records to rigorous computer analysis by the Case Pile Wave Analysis Program (CAPWAP) for determination of resistance distribution, soil resistance and properties, and estimation of anticipated gain/loss factors.

3.3.2.3 CAPWAP

Signal matching analysis by CAPWAP® software of the dynamic pile testing data must be performed on data obtained from the end of initial driving and the beginning of restrike of all control piles. CAPWAP analyses must be performed by an engineer who has achieved Advanced Level or better on the PDI / PDCA Dynamic Measurement and Analysis Proficiency Test for Providers of PDA Testing Services.

Upon completion of[ test] pile driving, allow the piles to set-up for at least [72 hours][_____days]. After evaluation of pile, hammer and soil performance by the Contractor's Geotechnical Consultant, the second step of the dynamic pile analysis may proceed. This portion of the evaluation requires striking the set-up piles a minimum of 20-50 times, or as directed by the Contractor's Geotechnical Consultant using the same hammer which was used for the[ test] pile driving and which will be used for production pile driving. "Warm up" the hammer and make it optimally ready prior to restriking, in order to avoid capacity losses during evaluation of restrike data. Apply maximum hammer energy during restrike in order to fully mobilize the soil resistance. However, exercise care so as to not overstress the pile. In addition to those items listed above, selected restrike driving records (as directed by the Contractor's Geotechnical Consultant are to be subjected to rigorous computer analysis by the Case Pile Wave Analysis Program (CAPWAP) for determination of resistance distribution, soil resistance and properties, and plot of applied load vs. average pile displacement based on the calculated soil properties.
3.3.2.4 Dynamic Load Test Reporting

Upon satisfactory completion of each dynamic load test, submit a minimum of three copies of a Pile Performance Report for the Contractor by the Contractor's Geotechnical Consultant. The submittal must be prepared and sealed by a Professional Engineer registered in [______].

The report for the Dynamic Pile Analysis must contain the following information:

a. Capacity of pile from Case Pile Wave Analysis Program (CAPWAP). Information resulting from analysis of a selected restrike blow.

b. Maximum and final transferred energy, hammer system efficiency during pile installation.

c. Maximum compressive stress, velocity, acceleration and displacement.

d. Maximum tensile stress in pile.

e. Pile structural integrity, damage detection, extent and location.

f. Blows per minute and blow number.

g. Input and reflection values of force and velocity, upward and downward traveling force wave with time.

h. Pile skin friction and toe resistance distribution.

i. Maximum energy transferred to pile.

The maximum allowable pile design load must be proposed by the Contractor's Geotechnical Consultant based upon the results of a satisfactory pile load test conducted on a pile driven as specified herein and must include the effects of load transfer to the soil above the foundation stratum.

Use either a model 8G or PAX Pile Driving Analyzer as manufactured by Pile Dynamics, Inc., of Cleveland Ohio or approved equivalent, for dynamic testing of the pile hammer and for dynamic load testing of the test pile. All equipment necessary for the dynamic monitoring such as sensors, cables or wireless transmitters, etc., must be furnished by the Contractor's Geotechnical Consultant. The equipment must conform to the requirements of ASTM D4945.

Pay for all services of the Contractor's Geotechnical Consultant. The Contractor's Geotechnical Consultant must be available throughout the pile driving operation to consult with the Contracting Officer when required by the Contracting Officer. The cost of changes in the Contractor's procedure, as required by evaluation of the results of the Pile Driving Analysis, will be at the Contractor's expense.

3.3.3 Static Load Tests

**************************************************************************

NOTE: If pile load tests are required and approved by the Contracting Officer, specify number and location of piles. Select method of load test. In ASTM D1143/D1143M, permit anchor piles only if...
Submit test set-up and procedures. Perform compressive load tests on [_____] test piles in accordance with ASTM D1143/D1143M (standard loading procedure) as modified herein. [ Allow a minimum of [72 hours][_____] days following final test pile driving for pile set-up prior to load testing.][ Do not use anchor piles.] Provide apparatus for applying vertical loads as required by method, using load from weighted box or platform (or reaction frame attached to sufficient uplift piles to safely take required load) applied to pile by hydraulic jack. Increase load in increments until rapid progressive settlement takes place or until application of total compressive load of [_____] kN kips for compressive load tests. Consider load test satisfactory when [after one hour at full test load gross settlement of pile butt is not greater than gross elastic pile compression plus 4 mm 0.15 inch plus one percent of pile tip diameter or width in [_____] mm inches,] [slope of gross load-settlement curve under full test load does not exceed 1.5 mm per metric ton 0.05 inches per ton,] [net settlement after removal of test load does not exceed 19 mm 3/4 inch]. Perform load tests at locations [as proposed by the Contractor's Geotechnical Consultant and] as directed by the Contracting Officer. Additional load tests, at Government expense, may be required by the Contracting Officer. Perform the loading, testing, and recording and analysis under the direct supervision of a Registered Professional Engineer, registered in the state of project location, and provided and paid for by the Contractor. [Submit test pile records][ and ][load test data] within [7] [_____] calendar days of test completion.

3.3.3.1 Safe Design Capacity

Determine the safe design capacity of a test pile as determined from the results of load tests according to UFC 3-220-01.

3.3.4 Tensile Load Test

Perform tensile load tests on [_____] test piles in accordance with ASTM D3689/D3689M. Apply a tensile load of [_____] kN kips to each tensile load test pile. In performing the tension load test, apply the ultimate load equal to one and one-half times the safe tension capacity, and employ the Standard Loading Procedure.

Perform load tests at locations [as proposed by the Contractor's Geotechnical Consultant and] as directed by the Contracting Officer. Additional load tests, at Government expense, may be required by the Contracting Officer. Perform the loading, testing, and recording and analysis under the direct supervision of a Registered Professional Engineer, registered in the state of project location, and provided and paid for by the Contractor.

Perform dynamic measurements on [_____] piles designated as dynamic test piles in accordance with ASTM D4945 during driving. During easy driving, ensure that damaging tension stresses do not develop in the pile. Signal matching must be performed by the Contractor's Geotechnical Consultant on representative data collected at the end of the initial driving and at the
beginning of all restrike events. Additional signal matching analysis must be performed as determined by the Engineer.

[3.3.5 Lateral Load Test]

Perform lateral load tests on [_____] piles in accordance with ASTM D3966/D3966M. Lateral load tests must consist of jacking two piles apart with a hydraulic jack, with one pile serving as the reaction pile for the other. Apply a lateral load of [_____] kN kips to each pair of lateral load test piles. Record required movement readings for each pile.

Perform load tests at locations[ as proposed by the Contractor's Geotechnical Consultant and] as directed by the Contracting Officer. Additional load tests, at Government expense, may be required by the Contracting Officer. Perform the loading, testing, and recording and analysis under the direct supervision of a Registered Professional Engineer, registered in the state of project location, and provided and paid for by the Contractor.

[3.3.6 Pile Records]

**************************************************************************
NOTE: Omit reference to load test when not required in project. Omit reference to test piles and "calculated tip elevation" when test piles are not driven. Where special or unusual soil conditions are expected, consultation with the Contracting Officer's Technical Representative (Geotechnical Branch) regarding special engineering supervision of driving, testing, recording and analysis of data for project may be useful.
**************************************************************************

**************************************************************************
NOTE: The Specifier must attach the specifications pile driving log graphic (for all pile driving projects) and the pile driving equipment data form (for projects using PDA) to the end of this specification section.
**************************************************************************

Submit pile [and test pile] records.[ Submit load test data and results.]

Keep a complete and accurate record of each pile driven. Indicate the pile location, deviations from pile location, cross section shape and dimensions, original length, ground elevation, tip elevation, cut-off elevations, [batter alignment,] number of blows required for each 300 mm foot of penetration and number of blows for the last 150 mm 6 inches penetration or fraction thereof [as required] for the "calculated" [driving resistance]. Include in the record the beginning and ending times of each operation during driving of pile, type and size of hammer used, rate of operation, stroke or equivalent stroke for diesel hammer, type of driving helmet, and type and dimension of hammer cushion (capblock) and pile cushion used. Record retap data and unusual occurrences during pile driving such as redriving, heaving, weaving, splicing, obstructions, [jetting,] and any driving interruptions.[ Install an energy monitor on the hammers and record readings every 250 mm of pile installation.] A preprinted pile driving log for recording pile driving data[ and pile driving equipment data form], which can be downloaded at:
[3.3.7 Testing Agency Qualifications]

Engage an independent testing agency qualified according to ASTM C1077 and ASTM E329 for testing indicated. Submit testing agency qualifications to the Contracting Officer for approval.

[3.4 SPECIAL INSPECTION AND TESTING FOR SEISMIC-RESISTING SYSTEMS]

**************************************************************************

NOTE: Include this paragraph only when special inspection and testing for seismic-resisting systems is required by the International Building Code (IBC).

This paragraph will be applicable to both new buildings designed and to existing building seismic rehabilitation designs done according to UFC 1-200-01, "General Building Requirements" and UFC 3-310-04, "Seismic Design for Buildings".

The designer must indicate on the drawings all locations and all features for which special inspection and testing is required in accordance with Chapter 17 of the IBC. This includes indicating the locations of all structural components and connections requiring inspection.

Add any additional requirements as necessary.

**************************************************************************

Perform special inspections and testing for seismic-resisting systems and components in accordance with Section 01 45 35 SPECIAL INSPECTIONS.

[3.5 VIBRATION CONTROL]

**************************************************************************

NOTE: Include this paragraph when vibration monitoring is required. Add any additional criteria or requirements as necessary to the particular project.

**************************************************************************

Perform vibration monitoring at the locations [shown in the plan] [decided by the Contracting Officer] during the pile driving operations. Perform vibration monitoring [using] [seismographs][ and geophones] within a distance of [61] [_____] meters [200] [_____] feet from the pile driving activity.[ Engage the services of a qualified, independent vibration consultant, acceptable to the Government, to conduct the vibration monitoring. The vibration consultant must have minimum of [5] [_____] years of experience in vibration monitoring. A minimum of [28] [_____] days before the installation of vibration monitors, submit to the Government the name of the vibration consultant and a list of at least [three] [_____] previously completed projects of similar scope and purpose.]

Prior to the pile driving activities, obtain baseline readings of ambient vibrations. The vibration during the pile driving activities must be limited to [a peak particle velocity of not more than [5] [_____] cm [2.0] [_____] inches per second.] [the limits mentioned in the [contract
Determine appropriate vibration limits as per [US Bureau of Mines] [American Association of State Highway and Transportation Officials (AASHTO)] guidelines.] During pile driving activities, monitor the vibrations to ensure the limits are not exceeded. If the limits are exceeded, cease the pile driving activity causing the vibration until [the Vibration consultant and the Contracting Officer] are on site to observe the structures nearest to the vibration monitor which has exceeded the limits.

The Contractor must be responsible for all damages resulting from the pile driving operations and must take whatever measures necessary to maintain peak particle velocity within the specified limit. After completion of the project, remove the vibration monitors off the site and off Government property and restore the monitoring locations back to their original condition.

NOISE CONTROL

NOTE: Include this paragraph when noise monitoring is required. Add any additional criteria, references or requirements as necessary to the particular project.

Perform noise monitoring at the locations [shown in the plan] [decided by the Contracting Officer] [at noise sensitive public areas] during the pile driving operations. Perform noise monitoring using [noise meters], [and] [______]. Engage the services of a qualified, independent noise consultant, acceptable to the Government, to conduct the noise monitoring. The noise consultant must have minimum of [5] [______] years of experience in noise monitoring. A minimum of [28] [______] days before the installation of noise monitors, submit to the Government the name of the noise consultant and a list of at least [three] [______] previously completed projects of similar scope and purpose.

Prior to the pile driving activities, obtain baseline readings of ambient noise levels. The noise limits are mentioned in the [plan] [contract documents]. Determine appropriate noise limits as per [local agency] [Occupation Safety and Health Administration] guidelines. During pile driving activities, monitor the noise to ensure the limits are not exceeded. If the limits are exceeded, cease the pile driving activity and install noise mitigation measures.

The Contractor must be responsible for all damages resulting from the pile driving operations and must take whatever measures necessary to maintain noise within the specified limit. After completion of the project, remove the noise monitors off the site and off Government property and restore the monitoring locations back to their original condition.

PRECONSTRUCTION CONDITION SURVEY

NOTE: Add any additional criteria, references or requirements as necessary to the particular project.

Perform preconstruction condition survey of [structures][and utilities] [within [61] [______] meters [200] [______] feet of the pile driving activity][specified in the plans][decided by the Contracting Officer]. Perform outreach to the owner of the structures [28] [______] days before
performing the preconstruction condition survey. The Contractor must obtain written permission from the owner of the structure prior to accessing the structure. The preconstruction condition survey must include video and photographic documentation of the exterior and interior of above ground structures and of the interior of underground structures. Video documentation must be in high definition, and show existing conditions and highlight, where possible, existing cracks, deteriorated concrete, exposed and corroded reinforcement, cracked or broken brick or mortar, and other signs of distress. For utilities, perform the survey when the greatest extent of the interior is exposed. Provide supplementary artificial lighting as needed. The video must include annotation with location and structure nomenclature which describes any areas of distress over the video and time code superimposed on the video. Photographs must be accompanied by sketches or descriptions that indicate the location and direction of each photograph. For each structure surveyed, provide a Pre-Construction Condition Survey Report following completion of the survey. The report must contain all documentation associated with the survey including DVD copies. In the report, include notes, sketches, photographs, and videos. Provide general information, such as location details and structure type, as well as particular information on materials, condition, existing damage, aperture and persistence of cracks, and disrepair observed during visual survey. Provide a graphical depiction of locations of damage or other features of concern. Submit the Preconstruction Condition Survey Reports no later than [28] [_____] days before the commencement of pile driving activity. Accept responsibility for damages to existing adjacent or adjoining structures created by pile driving work, and repair any damages to these structures without cost to the Government.

3.8 CONSTRUCTION INSTRUMENTATION AND MONITORING PROGRAM

NOTE: Include this section if instrumentation is to be installed due to concerns about vibration, settlement, lateral movement, etc. during pile driving activities. Instrumentation should be specified and included in the specification. This section can be deleted if there are no instrumentation requirements.

Add any additional criteria or requirements as necessary for the particular project.

Prepare a geotechnical instrumentation program to monitor settlement[ and lateral movement] of temporary and permanent structures, utilities, [embankments] [and excavations] during pile driving. The design and distribution of instrumentation must demonstrate an understanding of the need, purpose and application of each proposed type.[ Perform noise and vibration monitoring in accordance with NOISE CONTROL and VIBRATION CONTROL sections.]

Monitoring must extend before, during and for a period after completion of construction activities related to pile driving when long-term performance issues are a concern. The monitoring plan must be designed to protect adjacent structures and utilities against damage due to the pile driving activities. Establish limiting values of vertical [and horizontal] movement [and angular distortion] [and vibration] for each structure and utility within the zone of influence, subject to review by the Government.

Prepare a Instrumentation and Monitoring Program Report detailing the
proposed program of instrumentation and monitoring, establishing threshold values of monitored parameters, and describing the response plans that will be implemented when threshold parameters are exceeded. The report must include details about instrumentation consultant's experience, appropriate types, quantities, locations and monitoring frequencies of the instruments.

Upon acceptance of the instrumentation and monitoring program, provide, install and monitor the instrumentation and interpret the data. Submit instrumentation data reports not less than every [_____] days after the monitoring program has begun. Take corrective actions, as necessary, based on the field instrumentation data and as defined in the instrumentation and monitoring program.

Pile and Driving Equipment Data Form

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for post-tensioned, centrifugally cast cylinder piles and prestressed statically cast cylinder piles. Pile reinforcing specified in this guide specification is for steel, special reinforcement materials (i.e., composite, non-magnetic, etc.) should be added on a project by project basis.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

NOTE: The extent and location of the work to be accomplished should be indicated on the project drawings or included in the project specification.
NOTE: Show the following information on the drawings:

1. Locations and design loads on piles. If both tension and compression piles are contained in design, identify by type.

2. Size, shape, and length of piles.

3. Locations, sizes, and number of longitudinal ducts for post tensioned steel. Location, sizes and number of prestressing strands. Unit stresses for post tensioned and prestressing strands or wire.

4. Details of reinforcement and tendons.

5. Details of splices, if required.

6. Locations of test piles, if required.

7. Soil data, where required.

PART 1   GENERAL

NOTE: Structural engineer must confirm the structural capacity of piles and provide specific bending moments, lateral loads and other design requirements for pile design.

1.1 DESCRIPTION

Design, furnish, install and test concrete cylinder piles at the locations indicated on the drawings and specified herein.[Assume test pile[s] will be directed to be placed in [a] location[s] that can be incorporated into the work.][Test piles which meet performance requirements may be incorporated into permanent work.]

1.2 REFERENCES

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard’s Check Reference feature when you add a Reference Identifier (RID) outside of the Section’s Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard’s Check Reference feature to update the issue dates.

References not used in the text will automatically
be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

1.3 SUBSURFACE DATA

Subsurface soil data logs are indicated appended to the special contract requirements provided on the project drawings. The subsoil investigation report may be examined at [______].

1.4 BASIS OF BID

*****************************************************************************************************************************************
NOTE: Select one of the following options:
*****************************************************************************************************************************************

*****************************************************************************************************************************************
NOTE: Use "Lump Sum" paragraph below for lump (principal) sum bidding of piles. Use this in all projects except those where exact pile lengths cannot be practically determined prior to the actual work. Clearly show number of piles, pile capacity, pile locations, and tip and cutoff elevations on the drawings.

Use "Unit Price" paragraph for unit price bidding of piles. Specify unit price bid items for piles only for projects where exact quantities cannot be practically determined prior to the actual work. Determine lengths of piles as accurately as possible, prior to bidding, since the unit price per meter (foot) of the piles varies as the length increases or decreases. Refer to Standard Test Method for High-Strain Dynamic Testing of Deep Foundations (ASTM D4945).
*****************************************************************************************************************************************

1.4.1 Production Pile Acceptance Criteria

Safe design capacity for piles is [_____] KN [_____] kips. Drive piles to [minimum tip elevation] [a minimum depth of [_____] m [_____] feet below cut-off elevation], and to such additional depth as required to obtain a
bearing capacity of not less than [_____] KN [_____] kips. The 
Contractor's Geotechnical Consultant will determine the terminal driving 
criteria based on results of dynamic pile driving tests at end of drive or 
restrike, static load tests, wave equation analysis.

The following formulas can be used in cases where allowable pile loads are 
less than 355 KN 80 kips (determined using a factor of safety of 3 for 
individual piles and 4 for pile groups) and are presented only as a guide 
to aid in establishing the controlling penetration per blow, which, 

\[
R = \frac{2E}{S + 0.1} \text{ For double acting hammers}
\]

\[
R = \frac{2WH}{S + 0.1} \text{ For single acting hammers}
\]

Where \( R \) is the approximate allowable pile load in kips; \( E \) equals the energy 
in foot-kips per blow based on an acceptable certified statement from the 
manufacturer of the hammer; \( W \) equals the weight of the hammer or ram in 
kips; \( H \) equals the height of fall of the hammer of ram in feet; and \( S \) 
equals the average inches of penetration per blow for the last three 
blows. An allowance will be made for reduced penetration caused by shock 
absorption of the cushion or cap blocks.

[1.5 LUMP SUM PAYMENT]

**************************************************************************

NOTE: Use this paragraph for lump-sum contracts, 
consult with Contracting Officer's Technical 
Representative (Geotechnical Branch) on 
applicability of use prior to selection. This 
paragraph will be typically used when there are 1) 
relatively small quantity of piles, 2) allowable 
pile loading is less than 40 tons, and 3) the 
subsurface conditions are well defined. Fill in 
Table I as required selecting columns applicable to 
project. Generally, pile capacity, location, and 
minimum tip elevation are shown on plans. Test 
piles and load tests are not incorporated on lump 
sum contracts. Delete this paragraph for unit-price 
contracts.

**************************************************************************

Base bids upon providing the number, size, capacity, and length of piles as 
indicated on the [drawings.]

<table>
<thead>
<tr>
<th>Location</th>
<th>Number</th>
<th>Size</th>
<th>Capacity</th>
<th>Length (tip to cut-off)</th>
</tr>
</thead>
</table>

Include in the contract price for piling the cost of all necessary 
equipment, tools, material, labor, and supervision required to: deliver, 
handle, install, cut-off, dispose of any cut-offs, and meet the applicable 
contract requirements. The contract price also includes mobilization, 
pre-drilling, and redriving heaved piles. If, in redriving, it is found
that any pile is not of sufficient length to provide the capacity specified, notify the Contracting Officer, who reserves the right to increase or decrease the total length of piles to be furnished and installed by changing the pile locations or elevations, requiring the installation of additional piles, or directing the omission of piles from the requirements shown and specified. Should total number of piles or number of each length vary from that specified as the basis for bidding, an adjustment in the contract price or time for completion, or both, will be made in accordance with the contract documents. Payment for piles will be based on successfully installing piles to both the minimum tip elevation and satisfying the acceptance criteria identified herein. No additional payment will be made for: damaged, rejected, or misplaced piles; withdrawn piles; any portion of a pile remaining above the cut-off elevation; backdriving; cutting off piles; splicing; build-ups; any cut-off length of piles; or other excesses beyond the assumed pile length indicated for which the Contractor is responsible.

[1.6 UNIT PRICES

******************************************************************************

NOTE: Delete this paragraph for lump-sum contracts.

For NAVFAC PAC projects: Where there is unit pricing for piles, use this paragraph and edit applicable attachments for inclusion in Standard Form 1442, "Solicitation, Offer and Award" and "Schedule of Bid Items."

For NAVFAC Southeast projects, where there is a need for unit pricing of piles, include this paragraph. Refer to NAVFAC SE Instruction 00010, "Instructions for Preparing Basis of Bid Statement With Unit-Priced Items," for method of specifying unit price bid items.

******************************************************************************

For unit price bid, see SF 1442, "Solicitation, Offer and Award" and "Schedule of Bid Items."

******************************************************************************

NOTE: For NAVFAC LANT projects, use the following paragraph for measurement and payment and subsequent sub-parts.

******************************************************************************

Requirements of FAR 52.211-18 Variation in Estimated Quantity do not apply to payment for piling. Each pile and test pile acceptably provided will be paid for at the bid unit price per unit length, which will include items incidental to furnishing and driving the piles including mobilization and demobilization, [jetting][ predrilling][ probing], redriving uplifted piles, [an additional 1.5 m 5 feet in furnished length for any test pile not driven beyond estimated pile length,] and cutting off piles at the cut-off elevation. [Include the cost for additional length for the test piles in the total unit price cost for the job.] Payment will be made for production [and test piles] at the bid unit price for the length of pile, from tip to final cut-off, actually provided, excluding buildups and splices directed by the Contracting Officer to be made. If the actual cumulative pile length driven (tip to cut-off) vary more than 25 percent from the total pile length specified as a basis for bidding, at the
direction of the Contracting Officer, the unit price per unit length will be adjusted in accordance with provisions of FAR 52.236-2 Differing Site Conditions. Payments will be made per each at the respective bid unit price for pile cut-offs, pile build-ups, pile loads tests and pile splices. Include payments for vibration monitoring, sound monitoring, construction instrumentation and monitoring, and precondition construction surveys.

1.7 PAYMENT

**************************************************************************
NOTE: This paragraph is tailored for Army. If Section 01 20 00 PRICE AND PAYMENT PROCEDURES is included in the project specifications, this paragraph title (UNIT PRICES) should be deleted from this section and the remaining appropriately edited subparagraphs below should be inserted into Section 01 20 00 PRICE AND PAYMENT PROCEDURES.
**************************************************************************

1.7.1 Furnishing and Delivering Concrete Cylinder Piles

1.7.1.1 Payment

Payment will be made for costs associated with furnishing and delivering the required lengths of permanent concrete cylinder piles, which includes costs of furnishing and delivering piles to the work site. No payment will be made for the driving head or lengths of piles exceeding required lengths. No payment will be made for piles damaged during delivery, storage, or handling to the extent that they are rendered unsuitable for the work, in the opinion of the Contracting Officer.

1.7.1.2 Measurement

Furnishing and delivering permanent concrete cylinder piles will be measured for payment by the linear meter foot of piles required below the cutoff elevation as [determined by the Contracting Officer and furnished to the Contractor] [indicated].

1.7.1.3 Unit of Measure

Linear meter foot.

1.7.2 Driving Concrete Cylinder Piles

1.7.2.1 Payment

Payment will be made for costs associated with driving permanent concrete cylinder piles, which includes costs of handling, driving, [and splicing of piles, ][performing dynamic testing, interpreting data and submitting reports, ]measuring heave, redriving heaved piles, removal of [build-ups ]driving heads or cutting off piles at the cutoff elevation and removing from the work site, compiling and submitting pile driving records, backfilling voids around piles, and any other items incidental to driving piles to the required elevation.

1.7.2.2 Measurement

Permanent concrete cylinder piles will be measured for payment for driving
on the basis of lengths, to the nearest hundredth of a linear meter tenth of a linear foot, along the axis of each pile acceptably in place below the cutoff elevation shown.

1.7.2.3 Unit of Measure

Linear meter foot.

1.7.3 Pulled Concrete Cylinder Piles

1.7.3.1 Payment

Payment will be made for costs associated with piles pulled at the direction of the Contracting Officer and found to be undamaged. The cost of furnishing and delivering pulled and undamaged piles will be paid for at the applicable contract unit price for payment item "Furnishing and Delivering Concrete Cylinder Piles". The cost of driving pulled and undamaged piles will be paid for at the applicable contract unit price for payment item "Driving Concrete Cylinder Piles". The cost of pulling pulled and undamaged piles will be paid for at twice the applicable contract unit price for payment item "Driving Concrete Cylinder Piles", which includes backfilling any remaining void. The cost of redriving pulled and undamaged piles will be paid for at the applicable contract unit price for payment item "Driving Concrete Cylinder Piles". No payment will be made for furnishing, delivering, driving, pulling, and disposing of piles pulled and found to be damaged and backfilling voids. New piles replacing damaged piles will be paid for at the applicable contract unit price for payment items "Furnishing and Delivering Concrete Cylinder Piles" and "Driving Concrete Cylinder Piles".

1.7.3.2 Measurement

Furnishing and delivering pulled and undamaged permanent concrete cylinder piles will be measured for payment as specified in paragraph PAYMENT, subparagraph FURNISHING AND DELIVERING CONCRETE CYLINDER PILES. Pulling undamaged concrete cylinder piles will be measured for payment as specified in paragraph PAYMENT, subparagraph DRIVING CONCRETE CYLINDER PILES. Redriving pulled undamaged concrete cylinder piles will be measured for payment as specified in paragraph PAYMENT, subparagraph DRIVING CONCRETE CYLINDER PILES. New piles replacing damaged piles will be measured for payment as specified in paragraph PAYMENT, subparagraphs FURNISHING AND DELIVERING CONCRETE CYLINDER PILES and DRIVING CONCRETE CYLINDER PILES.

1.7.3.3 Unit of Measure

Linear meter foot.

1.7.4 Concrete Pile Driving Tests

1.7.4.1 Payment

Payment will be made for costs associated with furnishing, delivering, driving, pulling, and disposing of driven test piles; [including splices]; conducting pile driving tests; backfilling voids around piles; compiling pile driving test records[; performing dynamic testing; interpreting data; and submitting reports].
1.7.4.2 Measurement

Concrete pile driving tests will be measured for payment on the basis of the applicable contract unit price per pile driving test.

1.7.4.3 Unit of Measure

Each.

1.7.5 Concrete Cylinder Piles for Load Tests

1.7.5.1 Payment

Payment will be made for costs associated with furnishing, delivering, driving, pulling, and disposing of load test piles [including splices]; backfilling voids around piles; compiling pile driving records; furnishing, fabricating, and mounting of strain rods and protective assembly; furnishing, fabricating, and mounting of instrumentation and instrumentation protective assembly; performing dynamic testing; interpreting data; and submitting reports. No additional payment will be made for load test piles incorporated in the permanent work other than as provided.

1.7.5.2 Measurement

Concrete cylinder piles for load tests will be measured for payment on the basis of the applicable contract unit price per load test pile.

1.7.5.3 Unit of Measure

Each.

1.7.6 Concrete Pile Static Axial Compressive Load Tests

1.7.6.1 Payment

Payment will be made for costs associated with concrete pile static axial compressive load tests in accordance with ASTM D1143/D1143M, including material and labor for fabricating and furnishing load frames; calibrating load cells and hydraulic jacks; furnishing specified test equipment; installing strain rods; placing and removing test loads and test equipment; recording, reducing, and submitting test data; and compiling and submitting pile load test reports. No payment will be made for rejected pile static axial compressive load tests.

1.7.6.2 Measurement

Concrete pile compressive load tests will be measured for payment on the basis of the applicable contract unit price per load test.

1.7.6.3 Unit of Measure

Each.

1.7.7 Concrete Pile Static Tensile Load Tests

1.7.7.1 Payment

Payment will be made for costs associated with concrete pile static tensile...
load tests in accordance with ASTM D3689, including material and labor for fabricating and furnishing load frames; calibrating load cells and hydraulic jacks; furnishing specified test equipment; installing strain rods; placing and removing test loads and test equipment; recording, reducing, and submitting test data; and compiling and submitting pile load test reports. No payment will be made for rejected pile static tensile load tests.

1.7.7.2 Measurement

Concrete pile static tensile load tests will be measured for payment on the basis of the applicable contract unit price per number of tensile load test.

1.7.7.3 Unit of Measure

Each.

][1.7.8 Concrete Pile Lateral Load Tests

1.7.8.1 Payment

Payment will be made for costs associated with concrete pile lateral load tests in accordance with ASTM D3966/D3966M, including material and labor for fabricating and furnishing load frames; calibrating load cells and hydraulic jacks; furnishing specified test equipment; installing inclinometers; placing and removing test loads and test equipment; recording, reducing, and submitting test data; and compiling and submitting pile load test reports. No payment will be made for rejected pile lateral load tests.

1.7.8.2 Measurement

Concrete pile lateral load tests will be measured for payment on the basis of the applicable contract unit price per lateral load test.

1.7.8.3 Unit of Measure

Each.

][1.7.9 Pulled Load Test Concrete Cylinder Piles

1.7.9.1 Payment

Payment will be made for costs associated with load test concrete cylinder piles pulled prior to load testing at the direction of the Contracting Officer and found to be undamaged. The cost of furnishing, delivering, driving, and pulling undamaged load test piles will be paid for at the applicable contract unit price for payment item "Concrete Cylinder Piles for Load Tests". The cost of pulling undamaged load test piles the second time after redriving and testing will be paid for at twice the applicable contract unit price for payment item "Driving Concrete Cylinder Piles". The cost of redriving pulled undamaged load test piles will be paid for at the applicable contract unit price for payment item "Driving Concrete Cylinder Piles". No payment will be made for furnishing, delivering, driving, pulling, and disposing of load test piles pulled at the direction of the Contracting Officer and found to be damaged, unless the pile was damaged due to overdriving at the request of the Engineer. New load test piles replacing damaged piles will be paid for at the applicable contract unit price for payment item "Concrete Cylinder Piles for Load Tests".
1.7.9.2 Measurement

Pulled undamaged load test concrete cylinder piles will be measured for payment as specified in paragraph PAYMENT, subparagraph CONCRETE CYLINDER PILES FOR LOAD TESTS. Pulling undamaged load test concrete cylinder piles the second time after redriving and testing will be measured for payment as specified in paragraph PAYMENT, subparagraph DRIVING CONCRETE CYLINDER PILES. Redriving pulled undamaged concrete cylinder piles will be measured for payment as specified in paragraph PAYMENT, subparagraph DRIVING CONCRETE CYLINDER PILES. New load test concrete cylinder piles replacing damaged piles will be measured for payment as specified in paragraph PAYMENT, subparagraph CONCRETE CYLINDER PILES FOR LOAD TESTS.

1.7.9.3 Unit of Measure

Unit of measure: as specified in paragraph PAYMENT, subparagraphs DRIVING CONCRETE CYLINDER PILES and CONCRETE CYLINDER PILES FOR LOAD TESTS, respectively.

1.7.10 Concrete Pile Splices

1.7.10.1 Payment

Payment will be made for costs associated with concrete pile splices, including all plant, labor, and material required to make the splice.

1.7.10.2 Measurement

Concrete pile splices will be measured for payment on the basis of the applicable contract unit price per pile splice.

1.7.10.3 Unit of Measure

Each.

1.7.11 Pile Driving Shoes

1.7.11.1 Payment

Payment will be made for costs associated with pile driving shoes, including furnishing, delivering, and installing.

1.7.11.2 Measurement

Pile driving shoes will be measured for payment on the basis of the number of pile driving shoes required.

1.7.11.3 Unit of Measure

Unit of measure: each.

1.7.12 Vibration Monitoring

1.7.12.1 Payment

Payment will be made for costs associated with vibration monitoring.
1.7.12.2 Measurement
Vibration monitoring will be measured for payment on the basis of the applicable contract unit price per vibration monitoring point.

1.7.12.3 Unit of Measure
Each.

1.7.13 Sound Monitoring

1.7.13.1 Payment
Payment will be made for costs associated with sound monitoring.

1.7.13.2 Measurement
Sound monitoring will be measured for payment on the basis of the applicable contract unit price per sound monitoring point.

1.7.13.3 Unit of Measure
Each.

1.7.14 Preconstruction Condition Survey

1.7.14.1 Payment
Payment will be made for costs associated with preconstruction condition surveys.

1.7.14.2 Measurement
Preconstruction condition survey will be measured for payment on the basis of the applicable contract unit price per structure to be surveyed.

1.7.14.3 Unit of Measure
Each.

1.7.15 Construction Instrumentation and Monitoring

1.7.15.1 Payment
Payment will be made for costs associated with construction instrumentation and monitoring.

1.7.15.2 Measurement
Construction instrumentation and monitoring will be measured as a single pay item.

1.7.15.3 Unit of Measure
One.

1.8 SUBMITTALS

**************************************************************************
NOTE: Review Submittal Description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.

******************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

1.9 DELIVERY, STORAGE, AND HANDLING

Store, handle, and transport piles in accordance with PCI MNL-116 except as follows. Use methods for handling and storage of piles such that the piles are not subjected to excessive bending stress, cracking, spalling, or other damage. Follow the lifting instructions of the precaster.

1.9.1 Damaged Piles

Inspect each pile for sweep and structural damage such as cracking and spalling before transporting them to the project site and immediately prior to placement in the driving leads. Bring any unusual cracks (cracks other than crazing, surface drying, shrinkage cracks and end cracks) to the attention of the Contracting Officer. Piles which are damaged during delivery, storage, or handling to the extent they are rendered unsuitable for the work, in the opinion of the Contracting Officer, will be rejected and removed from the project site, or may be repaired, if approved, at no cost to the Government.

Correct any pile damaged by reason of internal defects or by improper driving by one of the following methods approved by the Engineer for the pile in question and the Structural Engineer of Record:

a. The pile is withdrawn, if practicable, and replaced by a new and, if necessary, longer pile.

b. One or more replacement piles are driven adjacent to the defective pile.

c. A Pile Dynamic Analysis and low integrity testing must be performed by the Contractor's Geotechnical Consultant to assess the structural integrity of the driven pile(s).

Correct piles driven below the specified butt elevation by one of the following methods approved by the Engineer:

a. The pile is spliced (if approved).

b. A sufficient portion of the footing is extended down to properly embed the pile.

Correct piles driven out of its proper location or out of plumb as approved by the Engineer, by one of the following methods approved by the engineer:

a. One or more replacement piles are driven next to the pile in question.
b. As directed by the structural engineer.

1.9.1.1 Repairable Cracks

Piles with cracks equal to or greater than 0.15 mm 0.006 inches but less than 1.5 mm 0.06 inches may be repaired or rejected at the discretion of the Contracting Officer. As an alternate to pile rejection, the Contractor may submit a proposal to repair deficient piles. Prior to driving, piles must be restored to their required design capacity so that they can perform their intended structural function and achieve long term durability in corrosive environment.

1.9.1.2 Non-Repairable Cracks

Piles with cracks equal to or greater than 1.5 mm 0.06 inches will be rejected.

1.9.2 Pile Sweep

**************************************************************************
NOTE: Sweep and camber typically apply to steel piles. In special cases, this paragraph may apply to precast concrete piles.
**************************************************************************

Limit sweep to the tolerances specified in PCI MNL-116 over the length of the pile. Piles having excessive sweep will be rejected. Piles that develop non repairable cracks due to handling and installation will be rejected.

1.10 QUALITY CONTROL

1.10.1 Piles

**************************************************************************
NOTE: When the size and complexity of project warrants certification by a registered engineer, insert requirements; otherwise delete.
**************************************************************************

Prepare in accordance with ACI SP-66. Indicate placement of reinforcement including tendons. Indicate location of special embedded or attached lifting devices, employment of pick-up points, support points other than pick-up points, and any other methods of pick-up.[ Provide certification by a professional engineer registered in any jurisdiction, that layout and details of reinforcement and tendons conform with that shown on the structural design drawings.]

1.10.2 Quality Control Procedures

Submit the precasting manufacturer's quality control procedures and inspection records established in accordance with PCI MNL-116.

1.10.3 Installation Procedures

a. Submit information on the type of equipment proposed to be used, proposed methods of operation, pile driving plan including proposed sequence of driving, and details of all pile driving equipment and
accessories.

[ b. Provide details of pile driving equipment and a Wave Equation Analysis of pile drivability for selection of the hammer along with a statement of driving procedures. The Wave Equation Analysis is to be completed by the Contractor's Geotechnical Consultant for each test pile location where different subsurface conditions exist and is to include the following information pertaining to the proposed pile driving equipment:

(1) Completed Pile and Driving Equipment Data Form (which can be downloaded at: http://www.wbdg.org/ffc/dod/unified-facilities-guide-specifications-ufgs/forms-graphics-tables), for each proposed pile hammer and pile type combination.

(2) Copies of computer input and output sheets and graphs showing soil resistance versus blow count as well as maximum tension and compression stresses versus blow count. Analysis must be run at the estimated tip elevation as well as other required elevations to define maximum stress levels in the pile during driving.

c. Provide detailed procedures for conducting the dynamic pile load test and equipment to be used for conducting the load test. The detailed description must explain how specific information of pile performance will be evaluated.

] [1.10.4 Contractor's Geotechnical Consultant Documentation

Hire the services of an independent, Registered Professional Geotechnical Engineer, experienced in soil mechanics and Pile Dynamic Analysis, to observe test pile installation and production pile installation as specified herein. The Contractor's Geotechnical Consultant must be independent of the Contractor and have no employee of employer relationship which could constitute a conflict of interest.

Provide instructions and procedures on how the Contractor will assist the Government in the processes of Dynamic Pile Testing and Interior Inspection of Damaged Piles.

] [1.10.5 Concrete Mix Design

Submit a concrete mix design before concrete is placed, for each type of concrete used for the piles. Certify, using a Government-approved independent commercial testing laboratory, that proportioning of mix is in accordance with ACI 211.1 or ACI 318M ACI 318 for specified strength and is based on aggregate data which has been determined by laboratory tests during last 12 months. Submit a complete list of materials including type; brand; source and amount of cement, fly ash, pozzolan, ground slag, and admixtures; and applicable reference specifications. Submit additional data regarding concrete aggregates if the source of aggregate changes. Clearly indicate in submittal where each mix design will be used when more than one mix design is submitted.

] [1.10.6 Load Test Supporting Data

Submit Jack calibration records, a testing arrangement description and diagram, and the proposed loading sequence.
1.10.7 **Silica Fume Manufacturer's Representative**

Provide statement that the manufacturer's representative will be present at plant to ensure proper mix, including high range water reducer (HRWR), and batching methods.

**PART 2   PRODUCTS**

2.1 **PILE MATERIALS**

**************************************************************************

NOTE: Delete sentence in brackets when test piles are not required. Government requires the Contractor to employ a Geotechnical Consultant to determine the calculated tip elevation and provide oversight of piling installation and testing.

**************************************************************************

Provide precast concrete cylinder piles per PCI Journal Volume 38, Number 2 (PCI JR-382). Production of piles must be in accordance with PCI MNL-116. [Order test piles [3] [_____] meters [10] [_____] feet longer in length than production piles.][ Drive the additional test pile length only when based upon the recommendation of the Contractor's Geotechnical Consultant and approved by the Contracting Officer.][ The [Contractor's Geotechnical Consultant] [Contracting Officer] will use test pile data to determine "calculated" pile tip elevation and necessary driving resistance. This information will be given to the Contractor no later than 7 days from receipt of complete test data. Use this list as the basis for ordering the piles. Do not order piles until list is provided by the [Contractor's Geotechnical Consultant] [Contracting Officer].[ Provide test piles [1.5] [_____] meters [5] [_____] feet longer than the bid length.]

2.2 **MATERIALS**

2.2.1 **Cementitious Materials**

Cementitious materials may be portland cement, [blended cement ]or only portland cement in combination with natural pozzolan or fly ash [or ground granulated blast furnace slag ]and conforming to appropriate specifications listed below.

2.2.1.1 **Cement**

**************************************************************************

NOTE: Insert type of cement required. Generally, Types II, or I/II, is preferred. Type I, or Type III with 8 percent maximum C3A and "low alkali" may be used. Do not use Type III in conjunction with silica fume. In very special cases, Type V, "low alkali," which has limited availability, may be used.

**************************************************************************

NOTE: Cement type and quantity of cement required in mix design is dependent upon the environment, soil conditions, need for corrosion protection, and location of piling:

(a) **CHLORIDE PROTECTION:**
Normal Use. In fresh water or air environment, specify Type I or Type II cement. Type III may be permitted provided tricalcium aluminate (C3A) content is limited to 8 percent and it is low alkali.

Marine Use. In soil or water environments, subject to chlorides above 1,000 ppm, within about 300 m (1000 feet) of the ocean or tidal water, specify Type II or Type III (with a maximum tricalcium aluminate (C3A) content of 8 percent and low alkali) cement, a minimum cementitious materials content of 335 kilograms per cubic meter (564 pounds per cubic yard) and a maximum water to cementitious materials ratio of 0.40.

Seawater Exposure. In direct contact with ocean water, specify Type II or Type III (with a maximum tricalcium aluminate (C3A) content of 8 percent and low alkali) cement, a minimum cementitious materials content of 390 kilograms per cubic meter (658 pounds per cubic yard) and a maximum water to cementitious materials ratio of 0.40.

(b) SULFATE RESISTANCE:

A minimum cementitious materials content of 335 kilograms per cubic meter (564 pounds per cubic yard) is recommended.

Normal Use. In soils with negligible amount of sulfate, specify Type I or Type II cement. Type III cement may be permitted provided tricalcium aluminate (C3A) content is limited to 8 percent and it is low alkali.

Moderate Sulfate Exposure. In exposures with moderate sulfate content (between 0.10 and 0.20 percent in soil and less than 1500 ppm in water), specify Type II or Type III (with a maximum tricalcium aluminate (C3A) content of 8 percent and low alkali) cement and a maximum water to cementitious materials ratio of 0.40. Do not use Class C fly ash, blast furnace slag, or silica fume for cement replacement.

Severe Sulfate Exposure. In exposures with high sulfate content (exceeds 0.20 percent in soil or 1500 ppm in water), specify Type V or Type II (with a maximum tricalcium aluminate content of 5 percent) cement, and a maximum water to cementitious materials ratio of 0.40. Do not use Class C fly ash, blast furnace slag, or silica fume for cement replacement.

**************************************************************************

ASTM C150/C150M, [Type I, II, or III [_____] with a maximum alkali content of 0.60 percent; or] ASTM C595/C595M, Type [IP(MS) or IS(MS)] [_____] blended cement except as modified herein.] The blended cement will consist
of a mixture of ASTM C150/C150M cement (with alkali content not exceeding 0.60 percent) and one of the following materials: ASTM C618 pozzolan or fly ash, or ASTM C989/C989M ground iron blast-furnace slag, or ASTM C1240 silica fume. Include in cement certificates test results in accordance with ASTM C150/C150M, including equivalent alkalies indicated in the optional chemical requirements. Use cement with a tricalcium aluminate (C3A) content of less than 8 percent. Do not use Type III cement in conjunction with silica fume.

**************************************************************************

NOTE: Fly ash, pozzolan, and ground iron blast-furnace slag increase durability. They may produce uneven discoloration of the concrete during the early stages of construction, depending upon the type of curing provided. Use Fly ash/pozzolan (loss on ignition not exceeding 3 percent) for frost areas to reduce carbon interference with air entraining admixture. Straight replacement with fly ash or natural pozzolan beyond 15 percent may decrease the concrete's strength gain rate. The following options can help mitigate this slower gain rate: (1) a lower water/cement ratio may be used, (2) partial cement replacement can be completed, e. g., one sack of cement can be replaced by 1.5 sacks of fly ash, as long as the final replacement ratio meets the requirements, and (3) very fine fly ashes or pozzolans (e. g. with average particle sizes below 5 microns) can be used.

**************************************************************************

2.2.1.2 Fly Ash and Pozzolan

**************************************************************************

NOTE: Loss on ignition greater than 3 percent may result in significant variations in air content. The air entrainment admixture content may need to be varied often to maintain the same level of entrained air.

**************************************************************************

ASTM C618, Class N, or F except that the maximum total alkalies will be 3 percent. If the aggregates are reactive the maximum calcium oxide content will be 13.0 percent. Do not use Class C.

2.2.1.3 Ground Iron Blast-Furnace Slag

ASTM C989/C989M, Grade 120.

[2.2.1.4 Silica Fume

**************************************************************************

NOTE: Use silica fume concrete for marine structures where low permeability and enhanced durability are necessary. The silica fume and HRWR additive should be from the same manufacturer. The Contractor and batch plant may need help from the manufacturer. Select weight percentage based on performance required. If used, a replacement of 7 percent is recommended.
NOTE: Use for high durability and low permeability. The initial cost of the concrete will increase, and supervision at the batch plant, finishing, and curing is necessary. A HRWR must be used with silica fume. The slump can be increased 50 to 125 mm 2 to 5 inches without reducing strength. Finishing may be more difficult. Proper curing is essential because there is a tendency for plastic shrinkage cracking.

ASTM C1240, provide silica fume that is a by-product of silicon or ferrosilicon production. Provide percent by weight of the total cementitious materials as indicated in table below.

2.2.2 Water

Fresh, clean, and potable; free from injurious amounts of oils, acids, alkalis, salts, organic materials, or other substances deleterious to concrete or steel.

2.2.3 Aggregates

NOTE: For piles in areas where reactive aggregates
are likely to be supplied, provide for additional tests and certification to insure that reactive aggregates will not be used. While not wholly conclusive, petrographic examination (ASTM C295/C295M), chemical test (ASTM C289), and mortar bar method (ASTM C227) are valuable indicators. While more reliable, the concrete prism test (ASTM C1293) takes 1 to 2 years to complete and is not practical. The accelerated mortar bar method (ASTM C1260) is similarly reliable and takes only 16 days to yield results. In areas where reactive aggregates cannot be avoided, specify use of low alkali cement, and/or cements modified to mitigate alkali-silica reactivity. Service records of concrete made with these materials along with tests should be used in evaluating these materials.

**************************************************************************

NOTE: Include modification to ASTM C33 when reactive aggregates could be encountered. More modifications may be required. Additional tests and certifications may be required in the submittal paragraphs.

**************************************************************************

ASTM C33/C33M[, except as modified herein. Provide aggregate free from any substance which may be deleteriously reactive with alkali in cement in an amount sufficient to cause excessive expansion of concrete]. Do not use dune sand as fine aggregate.) Do not mix, store in same stockpile, or use fine aggregates from different sources of supply in same concrete mix or same structure without approval. The fineness modulus of fine aggregate must be not less than 2.40 or greater than 3.0. For piles that will be exposed to freezing and thawing, fine and coarse aggregate subjected to five cycles of the sodium sulfate soundness test must show a loss not greater than 10 percent. If the selected aggregates fail the soundness test, the Contractor may use the aggregate source, provided concrete specimens made with the aggregates to be used for the piles have a durability factor of not less than 80 based on 300 cycles of freezing and thawing when tested in accordance with ASTM C666/C666M. Prior to pile fabrication, submit certified test reports for the following tests specified in ASTM C33/C33M[, in addition, [twice] [_____] during each shift when the concrete plant is operating, test the gradation of each size of aggregate in accordance with ASTM C136/C136M):

a. Grading
b. Amount of material finer than 75 micrometers No. 200 sieve
c. Organic impurities
d. Soundness
e. Clay lumps and friable particles
f. Coal and lignite
g. Weight of slag
h. Abrasion of coarse aggregate
i. Fineness modulus
j. Reactive aggregates
k. Freezing and thawing

2.2.3.1 Alkali-Silica Reactivity (ASR)

Evaluate and test fine and coarse aggregates to be used in all concrete for alkali-aggregate activity.

Evaluate the fine and coarse aggregates separately, using ASTM C1260. Test results of the individual aggregates must have a measured expansion equal to or less than 0.08 percent at 16 days after casting. Should the test data indicate an expansion of greater than 0.08 percent, the aggregates(s) will be rejected or additional testing, using ASTM C1567 performed as follows: utilize the Contractor's proposed low alkali portland cement[ blended cement] and SCM in combination with the proposed aggregate for the test portioning. The SCM quantity must be determined that will meet all the requirements of these specifications and that will lower the ASTM C1567 expansion to equal or less than 0.08 percent at 16 days after casting.

If the above option does not lower the expansion to less than 0.08 percent at 16 days after casting, reject the aggregate(s) and submit new aggregate sources for retesting. Submit the results of testing to the Contracting Officer for evaluation and acceptance.

2.2.4 Admixtures

******************************************************************************
NOTE: For guidance in use of either water-reducing admixtures, set retarding admixtures, or combination of admixtures, see ACI 543R, "Recommendations for Design, Manufacture, and Installation of Concrete Piles.
******************************************************************************

2.2.5 Prestressing Steel

Use seven-wire stress-relieved or low-relaxation strand conforming to ASTM A416/A416M, Grade 270. Use prestressing steel free of grease, oil, wax, paint, soil, dirt, and loose rust. Do not use prestressing strands or wire having kinks, bends, or other defects.

2.2.6 Reinforcing Steel

******************************************************************************
NOTE: Minimum cover for reinforcing steel in concrete structures is dependent upon the environment, soil conditions, need for corrosion protection, and location of piling. For normal exposure minimum cover is 50 mm 2 inches. For piles exposed to marine conditions (chloride content above
1000 ppm) in or within about 300 m 1000 feet of the ocean or tidal water, use 75 mm 3 inches minimum cover, including chamfered corners. For additional detailed guidance, see following publications: ACI 543R, "Recommendations for Design, Manufacture and Installation of Concrete Piles" (ACI Manual, Part 3); State of California, Department of Public Works, Design Specifications, Volume 1, Bridge Planning and Design Manual, Chapter 6. Piles to be used in a marine environment may receive a protective coating, particularly if the piles are steam cured. The protective coating should be applied to that portion of pile which remains aboveground or water line. Show areas to be protected on drawings.

**************************************************************************
**************************************************************************
NOTE: Insert grade of reinforcement. Specify ASTM A706/A706M reinforcing where welding or bending of reinforcement bars is important. In addition, ASTM A934/A934M may be specified for epoxy coating of reinforcing where extra reinforcement protection is required.
**************************************************************************
**************************************************************************

ASTM A615/A615M, Grade [300 MPa] [420 MPa] [40 ksi] [60 ksi];
ASTM A706/A706M, Grade [420 MPa] [_____ MPa] [60 ksi] [_____ ksi];
ASTM A996/A996M, Grade [420 MPa] [_____ MPa] [60 ksi] [_____ ksi].
Weld reinforcing steel in accordance with AWS D1.4/D1.4M.

2.2.6.1 Spirals and Ties

**************************************************************************
**************************************************************************
NOTE: If project has been designed for epoxy rebar, add ASTM A934/A934M, "Epoxy-Coated Prefabricated Steel Reinforcing Bars" in this paragraph and in the paragraph REFERENCES.
**************************************************************************
**************************************************************************

2.2.7 Grout

Provide cement grout for prestressed piles using materials conforming to requirements stipulated herein for concrete mixes or for post-tensioned piles, PTI M55.1. Use admixtures, if required, known to have no injurious effects on steel or concrete. Do not use admixtures containing calcium chloride. Grout must have a minimum compressive strength of 48 MPa 7,000 psi in 28 days, as determined by testing 50 mm by 50 mm by 50 mm 2 inch by 2 inch by 2 inch cubes.

2.2.8 Joint Sealing Material

Cover the abutting joint surfaces of precast segments by a sealing material of sufficient thickness to fill all voids between the end surface, except at the core holes for the stressing strands and telltales, when brought together under compression as specified. This sealing material must attain a minimum ultimate compressive strength of 48 MPa 7,000 psi in 28 days, and
be as resistant to exposure and weathering as is the concrete.

2.2.9  Epoxy Coating

2.2.10  Pressure Grouting Epoxy

2.2.10.1  Crack Sealer for Pressure Grouting

ASTM C881/C881M, Type IV, Grade 1, Class B or C without filler.

2.2.10.2  Crack Surface Sealer for Pressure Grouting

ASTM C881/C881M, Type IV, Grade 3, Class B or C with mineral filler.

[2.2.11  H-Pile Extensions

Use H-pile extensions for composite prestressed concrete-steel piles of steel conforming to the requirements of [ASTM A36/A36M] [ASTM A572/A572M].

[2.2.12  Pile Driving Points

Use pile driving points of steel conforming to the requirements of ASTM A27/A27M or [ASTM A36/A36M] [ASTM A572/A572M], of the [type] [details] indicated.

2.2.13  Prestressing/Post Tensioning Tendons

ASTM A416/A416M, Grade [1720 MPa] [1860 MPa] [250 ksi] [270 ksi], uncoated, 7 wire, low-relaxation strand or ASTM A886/A886M, Grade [1860 MPa] [_____] MPa] [270 ksi] [_____] ksi], indented, 7 wire, low-relaxation strand (including supplement).

2.3  CONCRETE

2.3.1  Concrete Mix Design

**************************************************************************
NOTE: Insert the specified compressive strength, f'c. A minimum of 48 MPa 7000 psi is normally specified. Consider reducing average overstrength factor to produce a more economical concrete mix design. ACI 318M ACI 318 may be modified for a specified compressive strength, f'c, over 35 MPa 5000 psi to permit a required average compressive strength, f'cr, of f'c plus 4.8 MPa 700 psi. Concrete may be proportioned in accordance with ACI 214R for the probability of one test in 10 falling below the specified compressive strength, f'c, if the mix design reflects actual concrete plant standard deviations and the resulting production concrete conforms to specified requirements. Do not use lightweight or fiber-reinforced concrete.
**************************************************************************

Provide concrete with a minimum specified compressive strength, f'c, of [_____] [7000] psi at 28 days. The minimum cementitious materials content
will be 354 kg per cubic meter 600 pounds per cubic yard of concrete. Prepare the design in accordance with ACI 211.1 and ACI 318M ACI 318. Base the mix design on current materials previously evaluated by the concrete producer whose established methods of statistical quality control is in conformance with ACI 318M ACI 318. In the absence of such data, sample and test the aggregates for the design of concrete. Calcium Nitrite may be added to the mix at a rate of 10 liters per cubic meter 2.0 gallons per cubic yard.

2.3.2 Concrete Mix Design Proportioning

a. Water and cement ratio must be equal to or less than 0.40. If fly ash is used, calculate the water and cement ratio as the weight of water divided by the weight of cement plus 60 percent of the weight of fly ash. If silica fume is used, calculate the water and cement ratio as the weight of water divided by the weight of cement plus the weight of silica fume.

b. Maximum aggregate size must not exceed 19 mm 3/4 inch.

**************************************************************************
NOTE: Air-entrainment may be considered optional only in regions that do not experience freezing temperatures.
**************************************************************************

c. Air-entrainment will be 4.5 to 7.5 percent. Determine air void structure in accordance with ACI 212.3R. Spacing factor must be less than 2.5 mm 0.01 inch, the specific surface area greater than 0.39 square meter per 0.000016 cubic meter 600 square inches per cubic inch of air void volume, and the number of air voids per mm inch of traverse significantly greater than the numerical value of the percentage of air in the concrete.

2.3.3 Trial Mixtures

Make trial mixtures having proportions and consistencies of the proposed mix design to document ability to produce workable concrete which does not segregate or show excessive slump loss characteristics.

2.4 FABRICATION

Fabrication of the concrete cylinder piles, including storage and handling of materials, batching and mixing of concrete, stressing, sampling, testing and recording must follow the guidelines set forth in PCI MNL-116 "Manual for Quality Control for Plants and Production of Precast and Prestressed Products" or the QA/QC procedure established under the ISO 9002 certification program, unless otherwise noted in the specifications or approved by the Contracting Officer. Test piles must be identical to and manufactured by the same firm as the production piles.

2.4.1 Manufacturing of Piles and Pile Sections

The aggregates, cement and water must be proportioned batched by calibrated device and mixed thoroughly by suitable mixing plant to produce consistent and homogeneous concrete.

Full length, pretensioned concrete piles and post-tensioned pile sections can be manufactured by the centrifugal casting process. If this process is
utilized, individual piles and pile sections must be formed and compacted by centrifugal force in a machine of suitable type so designed that the concrete molds may be revolved at speeds sufficient to ensure even distribution and dense packing of concrete without the creation of voids behind reinforcing steel.

Filling the mold and spinning should be continuous and take place before any of the concrete in the mold has taken an initial set. Drain or remove excess water forced to the center prior to curing. Cure the section in the mold until the concrete has attained the indicated strength to prevent deformation or damage during demolding.

Alternatively, concrete cylinder piles can be made by the static cast method. Extruded dry cast method is not allowed for static cast piles.

Manufacturing by the static cast method must utilize rigid steel forms and be vibrated as necessary to ensure that the concrete is consolidated and homogeneous for the entire pile length.

Filling the mold should be continuous and completed for each individual pile before any of the concrete in the mold has taken an initial set. Cure the pile in the mold until the concrete has attained the indicated strength to prevent deformation or damage during demolding. After initial set has occurred, the top form section may be removed to allow finishing of the pour stop along the exterior top face of the pile.

For both fabrication methods, the wall thickness of the pile sections must be as specified on the plans.

2.4.2 Spiral Reinforcing

=================================================================================
NOTE: Minimum cover for reinforcing steel in concrete structures is dependent upon the environment, soil conditions, need for corrosion protection, and location of piling. For normal exposure minimum cover is 50 mm 2 inches. For piles exposed to marine conditions (chloride content above 1000 ppm), use 75 mm 3 inches minimum cover except at corners where 100 mm 4 inches of cover should be provided. In normal and marine conditions, 38 mm 1-1/2 inch cover may be used for post-tensioned, centrifugally cast piles using no-slump concrete, with minimum 9.15 sacks of cement per cubic meter 7 sacks cement per cubic yard. For additional detailed guidance, see following publications: ACI 543R, "Recommendations for Design, Manufacture and Installation of Concrete Piles" (ACI Manual, Part 3); State of California, Department of Public Works, Design Specifications, Volume 1, Bridge Planning and Design Manual, Chapter 6. Piles to be used in a marine environment may receive a protective coating, particularly if the piles are steam cured. The protective coating should be applied to that portion of pile which remains aboveground or water line. Show areas to be protected on drawings. A marine environment is defined as in or within about 300 m 1000 feet of the ocean or tidal water.
=================================================================================
Provide sections with a spiral reinforcement cage, arranged and dimensioned as shown on the contract drawings. This reinforcing cage must be securely held in position during the casting or spinning of the concrete.

Center to center spacing of spiral (defined as spiral pitch) must not exceed six times the spiral wire diameter in the portion of the pile extending from the soffit of the pile cap to a location equal to the point of fixity below mudline as shown on the contract drawings.

The spiral steel reinforcing must be outside the prestress bars and have a minimum concrete cover to the outside surface of the pile section as shown on the contract drawings.[ The spiral steel reinforcing must be outside the tendon ducts and have a minimum concrete cover of 38 mm 1-1/2 inches to the outside surface of the pile section.]

2.4.3 Arrangement of Strands

The number, size, and arrangement of the prestressing strands in accordance with the details shown on the contract drawings.

2.4.4 Curing of Piles

Cure piles using moist or accelerated curing. Curing of piles in accordance with the PCI MNL-116 except as follows.

2.4.4.1 Moist Curing

Moist cure using moist burlap coverings, plastic sheeting, or membrane curing compound until minimum strength to detension is achieved.

2.4.4.2 Accelerated Curing

After placement of concrete, moist cure for a period of 4 hours. Accelerated cure until concrete has reached specified release strength. Enclose casting bed for accelerated curing with a suitable enclosure. During application of steam or heat, increase the air temperature at a rate not to exceed 22 C degrees 40 F degrees per hour. Cure at a maximum temperature of 65 degrees C 150 degrees F until concrete has reached specified release strength. Reduce temperature at a rate not to exceed 11 C degrees 20 F degrees per hour until a temperature of 11 C degrees above ambient air temperature is reached. After accelerated curing, moist cure using either water or membrane curing until a total accelerated and moist curing time of 72 hours is achieved.

2.4.5 Handling

Piles may not be demolded or lifted off from casting beds unless the designed lifting strength or minimum works cube strength of 39.3 MPa 5,700 psi (whichever is greater) has been achieved. Lifting device or crane must be such that no shock or impact is imposed on piles.

Care should be taken at all stages or transporting, lifting and handling to ensure the piles are not damaged or cracked. Piles should be stored on firm stable ground not susceptible to settlement under the weight of piles. Place the piles on strong supports (hard wood) which are truly level and spaced so as to avoid undue bending stress in the piles. The supports should be vertically above one another.
No pile may be driven before the 28-day strength of concrete has been achieved.

2.5 CONCRETE CYLINDER PILE POST-TENSIONED CENTRIFUGALLY CAST (ALTERNATIVE I)

2.5.1 Anchorages and End Fittings

ACI 318|MACI 318, for post-tensioned assemblies.

2.5.2 Forms

Provide forms of metal, braced and stiffened against deformation, accurately constructed, watertight, and supported on unyielding casting beds. Forms must permit movement of pile without damage during release of the prestressing force. Make piles to dimensional tolerances in accordance with PCI MNL-116 and as follows:

a. Location of Reinforcing Steel

   (1) Main Reinforcement: 3 to 6 mm 1/8 to 1/4 inch from position designated on drawings.

   (2) Spacing of Spiral: Plus or minus 13 mm 1/2 inch from position designated on drawings exclusive of concrete cover requirements.

b. Location of Pipe Sleeves from True Position: Plus or minus 10 mm 3/8 inch.

2.5.3 Longitudinal Reinforcement

The number, size, and arrangement of the longitudinal post tensioned tendons in accordance with the details shown on the contract drawings.

The main longitude reinforcement must be fitted symmetrically, equally and continuously spread over the whole length without joint or lap. The main longitudinal post tensioned tendons should be level at the top of the pile and should fit tightly into the pile shoe and end plate.

2.5.4 Spin Casting

The spinning of the whole assembly must follow proven spinning procedure that has been used by the manufacturer in the manufacturing of similar pile sections.

2.5.5 Longitudinal Ducts (holes) for Prestressing Tendons

Details and positioning of ducts (holes) in accordance with PCI MNL-116, and as specified herein. Form longitudinal ducts for the prestressing tendons in the walls of the pile sections during casting. The ducts will be 35 mm 1-3/8 inches (nominal diameter) and positioned so that there is a minimum cover of 38 mm 1-1/2 inches from the edge of the ducts to the outside surface of the pile section.

2.5.6 Concrete Strength

**************************************************************************

NOTE: Specify "assembly strength." Assembly strength of 30 MPa 4000 psi for (Design strength) of 50 MPa 7000 psi or 0.7 of the 28-day design strength

SECTION 31 62 13.24 Page 35
is desirable; however, some regions use 0.8 of the design strength. Check with local pile manufacturers.

The pile sections may not be assembled together into a pile until the compressive strength of the concrete has reached 30 MPa 4,000 psi as determined by cylinders cured in the same manner as the sections.

2.5.7 Alignment of Sections

Position pile sections in accurate alignment so that the axis of the pile does not deviate from a straight line more than 3 mm per 3 m 1/8-inch per 10 feet of length. Position adjacent sections so that the maximum deviation of the outside surface of the joint does not exceed 6 mm 1/4-inch. Where membrane curing is used, remove curing compound from abutting end-surface of sections. Cover the abutting joining surfaces by a joint sealing material of sufficient thickness to fill voids between end surfaces, except at the core holes for the stressing. The pile section must be brought into contact and held together by a force equivalent to not less than 690 kPa 100 psi on the gross concrete area, until the sealing materials has set.

2.5.8 Post Tensioning

Tendons must be tensioned to an allowable unit stress as indicated on the plans. The specified tension will be measured by the gage pressure of the hydraulic stressing jack and verified by the elongation of the steel strand. Provide jack gage calibrated within past 6 months by a laboratory approved by the Contracting Officer. The variation in the actual elongation and the calculated elongation may not be greater than 5 percent. Maintain tension in the tendons by mechanical end-locks or anchors until final stress transfer. Aggregate prestress loss through transfer of stressing force from jack to temporary anchorage may not exceed an average of 10 percent in any one cable or an average of 5 percent for all cables in one pile.

2.5.9 Grouting

After tensioning all tendons, clean each tendon hole and completely fill with grout, including holes not used for tensioning. The pressure of the grout is to be slowly raised to a minimum of 690 kPa 100 psi but not over 1034 kPa 150 psi and held for at least one minute. While the grout is curing, the pile must not be moved or handled in any manner that could damage the pile.

2.5.10 Stress Transfer (Detensioning)

Transfer of the post tension force from temporary end locks to grouted tendons may not be done until the grout has reached a compressive strength of 30 MPa 4,000 psi. Prestressing tendons will be considered to be without slippage from the removal of the end locks when, upon cutting the wires between the end of the pile and the anchor with a burning torch, the wires do not part under stress with a "cup and cone" fracture, but are burned through with the torch. Piles that show evidence of prestressing cable slippage will be rejected.
2.6 CONCRETE CYLINDER PILE PRESTRESSED STATIC CAST (ALTERNATIVE II)

2.6.1 Forms

Use collapsible internal formwork to manufacture piles. Do not use a mandrel to manufacture piles. Provide forms of metal, braced and stiffened against deformation, accurately constructed, watertight, and supported on unyielding casting beds. Forms must permit movement of pile without damage during release of the prestressing force. Make piles to dimensional tolerances in accordance with PCI MNL-116, PCI MNL-135, and as follows:

a. Location of Reinforcing Steel

(1) Main Reinforcement: 3 to 6 mm 1/8 to 1/4 inch from position designated on drawings.

(2) Spacing of Spiral: Plus or minus 13 mm 1/2 inch from position designated on drawings exclusive of concrete cover requirements.

b. Location of Pipe Sleeves from True Position: Plus or minus 10 mm 3/8 inch.

2.6.2 Casting

2.6.2.1 Conveying

Convey concrete to formwork in accordance with PCI MNL-116, and as specified herein. Clean conveying equipment thoroughly before each run. During placing, make any free vertical drop of the concrete less than 0.91 m 3 feet. Remove concrete which has segregated in conveying or placing.

2.6.2.2 Placing and Casting

Perform concrete casting within 3 days after pretensioning steel; however, do not deposit concrete in forms until placement of reinforcement and anchorages has been inspected and approved by pile manufacturer’s quality control representative. Produce each pile of dense concrete straight with smooth surfaces with reinforcement retained in its proper position during fabrication. Use vibrator with heads smaller than the minimum distance between steel for pretensioning. Make surface of pile ends perpendicular to axis of pile. Chamfer, a minimum of [19 mm] [3/4 inch] [ends of piles].

2.6.3 Pretensioning

**************************************************************************
NOTE: Use minimum nominal level of prestress equal to 8.3 MPa 1200 psi in the gross pile section, resulting from the combined prestressing force in the strands after all losses.
**************************************************************************

Perform pretensioning in accordance with PCI MNL-116, and as specified herein. Measure tendon to which steel is to be pretensioned by jack pressure read on a calibrated gage and verify by elongation of steel. Use gage calibrated within last 6 months by a laboratory approved by Contracting Officer. Provide means for measuring elongation of steel to nearest 3 mm 1/8 inch. When difference between results of measurement and gage reading is more than 5 percent, determine cause of discrepancy and correct. Give tensioning steel a uniform prestress prior to being brought
to design prestress. Induce same initial prestress in each unit when several units of prestressing steel in a pile are stretched simultaneously.

2.6.4 Stress Transfer (Detensioning)

**************************************************************************
NOTE: Specify "release strength." Release strength of 30 MPa 4000 psi for (Design strength) of 35 MPa 5000 psi or 0.7 of the 28-day design strength is desirable; however, some regions use 0.8 of the design strength. Check with local pile manufacturers.
**************************************************************************

Perform release of prestressed steel in pretensioned piles in such an order that eccentricity of prestress will be minimized. Gradually release tension in strands from anchorage. Detension after approval by pile manufacturer's quality control representative. Perform transfer of prestressing force when concrete has reached a minimum compressive strength of [_____] MPa [_____] psi.

2.7 FABRICATION TOLERANCES

a. Pile ends must be plane surfaces and perpendicular to the longitudinal axis of the pile with a maximum deviation of 6 mm 1/4-inch per 12 inches at the pile head. End surfaces must also be free of spalls. Any end surface which exhibits more than ten percent of the end surface area spalled to a depth of more than 3 mm 1/8 inch will be rejected.

b. Accumulated deviation from straightness measured along two perpendicular faces of the pile, while not subjected to bending (sweep), must not exceed 3 mm per 1 m 1/8-inch per 10 feet of length.

c. Overall lengths of individual piles must be within 0.3 percent of the overall length specified.

d. The outside diameter of piles is defined as the average of two measurements taken along the axes at right angles to each other on cross section. The wall thickness is defined as the average of four measurements taken along pile axes at right angles to each other in a cross section:

<table>
<thead>
<tr>
<th>Cross Sectional Dimensions</th>
<th>Tolerances</th>
</tr>
</thead>
<tbody>
<tr>
<td>nominal outside diameter</td>
<td>minus 3 mm to plus 6 mm minus 1/8-inch to plus 1/4-inch</td>
</tr>
<tr>
<td>wall thickness of hollow section</td>
<td>minus 3 mm to plus 10 mm minus 1/8-inch to plus 3/8-inch</td>
</tr>
</tbody>
</table>

[2.8 PROTECTION FROM FREEZING]

For cylinder piles exposed to freezing, provide precast drain holes through pile wall at approximate ground water elevation and fill pile with free-draining material. For piles standing in open water, place a concrete plug from lowest freeze depth to a minimum of 300 mm one foot above maximum high-water level and provide precast drain holes through pile wall just above surface of concrete plug.
2.9 PRODUCT QUALITY CONTROL

Where piling is manufactured in a plant with an established quality control program as attested to by a current certification in the PCI "Certification Program for Quality Control" or the QA/QC procedure established under the ISO 9002 certification program, perform product quality control in accordance with PCI MNL-116 or ISO 9002, respectively. Where piling is manufactured by specialists or in plants not currently enrolled in the PCI "Certification Program for Quality Control," or the QA/QC procedure established under the ISO 9002 certification program, set-up a product quality control system in accordance with PCI MNL-116 or ISO 9002 and perform concrete and aggregate quality control testing using an independent commercial testing laboratory approved by the Contracting Officer in accordance with the following.

2.9.1 Aggregate Tests

Take samples of fine and coarse aggregate at concrete batch plant and test. Perform mechanical analysis (one test for each aggregate size) in accordance with ASTM C136/C136M. Tabulate results of tests in accordance with ASTM C33/C33M.

2.9.2 Slump and Strength Tests

Sample concrete in accordance with ASTM C172/C172M at time concrete is deposited for each production line. Perform slump tests in accordance with ASTM C143/C143M. Mold cylinders in accordance with ASTM C31/C31M. Mold at least six cylinders per day or one for every \( 15 \) cubic meter or \( 45 \) cubic yards of concrete placed, whichever is greater. Cure cylinders in same manner as piles and for accelerated curing, place at coolest point in casting bed. Perform strength tests in accordance with ASTM C39/C39M.

Test two cylinders of each set at 7 days or 14 days, or at a time for establishing transfer of prestressing force (release strength) and removal of pile from forms. Test remaining cylinders of each set 28 days after molding.

2.9.3 Compressive Strength Test Results

Evaluate compressive strength test results at 28 days in accordance with ACI 214R using a coefficient of variation of 10 percent. Evaluate strength of concrete by averaging test results of each set of standard cylinders tested at 28 days. Not more than 10 percent of individual cylinders tested may have a compressive strength less than specified design strength.

2.9.4 Changes in Proportions

If, after evaluation of strength test results, compressive strength is less than specified compressive strength, make adjustments in proportions and water content and changes in temperature, moisture, and curing procedures as necessary to secure specified strength. Submit changes in mix design to Contracting Officer in writing.

2.9.5 Chloride Ion Concentration

Sampling and determination of water-soluble chloride ion content in accordance with ASTM C1218/C1218M. Maximum water soluble-chloride ion concentrations in hardened concrete at ages from 28 to 42 days contributed from the ingredients including water, aggregates, cementitious materials, and admixtures must not exceed 0.06 percent by weight of cement.
2.9.6 Chloride Ion Penetration

To ensure the durability of concrete in marine environment, concrete must be proportioned to have the chloride ion penetration test in accordance with ASTM C1202, and be below 3,000 coulombs for concrete specimens tested at 60 days. Alternatively, a ponding test in accordance with AASHTO T 259 may be performed to validate chloride ion penetration in accordance with ASTM C1202.

2.9.7 Destructive Pile Testing

At the beginning of production, produce three additional piles with the same length as production piles which will be randomly selected by the Contracting Officer for testing by taking core samples. Take three core samples each location at 2.4 m 8 feet from head and toe and at mid length of the pile or as directed by the Contracting Officer for a total of 9 core samples per pile. Visually inspect each sample for evidence of segregation and distribution of reinforcements. Test all core samples for compressive strength according to ASTM C42/C42M. The average compressive strength of any three consecutively tested samples must not be less than 85 percent of specified 28-day compressive strength of concrete. If any of the above requirements for segregation, distribution of reinforcement and strength are not met, all production piles produced until the date of testing will be subject to rejection.

In addition to the above, saw cut each pile into three equal length sections. Each section will be inspected for specified dimension, strand placement and clear cover tolerances.

2.10 MATERIAL SUSTAINABILITY CRITERIA

For materials used, where applicable and to extent allowed by performance criteria, provide and document the following in accordance with Section 01 33 29 SUSTAINABILITY REQUIREMENTS AND REPORTING:

a. Recycled content for fly ash and pozzolan
b. Recycled content for Ground Iron Blast-Furnace Slag
c. Recycled content for Silica Fume
d. Minimum [75 percent] [_____] recycled content for steel used for stressed tendon reinforcing

2.11 PILE DRIVING EQUIPMENT

Submit descriptions of pile driving equipment, including hammers, power packs, driving helmets, hammer cushions, pile cushions, leads, extractors, jetting equipment, and preboring equipment at least 30 days prior to commencement of work. Provide Pile Driving Equipment as mentioned in this section.

2.11.1 Pile Hammers

Provide a hammer capable of developing the indicated ultimate pile capacity at blow count less than 100 per 300 mm foot considering hammer impact velocity; ram weight; stiffness of hammer and pile cushions; cross section, length, and total weight of pile; and character of subsurface material to
be encountered. Use the same pile hammer, operating at the same rate and in the same manner, as that used for driving test piles. Use wave equation analysis to verify that the hammer will develop stresses within acceptable limits in the piles. At final driving, operate pile hammer in accordance with manufacturer's recommendation. Provide the plant and equipment for air hammers that have sufficient capacity to maintain, under working conditions, the pressure at the hammer specified by the manufacturer. The hose connecting the compressor with the hammer must be at least the minimum size recommended by the Manufacturer. Evaluate hammer performance at the end of driving by measuring blows per minute and comparing with the manufacturer's recommendations. Measure impact velocity of open-end (single acting) diesel hammers at all times during pile driving operations with a device for this purpose. If such a device is not available, obtain the stroke by measuring the speed of operation either manually or with a device that makes the measurement automatically. Equip closed-end (double acting) diesel hammers with a bounce chamber pressure gauge in good working order, mounted near ground level so as to be easily read by the Contracting Officer. Provide a correlation chart of bounce chamber pressure and potential energy. Equip hydraulic hammers with a system for measurement of ram energy. The system must be in good working order and the results easily and immediately available to the Engineer.

2.11.2 Driving Helmets and Cushion Blocks

2.11.2.1 Driving Helmets or Caps and Pile Cushions

Use a steel driving helmet or cap including a pile cushion between top of pile and driving helmet or cap to prevent impact damage to pile. Use a driving helmet or cap and pile cushion combination capable of protecting pile head, minimizing energy absorption and dissipation, and transmitting hammer energy uniformly over top of pile. Provide driving helmet or cap that fits sufficiently loose around top of pile so that pile may be free to rotate without binding within driving helmet. During test pile installation, demonstrate to satisfaction of Contracting Officer that equipment to be used on project performs specified function. Use pile cushion of solid wood or of laminated construction using plywood, softwood or hardwood boards with grain parallel to end of pile. Select the pile cushion thickness placed on the pile head prior to driving by wave equation analysis so that the limiting driving stresses are not exceeded. Replace pile cushion at the start of driving of each pile and when it becomes highly compressed, charred or burned, or has become spongy or deteriorated in any manner. Show details of driving helmets, capblocks (hammer cushions), and pile cushions. Submit 2 weeks prior to [test] pile installation.

2.11.2.2 Hammer Cushion or Capblock

**************************************************************************
NOTE: Select either wood or aluminum/micarta capblock. Delete inappropriate sentences. An aluminum/micarta capblock is recommended because of its consistent elastic properties and long life. If final pile penetration resistance is based on a Wave Equation analysis, the type of capblock used should be the same as that used in the analysis.
**************************************************************************

Use a hammer cushion or capblock between driving helmet or cap and hammer ram consisting of [a solid hardwood block with grain parallel to the pile...
axis and enclosed in a close-fitting steel housing][ aluminum and micarta (or equal) discs stacked alternately in a steel housing or a suitable polymer designed for this specific purpose as indicated by the hammer manufacturer]. Use steel plates at top and bottom of capblock (hammer cushion).[ Replace wood capblock (hammer cushion) when it becomes highly compressed, charred or burned or becomes spongy or deteriorated in any manner].[ Replace aluminum, micarta or polymer discs that have become damaged, split or deteriorated in any manner.[ Do not replace wood capblock (hammer cushion) during final driving of any pile.] Do not use small wood blocks, wood chips, rope or other materials that permit excessive loss of hammer energy.

PART 3 EXECUTION

*****************************************************************************************************************************************
NOTE: In some cases, cylinder piles may be advanced using a collapsible auger inside the pile and washing the pile section down. In other cases, large diameter piles have been assembled by stacking precast rings and post tensioning them together.
*****************************************************************************************************************************************

3.1 PRELIMINARY WORK

3.1.1 Wave Equation Analysis of Pile Drivability

a. Prior to driving any pile, submit a pile Wave Equation Analysis, performed by Contractor's Geotechnical Consultant, for each size pile and distinct subsurface profile condition. These analyses must take into account the proposed hammer assembly, pile cap block and cushion characteristics, the pile properties and estimated lengths and the soil properties anticipated to be encountered throughout the installed pile length based on static capacity analysis with consideration of driving gain/loss factors. Only one specific model of pile hammer may be used for each pile type and capacity.

b. Demonstrate using the Wave Equation Analysis that the piles will not be damaged during driving, indicate that the driving stresses will be maintained within the limits below and indicate the blow count necessary to achieve the required ultimate static pile capacities.

<table>
<thead>
<tr>
<th>Allowable Driving Stresses</th>
</tr>

<tbody>
<tr>
<td>Concrete</td>
</tr>
<tr>
<td>Compression</td>
</tr>
<tr>
<td>Tension</td>
</tr>
</tbody>
</table>

f'c is compressive strength of concrete
UPL = Unit Prestress after Losses (Obtain values from pile manufacturer)

Perform a refined Wave Equation Analysis upon completion of the dynamic and static testing programs outlined in this specification section, taking into consideration the evaluated capacities, gain/loss factors and recommended production pile lengths.[ Develop production pile driving criteria based on the results of the refined Wave Equation Evaluations.]
d. All pile driving equipment provided by the Contractor will be subject to the approval of the Contractor's Geotechnical Consultant. Complete the attached pile and driving equipment data form, including hammer information, in full as part of the submittal of the results of the Wave Equation Analyses.

e. Pay for the cost of performing the Wave Equation Analyses and include in the base bid.

3.1.2 Pile Length Markings

Mark each pile prior to driving with horizontal lines at 305 mm one foot intervals. Mark the interval number on pile every 1.52 m 5 feet from pile tip.

3.2 PILE DRIVING

3.2.1 Driving Piles

**************************************************************************

NOTE: Delete bracketed option for foundation excavation when not required. Delete items in brackets dealing with tip elevation and driving resistance when test piles or load tests are not used. Delete item in brackets regarding predrilling or jetting when procedure is not used. If needed, insert maximum hammer energy for no tip resistance. This can be determined by comparing tensile stresses in pile resulting from a Wave Equation Analysis with effective prestress in pile.

**************************************************************************

Notify Contracting Officer 10 days prior to driving of [test ]piles[ and load test]. Stop foundation excavation at 300 mm one foot above foundation grade before piles are driven. Do not drive piles within 30 meter 100 feet of concrete less than 7 days old. Complete excavation to lines and grades shown when pile driving is completed.] Piles may be driven when the specified 28-day concrete strength has been achieved but not less than 7 days after casting.[ The Contractor's Geotechnical Consultant will determine the terminal driving criteria based on results of [dynamic pile driving tests at the end of drive or restrike] [static load tests] [wave equation analysis].] Drive piles to [the terminal driving criteria] [or below "calculated"] [indicated tip elevation] [to reach a driving resistance established by the [dynamic pile driving tests at the end of drive or restrike] [static load tests] [wave equation analyses (WEAP)] in accordance with the schedule which the [Contractor's Geotechnical Consultant] [Contracting Officer] will prepare from the test-pile driving data]. During initial driving and until pile tip has penetrated beyond layers of very soft soil [or below bottom of predrilled or prejetted holes], use a reduced driving energy of the hammer as required to prevent pile damage. Refusal criteria will be established by the Contracting Officer. If a pile fails to reach ["calculated"] [indicated] tip elevation, [or if a pile reaches ["calculated"] tip elevation without reaching required driving resistance,] notify Contracting Officer and perform corrective measures as directed. Provide hearing protection when noise levels exceed 140 dB. Do not handle or move piles or pile sections in any manner that would result in cracking or permanent damage to the concrete or to the grout surrounding the prestressing cables. Piles may be
driven without pile guides or leads providing a hammer guide frame is used to keep the pile and hammer in alignment.

3.2.2 Protection of Piles

**************************************************************************
NOTE: Delete references to batter piles when not applicable to the project.
**************************************************************************

Take care to avoid damage to piles during handling, placing pile in leads, and during pile driving operations. Support piles laterally during driving, but allow rotation in leads.[ Where pile or projecting reinforcement orientation is essential, take precautionary measures to maintain the orientation during driving.][ Take special care in supporting battered piles to prevent excessive bending stresses in pile. ] Square top of pile to longitudinal axis of pile. Maintain axial alignment of pile hammer with that of the pile. If the Contractor elects to use a pile head with projecting strands or mild steel reinforcement, prevent direct impact forces from being transmitted through the reinforcement, by using a special driving head.

3.2.3 Pile Placement and Tolerances in Driving

**************************************************************************
NOTE: Omit references to batter piles when not applicable to the project. Select appropriate tolerances for type of pile. Use more stringent criteria as necessary based on the application. Confirm with the structural engineer.
**************************************************************************

Submit pile placement plans at least 30 days prior to delivery of piles to the job site. Drive piles with a variation of not more than 2 percent from vertical for plumb piles or more than 4 percent from required angle for batter piles. Maintain and check axial alignment of pile and leads at all times. If subsurface conditions cause pile drifting beyond allowable axial alignment tolerance, notify Contracting Officer and perform corrective measures as directed. Place butts within 100 mm 4 inches of location indicated.[ Manipulation of piles within specified tolerances[ will not be permitted.][ will be permitted, to a maximum of 1-1/2-percent of their exposed length above ground surface or mudline.]] In addition to specified tolerances, maintain a location to provide a clear distance of at least 125 mm 5 inches from butt to edge of pile cap. If clear distance can not be maintained, then notify Contracting Officer. Check each pile for heave. Redrive heaved piles to required point elevation.

3.2.4 Rejected Piles

Withdraw piles damaged or impaired for use during handling or driving, mislocated, or driven out of alignment beyond the maximum tolerance. Replace with new piles or cut-off and abandon damaged or impaired piles and drive new piles as directed. Remove excess cut-off from piles and unacceptable piles from the work site. Perform all work in connection with withdrawing and removing rejected piles from the site at no additional cost to the Government.
3.2.5 Jetting of Piles

**NOTE:** Jetting should generally not be permitted for piles:

1. Dependent on side friction in fine-grained low permeability soils (high clay or silt content) where considerable time is required for the soil to reconsolidate around the piles.

2. Subject to uplift or lateral forces.

3. Adjacent to existing structures.

4. In closely spaced clusters unless the load capacity is confirmed by test.

Water jets will not be permitted. Use jetting to assist driving piles through strata that cannot be penetrated practicably by use of the hammer alone. Restrict driving to a static weight while water is being injected to prevent inducing tensile stresses in the piles which damage the concrete. Discontinue jetting and resume hammer driving after the penetration of the strata requiring jetting has been accomplished. Discontinue jetting when the pile tip is approximately 1.5 m 5 feet above the [calculated] pile tip elevation. Drive pile the final 1.5 m 5 feet of penetration or more to meet the required driving criteria. Take adequate measures for collecting and disposing of runoff water. Jetting method and equipment will be approved by the Contracting Officer prior to commencing jetting operation. Before starting final driving, firmly seat piles in place by application of a number of reduced energy hammer blows. Employ measures, including use of a silt curtain, to contain turbid water created by jetting piles.

3.2.6 Predrilling of Piles

Predrilling to remove soil or other material representing the bulk of the volume of the pile to be driven will not be permitted. The diameter of the hole must not exceed two-thirds the width of the pile. Predrill only to a depth of [_____] meters feet below cut-off elevation prior to setting piles. Discontinue drilling when the pile tip is approximately 1.5 m 5 feet above the [calculated] pile tip elevation. Drive pile the final 1.5 m 5 feet of penetration or more to meet the required driving criteria.

3.2.7 Pile Splices

**NOTE:** Splicing of piles normally should not be permitted except where extremely long or heavy piles are required. If splices are permitted, drawings should indicate splice details. (See PCI standard drawings for typical splice details).

Splicing of piles is not permitted. Make splices as indicated. Splices must be capable of developing the full strength of the member in compression, tension, shear, and bending. Submit detail drawings of
splices and design calculations demonstrating the strength of the splice for approval. Submit information for shop and field pile splices prior to fabrication.

3.2.8 Build-Ups

******************************************************************************
NOTE: Insert compressive strength required by design, usually a minimum of 35 MPa 5,000 psi. Insert maximum percent of build-ups permitted for project. The percent will depend on criticality of pile failure at build-up; whether the top of the pile is designed as a moment connection; exposure of piles to external physical or corrosive damage. Normally, for piles supporting piers exposed to seawater, limit percentage of build-ups to 10 percent.
******************************************************************************

Where required, pile section may be extended to cut-off elevation by means of a cast-in-place reinforced concrete build-up. Make build-up in accordance with PCI BDM. Construct build-ups made after completion of driving in accordance with detail, "Build-Up Without Driving." Make build-ups to be driven in accordance with detail "Build-Up With Driving." Have details of means for protecting joints by a suitable mortar or epoxy approved by Contracting Officer. Where build-ups are exposed to water, protect cast-in-place section from water during curing period. Concrete in build-up must have a minimum compressive strength of [_____] MPa psi. Build-ups will not be permitted on more than [_____] percent of total number of piles. If this percent figure is exceeded, or if in the judgment of the Contracting Officer, the clustered location of build-ups is undesirable, withdraw piles of insufficient length and replace with longer piles. Payment for such withdrawal and replacement will be made as an adjustment to the contract price.

3.2.9 Pile Cut-Off

Cut-off piles with a smooth level cut using pneumatic tools, sawing, or other suitable methods approved by Contracting Officer. Use of explosives for cutting is not permitted. Remove cut-off sections of piles from the site and off government property upon completion of the work.

3.2.10 As-Driven Survey

After the driving of each pile group is complete and before concrete is placed, provide the Contracting Officer with an as-driven survey showing actual location and top elevation of each pile. Do not proceed with placing concrete until the Contracting Officer has reviewed the survey and verified the safe load for the pile group driven. Present a survey in such form that it gives deviation from plan location in two perpendicular directions and elevations of each pile to nearest 13 mm half inch. Survey must be prepared and certified by a licensed land surveyor.

3.2.11 Protection of Existing Structures

******************************************************************************
NOTE: Include this paragraph only when protection of existing structures from pile driving activities is required.
Indicate on the drawings all structures and facilities for which protection is required. Also provide a project specific document that details design criteria, requirements for preconstruction condition surveys, post construction condition surveys, geotechnical instrumentation to measure ground movements and any other requirements.

Add any additional requirements as necessary.

Mitigate impact on existing facilities due to pile driving activities in accordance with the [project specific document] [______].

3.2.12 Pile Shoe

Submit details about pile shoe used, if any. Where indicated or directed, securely attach pile shoes of an approved design to the piles in a manner described in the detail drawings.

3.3 FIELD QUALITY CONTROL

3.3.1 Test Piles

**NOTE:** Select the second bracketed option when soil conditions dictate the use of a test pile longer than production piles. The ordered pile length for test piles should be 1.5 m 5 feet longer than ordered length for production piles to allow additional penetration if driving conditions dictate. Indicate location and number (if required) of test piles on plans, or list appropriate soil boring test hole numbers.

[Use test piles of type, and drive as specified for piling elsewhere in this section.][ Order test piles [______] meters feet longer in length than production piles. Drive the additional test pile length only at the direction of the Contracting Officer.] The [Contractor's Geotechnical Consultant] [Contracting Officer] will use test pile data to determine "calculated" pile tip elevation or necessary driving criteria. Drive test piles [at the locations indicated] [in vicinity of soil boring test holes Nos. [______], [______], and [______]]. Drive test piles to [indicated tip elevation] [indicated bidding lengths] [required driving criteria]. Use test piles, if located properly and offering adequate driving resistance in finished work.[ Pre-drilling or jetting is permitted only when test piles clearly establish validity of its use, or as directed by the Contracting Officer.][ Provide and operate a pile driving analyzer as specified in paragraph DYNAMIC PILE ANALYSIS during the driving of each test pile. Modify driving as required based upon recommendation of [Contracting Officer] [Contractor's Geotechnical Consultant and approval of the Contracting Officer].]

3.3.1.1 Dynamic Pile Analysis

Submit a performance report summarizing dynamic test results for [test]
piles within [7] [_____] calendar days of completing field work. [For production piles, submit a performance report within one day of testing. Submit a typed report summarizing the results of dynamic testing of production piles on a monthly basis.]

Dynamic testing provides supplemental information for evaluating pile integrity, hammer and drive system performance, assess pile installation driving stresses, and pile capacities. Perform dynamic testing on [_____] percent of the [_____] piles during the full length of the pile driving and during restrike a minimum of [_____] days after initial driving. Dynamic pile testing may also be performed on [_____] production piles as chosen by the Contracting Officer. Use [test] piles of type as specified elsewhere in this section. Provide equipment to obtain dynamic measurements, record, reduce and display its data that meet the requirements of ASTM D4945. The equipment must have been calibrated within [6] [_____] months prior to the start of the testing operations and thereafter throughout the contract duration. Drive [test] piles at the locations indicated or at the locations selected by the Contracting Officer. Employ an independent inspection firm, hereinafter referred to as the "Contractor's Geotechnical Consultant", experienced in the pile driving process[, monitoring of test pile installation,] and in the use of the Pile Driving Analyzer and its related equipment. Perform dynamic pile analysis as follows:

3.3.1.2 Pile Analyzing

[_____] working days prior to driving the [test] piles, submit the pile and complete driving equipment data to the Contracting Officer. The Contractor's Geotechnical Consultant must use the submitted information to perform wave equation analyses and prepare a summary report of the wave equation results. The wave equation analysis using GRLWEAP software by Pile Dynamics, Inc. or equivalent must be used to assess the ability of the proposed driving system to install the pile to the required capacity and desired penetration depth within the allowable driving stresses. Approval of the proposed driving system by the Contracting Officer will be based upon the wave equation analyses indicating that the proposed driving system can develop a pile capacity of [_____] KN kips at a driving resistance not greater than [_____] blows per mm blows per inch within allowable driving stress limits. The hammer must also be sized or adjustable such that the penetration per blow at the required ultimate capacity does not exceed 12 mm 0.5 inches.

3.3.1.3 Pile Drivability

Perform each dynamic pile analysis in two steps. The first step is to check the hammer, pile and soil performance, and to determine the suitability of the proposed hammer for the size, length and type of pile being installed for the soil types encountered as the piles are driven. This initial monitoring will determine whether pre-augering or jetting is appropriate, efficiency of the hammer relative to specified efficiency, effectiveness of cushion, level of compressive and tensile stress in pile and extent/location of any pile damage caused by the initial driving. With each blow of the pile, record the information listed below electronically and analyze the information using the Pile Driving Analyzer:

a. Blow number

b. Blow rate per minute and stroke.

c. Input and reflected values of force and velocity.

SECTION 31 62 13.24 Page 48
d. Value of upward and downward traveling force wave with time.
e. Maximum and final transferred energy to pile, hammer system efficiency.
f. Maximum compressive stress, velocity, acceleration and displacement.
g. Maximum tensile stress in pile.
h. Pile structural integrity, damage detection, extent and location.
i. Bearing capacity of pile by Case method.

If the pile, hammer and soil performance evaluation recommends changes to
the hammer stroke, pile cushioning, augering or any other aspect for the
pile driving operation, incorporate these changes into production pile
driving in an effort to control excessive stresses and pile damage.
Replace test piles damaged or broken during installation, incorporating
driving modifications as determined by the Contractor's Geotechnical
Consultant and reviewed and approved by the Contracting Officer. Repeat
this procedure until allowable tensile and compressive stresses are
achieved in the pile and pile damage is minimized. Subject selected
initial driving records to rigorous computer analysis by the Case Pile Wave
Analysis Program (CAPWAP) for determination of resistance distribution,
soil resistance and properties, and estimation of anticipated gain/loss
factors.

3.3.1.4 CAPWAP

Signal matching analysis by CAPWAP software of the dynamic pile testing
data will be performed on data obtained from the end of initial driving and
the beginning of restrike of all control piles. CAPWAP analyses must be
performed by an engineer who has achieved Advanced Level or better on the
PDI / PDCA Dynamic Measurement and Analysis Proficiency Test for Providers
of PDA Testing Services.

Upon completion of [test] pile driving, allow the piles to set-up for at
least [72 hours] [_____ days]. After evaluation of pile, hammer and soil
performance by the Contractor's Geotechnical Consultant, the second step of
the dynamic pile analysis may proceed. This portion of the evaluation
requires striking the set-up piles a minimum of 20-50 times, or as directed
by the Contractor's Geotechnical Consultant using the same hammer which was
used for the [test] pile driving and which will be used for production pile
driving. "Warm up" the hammer and make it optimally ready prior to
restricking, in order to avoid capacity losses during evaluation of restrike
data. Apply maximum hammer energy during restrike in order to fully
mobilize the soil resistance. However, exercise care so as to not
overstress the pile. In addition to those items listed above, selected
restrike driving records (as directed by the Contractor's Geotechnical
Consultant) are to be subjected to rigorous computer analysis by the Case
Pile Wave Analysis Program (CAPWAP) for determination of resistance
distribution, soil resistance and properties, and plot of applied load vs.
average pile displacement based on the calculated soil properties.

3.3.1.5 Dynamic Load Test Reporting

a. Upon satisfactory completion of each dynamic load test, submit[ a
minimum of three copies of] a Pile Performance Report for the
Contractor by the Contractor's Geotechnical Consultant. The submittal
must be prepared and sealed by a Professional Engineer registered in [____].

b. The report for the Dynamic Pile Analysis must contain the following information:

(1) Capacity of pile from Case Pile Wave Analysis Program (CAPWAP). Information resulting from analysis of a selected restrike blow.

(2) Maximum and final transferred energy, hammer system efficiency during pile installation.

(3) Maximum compressive stress, velocity, acceleration and displacement.

(4) Maximum tensile stress in pile.

(5) Pile structural integrity, damage detection, extent and location.

(6) Blows per minute and blow number.

(7) Input and reflection values of force and velocity, upward and downward traveling force wave with time.

(8) Pile skin friction and toe resistance distribution.

(9) Maximum energy transferred to pile.

c. The maximum allowable pile design load must be proposed by the Contractor's Geotechnical Consultant based upon the results of a satisfactory pile load test conducted on a pile driven as specified herein and include the effects of load transfer to the soil above the foundation stratum.

Use either a model Model 8G or PAX Pile Driving Analyzer as manufactured by Pile Dynamics, Inc., of Cleveland Ohio or approved equivalent, for dynamic testing of the pile hammer and for dynamic load testing of the test pile. All equipment necessary for the dynamic monitoring such as sensors, cables or wireless transmitters, must be furnished by the Contractor's Geotechnical Consultant, and conforming to the requirements of ASTM D4945.

Pay for all services of the Contractor's Geotechnical Consultant. The Contractor's Geotechnical Consultant must be available throughout the pile driving operation to consult with the Contracting Officer when required by the Contracting Officer. The cost of changes in the Contractor's procedure, as required by evaluation of the results of the Pile Driving Analysis, will be at the Contractor's expense.

3.3.2 Load Tests

3.3.2.1 Static Load Tests

**************************************************************************
NOTE: If pile load tests are required and approved by the Contracting Officer, specify number and location of piles. Select method of load test. In ASTM D1143/D1143M, permit anchor piles only if approved by the Contracting Officer's Technical Representative (Geotechnical Branch). Insert figure
Submit test set-up and procedures. Perform compressive load tests on [
] test piles in accordance with ASTM D1143/D1143M (standard loading procedure) as modified herein. [ Allow a minimum of [72 hours] [
] following final test pile driving for pile set-up prior to load testing. ] [ Do not use anchor piles. ] Provide apparatus for applying vertical loads as required by method, using load from weighted box or platform[ or reaction frame attached to sufficient uplift piles to safely take required load] applied to pile by hydraulic jack. Increase load in increments until rapid progressive settlement takes place or until application of total compressive load of [
] KN kips for compressive load tests. Consider load test satisfactory when[ after one hour at full test load gross settlement of pile butt is not greater than gross elastic pile compression plus 4 mm 0.15 inch plus one percent of pile tip diameter or width in [
] mm inches,][ slope of gross load-settlement curve under full test load does not exceed 1.5 mm per metric ton 0.05 inches per ton,][ net settlement after removal of test load does not exceed 19 mm 3/4 inch.]
Perform load tests at locations[ as proposed by the Contractor's Geotechnical Consultant and] as directed by the Contracting Officer. Additional load tests, at Government expense, may be required by the Contracting Officer. Perform the loading, testing, and recording and analysis under the direct supervision of a Registered Professional Engineer, registered in the state of project location, and provided and paid for by the Contractor. [ Submit test pile records][ and ] [load test data] within seven calendar days of conducting the test.

[3.3.2.1.1 Safe Design Capacity
Determine the safe design capacity of a test pile as determined from the results of load tests according to UFC 3-220-01.
]

3.3.2.2 Tensile Load Tests
Perform tensile load tests on [
] test piles in accordance with ASTM D3689, as modified[ and ] in paragraph LOAD TESTS. Apply a tensile load of [
] kN kips to each tensile load test pile. In performing the tension load test, apply the ultimate load equal to one and one-half times the safe tension capacity, and employ the Standard Loading Procedure. Perform dynamic measurements on [
] piles designated as dynamic test piles in accordance with ASTM D4945 during driving. During easy driving, ensure that damaging tension stresses do not develop in the pile. Signal matching will be performed by the Contractor's Geotechnical Consultant on representative data collected at the end of the initial driving and at the beginning of all restrike events. Additional signal matching analysis will be performed as determined by the Engineer.

3.3.2.3 Lateral Load Tests
Perform lateral load tests on [
] piles in accordance with ASTM D3966/D3966M, as modified[ and ] in paragraph LOAD TESTS. Lateral load tests will consist of jacking two piles apart with a hydraulic jack, with one pile serving as the reaction pile for the other. Apply a lateral load of [
] kN kips to each pair of lateral load test piles. Record required movement readings for each pile.
3.3.3 Pile Records

Submit pile[ and test pile] records.[ Submit load test data and results.]

Keep a complete and accurate record of each pile driven. Indicate the pile location, deviations from pile location, cross section shape and dimensions, original length, ground elevation, tip elevation, cut-off elevations, [batter alignment, ]number of blows required for each 300 mm foot of penetration and number of blows for the last 150 mm 6 inches penetration or fraction thereof [as required ]for the "calculated" [driving resistance]. Include in the record the beginning and ending times of each operation during driving of pile, type and size of hammer used, rate of operation, stroke or equivalent stroke for diesel hammer, type of driving helmet, and type and dimension of hammer cushion (capblock) and pile cushion used. Record retap data and unusual occurrences during pile driving such as redriving, heaving, weaving, splicing, obstructions, [jetting, ]and any driving interruptions.[ Install an energy monitor on the hammers and record readings every 300 mm 12 inches of pile installation.] A preprinted pile driving log for recording pile driving data[ and pile driving equipment data form], which can be downloaded at: https://www.wbdg.org/ffc/dod/unified-facilities-guide-specifications-ufgs/forms-graphics-tables

3.3.4 Testing Agency Qualifications

Engage an independent testing agency qualified according to ASTM C1077 and ASTM E329 for testing indicated. Submit testing agency qualifications to the Contracting Officer for approval.

3.4 SPECIAL INSPECTION AND TESTING FOR SEISMIC-RESISTING SYSTEMS

**************************************************************************

NOTE: Include this paragraph only when special inspection and testing for seismic-resisting systems is required by the International Building Code (IBC).

This paragraph will be applicable to both new buildings designed and to existing building seismic rehabilitation designs done according to UFC 1-200-01, "General Building Requirements" and UFC 3-310-04, "Seismic Design for Buildings".

Indicate on the drawings all locations and all features for which special inspection and testing is required in accordance with Chapter 17 of the IBC. This includes indicating the locations of all structural components and connections requiring inspection.

Add any additional requirements as necessary.

**************************************************************************

Perform special inspections and testing for seismic-resisting systems and components in accordance with Section 01 45 35 SPECIAL INSPECTIONS.

3.5 VIBRATION CONTROL

**************************************************************************
NOTE: Include this paragraph when vibration monitoring is required. Add any additional criteria or requirements as necessary to the particular project.

Perform vibration monitoring at the locations [shown in the plan] [decided by the Contracting Officer] during the pile driving operations. Perform vibration monitoring [using] [seismographs] [and geophones] within a distance of [61] [_____] meters [200] [_____] feet from the pile driving activity. Engage the services of a qualified, independent vibration consultant, acceptable to the Government, to conduct the vibration monitoring. The vibration consultant must have minimum of [5] [_____] years of experience in vibration monitoring. A minimum of [28] [_____] days before the installation of vibration monitors, submit to the Government the name of the vibration consultant and a list of at least [three] [_____] previously completed projects of similar scope and purpose.

Prior to the pile driving activities, obtain baseline readings of ambient vibrations. The vibration during the pile driving activities must be limited to [a peak particle velocity of not more than [5] [_____] cm [2.0] [_____] inches per second] [the limits mentioned in the [contract documents]]. Determine appropriate vibration limits as per [US Bureau of Mines] [American Association of State Highway and Transportation Officials (AASHTO)] guidelines. During pile driving activities, monitor the vibrations to ensure the limits are not exceeded. If the limits are exceeded, cease the pile driving activity causing the vibration until [the Vibration consultant and the Contracting Officer] [_____] are on site to observe the structures nearest to the vibration monitor which has exceeded the limits.

The Contractor is responsible for all damages resulting from the pile driving operations and must take whatever measures necessary to maintain peak particle velocity within the specified limit. After completion of the project, remove the vibration monitors off the site and off Government property and restore the monitoring locations back to their original condition.

[3.6 NOISE CONTROL

NOTE: Include this paragraph when noise monitoring is required. Add any additional criteria, references or requirements as necessary to the particular project.

Perform noise monitoring at the locations [shown in the plan] [decided by the Contracting Officer] [at noise sensitive public areas] during the pile driving operations. Perform noise monitoring using [noise meters] [, and] [_____] . Engage the services of a qualified, independent noise consultant, acceptable to the Government, to conduct the noise monitoring. The noise consultant must have minimum of [5] [_____] years of experience in noise monitoring. A minimum of [28] [_____] days before the installation of noise monitors, submit to the Government the name of the noise consultant and a list of at least [three] [_____] previously completed projects of similar scope and purpose.

Prior to the pile driving activities, obtain baseline readings of ambient vibrations.
noise levels. The noise limits are mentioned in the [plan] [contract documents]. Determine appropriate noise limits as per [local agency] [Occupation Safety and Health Administration] guidelines. During pile driving activities, monitor the noise to ensure the limits are not exceeded. If the limits are exceeded, cease the pile driving activity and install noise mitigation measures.

The Contractor is responsible for all damages resulting from the pile driving operations and must take whatever measures necessary to maintain noise within the specified limit. After completion of the project, remove the noise monitors off the site and off Government property and restore the monitoring locations back to their original condition.

[3.7] PRECONSTRUCTION CONDITION SURVEY

**************************************************************************
NOTE: Add any additional criteria, references or requirements as necessary to the particular project.
**************************************************************************

Perform preconstruction condition survey of structures and utilities within [61] [_____] meters [200] [_____] feet of the pile driving activity specified in the plans decided by the Contracting Officer. Perform outreach to the owner of the structures [28] [_____] days before performing the preconstruction condition survey. Obtain written permission from the owner of the structure prior to accessing the structure. The preconstruction condition survey will include video and photographic documentation of the exterior and interior of above ground structures and of the interior of underground structures. Video documentation must be in high definition, and show existing conditions and highlight, where possible, existing cracks, deteriorated concrete, exposed and corroded reinforcement, cracked or broken brick or mortar, and other signs of distress. For utilities, perform the survey when the greatest extent of the interior is exposed. Provide supplementary artificial lighting as needed. The video must include annotation with location and structure nomenclature which describes any areas of distress over the video and time code superimposed on the video. Photographs must be accompanied by sketches or descriptions that indicate the location and direction of each photograph. For each structure surveyed, provide a Pre-Construction Condition Survey Report following completion of the survey. The report must contain all documentation associated with the survey including DVD copies. In the report, include notes, sketches, photographs, and videos. Provide general information, such as location details and structure type, as well as particular information on materials, condition, existing damage, aperture and persistence of cracks, and disrepair observed during visual survey. Provide a graphical depiction of locations of damage or other features of concern. Submit the Preconstruction Condition Survey Reports no later than [28] [_____] days before the commencement of pile driving activity. Accept responsibility for damages to existing adjacent or adjoining structures created by pile driving work, and repair any damages to these structures without cost to the Government.

[3.8] CONSTRUCTION INSTRUMENTATION AND MONITORING PROGRAM

**************************************************************************
NOTE: Include this section if instrumentation is to be installed due to concerns about vibration, settlement, lateral movement, etc. during pile driving activities. Instrumentation should be
specified and included in the specification. This section can be deleted if there are no instrumentation requirements.

Add any additional criteria or requirements as necessary for the particular project.

**************************************************************************

Prepare a geotechnical instrumentation program to monitor settlement[ and lateral movement] of temporary and permanent structures, utilities, [embankments] [and excavations] during pile driving. The design and distribution of instrumentation must demonstrate an understanding of the need, purpose and application of each proposed type.[ Perform noise and vibration monitoring in accordance with NOISE CONTROL and VIBRATION CONTROL sections.]

Monitoring must extend before, during and for a period after completion of construction activities related to pile driving when long-term performance issues are a concern. The monitoring plan must be designed to protect adjacent structures and utilities against damage due to the pile driving activities. Establish limiting values of vertical [and horizontal] movement [and angular distortion] [and vibration] for each structure and utility within the zone of influence, subject to review by the Government.

Prepare an Instrumentation and Monitoring Program Report detailing the proposed program of instrumentation and monitoring, establishing threshold values of monitored parameters, and describing the response plans that will be implemented when threshold parameters are exceeded. The report must include details about instrumentation consultant's experience, appropriate types, quantities, locations and monitoring frequencies of the instruments.

Upon acceptance of the instrumentation and monitoring program, provide, install and monitor the instrumentation and interpret the data. Submit instrumentation data reports not less than every [_____] days after the monitoring program has begun. Take corrective actions, as necessary, based on the field instrumentation data and as defined in the instrumentation and monitoring program.

NOTE: This guide specification covers the requirements for the installation, testing, and forming of enlarged concrete footings and cylindrical shafts by ramming the concrete into place under a specific energy of impact.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

NOTE: Show the following information on the project drawings:

1. Plan of Pressure Injected Footings (PIF) (singles and clusters) and cluster configurations

2. Batter PIF angle

3. Design loads

4. Location of test PIF, unless option to allow direction by Contracting Officer is selected.
PART 1   GENERAL

1.1   DESCRIPTION

Design, furnish, install, and test pressure injected footings (PIF) at the locations indicated on the drawings and as specified herein. Assume test location[s] can be incorporated into the work.

1.2   REFERENCES

**************************************************************************
NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.
**************************************************************************

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

AMERICAN CONCRETE INSTITUTE (ACI)

ACI 211.3R (2016) Guide for Selecting Proportions for No-Slump Concrete

ACI 214R (2011) Evaluation of Strength Test Results of Concrete

ASTM INTERNATIONAL (ASTM)

ASTM C33/C33M (2023) Standard Specification for Concrete Aggregates

ASTM C1077 (2017) Standard Practice for Agencies Testing Concrete and Concrete Aggregates
**1.3 SUBSURFACE DATA**

Subsurface soil data logs are appended to the special contract requirements provided on the project drawings. The subsoil investigation report may be examined at [_____].

**1.4 BASIS OF BID**

**************************************************************************

NOTE: Select one of the following options:

Use "Lump Sum" paragraph below for lump (principal) sum bidding of PIF. Use this in all projects except those where exact PIF lengths cannot be practically determined prior to the actual work. Clearly show number of PIF, PIF capacity, PIF locations, and tip and cutoff elevations on the drawings.

Use "Unit Price" paragraph for unit price bidding of PIF. Specify unit price bid items for PIF only for projects where exact quantities cannot be practically determined prior to the actual work. Determine lengths of PIF as accurately as possible, prior to bidding, since the unit price per meter (foot) of the PIF varies as the length increases or decreases.

**************************************************************************

**1.4.1 Production Acceptance Criteria**

Safe design bearing capacity for PIF is [_____] KN [_____] kips. Install PIFs to minimum tip elevation [a minimum depth of [_____] m [_____] feet below foundation level], and to such additional depth as required to obtain a bearing capacity of not less than [_____] KN [_____] kips. The Contractor's Geotechnical Consultant will determine the terminal driving criteria based on results of static load tests.

**************************************************************************

NOTE: PIF bearing capacity must be computed per formula. In absence of a load test, use K-value from table below: (K-values and Bearing Capacity
Recommended K-Values

<table>
<thead>
<tr>
<th>Recommended K with Compacted Soil Description</th>
<th>Recommended K with Cased Shafts</th>
</tr>
</thead>
<tbody>

</tbody>
</table>

Determine safe bearing capacity by ramming zero-slump concrete, in batches of 0.14 cubic meter 5 cubic feet, into granular soil stratum by drop hammer in accordance with the following formula:

\[ L = \frac{B \times W \times H \times V^{(2/3)}}{K} \]

where

\[ L = \text{Safe bearing capacity of PIF in metric tons (tons)} \]
B = Average number of blows of hammer required to inject one cubic meter one cubic foot of concrete in expanded base, during injection of the last batch

W = Weight of drop hammer in metric tons tons

H = Height of fall of drop hammer in meters feet

V = Total volume of concrete in expanded base measured in cubic meters cubic feet, and

K = [Constant determined from the load test] [____]

[1.4.2 Lump Sum Payment]

**********************************************************************************************************************************************
NOTE: Use this paragraph for lump-sum contracts, consult with Contracting Officer's Technical Representative (Geotechnical Branch) on applicability of use prior to selection.
**********************************************************************************************************************************************

Base bids upon providing the number, size, capacity, and length of PIF as indicated on the [drawings.] [following Table I:

<table>
<thead>
<tr>
<th>Location</th>
<th>Number</th>
<th>Size</th>
<th>Bearing Capacity</th>
<th>Length</th>
<th>Maximum Bending Moment</th>
<th>Maximum Shear Force</th>
</tr>
</thead>
</table>

Include the cost of all necessary equipment, tools, material, labor, and supervision required to: install, test, and meet the applicable contract requirements. Include mobilization and pre-drilling. If it is found that any PIF is not of sufficient length to provide the capacity specified, notify the Contracting Officer, who reserves the right to increase or decrease the total length of PIF to be provided and installed by changing the PIF locations or elevations, requiring the installation of additional PIF, or directing the omission of PIF from the requirements shown and specified. If total number of PIF or number of each length vary from that specified as the basis for bidding, an adjustment in the contract price or time for completion, or both, will be made in accordance with the contract documents. Payment for PIF will be based on successfully installing PIF to both the minimum tip elevation and satisfying the acceptance criteria identified herein. No additional payment will be made for: rejected PIF or other excesses beyond the assumed PIF length indicated for which the Contractor is responsible. Include payments for vibration monitoring, sound monitoring and precondition construction surveys.

[1.4.3 Unit Price]

******************************************************************************
NOTE: Delete this paragraph for lump-sum contracts.
******************************************************************************

For NAVFAC PAC projects: Where there is unit pricing for PIF, use this paragraph and edit applicable attachments in price schedule for

SECTION 31 62 13.26 Page 8
inclusion in Standard Form 1442, "Solicitation, Offer and Award" and "Schedule of Bid Items."

For NAVFAC Southeast projects, where there is a need for unit pricing of PIF, include this paragraph. Refer to NAVFAC SE Instruction 00010, "Instructions for Preparing Basis of Bid Statement With Unit-Priced Items," for method of specifying unit price bid items.

**************************************************************************
For unit price bid, see SF 1442, "Solicitation, Offer and Award" and "Schedule of Bid Items."
**************************************************************************

NOTE: For NAVFAC LANT projects, use the following paragraph for measurement and payment and subsequent sub-parts.
**************************************************************************
Requirements of FAR 52.211-18 Variation in Estimated Quantity do not apply to payment for PIF. Each PIF and test PIF acceptably provided will be paid for at the bid unit price per unit length, which will include items incidental to furnishing and driving the PIF including mobilization and demobilization, and jetting/predrilling. Payment will be made for production and test PIF at the bid unit price for the length of PIF, from tip to final cut-off, actually provided, excluding buildups directed by the Contracting Officer to be made. If the actual cumulative PIF length driven (tip to cut-off) vary more than 25 percent from the total PIF length specified as a basis for bidding, at the direction of the Contracting Officer, the unit price per unit length will be adjusted in accordance with provisions of FAR 52.236-2 Differing Site Conditions. Payments will be made per each at the respective bid unit price for PIF build-ups and loads tests. Include payments for vibration monitoring, sound monitoring, construction instrumentation and monitoring, and precondition construction surveys.

1.5 PAYMENT

**************************************************************************
NOTE: Delete this paragraph for lump-sum contracts.

If Section 01 20 00 PRICE AND PAYMENT PROCEDURES is included in the project specifications, this paragraph title (UNIT PRICES) should be deleted from this section and the remaining appropriately edited subparagraphs below should be inserted into Section 01 20 00 PRICE AND PAYMENT PROCEDURES.
**************************************************************************

1.5.1 Mobilization and Demobilization

1.5.1.1 Payment

Payment will be made for costs associated with mobilization and demobilization as a separate single lump sum item.
1.5.1.2 Measurement
Lump sum.

1.5.1.3 Unit of Measure
Lump sum.

1.5.2 Installing PIF

1.5.2.1 Payment
Payment will be made for costs associated with installing PIF, which includes costs of installing PIFs and removing excess waste from the work site, compiling and submitting PIF records, and any other items incidental to installing PIF to the required elevation.

1.5.2.2 Unit of Measure
Linear meter. Foot.

[1.5.3 PIF Static Axial Compressive Load Tests

1.5.3.1 Payment
Payment will be made for costs associated with PIF static axial compressive load tests in accordance with ASTM D1143/D1143M, including material and labor for fabricating and furnishing load frames; calibrating load cells and hydraulic jacks; furnishing specified test equipment; installing strain rods; placing and removing test loads and test equipment; recording, reducing, and submitting test data; and compiling and submitting load test reports. No payment will be made for rejected static axial compressive load tests.

1.5.3.2 Measurement
PIF static axial compressive load tests will be measured for payment on the basis of the applicable contract unit price per load test.

1.5.3.3 Unit of Measure
Each.

][1.5.4 PIF Static Tensile Load Tests

1.5.4.1 Payment
Payment will be made for costs associated with PIF static tensile load tests in accordance with ASTM D3689, including material and labor for fabricating and furnishing load frames; calibrating load cells and hydraulic jacks; furnishing specified test equipment; installing strain rods; placing and removing test loads and test equipment; recording, reducing, and submitting test data; and compiling and submitting load test reports. No payment will be made for rejected static tensile load tests.

1.5.4.2 Measurement
PIF tensile load tests will be measured for payment on the basis of the applicable contract unit price per number of tensile load test.
1.5.4.3 Unit of Measure

Each.

1.5.5 PIF Lateral Load Tests

1.5.5.1 Payment

Payment will be made for costs associated with PIF lateral load tests in accordance with ASTM D3966/D3966M, including material and labor for fabricating and furnishing load frames; calibrating load cells and hydraulic jacks; furnishing specified test equipment; installing inclinometers; placing and removing test loads and test equipment; recording, reducing, and submitting test data; and compiling and submitting load test reports. No payment will be made for rejected lateral load tests.

1.5.5.2 Measurement

PIF lateral load tests will be measured for payment on the basis of the applicable contract unit price per lateral load test.

1.5.5.3 Unit of Measure

Each.

1.5.6 Vibration Monitoring

1.5.6.1 Payment

Payment will be made for costs associated with vibration monitoring.

1.5.6.2 Measurement

Vibration monitoring will be measured for payment on the basis of the applicable contract unit price per vibration monitoring point.

1.5.6.3 Unit of Measure

Each.

1.5.7 Sound Monitoring

1.5.7.1 Payment

Payment will be made for costs associated with sound monitoring.

1.5.7.2 Measurement

Sound monitoring will be measured for payment on the basis of the applicable contract unit price per vibration monitoring point.

1.5.7.3 Unit of Measure

Each.
1.5.8 Preconstruction Condition Survey

1.5.8.1 Payment

Payment will be made for costs associated with preconstruction condition surveys.

1.5.8.2 Measurement

Preconstruction condition survey will be measured for payment on the basis of the applicable contract unit price per structure to be surveyed.

1.5.8.3 Unit of Measure

Each.

1.5.9 Construction Instrumentation and Monitoring

1.5.9.1 Payment

Payment will be made for costs associated with construction instrumentation and monitoring.

1.5.9.2 Measurement

Construction instrumentation and monitoring will be measured as a single pay item.

1.5.9.3 Unit of Measure

One.

1.6 SUBMITTALS

**************************************************************************

NOTE: Review Submittal Description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.

**************************************************************************
The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-01 Preconstruction Submittals

Designer and Installer's Qualifications; G[, [____]]

Testing Agency Qualifications; G[, [____]]

Contractor's Geotechnical Consultant Documentation

SD-02 Shop Drawings

Steel-Shell Shaft Casings

Reinforcement

SD-11 Closeout Submittals

PIF Records

1.7 QUALITY CONTROL

1.7.1 PIF Records

Pressure-injected footings (PIF) consist of an expanded base of concrete, formed by ramming concrete into place, and a [cased ] [uncased ] [reinforced ] concrete shaft to transmit the superstructure load to the expanded base.

1.7.2 PIF Installation Equipment

Submit descriptions of proposed PIF installation equipment before commencing work. Include details of the rig, hammer type, and available energy.

1.7.3 Load Test Apparatus

******************************************************************************************************************************************************
NOTE: Delete this paragraph if load testing is not required.
******************************************************************************************************************************************************
Submit equipment description lists or catalog cuts and a brief description of the load test procedure, including maximum load and modifications in accordance with the procedure required by ASTM D1143/D1143M before commencing tests.

1.7.4 Contractor's Geotechnical Consultant Documentation

Hire the services of an independent, Registered Professional Geotechnical Engineer, experienced in soil mechanics to observe test PIF installation and production PIF installation as specified herein. The Contractor's Geotechnical Consultant must be independent of the Contractor and have no employee or employer relationship which could constitute a conflict of interest.

1.8 QUALIFICATIONS

Installation of PIF must be performed by a specialty Contractor experienced and competent in the installation of PIF as specified herein. Submit evidence that the contractor has had similar type projects. The projects must demonstrate proficiency of the designer as applicable to the intent of the project. The Designer must be a Professional Engineer registered in the state where the project is located.

Submit Designer and Installer's Qualifications at least 30 calendar days
prior to installation.

[1.9 DESIGN CALCULATIONS

Submit two sets of detailed design calculations for approval at least 30 calendar days prior to the beginning of construction. Include a detailed explanation of the design parameters for the calculations. Additionally, submit the quality control test program confirming the design requirements. All calculations and drawings must be prepared and sealed by a Professional Engineer in the State in which the project is constructed.

]PART 2 PRODUCTS

2.1 CONCRETE

******************************************************************************
NOTE: Insert the correlated section number and title or include concrete specification in this section in the blank below in the correct format per UFC 1-300-02.
******************************************************************************

Provide as specified in [_____] except as specified otherwise herein, for minimum 28-day concrete compressive strength of [_____] MPa pounds per square inch, using 19 mm 3/4 inch maximum coarse aggregate. Concrete for base [and for uncased shaft ]must have minimum 3-day compressive strength of [_____] MPa pounds per square inch.[ Cased shaft must have minimum 3-day compressive strength of [_____] MPa pounds per square inch.] The expanded base must be made of zero-slump concrete. Use[ zero-slump concrete for uncased shaft][ 75 mm 3 inch slump concrete for cased or uncased shaft][ 100 to 150 mm 4 to 6 inch slump concrete for cased shaft]. Develop zero-slump concrete by reducing water in regular-mix concrete in accordance with ACI 211.3R. Submit concrete mix design for approval at least 30 calendar days prior to installation.

2.1.1 Portland Cement

Conform to ASTM C150/C150M and Section 03 30 00 CAST-IN-PLACE CONCRETE.

2.1.2 Water

Fresh, clean, and free from sewage, oil, acid, alkali, salts, or organic matter.

2.1.3 Fine Aggregate

Meet the requirements of ASTM C33/C33M. The sand must consist of hard, dense, durable, uncoated rock particles and be free from injurious amounts of silt, loam, lumps, soft or flaky particles, shale, alkali, organic matter, mica, and other deleterious substances. If washed, use a washing method that will not remove desirable fines, and the sand must subsequently be permitted to drain until the residual-free moisture is reasonably uniform and stable. The sand must be well-graded from fine to coarse, with fineness modulus between 1.30 and 3.40.

2.1.4 Aggregates

Meet the requirements of ASTM C33/C33M, for fine aggregate, except as to
