#### 2.5.2 Durability

**************************************************************************

**NOTE:** Proportions required for durable concrete may take precedence over those for strength. Durability can be more important than strength to the overall performance of the completed work. Concrete should be proportioned to resist the effects of exposures that can deprive it of serviceability. Durability is related to strength, but is also affected by factors which strength alone does not indicate. Strength tests alone are not a good predictor of durability. Additional durability tests on concrete and its components could be performed to insure that durable concrete is produced.

**************************************************************************

#### 2.5.2.1 Alkali-Aggregate Reaction

Do not use any aggregate susceptible to alkali-carbonate reaction (ACR).
Use one of the three options below for qualifying concrete mixtures to reduce the potential of alkali-silica reaction (ASR):

a. For each aggregate used in concrete, the expansion result determined in accordance with ASTM C1293 must not exceed 0.04 percent at one year.

b. For each aggregate used in concrete, the expansion result of the aggregate and cementitious materials combination determined in accordance with ASTM C1567 must not exceed 0.10 percent at an age of 16 days.

******************************************************************************

NOTE: Alkali content in concrete (LBA), which is sometimes referred to as alkali loading in concrete, is a function of how reactive an aggregate is to alkalis. A lower LBA should be used with highly reactive aggregate.

The limit required below was obtained from ACI 301 and should cover most available aggregates. Limits specific to certain aggregates could be obtained by testing a combination of cementitious materials and reactive aggregate being considered. If a highly reactive aggregate is being considered for a project, the value of LBA being specified should be verified or determined for that specific aggregate.

******************************************************************************

c. Alkali content in concrete (LBA) must not exceed [2.4 kg per cubic meter] [4 pounds per cubic yard] [_____] for moderately reactive aggregate or [1.8 kg per cubic meter] [3 pounds per cubic yard] [_____] for highly reactive aggregate. Reactivity must be determined by testing in accordance with ASTM C1293 and categorized in accordance with ASTM C1778. Alkali content is calculated as follows: LBA = (cement content, kg per cubic meter pounds per cubic yard) × (equivalent alkali content of portland cement in percent/100 percent)

2.5.2.2 Freezing and Thawing Resistance

a. Provide concrete meeting the following requirements based on exposure class assigned to members for freezing-and-thawing exposure in Contract Documents:

<table>
<thead>
<tr>
<th>Exposure class</th>
<th>Maximum w/cm*</th>
<th>Minimum f’c, MPa psi</th>
<th>Air content</th>
<th>Additional Requirements</th>
</tr>
</thead>
<tbody>
<tr>
<td>F0</td>
<td>N/A</td>
<td>17 2500</td>
<td>N/A</td>
<td></td>
</tr>
<tr>
<td>F1</td>
<td>0.55</td>
<td>24 3500</td>

<tr>
<td>F2</td>
<td>0.45</td>
<td>31 4500</td>
<td>Depends on aggregate size</td>
<td>See limits on maximum cementitious material by mass</td>
</tr>
</tbody>
</table>
**b.** Concrete must be air entrained for members assigned to Exposure Class F1, F2, or F3. The total air content must meet the requirements of the following table:

<table>
<thead>
<tr>
<th>Nominal maximum aggregate size, mm in.</th>
<th>Total air content, percent*^</th>
<th>Exposure Class F2 and F3</th>
<th>Exposure Class F1</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>75 3</td>
<td>5.5</td>
<td>3.5</td>
<td></td>
</tr>
</tbody>
</table>

*Tolerance on air content as delivered must be plus/minus 1.5 percent.

^For f\'c greater than 5000 psi, reducing air content by 1.0 percentage point is acceptable.

c. Submit documentation verifying compliance with specified requirements.

d. For sections of the structure that are assigned Exposure Class F3, submit certification on cement composition verifying that concrete mixture meets the requirements of the following table:
Cementitious material | Maximum percent of total cementitious material by mass*
---|---
Fly ash or other pozzolans conforming to ASTM C618 | 25
Slag cement conforming to ASTM C989/C989M | 50
Silica fume conforming to ASTM C1240 | 10
Total of fly ash or other pozzolans, slag cement, and silica fume | 50^
Total of fly ash or other pozzolans and silica fume | 35^

*Total cementitious material also includes ASTM C150/C150M, ASTM C595/C595M, ASTM C845/C845M, and ASTM C1157/C1157M cement. The maximum percentages above must include:

i. Fly ash or other pozzolans present in ASTM C1157/C1157M or ASTM C595/C595M Type IP blended cement.

ii. Slag cement present in ASTM C1157/C1157M or ASTM C595/C595M Type IS blended cement.

iii. Silica fume conforming to ASTM C1240 present in ASTM C1157/C1157M or ASTM C595/C595M Type IP blended cement.

^Fly ash or other pozzolans and silica fume must constitute no more than 25 percent and 10 percent, respectively, of the total mass of the cementitious materials.

2.5.2.3 Corrosion and Chloride Content

a. Provide concrete meeting the requirements of the following table based on the exposure class assigned to members requiring protection against reinforcement corrosion in Contract Documents.

b. Submit documentation verifying compliance with specified requirements.

c. Water-soluble chloride ion content contributed from constituents including water, aggregates, cementitious materials, and admixtures must be determined for the concrete mixture by ASTM C1218/C1218M at age between 28 and 42 days.

d. The maximum water-soluble chloride ion (Cl−) content in concrete, percent by mass of cement is as follows:

<table>
<thead>
<tr>
<th>Exposure class</th>
<th>Maximum w/cm*</th>
<th>Minimum f'c, MPa</th>
<th>Maximum water-soluble chloride ion (Cl−) content in concrete, percent by mass of cement</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reinforced concrete</td>
<td></td>
<td></td>
<td></td>

<td>0.06</td>
</tr>
<tr>
<td>C2</td>
<td>0.4</td>
<td>35 5000</td>
<td>0.06</td>
</tr>
</tbody>
</table>

*The maximum w/cm limits do not apply to lightweight concrete.

#### 2.5.2.4 Sulfate Resistance

**a.** Provide concrete meeting the requirements of the following table based on the exposure class assigned to members for sulfate exposure.

<table>
<thead>
<tr>
<th>Exposure class</th>
<th>Maximum w/cm</th>
<th>Minimum ( f'c, \text{ MPa} )</th>
<th>Required cementitious materials-types</th>
<th>Calcium chloride admixture</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td>ASTM C150/C150M</td>
<td>ASTM C595/C595M</td>
</tr>
<tr>
<td>S0</td>
<td>N/A</td>
<td>17 2500</td>
<td>N/A</td>
<td>N/A</td>
</tr>
<tr>
<td>S1</td>
<td>0.50</td>
<td>28 4000</td>
<td>II**</td>
<td>Types with (MS) designation</td>
</tr>
<tr>
<td>S2</td>
<td>0.45</td>
<td>31 4500</td>
<td>V^</td>
<td>Types with (HS) designation</td>
</tr>
<tr>
<td>S3</td>
<td>0.45</td>
<td>31 4500</td>
<td>V + pozzolan or slag cement**</td>
<td>Types with (HS) designation plus pozzolan or slag cement**</td>
</tr>
<tr>
<td>S3</td>
<td>0.40</td>
<td>34 5000</td>
<td>V***</td>
<td>Types with (HS) designation</td>
</tr>
</tbody>
</table>

* For seawater exposure, other types of portland cements with tricalcium aluminate (C3A) contents up to 10 percent are acceptable if the w/cm does not exceed 0.40.

** The amount of the specific source of the pozzolan or slag cement to be used shall be at least the amount determined by test or service record to improve sulfate resistance when used in concrete containing Type V cement. Alternatively, the amount of the specific source of the pozzolan or slag used shall not be less than the amount tested in accordance with ASTM C1012/C1012M and meeting the requirements maximum.
expansion requirements listed herein.

*** If Type V cement is used as the sole cementitious material, the optional sulfate requirement of 0.040 percent maximum expansion in ASTM C150/C150M shall be required.

^ Other available types of cement, such as Type III or Type I, are acceptable in exposure classes S1 or S2 if the C3A contents are less than 8 or 5 percent, respectively.

b. The maximum w/cm limits for sulfate exposure do not apply to lightweight concrete.

c. Alternative combinations of cementitious materials of those listed in this paragraph are acceptable if they meet the maximum expansion requirements listed in the following table:

<table>
<thead>
<tr>
<th>Exposure class</th>
<th>Maximum expansion when tested using ASTM C1012/C1012M</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>At 6 months</td>
</tr>
<tr>
<td>S1</td>
<td>0.10 percent</td>
</tr>
<tr>
<td>S2</td>
<td>0.05 percent</td>
</tr>
<tr>
<td>S3</td>
<td>N/A</td>
</tr>
</tbody>
</table>

^The 12-month expansion limit applies only when the measured expansion exceeds the 6-month maximum expansion limit.

2.5.2.5 Concrete Temperature

**************************************************************************
NOTE: Specify alternative maximum concrete temperature. If concrete delivered in hot weather with a temperature higher than 35°C 95°F has been used successfully in given climates or situations, the higher temperature may be specified in place of the 35°C 95°F limit. Review ACI 305R for guidance on specifying a higher temperature limit.
**************************************************************************

The temperature of concrete as delivered must not exceed [35°C95°F] [____].

2.5.2.6 Concrete permeability

a. Provide concrete meeting the requirements of the following table based on exposure class assigned to members requiring low permeability in the Contract Documents.
<table>
<thead>
<tr>
<th>Exposure class</th>
<th>Maximum w/cm*</th>
<th>Minimum f'c, MPa psi</th>
<th>Additional minimum requirements</th>
</tr>
</thead>
<tbody>
<tr>
<td>W0</td>
<td>N/A</td>
<td>17 2500</td>
<td>None</td>
</tr>
<tr>
<td>W1</td>
<td>0.5</td>
<td>28 4000</td>
<td>None</td>
</tr>
</tbody>
</table>

*The maximum w/cm limits do not apply to lightweight concrete.

b. Submit documentation verifying compliance with specified requirements.

2.5.3 Contractor's Option for Material Only

******************************************************************************
NOTE: Fill in appropriate state and title of referenced specification where work is to be accomplished. If a special class of aggregate and a choice of other materials exists in the state specification, specify that class of aggregate and choice of material. Fill in applicable strength class or other appropriate identification of concrete strength specified in state Department of Transportation specifications. Do not use for NAVFAC LANT projects.
******************************************************************************

At the option of the Contractor, those applicable material sections of [_____] DOT RBS for Class [A] [_____] strength concrete must govern in lieu of this specification for concrete. Do not change the selected option during the course of the work.

2.5.4 Trial Mixtures

Trial mixtures must be in accordance to ACI 301.

2.5.5 Ready-Mix Concrete

******************************************************************************
NOTE: ASTM C94 covers requirements for ready-mix concrete but does not cover requirements for placement, consolidation, curing, or protection of the concrete after delivery to the purchaser.
******************************************************************************

Provide concrete that meets the requirements of ASTM C94/C94M.

Ready-mixed concrete manufacturer must provide duplicate delivery tickets with each load of concrete delivered. Provide delivery tickets with the following information in addition to that required by ASTM C94/C94M:

a. Type and brand cement

b. Cement and supplementary cementitious materials content in 43-kilogram 94-pound bags per cubic meter yard of concrete

c. Maximum size of aggregate
d. Amount and brand name of admixtures

e. Total water content expressed by water cementitious material ratio

2.6 REINFORCEMENT

a. Bend reinforcement cold. Fabricate reinforcement in accordance with fabricating tolerances of ACI 117.

b. Submit manufacturer's certified test report for reinforcement.

c. Submit placing drawings showing fabrication dimensions and placement locations of reinforcement and reinforcement supports. Placing drawings must indicate locations of splices, lengths of lap splices, and details of mechanical and welded splices.

d. Submit request with locations and details of splices not indicated in Contract Documents.

e. Submit request to place column dowels without using templates.

**************************************************************************

NOTE: Specify if and where (locations) field bending or straightening of reinforcing bars is permitted.
**************************************************************************

f. Submit request and procedure to field-bend or straighten reinforcing bars partially embedded in concrete at locations not indicated in Contract Documents. Field bending or straightening of reinforcing bars is permitted [where indicated in the Contract Documents][in the following locations: [______]]

g. Submit request for field cutting, including location and type of bar to be cut and reason field cutting is required.

2.6.1 Reinforcing Bars

**************************************************************************

NOTE: ASTM A706/A706M bars are mainly used in seismic design or for welding. Include ASTM A767/A767M for galvanized reinforcing bars.
**************************************************************************

**************************************************************************

NOTE: Use second recycled content option throughout this section if Contractor is choosing recycled content products in accordance with Section 01 33 29 SUSTAINABILITY REQUIREMENTS AND REPORTING.
**************************************************************************

a. Reinforcing bars must be deformed, except spirals, load-transfer dowels, and welded wire reinforcement, which may be plain.

b. ASTM A615/A615M with the bars marked S, Grade [420][550][690] [60][80][100]; or ASTM A996/A996M with the bars marked R, Grade [350][420] [50][60], or marked A, Grade [300][420] [40][60]. Cold drawn wire used for spiral reinforcement must conform to
ASTM A1064/A1064M][ Provide reinforcing bars that contain a minimum of [100][_____] percent recycled content.][ See Section 01 33 29 SUSTAINABILITY REQUIREMENTS AND REPORTING for cumulative total recycled content requirements.]

c. [Reinforcing bars may contain post-consumer or post-industrial recycled content.][Submit documentation indicating percentage of post-industrial and post-consumer recycled content per unit of product. Indicate relative dollar value of recycled content products to total dollar value of products included in project.]

d. Submit mill certificates for reinforcing bars.

2.6.1.1 Galvanized Reinforcing Bars

**************************************************************************
NOTE: Class 1 has a zinc coating that is thicker than Class 2. For Class 1 bars, fabrication can be performed before or after coating. If fabrication is performed after coating then damage caused by fabrication should be repaired according to ASTM A767/767M.

If needed, add any requirements for bars that require special finished bend diameters and indicate their locations.

ASTM A1094 provides 2 mils of coating and can be fabricated after coating. Any damage should be repaired according to ASTM A1094/A1094M. The systems are not equals and the designer should choose based on the requirements of the project.
**************************************************************************

a. Provide zinc-coated (galvanized) reinforcing bars that conform to [ASTM A767/A767M, [Class 1] [Class 2] [with galvanizing [before][after] fabrication] as required by the contract Documents][ or ][ASTM A1094/A1094M].

b. Coating damage incurred during shipment, handling, and placing of zinc-coated (galvanized) reinforcing bars must be repaired in accordance with ASTM A780/A780M. Damaged areas must not exceed 2 percent of surface area in each linear foot of each bar or bar must not be used. The 2 percent limit on maximum allowed damaged coating area must include previously repaired areas damaged before shipment as required by ASTM A767/A767M.

2.6.1.2 Epoxy-Coated Reinforcing Bars

**************************************************************************
NOTE: ASTM A775/A775M are coated in a straight and then bent as needed while ASTM A934/A934M are bent prior to coating. Bending after coating might result in the epoxy coating to crack or debond from steel.
**************************************************************************

a. Provide epoxy-coated reinforcing bars that conform to[ ASTM A775/A775M ][ ASTM A934/A934M], Grade[ 60][ 80][ 100].
b. Coatings must be applied in plants that are certified in accordance with Concrete Reinforcing Steel Institute (CRSI) Epoxy Coating Plant Certification Program or an equivalent program acceptable to the contracting officer.

c. Coating damage incurred during shipment, storage, handling, and placing of epoxy-coated reinforcing bars must be repaired. Repair damaged coating areas with patching material conforming to ASTM A775/A775M or ASTM A934/A934M as applicable and in accordance with material manufacturer's written recommendations. Damaged coating area must not exceed 2 percent of surface area in each linear foot of each bar or bar must not be used. The 2 percent limit on damaged coating area must include repaired areas damaged before shipment as required by ASTM A775/A775M or ASTM A934/A934M as applicable. Fading of coating color shall not be cause for rejection of epoxy-coated reinforcing bars.

d. [Submit concrete Reinforcing Steel Institute (CRSI) Epoxy Coating Plant Certification inspection and quality-control program of plant applying epoxy coating if proposed plant is not certified in accordance with CRSI Epoxy Coating Plant Certification Program].

e. Epoxy coated reinforcing bars shall be handled and stored in accordance with [ASTM A775/A775M] or [ASTM A934/A934M]. If the manufacturer stores bars outdoors for more than 2 months, cover coated reinforcement with opaque protective material.

2.6.1.3 Dual-coated Reinforcing Bars

a. Zinc and epoxy dual-coated reinforcing bars must conform to ASTM A1055/A1055M

b. Coating damage incurred during shipment, storage, handling, and placing of zinc and epoxy dual-coated reinforcing bars must be repaired. Repair damaged coating areas with patching material conforming to ASTM A1055/A1055M and in accordance with material manufacturer's written recommendations. Damaged coating area must not exceed 2 percent of surface area in each linear foot of each bar or bar must not be used. The 2 percent limit on damaged coating area must include repaired areas damaged before shipment as required by ASTM A1055/A1055M. Fading of coating color shall not be cause for rejection of zinc and epoxy dual-coated reinforcing bars.

2.6.1.4 Stainless Steel Reinforcing Bars

Stainless steel bars must meet the requirements of ASTM A955/A955M.

2.6.1.5 Headed Reinforcing Bars

Headed reinforcing bars must conform to ASTM A970/A970M including Annex A1, and other specified requirements.

2.6.1.6 Bar Mats

a. Bar mats must conform to ASTM A184/A184M.

b. If coated bar mats are required, repair damaged coating as required in the paragraph titled GALVANIZED REINFORCING BARS EPOXY-COATED REINFORCING BARS and DUAL-COATED REINFORCING BARS.
2.6.1.7 Headed Shear Stud Reinforcement

Headed studs and headed stud assemblies must conform to ASTM A1044/A1044M.

2.6.2 Mechanical Reinforcing Bar Connectors

a. Provide 125 percent minimum yield strength of the reinforcement bar.

b. Mechanical splices for galvanized reinforcing bars must be galvanized or coated with dielectric material.

c. Mechanical splices used with epoxy-coated or dual-coated reinforcing bars must be coated with dielectric material.

d. Submit data on mechanical splices demonstrating compliance with this paragraph.

2.6.3 Wire

**************************************************************************
NOTE: Include in your Contract Documents the wire size, yield strength or grade, and any additional requirements not specified here for wires.
For more information on wire reinforcement refer to WRI (Wire Reinforcement Institute) documents.
**************************************************************************

a. [Provide wire reinforcement that contains a minimum of [100] [_____] percent recycled content.] [See Section 01 33 29 SUSTAINABILITY REQUIREMENTS AND REPORTING for cumulative total recycled content requirements. Wire reinforcement may contain post-consumer or post-industrial recycled content.] Provide flat sheets of welded wire reinforcement for slabs and toppings.

b. Plain or deformed steel wire must conform to ASTM A1064/A1064M.

c. Stainless steel wire must conform to ASTM A1022/A1022M.

d. Epoxy-coated wire must conform to ASTM A884/A884M. Coating damage incurred during shipment, storage, handling, and placing of epoxy-coated wires must be repaired. Repair damaged coating areas with patching material in accordance with material manufacturer's written recommendations. If damaged area exceeds 2 percent of surface area in each linear foot of each wire, wire must not be used. The 2 percent limit on damaged coating area must include repaired areas damaged before shipment as required by ASTM A884/A884M. Fading of coating color shall not be cause for rejection of epoxy-coated wire reinforcement.

2.6.4 Welded wire reinforcement

**************************************************************************
NOTE: Include in your Contract Documents the welded wire yield strength or grade, size and spacing, and any additional requirements not specified here for wires.
**************************************************************************
a. Use welded wire reinforcement specified in Contract Documents and conforming to one or more of the specifications given herein.

b. Plain welded wire reinforcement must conform to ASTM A1064/A1064M, with welded intersections spaced no greater than 300 mm 12 in. apart in direction of principal reinforcement.

c. Deformed welded wire reinforcement must conform to ASTM A1064/A1064M, with welded intersections spaced no greater than 400 mm 16 in. apart in direction of principal reinforcement.

d. Epoxy-coated welded wire reinforcement must conform to ASTM A884/A884M. Coating damage incurred during shipment, storage, handling, and placing of epoxy-coated welded wire reinforcement must be repaired in accordance with ASTM A884/A884M. Repair damaged coating areas with patching material in accordance with material manufacturer's written recommendations. If damaged area exceeds 2 percent of surface area in each linear foot of each wire or welded wire reinforcement, the sheet containing the damaged area must not be used. The 2 percent limit on damaged coating area must include repaired areas damaged before shipment as required by ASTM A884/A884M. Fading of coating color shall not be cause for rejection of epoxy-coated welded wire reinforcement.

e. Stainless steel welded wire reinforcement must conform to ASTM A1022/A1022M.

f. Zinc-coated (galvanized) welded wire reinforcement must conform to ASTM A1060/A1060M. Coating damage incurred during shipment, storage, handling, and placing of zinc-coated (galvanized) welded wire reinforcement must be repaired in accordance with ASTM A780/A780M. If damaged area exceeds 2 percent of surface area in each linear foot of each wire or welded wire reinforcement, the sheet containing the damaged area must not be used. The 2 percent limit on damaged coating area shall include repaired areas damaged before shipment as required by ASTM A1060/A1060M.

2.6.5 Reinforcing Bar Supports

**************************************************************************
NOTE: Include in your Contract Documents the types of reinforcement supports and location used within the structure. Refer to Chapter 3 in CRSI MSP 2.
**************************************************************************

a. Provide reinforcement support types within structure as required by Contract Documents. Reinforcement supports must conform to CRSI RB4.1. Submit description of reinforcement supports and materials for fastening coated reinforcement if not in conformance with CRSI RB4.1.

b. [For epoxy-coated reinforcement, use epoxy-coated or other dielectric-polymer-coated wire bar support.] [For zinc-coated reinforcement, use galvanized wire or dielectric-polymer coated wire bar supports.]

**************************************************************************
NOTE: Supports must be coated when using epoxy-coated reinforcing bars.
**************************************************************************
c. Legs of supports in contact with formwork must be hot-dip galvanized, or plastic coated after fabrication, or stainless-steel bar supports.

d. [Minimum [5][10][_____] percent post-consumer recycled content, or minimum [20][40][_____] percent post-industrial recycled content. ] [See Section 01 33 29 SUSTAINABILITY REQUIREMENTS AND REPORTING for cumulative total recycled content requirements. Plastic and steel may contain post-consumer or post-industrial recycled content.]

2.6.6 Reinforcing Fibers

**************************************************************************
NOTE: Only use fiber reinforcement when approved by the designer. Drawings should indicate where fiber reinforced concrete is located. Fiber reinforcing is used to help: control cracking due to plastic shrinkage; reduce permeability; and increase impact capacity; shatter resistance, abrasion resistance, and toughness. Fiber reinforcing does not: control cracking due to structural stresses; significantly increase strength; control curling or creeping; justify reducing structural members; eliminate control joints; or replace any moment or structural steel reinforcement. Include flexural toughness tests when reinforcement fibers are used to increase toughness and when justified by size and importance of job, but not when fibers are used only to control plastic shrinkage cracking. Include technical representative when warranted by size and importance of job.

For more information on fibers and their use in concrete, refer to ACI 544 documents.
**************************************************************************

2.6.6.1 Synthetic Fibers

In addition to the requirements specified above, provide fiber reinforced concrete in accordance with ASTM C1116/C1116M Type III, synthetic fiber reinforced concrete, and as follows. Synthetic reinforcing fibers must be [100 percent virgin] monofilament polypropylene fibers[, with a minimum of [5] [10] [_____] percent post-consumer recycled content, or a minimum of [20] [40] [_____] percent post-industrial recycled content]. [ See Section 01 33 29 SUSTAINABILITY REQUIREMENTS AND REPORTING for cumulative total recycled content requirements. Fibers may contain post-consumer or post-industrial recycled content.]

Provide fibers that have a specific gravity of 0.9, a minimum tensile strength of 480 MPa 70 ksi, graded per manufacturer, and specifically manufactured to an optimum gradation for use as concrete secondary reinforcement. Add fibers at the batch plant. [ Toughness indices must meet requirements for performance level I. ] [ Provide the services of a qualified technical representative to instruct the concrete supplier in proper batching and mixing of materials to be provided.]

2.6.6.2 Steel Fibers

If steel fiber-reinforced concrete is specified in Contract Documents for providing shear resistance, steel fibers must be deformed and conform to
ASTM A820/A820M. Steel fibers must have a length-to-diameter ratio of at least 50 and not exceed 100.

2.6.7 Dowels for Load Transfer in Floors

Provide greased dowels for load transfer in floors of the type, design, weight, and dimensions indicated. Provide dowel bars that are plain-billet steel conforming to ASTM A615/A615M, Grade 40. Provide dowel pipe that is steel conforming to ASTM A53/A53M.

[Plate dowels must conform to ASTM A36/A36M, and must be of size and spacing indicated. Plate dowel system must minimize shrinkage restraint by [using a tapered shape] [or] [formed void] [or] [by having compressible material on the vertical faces with a thin bond breaker on the top and bottom dowel surfaces.]

2.6.8 Welding

a. Provide weldable reinforcing bars that conform to ASTM A706/A706M and ASTM A615/A615M and Supplement S1, Grade 420, except that the maximum carbon content must be 0.55 percent.

b. Comply with AWS D1.4/D1.4M unless otherwise specified. Do not tack weld reinforcing bars.

c. Welded assemblies of steel reinforcement produced under factory conditions, such as welded wire reinforcement, bar mats, and deformed bar anchors, are allowed.

d. After completing welds on zinc-coated (galvanized), epoxy-coated, or zinc and epoxy dual-coated reinforcement, coat welds and repair coating damage as previously specified.

PART 3 EXECUTION

3.1 EXAMINATION

a. Do not begin installation until substrates have been properly constructed; verify that substrates are level.

b. If substrate preparation is the responsibility of another installer, notify Contracting Officer of unsatisfactory preparation before processing.

c. Check field dimensions before beginning installation. If dimensions vary too much from design dimensions for proper installation, notify Contracting Officer and wait for instructions before beginning installation.

3.2 PREPARATION

**************************************************************************
NOTE: Options for uses of excess concrete include:
additional paving, post footing anchorage, swale riprap reinforcing, mud slab, flowable fill, footing bottom, retaining wall footing ballast, storm structure covers, underground utility pipe kickers, storm pipe flared end section, toe wash protection, and shoulder and toe outfall restraints for
temporary erosion pipes. Diverting waste from the landfill contributes to the following LEED credit: MR2. Coordinate with Section 01 33 29 SUSTAINABILITY REQUIREMENTS AND REPORTING.

**************************************************************************

Determine quantity of concrete needed and minimize the production of excess concrete. Designate locations or uses for potential excess concrete before the concrete is poured.

3.2.1 General

a. Surfaces against which concrete is to be placed must be free of debris, loose material, standing water, snow, ice, and other deleterious substances before start of concrete placing.

b. Remove standing water without washing over freshly deposited concrete. Divert flow of water through side drains provided for such purpose.

3.2.2 Subgrade Under Foundations and Footings

a. When subgrade material is semi-porous and dry, sprinkle subgrade surface with water as required to eliminate suction at the time concrete is deposited, or seal subgrade surface by covering surface with specified vapor retarder.

b. When subgrade material is porous, seal subgrade surface by covering surface with specified vapor retarder.

3.2.3 Subgrade Under Slabs on Ground

a. Before construction of slabs on ground, have underground work on pipes and conduits completed and approved.

b. Previously constructed subgrade or fill must be cleaned of foreign materials

c. Finish surface of capillary water barrier under interior slabs on ground must not show deviation in excess of 6.4 mm 1/4 inch when tested with a 3000 mm 10-foot straightedge parallel with and at right angles to building lines.

d. Finished surface of subgrade or fill under exterior slabs on ground must not be more than 6.10 mm 0.02-foot above or 30.50 mm 0.10-foot below elevation indicated.

3.2.4 Edge Forms and Screed Strips for Slabs

a. Set edge forms or bulkheads and intermediate screed strips for slabs to obtain indicated elevations and contours in finished slab surface and must be strong enough to support vibrating bridge screeds or roller pipe screeds if nature of specified slab finish requires use of such equipment.

b. Align concrete surface to elevation of screed strips by use of strike-off templates or approved compacting-type screeds.
3.2.5 Reinforcement and Other Embedded Items

a. Secure reinforcement, joint materials, and other embedded materials in position, inspected, and approved before start of concrete placing.

b. When concrete is placed, reinforcement must be free of materials deleterious to bond. Reinforcement with rust, mill scale, or a combination of both will be considered satisfactory, provided minimum nominal dimensions, nominal weight, and minimum average height of deformations of a hand-wire-brushed test specimen are not less than applicable ASTM specification requirements.

3.3 FORMS

**************************************************************************

NOTE: For more information on formwork construction and best practices refer to ACI SP-004 "Formwork for Concrete" or ACI 347R "Guide to Formwork for Concrete".

**************************************************************************

a. Provide forms, shoring, and scaffolding for concrete placement. Set forms mortar-tight and true to line and grade.

b. Chamfer above grade exposed joints, edges, and external corners of concrete [20 mm] [0.75 inch]. Place chamfer strips in corners of formwork to produce beveled edges on permanently exposed surfaces. Do not bevel reentrant corners or edges of formed joints of concrete.

c. Provide formwork with clean-out openings to permit inspection and removal of debris.

d. Inspect formwork and remove foreign material before concrete is placed.

e. At construction joints, lap form-facing materials over the concrete of previous placement. Ensure formwork is placed against hardened concrete so offsets at construction joints conform to specified tolerances.

f. Provide positive means of adjustment (such as wedges or jacks) of shores and struts. Do not make adjustments in formwork after concrete has reached initial setting. Brace formwork to resist lateral deflection and lateral instability.

g. Fasten form wedges in place after final adjustment of forms and before concrete placement.

h. Provide anchoring and bracing to control upward and lateral movement of formwork system.

i. Construct formwork for openings to facilitate removal and to produce opening dimensions as specified and within tolerances.

j. Provide runways for moving equipment. Support runways directly on formwork or structural members. Do not support runways on reinforcement. Loading applied by runways must not exceed capacity of formwork or structural members.

k. Position and support expansion joint materials, waterstops, and other
embedded items to prevent displacement. Fill voids in sleeves, inserts, and anchor slots temporarily with removable material to prevent concrete entry into voids.

3.3.1 Coating

----------------------------------------------------------------------------------
NOTE: Coating forms with a film-forming material such as epoxy or polyurethane, along with the use of a proper release agent, will make stripping easier and allow more reuses of the forms. It is important however to not allow the release agent to reach the reinforcement because it would hinder the formation of a bond between concrete and the reinforcement.
----------------------------------------------------------------------------------

a. Cover formwork surfaces with an acceptable material that inhibits bond with concrete.

b. If formwork release agent is used, apply to formwork surfaces in accordance with manufacturer's recommendations before placing reinforcement. Remove excess release agent on formwork prior to concrete placement.

c. Do not allow formwork release agent to contact reinforcement or hardened concrete against which fresh concrete is to be placed.

3.3.2 Reshoring

----------------------------------------------------------------------------------
NOTE: Reshores, as defined in ACI 347R, are shores placed snugly under a stripped concrete slab or other structural member after the original forms and shores have been removed from a full bay, requiring the new slab or structural member to deflect and support its own weight and existing construction loads applied before installation of the reshores. Such reshores are provided to transfer additional construction loads to other slabs or members and/or to impede deflection due to creep that might otherwise occur.
----------------------------------------------------------------------------------

a. Do not allow structural members to be loaded with combined dead and construction loads in excess of loads indicated in the accepted procedure.

b. Install and remove reshores or backshores in accordance with accepted procedure.

c. For floors supporting shores under newly placed concrete, either leave original supporting shores in place, or install reshores or backshores. Shoring system and supporting slabs must resist anticipated loads. Locate reshores and backshores directly under a shore position or as indicated on formwork shop drawings.
d. In multistory buildings, place reshoring or backshoring over a sufficient number of stories to distribute weight of newly placed concrete, forms, and construction live loads.

3.3.3 Reuse

a. Reuse forms providing the structural integrity of concrete and the aesthetics of exposed concrete are not compromised.

b. Wood forms must not be clogged with paste and must be capable of absorbing high water-cementitious material ratio paste.

c. Remove leaked mortar from formwork joints before reuse.

3.3.4 Forms for Standard Rough Form Finish

NOTE: According to ACI 301, surface finish-1.0 (SF-1.0) has the following requirements:
(a) No formwork facing material is specified
(b) Patch voids larger than 1-1/2 in. wide or 1/2 in. deep
(c) Remove projections larger than 1-in.
(d) Tie holes need not be patched
(e) Surface tolerance Class D as specified in ACI 117
(f) Mockup not required

Provide formwork in accordance with ACI 301 Section 5 with a surface finish, SF-1.0, for formed surfaces that are to be concealed by other construction.

3.3.5 Forms for Standard Smooth Form Finish

NOTE: When exposed to view, formed surfaces require a special architectural finish such as textured form finishes, sculptured inserts, special panel finish, and aggregate transfer finish. Requirements for such formwork must be specified. Select bracketed line for no mockup of the form finish otherwise mockup is required per ACI 301.

According to ACI 301, surface finish-3.0 (SF-3.0) has the following requirements:
(a) Patch voids larger than 3/4 in. wide or 1/2 in. deep
(b) Remove projections larger than 1/8 in.
(c) Patch tie holes
(d) Surface tolerance Class A as specified in ACI 117
(e) Provide mockup of concrete surface appearance and texture

Provide formwork in accordance with ACI 301 Section 5 with a surface finish, SF-3.0, for formed surfaces that are exposed to view.[ Do not provide mockup of concrete surface appearance and texture.]
3.3.6 Form Ties

a. For post-tensioned structures, do not remove formwork supports until stressing records have been accepted by the Contracting Officer.

b. After ends or end fasteners of form ties have been removed, repair tie holes in accordance with ACI 301 Section 5 requirements.

3.3.7 Forms for Concrete Pan Joist Construction

Pan-form units for one-way or two-way concrete joist and slab construction must be factory-fabricated units of the approximate section indicated. Units must consist of steel or molded fiberglass concrete form pans. Closure units must be furnished as required.

3.3.8 Tolerances for Form Construction

a. Construct formwork so concrete surfaces conform to tolerances in ACI 117.

b. Position and secure sleeves, inserts, anchors, and other embedded items such that embedded items are positioned within ACI 117 tolerances.

c. To maintain specified elevation and thickness within tolerances, install formwork to compensate for deflection and anticipated settlement in formwork during concrete placement. Set formwork and intermediate screed strips for slabs to produce designated elevation, camber, and contour of finished surface before formwork removal. If specified finish requires use of vibrating screeds or roller pipe screeds, ensure that edge forms and screed strips are strong enough to support such equipment.

3.3.9 Removal of Forms and Supports

a. If vertical formed surfaces require finishing, remove forms as soon as removal operations will not damage concrete.

b. Remove top forms on sloping surfaces of concrete as soon as removal will not allow concrete to sag. Perform repairs and finishing operations required. If forms are removed before end of specified curing period, provide curing and protection.

c. Do not damage concrete during removal of vertical formwork for columns, walls, and sides of beams. Perform needed repair and finishing operations required on vertical surfaces. If forms are removed before end of specified curing period, provide curing and protection.

[ d. Leave formwork and shoring in place to support construction loads and weight of concrete in beams, slabs, and other structural members until in-place required strength of concrete is reached.

] e. Form-facing material and horizontal facing support members may be removed before in-place concrete reaches specified compressive strength if shores and other supports are designed to allow facing removal without deflection of supported slab or member.

3.3.10 Strength of Concrete Required for Removal of Formwork

**************************************************************************

NOTE: Supporting forms and shores should not be
removed from beams, floors, and walls until these structural units are strong enough to carry their own weight and any approved super-imposed load. In no case should supporting forms and shores be removed from horizontal members before the concrete has achieved the specified stripping strength. Shores supporting post-tensioned construction should not be removed until sufficient tensioning force is applied to support the dead load, formwork, and anticipated construction loads.

If removal of formwork, reshoring, or backshoring is based on concrete reaching a specified in-place strength, mold and field-cure cylinders in accordance with ASTM C31/C31M. Test cylinders in accordance with ASTM C39/C39M. Alternatively, use one or more of the methods listed herein to evaluate in-place concrete strength for formwork removal.

a. Tests of cast-in-place cylinders in accordance with ASTM C873/C873M. This option is limited to slabs with concrete depths from 12.5 to 30 cm (5 to 12 in).

b. Penetration resistance in accordance with ASTM C803/C803M.

c. Pullout strength in accordance with ASTM C900.

d. Maturity method in accordance with ASTM C1074. Submit maturity method data using project materials and concrete mix proportions used on the project to demonstrate the correlation between maturity and compressive strength of laboratory cured test specimens to the Contracting Officer.

3.4 WATERSTOP INSTALLATION AND SPLICES

a. Provide waterstops in construction joints as indicated.

c. Install waterstops to form a continuous diaphragm in each joint. Make adequate provisions to support and protect waterstops during progress of work. Protect waterstops protruding from joints from damage.

3.4.1 PVC Waterstop

Make splices by heat sealing the adjacent waterstop edges together using a thermoplastic splicing iron utilizing a non-stick surface specifically designed for waterstop welding. Reform waterstops at splices with a remolding iron with ribs or corrugations to match the pattern of the waterstop. The spliced area, when cooled, must show no signs of separation, holes, or other imperfections when bent by hand in as sharp an angle as possible.

3.4.2 Rubber Waterstop

Rubber waterstops must be spliced using cold bond adhesive as recommended by the manufacturer.
3.4.3 Thermoplastic Elastomeric Rubber Waterstop

Fittings must be shop made using a machine specifically designed to mechanically weld the waterstop. A portable power saw must be used to miter or straight cut the ends to be joined to ensure good alignment and contact between joined surfaces. Maintain continuity of the characteristic features of the cross section of the waterstop (for example ribs, tabular center axis, and protrusions) across the splice.

3.4.4 Hydrophilic Waterstop

Miter cut ends to be joined with sharp knife or shears. The ends must be adhered with adhesive.

3.5 PLACING REINFORCEMENT AND MISCELLANEOUS MATERIALS

a. Unless otherwise specified, placing reinforcement and miscellaneous materials must be in accordance to ACI 301. Provide bars, welded wire reinforcement, wire ties, supports, and other devices necessary to install and secure reinforcement.

b. Reinforcement must not have rust, scale, oil, grease, clay, or foreign substances that would reduce the bond. Rusting of reinforcement is a basis of rejection if the effective cross-sectional area or the nominal weight per unit length has been reduced. Remove loose rust prior to placing steel. Tack welding is prohibited.

c. Nonprestressed cast-in-place concrete members must have concrete cover for reinforcement given in the following table:

<table>
<thead>
<tr>
<th>Concrete Exposure</th>
<th>Member</th>
<th>Reinforcement</th>
<th>Specified cover, mm in.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cast against and permanently in contact with ground</td>
<td>All</td>
<td>All</td>
<td>75 3</td>
</tr>
<tr>
<td>Exposed to weather or in contact with ground</td>
<td>All</td>
<td>No. 19 6 through No. 57 18 bars</td>
<td>50 2</td>
</tr>
<tr>
<td></td>
<td></td>
<td>No. 16 5 bar, MW200 W31 or MD200 D31 wire, and smaller</td>
<td>40 1-1/2</td>
</tr>
</tbody>
</table>
d. Cast-in-place prestressed concrete members must have concrete cover for reinforcement, ducts, and end fittings given in the following table:

<table>
<thead>
<tr>
<th>Concrete Exposure</th>
<th>Member</th>
<th>Reinforcement</th>
<th>Specified cover, mm in.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cast against and permanently in contact with ground</td>
<td>All</td>
<td>All</td>
<td>75 3</td>
</tr>
<tr>
<td>Exposed to weather or in contact with ground</td>
<td>Slabs, joists, and walls</td>
<td>All</td>
<td>25 1</td>
</tr>
<tr>
<td></td>
<td>All other</td>
<td>All</td>
<td>40 1-1/2</td>
</tr>
<tr>
<td>Not exposed to weather or in contact with ground</td>
<td>Slabs, joists, and walls</td>
<td>All</td>
<td>20 3/4</td>
</tr>
<tr>
<td></td>
<td>Beams, columns, and tension ties</td>
<td>Primary reinforcement</td>
<td>40 1-1/2</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Stirrups, ties, spirals, and hoops</td>
<td>25 1</td>
</tr>
</tbody>
</table>

e. Precast nonprestressed or prestressed concrete members manufactured under plant conditions must have concrete cover for reinforcement, ducts, and end fittings given in the following table:
<table>
<thead>
<tr>
<th>Concrete Exposure</th>
<th>Member</th>
<th>Reinforcement</th>
<th>Specified cover, mm in.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Exposed to weather or in contact with ground</td>
<td>Walls</td>
<td>No. 43 14 and No. 57 18 bars; tendons larger than 40 mm 1-1/2 in. diameter</td>
<td>40 1-1/2</td>
</tr>
<tr>
<td></td>
<td></td>
<td>No. 36 11 bars and smaller; MW200 W31 and MD200 D31 wire, and smaller; tendons and strands 40 mm 1-1/2 in.</td>

</tbody>
</table>

### 3.5.1 General

Provide details of reinforcement that are in accordance with the Contract Documents.

### 3.5.2 Vapor Retarder [and Vapor Barrier]

**NOTE: Locate vapor retarder below the slab-on-grade per ACI 360R, figure 4.7.**

a. Install in accordance with ASTM E1643. Provide beneath the on-grade concrete floor slab. Use the greatest widths and lengths practicable to eliminate joints wherever possible. Lap joints a minimum of 300 mm 12 inches and tape.

b. Remove torn, punctured, or damaged vapor retarder[ and vapor barrier] material and provide with new vapor retarder[ and vapor barrier] prior to placing concrete. Concrete placement must not damage vapor retarder[ and vapor barrier material].[ Place a 50 mm 2 inch layer of clean concrete sand on vapor retarder[ and vapor barrier] before placing concrete.][ Place vapor barrier directly on underlying subgrade, base course, or capillary water barrier, unless it consists of crushed material or large granular material which could puncture the vapor barrier. In this case, a thin layer of approximately 13 mm 1/2 inch of fine graded material should be rolled or compacted over the...
fill before installation of the vapor barrier to reduce the possibility of puncture. Control concrete placement so as to prevent damage to the vapor barrier.

3.5.3 Perimeter Insulation

**************************************************************************
NOTE: When this paragraph is used, ensure that drawings indicate location and extent of perimeter insulation.
**************************************************************************
Install perimeter insulation at locations indicated. Adhesive must be used where insulation is applied to the interior surface of foundation walls and may be used for exterior application.

3.5.4 Reinforcement Supports

**************************************************************************
NOTE: ACI 301 requirements have change for welded wire reinforcement support. If reinforcement less than W4.0 or D4.0 is specified, the continuous support spacing should be less than or equal to 30 cm 12 in.
**************************************************************************
Provide reinforcement support in accordance with CRSI RB4.1 and ACI 301 Section 3 requirements. Supports for coated or galvanized bars must also be coated with electrically compatible material for a distance of at least 50 mm 2 inches beyond the point of contact with the bars.

[3.5.5 Epoxy Coated Reinforcing

Epoxy Coated Reinforcing must meet the requirements of [ASTM A934/A934M including Appendix X2,] "Guidelines for Job Site Practices" except as otherwise specified herein.

3.5.5.1 Epoxy Coated Reinforcing Steel Placement and Coating Repair

Carefully handle and install bars to minimize job site patching. Use the same precautions as described in the paragraph titled EPOXY-COATED REINFORCING BARS. Do not drag bars over other bars or over abrasive surfaces. Keep bar free of dirt and grit. When possible, assemble reinforcement as tied cages prior to final placement into the forms. Support assembled cages on padded supports. It is not expected that coated bars, when in final position ready for concrete placement, are completely free of damaged areas; however, excessive nicks and scrapes which expose steel is cause for rejection. Criteria for defects which require repair and for those that do not require repair are as indicated. Inspect for defects and provide required repairs prior to assembly. After assembly, reinspect and provide final repairs.

a. Immediately prior to application of the patching material, manually remove any rust and debonded coating from the reinforcement by suitable techniques employing devices such as wire brushes and emery paper. Exercise cars during this surface preparation so that the damaged areas are not enlarged more than necessary to accomplish the repair. Clean damaged areas of dirt, debris, oil, and similar materials prior to application of the patching material.
b. Do repair and patching in accordance with the patching material manufacturer's recommendations. These recommendations, including cure times, must be available at the job site at all times.

c. Allow adequate time for the patching materials to cure in accordance with the manufacturer's recommendation prior to concrete placement.

d. Rinse placed reinforcing bars with fresh water to remove chloride contamination prior to placing concrete.

3.5.6 Splicing

**NOTE: When indicated, include ASTM A767/A767M and ASTM A780/A780M for zinc-coated (galvanized) bars.**

As indicated in the Contract Documents. For splices not indicated follow ACI 301. Do not splice at points of maximum stress. Overlap welded wire reinforcement the spacing of the cross wires, plus 50 mm 2 inches. [AWS D1.4/D1.4M. Approve welded splices prior to use.] Repair the cut ends of hot-dipped galvanized reinforcement steel to completely coat exposed steel, ASTM A780/A780M.

3.5.7 Future Bonding

Plug exposed, threaded, mechanical reinforcement bar connectors with a greased bolt. Provide bolt threads that match the connector. Countersink the connector in the concrete. Caulk the depression after the bolt is installed.

3.5.8 Setting Miscellaneous Material

Place and secure anchors and bolts, pipe sleeves, conduits, and other such items in position before concrete placement and support against displacement. Plumb anchor bolts and check location and elevation. Temporarily fill voids in sleeves with readily removable material to prevent the entry of concrete.

3.5.9 Fabrication

Shop fabricate reinforcing bars to conform to shapes and dimensions indicated for reinforcement, and as follows:

a. Provide fabrication tolerances that are in accordance with ACI 117.

b. Provide hooks and bends that are in accordance with the Contract Documents.

Reinforcement must be bent cold to shapes as indicated. Bending must be done in the shop. Rebending of a reinforcing bar that has been bent incorrectly is not be permitted. Bending must be in accordance with standard approved practice and by approved machine methods.

Deliver reinforcing bars bundled, tagged, and marked. Tags must be metal with bar size, length, mark, and other information pressed in by machine. Marks must correspond with those used on the placing drawings.
Do not use reinforcement that has any of the following defects:

a. Bar lengths, depths, and bends beyond specified fabrication tolerances
b. Bends or kinks not indicated on drawings or approved shop drawings
c. Bars with reduced cross-section due to rusting or other cause

Replace defective reinforcement with new reinforcement having required shape, form, and cross-section area.

3.5.10 Placing Reinforcement

Place reinforcement in accordance with ACI 301.

For slabs on grade (over earth or over capillary water barrier) and for footing reinforcement, support bars or welded wire reinforcement on precast concrete blocks, spaced at intervals required by size of reinforcement, to keep reinforcement the minimum height specified above the underside of slab or footing.

For slabs other than on grade, supports for which any portion is less than 25 mm 1 inch from concrete surfaces that are exposed to view or to be painted must be of precast concrete units, plastic-coated steel, or stainless steel protected bar supports. Precast concrete units must be wedge shaped, not larger than 90 by 90 mm, 3-1/2 by 3-1/2 inches, and of thickness equal to that indicated for concrete protection of reinforcement. Provide precast units that have cast-in galvanized tie wire hooked for anchorage and blend with concrete surfaces after finishing is completed.

Provide reinforcement that is supported and secured together to prevent displacement by construction loads or by placing of wet concrete, and as follows:

a. Provide supports for reinforcing bars that are sufficient in number and have sufficient strength to carry the reinforcement they support, and in accordance with ACI 301 and CRSI 10MSP. Do not use supports to support runways for concrete conveying equipment and similar construction loads.

b. Equip supports on ground and similar surfaces with sand-plates.

c. Support welded wire reinforcement as required for reinforcing bars.

d. Secure reinforcements to supports by means of tie wire. Wire must be black, soft iron wire, not less than 1.6 mm 16 gage.

e. Reinforcement must be accurately placed, securely tied at intersections, and held in position during placing of concrete by spacers, chairs, or other approved supports. Point wire-tie ends away from the form. Unless otherwise indicated, numbers, type, and spacing of supports must conform to the Contract Documents.

f. Bending of reinforcing bars partially embedded in concrete is permitted only as specified in the Contract Documents.
3.5.11 Spacing of Reinforcing Bars

a. Spacing must be as indicated in the Contract Documents.

b. Reinforcing bars may be relocated to avoid interference with other reinforcement, or with conduit, pipe, or other embedded items. If any reinforcing bar is moved a distance exceeding one bar diameter or specified placing tolerance, resulting rearrangement of reinforcement is subject to preapproval by the Contracting Officer.

3.5.12 Concrete Protection for Reinforcement

**************************************************************************
NOTE: If the required concrete protection for reinforcement is greater than the thicknesses specified in the ACI building code requirements for reinforced concrete, (such as in extremely corrosive atmospheres or other severe exposures, for fire protection covering, and for concrete surface to receive exposed aggregate or tooled finish), such concrete protection for reinforcement must be indicated in the Contract Documents. ACI 201.2R and ACI 303R require additional concrete protection for severe exposure conditions. Also, refer to ACI 515.2R "Guide to Selecting Protective Treatments for Concrete" for more information about providing additional protection to concrete and reinforcing steel.
**************************************************************************

Additional concrete protection must be in accordance with the Contract Documents.

3.5.13 Welding

Welding must be in accordance with AWS D1.4/D1.4M.

3.6 BATCHING, MEASURING, MIXING, AND TRANSPORTING CONCRETE

In accordance with ASTM C94/C94M, ACI 301, ACI 302.1R and ACI 304R, except as modified herein. Batching equipment must be such that the concrete ingredients are consistently measured within the following tolerances: 1 percent for cement and water, 2 percent for aggregate, and 3 percent for admixtures. Furnish mandatory batch ticket information for each load of ready mix concrete.

3.6.1 Measuring

Make measurements at intervals as specified in paragraphs SAMPLING and TESTING.

3.6.2 Mixing

a. Mix concrete in accordance with ASTM C94/C94M, ACI 301 and ACI 304R.

**************************************************************************
NOTE: Include optional sentence if greater than 90 minutes will be allowed for concrete placing.
**************************************************************************
b. Machine mix concrete. Begin mixing within 30 minutes after the cement has been added to the aggregates. Place concrete within [90] minutes of either addition of mixing water to cement and aggregates or addition of cement to aggregates.  
[If discharge is acceptable after more than 90 minutes the air content, slump, and concrete temperature shall be tested and shall be within the specified limits.] A retarder shall be used to facilitate placing and finishing when concrete temperature is 30 degrees C 85 degrees F or greater.

c. [If the entrained air content falls below the specified limit, add a sufficient quantity of admixture, within the manufacturer's recommended dosage, to bring the entrained air content within the specified limits. ]Dissolve admixtures in the mixing water and mix in the drum to uniformly distribute the admixture throughout the batch. Do not reconstitute concrete that has begun to solidify.

d. When fibers are used, add fibers together with the aggregates and never as the first component in the mixer. Fibers must be dispensed into the mixing system using appropriate dispensing equipment and procedure as recommended by the manufacturer.

3.6.3 Transporting

Transport concrete from the mixer to the forms as rapidly as practicable. Prevent segregation or loss of ingredients. Clean transporting equipment thoroughly before each batch. Do not use aluminum pipe or chutes. Remove concrete which has segregated in transporting and dispose of as directed.

3.7 PLACING CONCRETE

*************************************************************************
NOTE: When necessary to deposit concrete under water, use specifications 03 31 30 MARINE CONCRETE.
*************************************************************************

Place concrete in accordance with ACI 301 Section 5. Concrete shall be placed within 15 minutes of discharge into non-agitating equipment.

[3.7.1 Footing Placement

Concrete for footings may be placed in excavations without forms upon inspection and approval by the Contracting Officer. Excavation width must be a minimum of 100 mm 4 inches greater than indicated.

][3.7.2 Pumping

*************************************************************************
NOTE: Pumping, especially lightweight concrete, requires careful attention to mix designs and pumping procedures. Allow pumping when other means of placement are impractical or more expensive.
*************************************************************************

ACI 304R and ACI 304.2R. Pumping must not result in separation or loss of materials nor cause interruptions sufficient to permit loss of plasticity between successive increments. Loss of slump in pumping equipment must not exceed 50 mm 2 inches at discharge/placement. Do not convey concrete through pipe made of aluminum or aluminum alloy. Avoid rapid changes in
pipe sizes. Limit maximum size of course aggregate to 33 percent of the
diameter of the pipe. Limit maximum size of well-rounded aggregate to 40
percent of the pipe diameter. Take samples for testing at both the point
of delivery to the pump and at the discharge end.

[3.7.2.1 Pumping Lightweight Concrete]

**************************************************************************
NOTE: Specify minimum of 330 kg per cubic meter 564
pounds per cubic yard unless structural
considerations require higher cement content.
Require field trial run only when justified by job
complexities or size.
**************************************************************************

In accordance with ACI 213R unless otherwise specified. Presoak or
presaturate aggregates. Cement content must be minimum of [330 kg per
cubic meter ] [564 pounds per cubic yard] [_____] and be sufficient to
accommodate a 100 to 150 mm 4 to 6 inch slump.[ Make field trial run in
accordance with ACI 213R.]

]]3.7.3 Cold Weather

**************************************************************************
NOTE: The major difference between ACI 301 and ACI
306.1 is that ACI 306.1 requires the contractor to
submit detailed procedures (a plan) for cold weather
concrete.
**************************************************************************

Cold weather concrete must meet the requirements of [ACI 301][ACI 306.1]
unless otherwise specified. Do not allow concrete temperature to decrease
below 10 degrees C 50 degrees F. Obtain approval prior to placing concrete
when the ambient temperature is below 4 degrees C 40 degrees F or when
cement is likely to be subjected to freezing temperatures within 24
hours. Cover concrete and provide sufficient heat to maintain 10 degrees C
50 degrees F minimum adjacent to both the formwork and the structure while
curing. Limit the rate of cooling to 3 degrees C 37 degrees F in any one
hour and 10 degrees C 50 degrees F per 24 hours after heat application.

3.7.4 Hot Weather

**************************************************************************
NOTE: The major difference between ACI 301 and ACI
305.1 is that ACI 305.1 requires the contractor to
submit detailed procedures (a plan) for hot weather
concrete.
**************************************************************************

[Hot weather concrete must meet the requirements of [ACI 301][ACI 305.1]
unless otherwise specified. ]Maintain required concrete temperature using
Figure 4.2 in ACI 305R to prevent the evaporation rate from exceeding 1 kg
per square meter 0.2 pound of water per square foot of exposed concrete per
hour. Cool ingredients before mixing or use other suitable means to
control concrete temperature and prevent rapid drying of newly placed
concrete. Shade the fresh concrete as soon as possible after placing.
Start curing when the surface of the fresh concrete is sufficiently hard to
permit curing without damage. Provide water hoses, pipes, spraying
equipment, and water hauling equipment, where job site is remote to water
source, to maintain a moist concrete surface throughout the curing period. Provide burlap cover or other suitable, permeable material with fog spray or continuous wetting of the concrete when weather conditions prevent the use of either liquid membrane curing compound or impervious sheets. For vertical surfaces, protect forms from direct sunlight and add water to top of structure once concrete is set.

3.7.5 Bonding

Surfaces of set concrete at joints, must be roughened and cleaned of laitance, coatings, loose particles, and foreign matter. Roughen surfaces in a manner that exposes the aggregate uniformly and does not leave laitance, loosened particles of aggregate, nor damaged concrete at the surface.

Obtain bonding of fresh concrete that has set as follows:

a. At joints between footings and walls or columns, between walls or columns and the beams or slabs they support, and elsewhere unless otherwise specified; roughened and cleaned surface of set concrete must be dampened, but not saturated, immediately prior to placing of fresh concrete.

b. At joints in exposed-to-view work; at vertical joints in walls; at joints near midpoint of span in girders, beams, supported slabs, other structural members; in work designed to contain liquids; the roughened and cleaned surface of set concrete must be dampened but not saturated and covered with a cement grout coating.

c. Provide cement grout that consists of equal parts of portland cement and fine aggregate by weight with not more than 22.5 liters 6 gallons of water per sack of cement. Apply cement grout with a stiff broom or brush to a minimum thickness of 1.6 mm 1/16 inch. Deposit fresh concrete before cement grout has attained its initial set.

3.8 WASTE MANAGEMENT

Provide as specified in the Waste Management Plan and as follows.

3.8.1 Mixing Equipment

Before concrete pours, designate[ Contractor-owned site meeting environmental standards][ on-site area to be paved later in project] for cleaning out concrete mixing trucks. Minimize water used to wash equipment.

**************************************************************************
NOTE: The use of crushed waste concrete as an aggregate in the production of new concrete should follow the recommendations of ACI 555R.
**************************************************************************

3.8.2 Hardened, Cured Waste Concrete

[Crush and reuse hardened, cured waste concrete as fill or as a base course for pavement. ][Use hardened, cured waste concrete as aggregate in concrete mix if approved by Contracting Officer.]
3.8.3 Reinforcing Steel

Collect reinforcing steel and place in designated area for recycling.

3.8.4 Other Waste

Identify concrete manufacturer's or supplier's policy for collection or return of construction waste, unused material, deconstruction waste, and/or packaging material. [Return excess cement to supplier.] [Institute deconstruction and construction waste separation and recycling for use in manufacturer's programs. When such a program is not available, seek local recyclers to reclaim the materials.]

3.9 SURFACE FINISHES EXCEPT FLOOR, SLAB, AND PAVEMENT FINISHES

3.9.1 Defects

Repair surface defects in accordance with ACI 301 Section 5.

3.9.2 Not Against Forms (Top of Walls)

Surfaces not otherwise specified must be finished with wood floats to even surfaces. Finish must match adjacent finishes.

3.9.3 Formed Surfaces

3.9.3.1 Tolerances

Tolerances in accordance with ACI 117 and as indicated.

3.9.3.2 As-Cast Rough Form

Provide for surfaces not exposed to public view a surface finish SF-1.0. Patch holes and defects in accordance with ACI 301.

3.9.3.3 Standard Smooth Finish

Provide for surfaces exposed to public view a surface finish SF-3.0. Patch holes and defects in accordance with ACI 301.

3.9.4 [Smooth-Rubbed][Grout-Cleaned Rubbed][Cork-Floated][Exposed Aggregate] Finish

******************************************************************************

NOTE: Add information where special type of finish is desired. See ACI 301 for information on smooth rubbed finish, grout cleaned finish, cork floated finish, and exposed aggregate. Areas requiring special finish should be clearly indicated on the drawings and coordinated with the specifications.

******************************************************************************

[Provide a smooth-rubbed finish per ACI 301 Section 5 in the locations indicated.] [Provide a grout-cleaned rubbed finish per ACI 301 Section 5 in the locations indicated.] [Provide a cork-floated finish per ACI 301 Section 5 in the locations indicated.] [Provide an exposed aggregate finish per ACI 301 Section 5 in the locations indicated.]
3.10  FLOOR, SLAB, AND PAVEMENT FINISHES AND MISCELLANEOUS CONSTRUCTION

**************************************************************************
NOTE: Where floor flatness is critical use paragraph FLAT FLOOR FINISHES. Coordinate concrete finish with applicable architectural finish material to be installed over concrete floor. For thin-set tile, coordinate with Section 09 30 10 CERAMIC, QUARRY, AND GLASS TILING
**************************************************************************

In accordance with ACI 301 and ACI 302.1R, unless otherwise specified. Slope floors uniformly to drains where drains are provided. Depress the concrete base slab where quarry tile, ceramic tile, [or] [_____] are indicated. Steel trowel and fine-broom finish concrete slabs that are to receive quarry tile, ceramic tile, or paver tile [_____]. Where straightedge measurements are specified, Contractor must provide straightedge.

3.10.1  Finish

Place, consolidate, and immediately strike off concrete to obtain proper contour, grade, and elevation before bleedwater appears. Permit concrete to attain a set sufficient for floating and supporting the weight of the finisher and equipment. If bleedwater is present prior to floating the surface, drag the excess water off or remove by absorption with porous materials. Do not use dry cement to absorb bleedwater. Grate tampers ("jitterbugs") shall not be used.

3.10.1.1  Scratched

Use for surfaces intended to receive bonded applied cementitious applications. Finish concrete in accordance with ACI 301 Section 5 for a scratched finish.

3.10.1.2  Floated

Use for [surfaces to receive [roofing,] [waterproofing membranes,] [sand bed terrazzo,]] [_____] [and] [exterior slabs where not otherwise specified.] Finish concrete in accordance with ACI 301 Section 5 for a floated finish.

[3.10.1.3  Concrete Containing Silica Fume

Finish using magnesium floats or darbies.[ Finish using techniques demonstrated in the sample installation.]

]3.10.1.4  Steel Troweled

**************************************************************************
NOTE: ACI 302.1R suggests power troweling three times for Class 5 floors and where increased wear resistance is needed.
**************************************************************************

Use for floors intended as walking surfaces[. and] [for reception of floor coverings[, and] [____]. Finish concrete in accordance with ACI 301 Section 5 for a steel troweled finish.
3.10.1.5  Nonslip Finish

**************************************************************************
NOTE: Include when nonslip finish using dry shake aggregate is desired.
**************************************************************************

Use on surfaces of exterior platforms, steps, and landings; and on exterior and interior pedestrian ramps. Finish concrete in accordance with ACI 301 Section 5 for a dry-shake finish. After the selected material has been embedded by the two floatings, complete the operation with a [broomed] [floated] [troweled] finish.

3.10.1.6  Broomed

Use on surfaces of exterior walks, platforms, patios, and ramps, unless otherwise indicated. Finish concrete in accordance with ACI 301 Section 5 for a broomed finish.

3.10.1.7  Pavement

Screed the concrete with a template advanced with a combined longitudinal and crosswise motion. Maintain a slight surplus of concrete ahead of the template. After screeding, float the concrete longitudinally. Use a straightedge to check slope and flatness; correct and refloat as necessary. Obtain final finish by [belting. Lay belt flat on the concrete surface and advance with a sawing motion; continue until a uniform but gritty nonslip surface is obtained.] [a burlap drag. Drag a strip of clean, wet burlap from 900 to 3000 mm wide and 600 mm longer 3 to 10 feet wide and 2 feet longer than the pavement width across the slab. Produce a fine, granular, sandy textured surface without disfiguring marks.] Round edges and joints with an edger having a radius of 3 mm 1/8 inch.

3.10.1.8  Concrete Toppings Placement

The following requirements apply to the placement of toppings of concrete on base slabs that are either freshly placed and still plastic, or on hardened base slabs.

a. Placing on a Fresh Base: Screed and bull float the base slab. As soon as the water sheen has disappeared, lightly rake the surface of the base slab with a stiff bristle broom to produce a bonding surface for the topping. Immediately spread the topping mixture evenly over the roughened base before final set takes place. Give the topping the finish [indicated on the drawings] [specified herein].

b. Bonding to a Hardened Base: When the topping is to be bonded to a floated or troweled hardened base, roughen the base by scarifying, grit-blasting, scabbling, planing, flame cleaning, or acid-etching to lightly expose aggregate and provide a bonding surface. Remove dirt, laitance, and loose aggregate by means of a stiff wire broom. Keep the clean base wet for a period of 12 hours preceding the application of the topping. Remove excess water and apply a 1:1:1/2 cement-sand-water grout, and brush into the surface of the base slab. Do not allow the cement grout to dry, and spread it only short distances ahead of the topping placement. Do not allow the temperature differential between the completed base and the topping mixture to exceed 5 degrees C 41 degrees F at the time of placing. Place the topping and finish as[ indicated][ specified herein].
3.10.1.9 Chemical-Hardener Treatment

**************************************************************************
NOTE: Slab surfaces requiring a chemical hardener must be indicated. Such treatment is suitable for surfaces of concrete floors in equipment rooms and on other floor surfaces that are subject to light foot traffic only and must not be covered with resilient flooring, paint, or other finish coating.
**************************************************************************

Apply liquid-chemical floor hardener where indicated after curing and drying concrete surface. Dilute liquid hardener with water and apply in three coats. First coat must be one-third strength, second coat one-half strength, and third coat two-thirds strength. Apply each coat evenly and allow to dry 24 hours between coats.

Approved proprietary chemical hardeners must be applied in accordance with manufacturer's printed directions.

3.10.1.10 Colored Wear-Resistant Finish

**************************************************************************
NOTE: Slab surfaces requiring colored, wear-resistant finish must be indicated. Such finish is suitable for exterior and interior slabs that are subject to medium-heavy foot traffic.
**************************************************************************

a. Give finish to monolithic slab surfaces where indicated.

b. Apply dry shake materials for colored wear-resistant finish at the rate of 29 kilogram per 10 square meter 60 pounds per 100 square feet of surface.

c. Immediately following first floating operation, approximately two-thirds of specified weight of dry shake material must be uniformly distributed over surface and embedded by means of power floating. After first dry-shake application has been embedded, uniformly distribute remainder of dry-shake material over surface at right angles to first dry-shake application and embed by means of power floating. Trueness of surface and other requirements for floating operations not specified in this paragraph must be as specified for float finish.

d. After completion of float finish, apply a trowel finish as specified.

3.10.1.11 Heavy-Duty Wear-Resistant Finish

**************************************************************************
NOTE: Delete paragraph heading and following paragraphs when not applicable. Slab surfaces requiring heavy-duty wear-resistant finish must be indicated. Traprock and emery aggregate finish are suitable for exterior and interior slabs that are subject to abrasive wear. Iron aggregate finish is suitable for interior slabs that are not subject to excessive amounts of moisture and are subject to abrasive wear and some impact.
**************************************************************************
a. Give finish to slab surfaces where indicated.

b. Dry-shake material for heavy-duty, wear-resistant finish must consist of a mixture of standard portland cement and aggregate for heavy-duty, wear-resistant finish proportioned by weight as follows:

One part standard portland cement and [two parts traprock aggregate for heavy-duty wear-resistant finish] [four parts emery aggregate for heavy-duty wear-resistant finish] [two parts by weight iron aggregate for heavy-duty, wear-resistant finish].

c. Apply blended dry-shake material as follows:

NOTE: Select type of aggregate.

<table>
<thead>
<tr>
<th>Maximum type of aggregate in dry shake</th>
<th>Amount per 100 square meter feet of Surface</th>
</tr>
</thead>
<tbody>
<tr>
<td>Traprock</td>
<td>73 kilogram 160 pounds</td>
</tr>
<tr>
<td>Emery</td>
<td>59 kilogram 130 pounds</td>
</tr>
<tr>
<td>Iron</td>
<td>59 kilogram 130 pounds</td>
</tr>
</tbody>
</table>

d. Immediately following the first floating operation, approximately one-half the specified weight of blended, uniformly distribute dry-shake materials over the surface and embedded by means of power floating. After the first dry-shake application has been embedded, uniformly distribute the remaining one-half of the blended dry-shake material over the surface at right angles to the first dry-shake application and embedded by means of power floating. Trueness of surface and other requirements for floating operations not specified in this paragraph must be as specified for float finish.

e. After completion of the float finish, trowel finish the surface as specified.

[3.10.2 Flat Floor Finishes]

NOTE: Use these paragraphs where floor flatness is critical. Indicate areas where these requirements apply. Flatness affects the appearance and function of finishes applied to the concrete and in situations such as large or long expanses of glossy floor materials. Low tolerance for product (for example thin set tile and wood gymnasium floors) and equipment dictates to the designer to specify higher than normal flatness requirements. The numbers provided in brackets are typical numbers, but A/E should research and select F numbers high enough to get desired results but not so high as to cause undue cost increases and construction problems.
**UFGS**  
Ff/FL 20/15 is equivalent to 8 mm in 5.05 mm 5/16 inches in 10 feet. This test method is not suitable for unshored deck. Fitted partitions need FL greater than or equal to 25.

When specifying floors where flatness is important, adhere primarily to good concrete fundamentals, including equalizing hydration on top and bottom, reducing shrinkage prone cement paste content, and paying attention to curing protocol (slower is better).

**************************************************************************

**ACI 302.1R.** Construct in accordance with one of the methods recommended in Table 10.15.3a, "Slab-on-ground flatness/levelness construction guide" or Table 10.15.3b, "Suspended slab flatness/levelness construction guide" appropriate for the type of construction. **ACI 117** for tolerance tested by **ASTM E1155**.

a. Specified Conventional Value:
   - Floor Flatness (Ff) [20] [_____] [13] [_____] minimum
   - Floor Levelness (FL) [15] [_____] [10] [_____] minimum

b. Specified Industrial:
   - Floor Flatness (Ff) [30] [_____] [15] [_____] minimum
   - Floor Levelness (FL) [20] [_____] [10] [_____] minimum

3.10.2.1 Measurement of Floor Tolerances

Test slab within 24 hours of the final troweling. Provide tests to Contracting Officer within 12 hours after collecting the data. Floor flatness inspector is required to provide a tolerance report which must include:

a. Key plan showing location of data collected.

b. Results required by **ASTM E1155**.

3.10.2.2 Remedies for Out of Tolerance Work

Contractor is required to repair and retest any floors not meeting specified tolerances. Prior to repair, Contractor must submit and receive approval for the proposed repair, including product data from any materials proposed. Repairs must not result in damage to structural integrity of the floor. For floors exposed to public view, repairs must prevent any uneven or unusual coloring of the surface.

3.10.3 Concrete Walks

Provide 100 mm 4 inches thick minimum. Provide contraction joints spaced every 1500 lineal mm 5 linear feet unless otherwise indicated. Cut contraction joints 25 mm 1 inch deep, or one fourth the slab thickness whichever is deeper, with a jointing tool after the surface has been finished. Provide 13 mm 0.5 inch thick transverse expansion joints at changes in direction where sidewalk abuts curb, steps, rigid pavement, or...
other similar structures; space expansion joints every 15 m 50 feet maximum. Give walks a broomed finish. Unless indicated otherwise, provide a transverse slope of 1/48. Limit variation in cross section to 6 mm in 1500 mm 1/4 inch in 5 feet.

3.10.4 Pits and Trenches

Place bottoms and walls monolithically or provide waterstops and keys.

3.10.5 Curbs[ and Gutters]

Provide contraction joints spaced every 3 m 10 feet maximum unless otherwise indicated. Cut contraction joints 20 mm 3/4 inch deep with a jointing tool after the surface has been finished. Provide expansion joints 13 mm 1/2 inch thick and spaced every 30 m 100 feet maximum unless otherwise indicated. Perform pavement finish.

3.10.6 Splash Blocks

Provide at outlets of downspouts emptying at grade. Splash blocks may be precast concrete, and must be 600 mm long, 300 mm wide and 100 mm thick 24 inches long, 12 inches wide and 4 inches thick, unless otherwise indicated, with smooth-finished countersunk dishes sloped to drain away from the building.

3.11 JOINTS

3.11.1 Construction Joints

Make and locate joints not indicated so as not to impair strength and appearance of the structure, as approved. Joints must be perpendicular to main reinforcement. Reinforcement must be continued and developed across construction joints. Locate construction joints as follows:

3.11.1.1 Construction Joints for Constructability Purposes

a. In walls, at top of footing; at top of slabs on ground; at top and bottom of door and window openings or where required to conform to architectural details; and at underside of deepest beam or girder framing into wall.

b. In columns or piers, at top of footing; at top of slabs on ground; and at underside of deepest beam or girder framing into column or pier.

c. Near midpoint of spans for supported slabs, beams, and girders unless a beam intersects a girder at the center, in which case construction joints in girder must offset a distance equal to twice the width of the beam. Make transfer of shear through construction joint by use of inclined reinforcement.

Provide keyways at least 40 mm 1-1/2-inches deep in construction joints in walls and slabs and between walls and footings; approved bulkheads may be used for slabs.

3.11.2 Isolation Joints in Slabs on Ground

******************************************************************************
NOTE: If inserts are to be used for slab on ground contraction joint use bracketed paragraph and remove

SECTION 03 30 00 Page 82
paragraph related to sawcut joints.

a. Provide joints at points of contact between slabs on ground and vertical surfaces, such as column pedestals, foundation walls, grade beams, and elsewhere as indicated.

b. Fill joints with premolded joint filler strips 13 mm 1/2 inch thick, extending full slab depth. Install filler strips at proper level below finish floor elevation with a slightly tapered, dress-and-oiled wood strip temporarily secured to top of filler strip to form a groove not less than 19 mm 3/4 inch in depth where joint is sealed with sealing compound and not less than 6 mm 1/4 inch in depth where joint sealing is not required. Remove wood strip after concrete has set. Contractor must clean groove of foreign matter and loose particles after surface has dried.

3.11.3 Contraction Joints in Slabs on Ground

a. Provide joints to form panels as indicated.

b. Under and on exact line of each control joint, cut 50 percent of welded wire reinforcement before placing concrete.

c. Sawcut contraction joints into slab on ground in accordance with ACI 301 Section 5.

[ d. Joints must be 4 mm 1/8-inch wide by 1/5 to 1/4 of slab depth and formed by inserting hand-pressed fiberboard strip into fresh concrete until top surface of strip is flush with slab surface. After concrete has cured for at least 7 days, the Contractor must remove inserts and clean groove of foreign matter and loose particles.

]**********************************************************************

NOTE: Use the following bracketed sentence for projects in Hawaii.
**********************************************************************

[ e. Sawcutting will be limited to within 12 hours after set and at 1/4 slab depth.

]3.11.4 Sealing Joints in Slabs on Ground

a. Contraction and control joints which are to receive finish flooring material must be sealed with joint sealing compound after concrete curing period. Slightly underfill groove with joint sealing compound to prevent extrusion of compound. Remove excess material as soon after sealing as possible.

b. Sealed groove must be left ready to receive filling material that is provided as part of finish floor covering work.

3.12 CONCRETE FLOOR TOPPING

3.12.1 Standard Floor Topping

**********************************************************************

NOTE: When standard floor topping is specifically
required, the location of standard floor topping must be indicated.

Provide topping for treads and platforms of metal steel stairs and elsewhere as indicated.

3.12.1.1 Preparations Prior to Placing

a. When topping is placed on a green concrete base slab, screed surface of base slab to a level not more than 38 mm 1-1/2 inches nor less than 25 mm 1 inch below required finish surface. Remove water and laitance from surface of base slab before placing topping mixture. As soon as water ceases to rise to surface of base slab, place topping.

b. When topping is placed on a hardened concrete base slab, remove dirt, loose material, oil, grease, asphalt, paint, and other contaminants from base slab surface, leaving a clean surface. Prior to placing topping mixture, 64 mm 2-1/2-inches minimum, slab surface must be dampened and left free of standing water. Immediately before topping mixture is placed, broom a coat of neat cement grout onto surface of slab. Do not allow cement grout to set or dry before topping is placed.

c. When topping is placed on a metal surface, such as metal pans for steel stairs, remove dirt, loose material, oil, grease, asphalt, paint, and other contaminants from metal surface.

3.12.1.2 Placing

Spread standard topping mixture evenly on previously prepared base slab or metal surface, brought to correct level with a straightedge, and struck off. Topping must be consolidated, floated, checked for trueness of surface, and refloated as specified for float finish.

3.12.1.3 Finishing

Give trowel finish standard floor topping surfaces.

NOTE: Standard floor topping surfaces requiring an applied finish such as a chemical-hardener, non-slip aggregate finish, colored wear-resistant finish, sealers, or heavy-duty, wear-resistant finish must be indicated.

Give other finishes standard floor topping surfaces as indicated.

3.12.2 Heavy-Duty Floor Topping

NOTE: Location of heavy-duty floor topping must be indicated. Heavy-duty floor topping is suitable for an industrial floor subject to continuous severe abrasion and impact such as steel-tire vehicles.

Provide topping where indicated.
3.12.2.1 Heavy-duty Topping Mixture

Provide mixture that consists of 1 part portland cement and 2-1/2 parts emery aggregate or 1 part fine aggregate and 1-1/2 parts traprock coarse aggregate, by volume. Exact proportions of mixture must conform to recommendations of aggregate manufacturer. Mixing water must not exceed 14.2 liter per 43 kilogram 3-1/4 gallons per 94-pound sack of cement including unabsorbed moisture in aggregate. Maximum slump must be 25 mm 1 inch.

3.12.2.2 Base Slab

a. Screed surface of slab to a level no more than 38 mm 1-1/2 inches nor less than 25 mm 1 inch below grade of finished floor.

b. Give slab a scratch finish as specified.

c. Preparations prior to placing.

Remove dirt, loose material, oil, grease, asphalt, paint and other contaminants from base slab surface. Prior to placing topping mixture, dampen slab surface and leave free of standing water. Immediately before topping mixture is placed, broom a coat of neat cement grout onto surface of slab. Allow cement grout to set or dry before topping mixture is placed.

3.12.2.3 Placing

Spread heavy-duty topping mixture evenly on previously prepared base slab, and bring to correct level with a straightedge, and strike off. Provide topping that is consolidated, floated, and checked for trueness of surface as specified for float finish, except that power-driven floats is the impact type.

3.12.2.4 Finishing

Give trowel finish heavy-duty floor topping surfaces. Provide trowel finish as specified, except that additional troweling after first power troweling must be not less than three hand-troweling operations.

3.13 CURING AND PROTECTION

**************************************************************************
NOTE: Add to "Curing and Protection" when using silica fume.

Prevent concrete with silica fume from drying by one or more of the following:

1. Misting surface of concrete with fog nozzle;

2. Liquid membrane-forming compound;

3. Pervious or impervious sheeting.

Increase curing time per manufacturer's recommendations.
**************************************************************************
Curing and protection in accordance with ACI 301 Section 5, unless otherwise specified. Begin curing immediately following form removal. Avoid damage to concrete from vibration created by blasting, pile driving, movement of equipment in the vicinity, disturbance of formwork or protruding reinforcement, and any other activity resulting in ground vibrations. Protect concrete from injurious action by sun, rain, flowing water, frost, mechanical injury, tire marks, and oil stains. Do not allow concrete to dry out from time of placement until the expiration of the specified curing period. Do not use membrane-forming compound on surfaces where appearance would be objectionable, on any surface to be painted, where coverings are to be bonded to the concrete, or on concrete to which other concrete is to be bonded. If forms are removed prior to the expiration of the curing period, provide another curing procedure specified herein for the remaining portion of the curing period. Provide moist curing for those areas receiving liquid chemical sealer, hardener, or epoxy coating. Allow curing compound/sealer installations to cure prior to the installation of materials that adsorb VOCs, including [______].

3.13.1 Requirements for Type III, High-Early-Strength Portland Cement

The curing periods are required to be not less than one-fourth of those specified for portland cement, but in no case less than 72 hours.

3.13.2 Curing Periods

ACI 301 Section 5, except 10 days for retaining walls, pavement or chimneys. Begin curing immediately after placement. Protect concrete from premature drying, excessively hot temperatures, and mechanical injury; and maintain minimal moisture loss at a relatively constant temperature for the period necessary for hydration of the cement and hardening of the concrete. The materials and methods of curing are subject to approval by the Contracting Officer.

3.13.3 Curing Formed Surfaces

Accomplish curing of formed surfaces, including undersurfaces of girders, beams, supported slabs, and other similar surfaces by moist curing with forms in place for full curing period or until forms are removed. If forms are removed before end of curing period, accomplish final curing of formed surfaces by any of the curing methods specified above, as applicable.

3.13.4 Curing Unformed Surfaces

a. Accomplish initial curing of unformed surfaces, such as monolithic slabs, floor topping, and other flat surfaces, by membrane curing.

b. Accomplish final curing of unformed surfaces by any of curing methods specified, as applicable.

c. Accomplish final curing of concrete surfaces to receive liquid floor hardener of finish flooring by moisture-retaining cover curing.

3.13.5 Temperature of Concrete During Curing

When temperature of atmosphere is 5 degrees C 41 degrees F and below, maintain temperature of concrete at not less than 13 degrees C 55 degrees F throughout concrete curing period or 7 degrees C 45 degrees F when the curing period is measured by maturity. When necessary, make arrangements before start of concrete placing for heating, covering, insulation, or
housing as required to maintain specified temperature and moisture conditions for concrete during curing period.

When the temperature of atmosphere is 27 degrees C 80 degrees F and above or during other climatic conditions which cause too rapid drying of concrete, make arrangements before start of concrete placing for installation of wind breaks, of shading, and for fog spraying, wet sprinkling, or moisture-retaining covering of light color as required to protect concrete during curing period.

Changes in temperature of concrete must be uniform and not exceed 3 degrees C 37 degrees F in any one hour nor 27 degrees C 80 degrees F in any 24-hour period.

3.13.6 Protection from Mechanical Injury

During curing period, protect concrete from damaging mechanical disturbances, particularly load stresses, heavy shock, and excessive vibration and from damage caused by rain or running water.

3.13.7 Protection After Curing

Protect finished concrete surfaces from damage by construction operations.

3.14 FIELD QUALITY CONTROL

3.14.1 Aggregate Testing

3.14.1.1 Fine Aggregate

At least once during each shift when the concrete plant is operating, there shall be one sieve analysis and fineness modulus determination in accordance with ASTM C136/C136M and COE CRD-C 104 for the fine aggregate or for each fine aggregate if it is batched in more than one size or classification. The location at which samples are taken may be selected by the Contractor as the most advantageous for control. However, the Contractor is responsible for delivering fine aggregate to the mixer within specification limits. When the amount passing on any sieve is outside the specification limits, the fine aggregate shall be immediately resampled and retested. If there is another failure on any sieve, the fact shall be immediately reported to the Contracting Officer, concreting shall be stopped, and immediate steps taken to correct the grading.

3.14.1.2 Coarse Aggregate

At least once during each shift in which the concrete plant is operating, there shall be a sieve analysis in accordance with ASTM C136/C136M for each size of coarse aggregate. The location at which samples are taken may be selected by the Contractor as the most advantageous for production control. However, the Contractor shall be responsible for delivering the aggregate to the mixer within specification limits. A test record of samples of aggregate taken at the same locations shall show the results of the current test as well as the average results of the five most recent tests including the current test. The Contractor may adopt limits for control coarser than the specification limits for samples taken other than as delivered to the mixer to allow for degradation during handling. When the amount passing any sieve is outside the specification limits, the coarse aggregate shall be immediately resampled and retested. If the second sample fails on any sieve, that fact shall be reported to the
Contracting Officer. Where two consecutive averages of 5 tests are outside specification limits, the operation shall be considered out of control and reported to the Contracting Officer. Concreting shall be stopped and immediate steps shall be taken to correct the grading.

3.14.2 Concrete Sampling

**ASTM C172/C172M.** Collect samples of fresh concrete to perform tests specified. **ASTM C31/C31M** for making test specimens.

3.14.3 Concrete Testing

3.14.3.1 Slump Tests

**ASTM C143/C143M.** Take concrete samples during concrete placement/discharge. The maximum slump may be increased as specified with the addition of an approved admixture provided that the water-cementitious material ratio is not exceeded. Perform tests at commencement of concrete placement, when test cylinders are made[, and for each _____ cubic meters cubic yards (maximum) of concrete].

3.14.3.2 Temperature Tests

Test the concrete delivered and the concrete in the forms. Perform tests in hot or cold weather conditions (below 10 degrees C and above 27 degrees C below 50 degrees F and above 80 degrees F) for each batch (minimum) or every 16 cubic meters 20 cubic yards (maximum) of concrete, until the specified temperature is obtained, and whenever test cylinders and slump tests are made.

3.14.3.3 Compressive Strength Tests

**************************************************************************

NOTE: When the same mix design is used for multiple elements such as slabs, beams, and walls, the design element type may be specified in lieu of or in addition to the mix design in order to better identify deficient concrete.

Use eight cylinders when specifying 56 or 90 day strengths. Use 6x12 cylinders for better prediction of strength and consistency.

**************************************************************************

**ASTM C39/C39M.** Make [six][eight] 150 mm by 300 mm 6 inch by 12 inch or [nine][12] 100 mm by 200 mm 4 inch by 8 inch test cylinders for each set of tests in accordance with **ASTM C31/C31M, ASTM C172/C172M** and applicable requirements of **ACI 305R** and **ACI 306R**. Take precautions to prevent evaporation and loss of water from the specimen. Test two 150 mm by 300 mm 6 inch by 12 inch or three 100 mm by 200 mm 4 inch by 8 inch cylinders at 7 days, two 150 mm by 300 mm 6 inch by 12 inch or three 100 mm by 200 mm 4 inch by 8 inch cylinders at 28 days,[ two 150 mm by 300 mm 6 inch by 12 inch or three 100 mm by 200 mm 4 inch by 8 inch cylinders at 90 days][ and hold two 150 mm by 300 mm 6 inch by 12 inch or three 100 mm by 200 mm 4 inch by 8 inch cylinders in reserve]. Take samples for strength tests for each concrete mixture placed each day not less than once a day, nor less than once for each 115 cubic meters 150 cubic yards of concrete, nor less than once for each 450 square meters 5000 square yards.
square feet of surface area for slabs or walls. For the entire project, take no less than five sets of samples and perform strength tests for each mix design of concrete placed. Each strength test result must be the average of two 150 mm by 300 mm 6 inch by 12 inch or three 100 mm by 200 mm 4 inch by 8 inch cylinders from the same concrete sample tested at 28 days [56 days] [90 days] [______]. Concrete compressive tests must meet the requirements of this section, the Contract Document, and ACI 301.

[3.14.3.4 Air Content]
ASTM C173/C173M or ASTM C231/C231M for normal weight concrete [and ASTM C173/C173M for lightweight concrete]. Test air-entrained concrete for air content at the same frequency as specified for slump tests.

[3.14.3.5 Unit Weight of Structural Concrete]

[3.14.3.6 Chloride Ion Concentration]
**************************************************************************
NOTE: Include only when justified by size of job or when quality of concrete is questionable.
**************************************************************************
Chloride ion concentration must meet the requirements of the paragraph titled CORROSION AND CHLORIDE CONTENT. Determine water soluble ion concentration in accordance with ASTM C1218/C1218M. Perform test once for each mix design.

[3.14.3.7 Strength of Concrete Structure]
The strength of the concrete structure will be considered to be deficient if any of the following conditions are identified:

a. Failure to meet compressive strength tests as evaluated.
b. Reinforcement not conforming to requirements specified.
c. Concrete which differs from required dimensions or location in such a manner as to reduce strength.
d. Concrete curing and protection of concrete against extremes of temperature during curing, not conforming to requirements specified.
e. Concrete subjected to damaging mechanical disturbances, particularly load stresses, heavy shock, and excessive vibration.
f. Poor workmanship likely to result in deficient strength.

Where the strength of the concrete structure is considered deficient submit a mitigation or remediation plan for review and approval by the contracting officer.

3.14.3.8 Non-Conforming Materials
Factors that indicate that there are non-conforming materials include (but
not limited to) excessive compressive strength, inadequate compressive strength, excessive slump, excessive voids and honeycombing, concrete delivery records that indicate excessive time between mixing and placement, or excessive water was added to the mixture during delivery and placement. Any of these indicators alone are sufficient reason for the Contracting Officer to request additional sampling and testing.

Investigations into non-conforming materials must be conducted at the Contractor's expense. The Contractor must be responsible for the investigation and must make written recommendations to adequately mitigate or remediate the non-conforming material. The Contracting Officer may accept, accept with reduced payment, require mitigation, or require removal and replacement of non-conforming material at no additional cost to the Government.

3.14.3.9 Testing Concrete Structure for Strength

**************************************************************************
NOTE: If the government is going to take cores and test them then include the bracketed paragraph.
**************************************************************************

When there is evidence that strength of concrete structure in place does not meet specification requirements or there are non-conforming materials, make cores drilled from hardened concrete for compressive strength determination in accordance with ASTM C42/C42M, and as follows:

a. Take at least three representative cores from each member or area of concrete-in-place that is considered potentially deficient. Location of cores will be determined by the Contracting Officer.

b. Test cores after moisture conditioning in accordance with ASTM C42/C42M if concrete they represent is more than superficially wet under service.

c. Air dry cores, (16 to 27 degrees C 60 to 80 degrees F with relative humidity less than 60 percent) for 7 days before test and test dry if concrete they represent is dry under service conditions.

d. Strength of cores from each member or area are considered satisfactory if their average compressive strength is equal to or greater than 85 percent of the design compressive strength, and if no single core strength is less than 75 percent of the design compressive strength. Additional testing of cores extracted from locations represented by erratic core strength results will be permitted only when approved by the Contracting Officer.

[ e. Core specimens will be taken and tested by the Government. If the results of core-boring tests indicate that the concrete as placed does not conform to the drawings and specification, the cost of such tests and restoration required must be borne by the Contractor. ]

] Fill core holes solid with patching mortar and finished to match adjacent concrete surfaces.

Correct concrete work that is found inadequate by core tests in a manner approved by the Contracting Officer.
3.15 REPAIR, REHABILITATION AND REMOVAL

Before the Contracting Officer accepts the structure the Contractor must inspect the structure for cracks, damage and substandard concrete placements that may adversely affect the service life of the structure. A report documenting these defects must be prepared which includes recommendations for repair, removal or remediation must be submitted to the Contracting Officer for approval before any corrective work is accomplished.

**************************************************************************
NOTE: Include this paragraph if the concrete structure is a water tank designed in accordance with ACI 530.
**************************************************************************

[3.15.1 Crack Repair

Prior to final acceptance, all cracks in excess of 0.50 mm 0.02 inches wide must be documented and repaired. The proposed method and materials to repair the cracks must be submitted to the Contracting Officer for approval. The proposal must address the amount of movement expected in the crack due to temperature changes and loading.

]3.15.2 Repair of Weak Surfaces

Weak surfaces are defined as mortar-rich, rain-damaged, uncured, or containing exposed voids or deleterious materials. Concrete surfaces with weak surfaces less than 6 mm 1/4 inch thick must be diamond ground to remove the weak surface. Surfaces containing weak surfaces greater than 6 mm 1/4 inch thick must be removed and replaced or mitigated in a manner acceptable to the Contracting Officer.

3.15.3 Failure of Quality Assurance Test Results

**************************************************************************
NOTE: Test results accomplished on concrete samples during concrete production that fall short of the acceptance criteria alert the Contractor to something in the production and placement process that has drifted out of calibration or that an error has been made. The goal is to track down the problem and correct it as quickly as possible. Unless the concrete producer makes a large error in batching or in placing, the chance that hardened concrete needs to be removed is remote. Removal and replacement is a last resort.
**************************************************************************

Proposed mitigation efforts by the Contractor must be approved by the Contracting Officer prior to proceeding.

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for projects involving amounts of concrete less than 380 cubic meters 500 cubic yards. This section was originally developed for USACE Civil Works projects. This section may not be applicable to NAVFAC projects without extensive editing to meet NAVFAC requirements.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1 GENERAL

NOTE: This specification requires furnishing all material and equipment, and performing all labor for the manufacturing, transporting, placing, finishing, and curing of concrete for recreation sites, road relocations, or other structures such as culvert headwalls, comfort stations, residences, or low head gate structures. Consideration should be given to using Section 03 30 00 CAST-IN-PLACE CONCRETE when the quantity of concrete is 380 cubic meters 500 cubic yards or greater per structure.
1.1 SUMMARY

Perform all work in accordance with ACI 318MACI 318.

1.2 UNIT PRICES

NOTE: If Section 01 20 00 PRICE AND PAYMENT PROCEDURES is included in the project specifications, this paragraph, title UNIT PRICES, should be deleted from this section and the remaining appropriately edited subparagraphs below should be inserted into Section 01 20 00.

1.2.1 Concrete Payment

Payment will cover all costs associated with[ manufacturing,] furnishing, delivering, placing, finishing, and curing of concrete for the various items of the schedule, including the cost of all formwork. Payment for concrete, for which payment is made as a lump sum, [is] [is not] to be included in this unit price payment item. Payment for grout, preformed expansion joints, field-molded sealants, waterstops, reinforcing steel bars or wire reinforcement [is] [is not] to be included in this unit price payment item.

1.2.2 Measurement

Concrete will be measured for payment on the basis of the actual volume of concrete within the pay lines of the structures as indicated. Measurement of concrete placed against the sides of any excavation without the use of intervening forms will be made only within the pay lines of the structure. No deductions will be made for rounded or beveled edge, for space occupied by metal work, for electrical conduits or timber, or for voids or embedded items that are either less than 0.14 cubic meter 5 cubic feet in volume or 0.1 square meter 1 square foot in cross section.

1.2.3 Unit of Measure

Unit of measure: cubic meter yard.

1.3 REFERENCES

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.
References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

1.4 SUBMITTALS

**************************************************************************

NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.

**************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

1.5 QUALITY ASSURANCE

Indicate specific locations of [Concrete Placement] [Forms] [Steel Reinforcement] [Accessories] [Expansion Joints] [Construction Joints] [Contraction Joints] [Control Joints] on installation drawings and include, but not be limited to, square meters feet of concrete placements, thicknesses and widths, plan dimensions, and arrangement of cast-in-place concrete section.

1.5.1 Regulatory Requirements

**************************************************************************
NOTE: This section relates to the implementation of RCRA of 1976 as amended (42 USC 6901) which requires
that EPA designated items be used to the maximum extent practicable.

One of the requirements of 40 CFR 247 is that agencies promote the use of products containing recycled materials. Parts of this guide specification are only promotional in nature in that they recommend or encourage, in lieu of requiring, the Contractor to use products containing recycled materials. Coordinate this section with Section 01 33 29 SUSTAINABILITY REQUIREMENTS AND REPORTING in every project where 40 CFR 247 is applicable.

Include the applicable state highway department document title in which an acceptable gradation for the concrete aggregate is presented.

**************************************************************************

The state statutory and regulatory requirements: [_____] form a part of this specification to the extent referenced. Submit CPG for recycled materials or appropriate Waiver Form.

1.5.2 Flatness and Levelness of Floor Slabs

Conduct floor flatness and levelness test, (FF and FL respectively), on floor slabs in accordance with the provisions set forth in ASTM E1155 or ASTM E1155. Make floor tolerance measurements by the approved laboratory and inspection service within 24 hours after completion of final troweling operation and before forms and shores have been removed. Provide results of floor tolerance tests, including formal notice of acceptance or rejection of the work, to the Contracting Officer within 24 hours after data collection.

PART 2 PRODUCTS

2.1 SYSTEM DESCRIPTION

The Government retains the option to sample and test [joint sealer, joint filler material, waterstop,] aggregates and concrete to determine compliance with the specifications. Provide facilities and labor as may be necessary to assist the Government in procurement of representative test samples. Obtain samples of aggregates at the point of batching in accordance with ASTM D75/D75M. Sample concrete in accordance with ASTM C172/C172M. Determine slump and air content in accordance with ASTM C143/C143M and ASTM C231/C231M, respectively, when cylinders are molded. Prepare, cure, and transport compression test specimens in accordance with ASTM C31/C31M. Test compression test specimens in accordance with ASTM C39/C39M. Take samples for strength tests not less than once each shift in which concrete is produced [from each strength of concrete required]. Provide a minimum of four 150 x 300 mm6 x 12 inch or six 100 x 200 mm4 x 8 inch specimens from each sample; two 150 x 300 mm6 x 12 inch or three 100 x 200 mm4 x 8 inch to be tested at 28 days (90 days if pozzolan or slag cement is used) for acceptance. Two 150 x 300mm6 x 12 inch or three 4 x 8 inch will be tested at 7 days for information.

2.1.1 Strength

Acceptance test results are the average strengths of two 150 x 300 mm6 x 12 inch or three 100 x 200 mm4 x 8 inch specimens tested at 28 days (90 days
if pozzolan or slag cement is used). The strength of the concrete is considered satisfactory so long as the average of all three consecutive acceptance test results equal or exceed the specified compressive strength, \( f'c \), and no individual acceptance test result falls below \( f'c \) by more than 3.4 MPa 500 psi.

2.1.2 Construction Tolerances

Apply a Class "C" finish to all surfaces except those specified to receive a Class "D" finish. Apply a Class "D" finish to all post-construction surfaces which will be permanently concealed. Surface requirements for the classes of finish required are as specified in ACI 117.

2.1.3 Concrete Mixture Proportions

**************************************************************************

NOTE: The nominal maximum size of the coarse aggregate is as specified in ACI 318, Chapter 3 and ACI 318M. Guidelines for the maximum water cementitious material ratio and air content can be found in ACI 318 Chapter 4.

**************************************************************************

Concrete mixture proportions are the responsibility of the Contractor. Mixture proportions must include the dry weights of cementitious material(s); the nominal maximum size of the coarse aggregate; the specific gravities, absorptions, and saturated surface-dry weights of fine and coarse aggregates; the quantities, types, and names of admixtures; and quantity of water per cubic meter yard of concrete. Provide materials included in the mixture proportions of the same type and from the same source as will be used on the project. The specified compressive strength \( f'c \) is \([20.7] [_____] \text{ MPa} [3,000] [_____] \text{ psi} \) at 28 days (90 days if pozzolan is used). The maximum nominal size coarse aggregate is \([19] [25] [37.5] \text{ mm} [3/4] [1] [1-1/2] \text{ inch} \), in accordance with ACI 304R. The air content must be between 4.5 and 7.5 percent with a slump between 50 and 125 mm 2 and 5 inches. The maximum water-cementitious material ratio is \([0.50] [_____] \). Submit the applicable test reports and mixture proportions that will produce concrete of the quality required, ten days prior to placement of concrete.

2.1.4 Slag Cement

Slag Cement must conform to ASTM C989/C989M, [Grade 80], [Grade 100] [or] [Grade 120].

2.2 MATERIALS

Submit manufacturer's literature from suppliers which demonstrates compliance with applicable specifications for the specified materials.

2.2.1 Cementitious Materials

Submit Manufacturer's certificates of compliance, accompanied by mill test reports, attesting that the concrete materials meet the requirements of the specifications in accordance with the Special Clause "CERTIFICATES OF COMPLIANCE". Also, certificates for all material conforming to EPA's Comprehensive Procurement Guidelines (CPG), in accordance with 40 CFR 247. Provide cementitious materials that conform to the appropriate specifications listed:
2.2.1.1 Portland Cement

**************************************************************************
NOTES: Limit the use of air-entraining cement to concrete placements where separate batching of air-entraining admixture is not practical.

If high early strength concrete is required, specify Type III after consulting the agency's Subject Matter Expert in Concrete Materials.

Tricalcium aluminate, for sulfate resistance, is limited to Type III cement. If high early strength is not required, specify Type II rather than Type I when moderate sulfate resistance is required, or Type V when high sulfate resistance is required.

Specify low-alkali cement when the aggregate is either silica or carbonate reactive.
**************************************************************************

ASTM C150/C150M, Type [I][II][III][V], [low alkali] [including false set requirements] with tri-calcium aluminates (C3A) content less than 10 percent and a maximum cement-alkali content of 0.80 percent Na2Oe (sodium oxide) equivalent.

[2.2.1.2 Blended Hydraulic Cement

**************************************************************************
NOTES: Limit the use of air-entraining cement to concrete placements where separate batching of air-entraining admixture is not practical.

Specify low-alkali cement when reactive aggregates are to be used.
**************************************************************************

Provide blended cement conforming to ASTM C595/C595M and ASTM C1157/C1157M, Type IP, IL or IS, including the optional requirement for mortar expansion [and sulfate soundness] and consist of a mixture of ASTM C150/C150M Type I, or Type II cement and a complementary cementing material. The slag added to the Type IS blend must be ASTM C989/C989M ground granulated blast-furnace slag. The pozzolan added to the Type IP blend must be ASTM C618 Class F, interground with the cement clinker. Provide the manufacturer's written statement that the amount of pozzolan in the finished cement will not vary more than plus or minus 5 mass percent of the finished cement from lot-to-lot or within a lot. Do not change the percentage and type of mineral admixture used in the blend from that submitted for the aggregate evaluation and mixture proportioning.

]2.2.1.3 Pozzolan

Provide pozzolan that conforms to ASTM C618, Class F, including requirements of Tables 1A and 2A.

2.2.2 Aggregates

**************************************************************************
NOTE: This note may be disregarded for regions where Alkali-Silica Reactivity (ASR) is not a concern. Some aggregate sources may exhibit an ASR potential. ASR is a potentially deleterious reaction between alkalis present in concrete and some siliceous aggregates, reference EM 1110-2-2000 paragraph 2-3b(6) and appendix D. Where ASR is known or suspected to pose a concern for concrete durability, it is recommended that aggregates proposed for use in concrete be evaluated to determine ASR potential and an effective mitigation. EM 1110-2-2000, provides recommendations for evaluating and mitigating ASR in concrete mixtures. Aggregate evaluations may not be practical for projects requiring small quantities of concrete (less than 190 cubic meters 250 cubic yards).

Section 32 13 14.13 CONCRETE PAVING FOR AIRFIELDS AND OTHER HEAVY DUTY PAVEMENTS, paragraph ALKALI-SILICA REACTIVITY, provides a specification method for the Contractor to evaluate and mitigate ASR in concrete mixtures. The expansion limits specified in Section 32 13 14.13 are requirements for pavements and exterior slab construction. For structural concrete applications the measured expansion must be less than 0.10 percent. It may not be economical or practical to specify different test limit requirements for use on the same project, in which case the lower limit is required by the application.

The designer may use the specification method in Section 32 13 14.13 by incorporating the relevant paragraphs into this specification, or may use the following requirements (retain either the 0.10 or the 0.08 percent expansion limits as appropriate).

**************************************************************************
For fine and coarse aggregates meet the quality and grading requirements of ASTM C33/C33M and test and evaluate for alkali-aggregate reactivity in accordance with ASTM C1260. Perform evaluation of fine and coarse aggregates separately and in combination, matching the proposed mix design proportioning. All results of the separate and combination testing must have a measured expansion less than 0.08 percent at 28 days after casting. If the test data indicates an expansion of 0.08 percent or greater, reject the aggregate(s) or perform additional testing using ASTM C1260 and ASTM C1567. Perform the additional testing using ASTM C1260 and ASTM C1567 using the low alkali portland cement in combination with ground granulated blast furnace (GGBF) slag, or Class F fly ash. Use GGBF slag in the range of 40 to 50 percent of the total cementitious material by mass. Use Class F fly ash in the range of 25 to 40 percent of the total cementitious material by mass]. Submit certificates of compliance and test reports for aggregates showing the material(s) meets the quality and grading requirements of the specifications under which it is furnished.

2.2.3 Admixtures

Provide admixtures, when required or approved, in compliance with the
appropriate specification listed. Retest chemical admixtures that have been in storage at the project site, for longer than 6 months or that have been subjected to freezing, at the expense of the Contractor at the request of the Contracting Officer and will be rejected if test results are not satisfactory.

2.2.3.1 Air-Entraining Admixture

Provide air-entraining admixture that meets the requirements of ASTM C260/C260M.

2.2.3.2 Accelerating Admixture

Provide calcium chloride meeting the requirements of ASTM D98. Other accelerators must meet the requirements of ASTM C494/C494M, Type C or E.

2.2.3.3 Water-Reducing or Retarding Admixture

Provide water-reducing or retarding admixture meeting the requirements of ASTM C494/C494M, Type A, B, or D. [High-range water reducing admixture Type F [or G] may be used only when approved, approval being contingent upon particular placement requirements as described in the Contractor's Quality Control Plan.]

2.2.4 Water

Mixing and curing water in compliance with the requirements of ASTM C1602/C1602M; [potable, and] free of injurious amounts of oil, acid, salt, or alkali. Submit test report showing water complies with ASTM C1602/C1602M.

2.2.5 Reinforcing Steel

Provide reinforcing bars conforming to the requirements of ASTM A615/A615M, Grade 60, deformed. Provide welded steel wire reinforcement conforming to the requirements of ASTM A1064/A1064M. Detail reinforcement not indicated in accordance with ACI 301M ACI 301 and ACI SP-66. Provide mechanical reinforcing bar connectors in accordance with ACI 301M ACI 301 and provide 125 percent minimum yield strength of the reinforcement bar.

2.2.6 Expansion Joint Filler Strips, Premolded

Expansion joint filler strips, premolded of sponge rubber conforming to ASTM D1752, Type I.

2.2.7 Joint Sealants - Field Molded Sealants

Conform to ASTM C920, Type M, Grade NS, Class 25, use NT for vertical joints and Type M, Grade P, Class 25, use T for horizontal joints. Provide
polyethylene tape, coated paper, metal foil, or similar type bond breaker materials. The backup material needs to be compressible, nonshrink, nonreactive with the sealant, and a nonabsorptive material such as extruded butyl or polychloroprene foam rubber. Immediately prior to installation of field-molded sealants, clean the joint of all debris and further cleaned using water, chemical solvents, or other means as recommended by the sealant manufacturer or directed.

2.2.8 Formwork

Design and engineer the formwork as well as its construction in accordance with ACI 301M ACI 301 Section 2 and 5 and ACI 347R. Fabricate of wood, steel, or other approved material. Submit formwork design prior to the first concrete placement.

2.2.9 Form Coatings

Provide form coating in accordance with ACI 301M ACI 301.

2.2.10 Vapor Retarder[ and VaporBarrier]

[ASTM E1745 Class [C] [A] [B] polyethylene sheeting, minimum [0.25] [0.38] mm [10] [15] mil thickness or other equivalent material with a maximum permeance rating of 0.04 perms per ASTM E96/E96M.] [ASTM E1745 Class [C] [A] [B] polyethylene sheeting, minimum [0.25] [0.38] mm [10] [15] mil thickness or ASTM E1993/E1993M bituminous membrane or other equivalent material with a maximum permeance rating of 0.01 perms per ASTM E96/E96M.]

Consider plastic vapor retarders and adhesives with a high recycled content, low toxicity low VOC (Volatile Organic Compounds) levels.

2.2.11 Curing Materials

Provide curing materials in accordance with ACI 301M ACI 301, Section 5.

2.3 READY-MIX CONCRETE

Provide ready-mix concrete with mix design data conforming to ACI 301M ACI 301 Part 4. Submit delivery tickets in accordance with ASTM C94/C94M for each ready-mix concrete delivery, include the following additional information: .

a. Type and brand cement

b. Cement content in 43 kilogram 94-pound bags per cubic meter yard of concrete

c. Maximum size of aggregate

d. Amount and brand name of admixture

e. Total water content expressed by water cementitious material ratio
2.4 ACCESSORIES

2.4.1 Waterstops

2.4.1.1 PVC Waterstop

Polyvinylchloride waterstops conforming to COE CRD-C 572.

2.4.1.2 Rubber Waterstop

Rubber waterstops conforming to COE CRD-C 513.

2.4.1.3 Thermoplastic Elastomeric Rubber Waterstop

Thermoplastic elastomeric rubber waterstops conforming to ASTM D471.

2.4.1.4 Hydrophilic Waterstop

Swellable strip type compound of polymer modified chloroprene rubber that swells upon contact with water conforming to ASTM D412 as follows: Tensile strength 2.9 MPa 420 psi minimum; ultimate elongation 600 percent minimum. Minimum hardness of 50 on the type A durometer and the volumetric expansion ratio in distilled water at 20 degrees C 70 degrees F; 3 to 1 minimum.

2.4.2 Chemical Floor Hardener

Provide hardener which is a colorless aqueous solution containing a blend of inorganic silicate or silicate material and proprietary components combined with a wetting agent; that penetrates, hardens, and densifies concrete surfaces. Submit manufactures instructions for placement of liquid chemical floor hardener.

2.4.3 Curing Compound

Provide curing compound conforming to ASTM C309. Submit manufactures instructions for placing curing compound.

PART 3 EXECUTION

3.1 PREPARATION

Prepare construction joints to expose coarse aggregate. The surface must be clean, damp, and free of laitance. Construct ramps and walkways, as necessary, to allow safe and expeditious access for concrete and workmen. Remove snow, ice, standing or flowing water, loose particles, debris, and foreign matter. Satisfactorily compact earth foundations. Make spare vibrators available. Placement cannot begin until the entire preparation has been accepted by the Government.

3.1.1 Embedded Items

Secure reinforcement in place after joints, anchors, and other embedded items have been positioned. Arrange internal ties so that when the forms are removed the metal part of the tie is not less than 50 mm 2 inches from concrete surfaces permanently exposed to view or exposed to water on the finished structures. Prepare embedded items so they are be free of oil and other foreign matters such as loose coatings or rust, paint, and scale. The embedding of wood in concrete is permitted only when specifically authorized or directed. Provide all equipment needed to place,
consolidate, protect, and cure the concrete at the placement site and in
good operating condition.

3.1.2 Formwork Installation

Forms must be properly aligned, adequately supported, and mortar-tight.
Provide smooth form surfaces, free from irregularities, dents, sags, or
holes when used for permanently exposed faces. Chamfer all exposed joints
and edges, unless otherwise indicated.

[3.1.3 Vapor Retarder[ and Vapor Barrier] Installation

**************************************************************************
NOTE: Use a vapor barrier only when it is desirable
to prevent migration of moisture through slabs of
buildings.
**************************************************************************

Install in accordance with ASTM E1643. Apply vapor retarder[ and barrier]
over gravel fill. Lap edges not less than 300 mm 12 inches. Seal all
joints with pressure-sensitive adhesive not less than 50 mm 2 inches wide.
Protect the vapor barrier at all times to prevent injury or displacement
prior to and during concrete placement.

]3.1.4 Production of Concrete

3.1.4.1 Ready-Mixed Concrete

Provide ready-mixed concrete conforming to ASTM C94/C94M except as
otherwise specified.

3.1.4.2 Concrete Made by Volumetric Batching and Continuous Mixing

Conform to ASTM C685/C685M.

[3.1.4.3 Batching and Mixing Equipment

The option of using an on-site batching and mixing facility is available.
The facility must provide sufficient batching and mixing equipment capacity
to prevent cold joints. Submit the method of measuring materials, batching
operation, and mixer for review, and manufacturer's data for batching and
mixing equipment demonstrating compliance with the applicable
specifications. [Provide an Onsite Plant conforming to the requirements of
either ASTM C94/C94M or ASTM C685/C685M.]

]3.1.5 Waterstops

Install and splice waterstops as directed by the manufacturer.

]3.2 CONVEYING AND PLACING CONCRETE

Convey and place concrete in accordance with ACI 301M ACI 301, Section 5.

3.2.1 Cold-Weather Requirements

Place concrete in cold weather in accordance with ACI 306R
3.2.2 Hot-Weather Requirements

Place concrete in hot weather in accordance with ACI 305R.

3.3 FINISHING

3.3.1 Temperature Requirement

Do not finish or repair concrete when either the concrete or the ambient temperature is below 10 degrees C 50 degrees F.

3.3.2 Finishing Formed Surfaces

Remove all fins and loose materials, and surface defects including filling of tie holes. Repair all honeycomb areas and other defects. Remove all unsound concrete from areas to be repaired. Ream or chip surface defects greater than 13 mm 1/2 inch in diameter and holes left by removal of tie rods in all surfaces not to receive additional concrete and fill with dry-pack mortar. Brush-coat the prepared area with an approved epoxy resin or latex bonding compound or with a neat cement grout after dampening and filling with mortar or concrete. Use a blend of portland cement and white cement in mortar or concrete for repairs to all surfaces permanently exposed to view so that the final color when cured is the same as adjacent concrete.

3.3.3 Finishing Unformed Surfaces

Finish unformed surfaces in accordance with ACI 301M ACI 301, Section 5.

<td></td>
</tr>
</tbody>
</table>

3.3.3.1 Flat Floor Finishes

**************************************************************************

NOTE: Floor flatness and floor levelness affects the appearance and function of finishes applied to the concrete and in situations such as large or long expanses of glossy floor materials. Low tolerances for subsequent finish materials (for example, thin set ceramic and porcelain tile and wood gymnasium floors) require the designer to specify higher than normal floor flatness requirements. Higher "F" ratings are more stringent and tighter tolerances of F numbers stop at 100. The numbers provided in brackets are typical numbers, but A/E should research and select F numbers high enough to get desired results but not so high as to cause undue cost increases and construction issues. An FF20/FL15 is equivalent to 8 mm in 3 meters 5/16 inches in 10 feet. This test method is not suitable for unshored decks. Fitted partitions need an FL.
greater than or equal to 25.

The F-numbers are given below for purposes of illustration only.

**************************************************************************

In accordance with ACI 302.1R, construct in accordance with one of the methods recommended in Table 7.15.3, "Typical Composite FF/FL Values for Various Construction Methods." ACI 117 for tolerances tested by ASTM E1155M or ASTM E1155. These requirements are based upon the latest FF/FL method.

3.3.3.1.1 Floor Slabs

Conform floor slabs on grade to the following ACI F-number requirements unless noted otherwise:

<table>
<thead>
<tr>
<th>Specified Overall Values</th>
<th>FF30/FL23 minimum [FF_____/FL_____]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum Local Values</td>
<td>FF17/FL15 minimum [FF_____/FL_____]</td>
</tr>
</tbody>
</table>

3.3.3.1.2 Subject to Vehicular Traffic

Conform floor slabs on grade subject to vehicular traffic or receiving thin-set flooring to the following ACI F-number requirements:

<table>
<thead>
<tr>
<th>Specified Overall Values</th>
<th>FF35/FL25 minimum [FF_____/FL_____]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum Local Values</td>
<td>FF25/FL17 minimum [FF_____/FL_____]</td>
</tr>
</tbody>
</table>

3.3.3.2 Measurement of Floor Tolerances

Test floor slabs within 24 hours of the final troweling. Submit test results to Contracting Officer within 12 hours after collecting data. Floor flatness inspector must provide a tolerance report which includes:

a. Name of Project
b. Name of Contractor
c. Date of Data Collection
d. Date of Tolerance Report
e. A Key Plan Showing Location of Data Collected
f. Results Required by ASTM E1155M ASTM E1155

3.3.3.3 Expansion and Contraction Joints

**************************************************************************

NOTES: Refer to ACI 224.3R for guidance on expansion joints.

The depth of contraction joints must be 1/4 to 1/3 of the thickness of the slab.

The maximum spacing (in mm feet) between adjacent joints must be 30 times the concrete thickness (in mm
feet) for slabs exposed to the environment.

Make expansion and contraction joints in accordance with the details shown or as otherwise specified. Provide 13 mm 1/2 inch thick transverse expansion joints where new work abuts an existing concrete. Provide expansion joints at a maximum spacing of 10 m 30 feet on center in sidewalks [and at a maximum spacing of [_____] meters feet in slabs], unless otherwise indicated. Provide contraction joints at a maximum spacing of [2] [_____] linear meters [6] [_____] linear feet in sidewalks [and at a maximum spacing of [_____] meters feet in slabs], unless otherwise indicated. Cut contraction joints at a minimum of [25] [_____] mm [1] [_____] inch(es) deep with a jointing tool after the surface has been finished.

3.4 CURING AND PROTECTION

Cure and protect in accordance with ACI 301M ACI 301, Section 5.

3.5 FORM WORK

Provide form work in accordance with ACI 301M ACI 301, Section 2 and Section 5.

3.5.1 Removal of Forms

Remove forms in accordance with ACI 301M ACI 301, Section 2.

3.6 STEEL REINFORCING

Reinforcement must be free from loose, flaky rust and scale, and free from oil, grease, or other coating which might destroy or reduce the reinforcement's bond with the concrete.

3.6.1 Fabrication

Shop fabricate steel reinforcement in accordance with ACI 318 and ACI SP-66. Provide shop details and bending in accordance with ACI 318 and ACI SP-66.

3.6.2 Splicing

Perform splices in accordance with ACI 318 and ACI SP-66.

3.6.3 Supports

Secure reinforcement in place by the use of metal or concrete supports, spacers, or ties.

3.7 EMBEDDED ITEMS

Before placing concrete, take care to determine that all embedded items are firmly and securely fastened in place. Provide embedded items free of oil and other foreign matter, such as loose coatings of rust, paint and scale. Embedding of wood in concrete is permitted only when specifically authorized or directed.
3.8 CHEMICAL FLOOR HARDENER

NOTE: Clearly indicate slab surfaces requiring a chemical hardener. Such treatment is suitable for surfaces of concrete floors in equipment rooms and on other floor surfaces that are subject to light foot traffic only and will not be covered with resilient flooring, paint, or other finish coating.

Apply Chemical Floor Hardener where indicated, after curing and drying concrete surface. Dilute liquid hardener with water and apply in three coats. First coat is one-third strength, second coat one-half strength, and third coat two-thirds strength. Apply each coat evenly and allow it to dry 24 hours before applying next coat. Apply proprietary chemical hardeners in accordance with manufacturer's printed directions.

3.9 TESTING AND INSPECTING

Report the results of all tests and inspections conducted at the project site informally at the end of each shift. Submit written reports weekly. Deliver within three days after the end of each weekly reporting period. See Section 01 45 00 QUALITY CONTROL.

3.9.1 Field Testing Technicians

The individuals who sample and test concrete must have demonstrated a knowledge and ability to perform the necessary test procedures equivalent to the ACI minimum guidelines for certification of Concrete Field Testing Technicians, Grade I.

3.9.2 Preparations for Placing

Inspect foundation or construction joints, forms, and embedded items in sufficient time prior to each concrete placement to certify that it is ready to receive concrete.

3.9.3 Sampling and Testing

a. Obtain samples and test concrete for quality control during placement. Sample fresh concrete for testing in accordance with ASTM C172/C172M. Make six test cylinders.

b. Test concrete for compressive strength at 7 and 28 days for each design mix and for every 77 cubic meters 100 cubic yards of concrete. Test two cylinders at 7 days; two cylinders at 28 days; and hold two cylinders in reserve. Conform test specimens to ASTM C31/C31M. Perform compressive strength testing conforming to ASTM C39/C39M.

c. Test slump at the [plant] [site of discharge] for each design mix in accordance with ASTM C143/C143M. Check slump [once] [twice] during each shift that concrete is produced [for each strength of concrete required].

d. Test air content for air-entrained concrete in accordance with ASTM C231/C231M. Test concrete using lightweight or extremely porous aggregates in accordance with ASTM C173/C173M. Check air content at least [once] [twice] during each shift that concrete is placed [for
e. Determine temperature of concrete at time of placement in accordance with ASTM C1064/C1064M. Check concrete temperature at least [once] [twice] during each shift that concrete is placed [for each strength of concrete required].

3.9.4 Action Required

3.9.4.1 Placing

Do not begin placement until the availability of an adequate number of acceptable vibrators, which are in working order and have competent operators, has been verified. Discontinue placing if any lift is inadequately consolidated.

3.9.4.2 Air Content

Whenever an air content test result is outside the specification limits, adjust the dosage of the air-entrainment admixture prior to delivery of concrete to forms.

3.9.4.3 Slump

Whenever a slump test result is outside the specification limits, adjust the batch weights of water and fine aggregate prior to delivery of concrete to the forms. Make the adjustments so that the water-cementitious material ratio does not exceed that specified in the submitted concrete mixture proportion and the required concrete strength is still met.

3.8.1.1 Slump Tests
3.8.1.2 Temperature Tests
3.8.1.3 Air Content Tests
3.8.1.4 Unit Weight Test
3.8.2 Hardened Concrete Properties
3.8.2.1 Compressive Strength Tests
3.8.2.2 Transport Property Tests
3.8.2.3 Chloride Ion Concentration
3.8.2.4 Anti-Washout Admixture
3.8.2.5 Non-Destructive Tests
3.8.3 Core Samples and Compressive Strength Testing
3.8.4 Acceptance of Concrete Strength
3.8.4.1 Standard Molded and Cured Strength Specimens
3.8.4.2 Non-Destructive Tests
3.8.4.3 Extracted Core Tests
3.8.5 Inspection

3.9 REPAIR, REHABILITATION AND REMOVAL
3.9.1 Crack Repair
3.9.2 Repair of Weak Surfaces
3.9.3 Failure of Quality Assurance Test Results

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for reinforced concrete exposed to marine and chloride environments for projects with a defined service life. In addition, use this guide specification for projects with concrete exposed to weather in locations with Environmental Severity Classifications (ESC) of C4 and C5 and where deicing salts are used on the structure, where service life modeling is appropriate. See UFC 1-200-01 for determination of the ESC for project locations.

The defined service life approach mandates that the Government define the service life expectations of the structure (in years) prior to design. This document is a combination of prescriptive and performance based specifications. It contains specific requirements for quality control (actions taken by the Contractor) and quality assurance (actions that may be taken by the Government).

This guide specification includes provisions for performing concrete service life modeling. If it is determined that concrete service life modeling is not required for the project, then Section 03 31 30 Marine Concrete (without Service Life Modeling) should be used.

It is recommended that every significant structure employ service life modeling. Generally, significant structures are defined as having at least one of the following characteristics:

- Required Service Life: Greater than 60 years; or
- Volume of Concrete Works: Greater than 10,000 cubic yards; or
- Monetary Construction Value of the entire project: Greater than $15M; or
Service life modeling is required by the Government.

For projects meeting the above criteria, enhanced durability is required, and therefore, a full service life modeling and durability assessment as described in the specification shall be performed.

Other criteria to consider when evaluating the applicability of service life design, and if Service Life Modeling is required, include:

- **Mission Criticality** based on the Mission Dependency Index (MDI) Score. For example, consider service life modeling for an MDI score higher than 54.

- **Consequences of Failure**: Consider service life modeling for UFC 3-301-01 Risk Categories IV or higher.

The performance-based portion of this document includes requirements to predict the service life of the candidate concrete mixtures prior to proceeding with construction. During construction, concrete cylinders are made from the production concrete at intervals specified by the Engineer of Record to measure transport properties and for microscopic examination of the hardened concrete to verify that the concrete quality remains consistent and acceptable. Conventional requirements for compressive strength and slump remain the same.

Service life modeling software is a tool that, when used in combination with other tools and good engineering judgment, enhances the Contractor's and Government’s confidence that the completed structure will perform for the defined service life. TR-NAVFAC ESC-CI-1215, the "Navy User's Guide to Quality Assurance of New Concrete Construction" provides a commentary for the user of this methodology. Generally, this version of the marine concrete UFGS is for major projects. For smaller marine concrete projects and for projects without a defined service life the Specifier can consider use of Section 03 31 30 MARINE CONCRETE that excludes service life modeling requirements and testing for transport properties during construction.

Adhere to **UFC 1-300-02** Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in
respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

**************************************************************************

NOTE: Development team of this section considered the International Green Construction Code, which is "the first model code that includes sustainability measures for the entire construction project and its site - from design through construction, certificate of occupancy and beyond. The new code is expected to make buildings more efficient, reduce waste, and have a positive impact on health, safety and community welfare."

**************************************************************************

NOTE: The following information shall be shown on the project drawings:

1. Design assumptions.

2. Assumed temperature range when temperature stresses are a factor in design.

3. Material strengths used in design, f'c.

4. Yield strength of reinforcement required (414 mPa 60,000 psi or other grade as available).

5. Details of concrete sections, showing dimensions, reinforcement cover, and required camber.

6. Joint details, showing locations and dimensions.

7. Details and locations of critical construction joints, including water stop locations and splices, keys, and dowels when required, and location of fiber-reinforced concrete elements.

**************************************************************************

PART 1 GENERAL

1.1 REFERENCES

**************************************************************************

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature
when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

1.2 DEFINITIONS

a. "Aging factor" is used to estimate the change in the diffusion or migration coefficient over time.

b. "Atmospheric zone" is any portion of the waterfront structure above the splash zone.

c. "Boundary Condition" is the environmental conditions in contact with the concrete. The service life modeling tool must account for short term and long-term changes in environmental conditions at the boundary interface between the specific concrete element and the environment,
including wetting and drying due to daily tidal cycles and/or changes over its lifecycle.

d. "Buried zone" is any portion of the waterfront structure permanently buried in soil.

e. "Cementitious material" as used herein shall include portland cement and any pozzolanic material such as fly ash, natural pozzolans, ground granulated blast-furnace slag and silica fume.

f. "Chloride threshold" (CTH) is the concentration of chloride ions in concrete that is generally assumed to be the minimum necessary to initiate corrosion of the reinforcing steel when all other necessary conditions are satisfied. The threshold value is expressed in parts per million (ppm) by mass of concrete in this specification.

g. "Chloride migration coefficient" is the main parameter describing the concrete transport properties in the fib Bulletin 34 methodology. It is measured using the NT Build 492 test method.

h. "Concrete System" is the term describing a structural element comprised of concrete, reinforcing steel and concrete cover.

i. "Corrosion initiation period" (Ti) is the number of years assumed before the chloride ion reaches the chloride threshold for the reinforcing steel at the depth of the steel. The corrosion initiation period will be determined by numerical modeling in accordance with this specification.

j. "Corrosion Propagation period" (Tp) is the number of years after the corrosion initiation period until corrosion manifests as visible cracking and spalling of the concrete cover to a degree that will require extensive concrete repair. Based on evidence provided by the Contractor and reviewed by the agency's Subject Matter Expert in Concrete Materials, on a case-by-case basis the Contracting Officer may approve extension to the typical corrosion propagation period of 10 to 15 years. Use of supplemental corrosion protection methods and benign environmental conditions are two ways to extend the assumed propagation period.

k. "Design strength" (f'c) is the specified compressive strength of concrete at time(s) specified by Contracting Officer to meet structural design criteria. Typical duration is 28 days; however, the Contracting Officer and Engineer of Record are encouraged to consider specifying strength at 56 or 90 days. For concrete mixtures containing 35 percent fly ash or more, the duration shall be a minimum of 56 days.

l. "Effective Diffusion Coefficient" (D_{eff}) is, in the STADIUM® methodology, a coefficient that combines the ionic diffusion coefficient D_{oh} and volume of permeable voids.

m. "Exposure Conditions" are the environmental parameters used in service life modeling for each type of concrete element based on the structure location and anticipated boundary conditions.

n. "Field test strength" (fcr) is the required compressive strength of concrete to meet structural and durability criteria. Determine (fcr) during mixture proportioning process.
o. "High-volume fly ash concrete" has a minimum of 35 percent Class F fly ash as a partial replacement to portland cement.

p. "Ionic Diffusion Coefficient" ($D_{oh}$) is, in the STADIUM® methodology, the ionic diffusion coefficient as determined per the ionic diffusion coefficient migration testing for the service life modeling.

q. "Marine concrete" is all concrete that will be in contact with seawater or brackish water, tidal variations, splash, or spray from water in navigable waterways. Piles driven on land that extend below the water table that contains saltwater or brackish water shall be designed as marine concrete. Components of a marine structure that are permanently buried in soil shall be considered marine concrete. In addition, structures may need to be designed using these criteria even though they are not adjacent to the waterfront. For example, structures located several hundred yards from the waterfront often deteriorate prematurely due to salt spray and salt fog brought to the structure by prevailing winds. An assessment of existing structures near the construction site can be an excellent indicator for the Engineer of Record and Owner to decide if the proposed structure should follow the guidelines for marine concrete.

r. "Mass Concrete" is any concrete system that approaches a maximum temperature of 70 degrees C (158 degrees F) within the first 72 hours of placement. In addition, it includes all concrete elements with a section thickness of 1 meter (3 feet) or more regardless of temperature.

s. "Mixture proportioning" is the process of designing concrete mixture proportions to enable it to meet the strength, service life and constructability requirements and of the project while minimizing the initial and life-cycle cost.

t. "Mixture proportions" are the masses or volumes of individual ingredients used to make a unit measure (cubic yard or meter) of concrete.

u. "Moisture Transport Coefficient" (MTC) is, in the STADIUM® methodology, the value determined per the moisture transport coefficient drying test.

v. "Permeability" ($K$) is, in the STADIUM® methodology, the intrinsic permeability of the concrete evaluated from the moisture transport coefficient drying test.

w. "Pozzolan" is a siliceous or siliceous and aluminous material, which in itself possesses little or no cementitious value but will, in finely divided form and in the presence of moisture, chemically react with calcium hydroxide at ordinary temperatures to form compounds possessing cementitious properties.

x. "Process control sampling" is sampling and testing conducted by the Contractor to monitor the quality of materials or processes. Process control sampling is intended to indicate the quality of materials at critical steps in production that allow intervention prior to using a material on the project.

y. "Quality Acceptance Limit" (QAL) is the limiting value of a test result that indicates acceptable material quality. Quality acceptance limits are based on design criteria that may be either upper-bound limits where smaller values indicate acceptable material; or lower-bound
limits where larger values indicate acceptable material, such as compressive strength.

z. "Quality acceptance sampling" is sampling and testing conducted by the Contractor, or an independent testing agency, to evaluate the quality of materials used on the project. Quality acceptance sampling is conducted at regular intervals identified as "lots" to represent the quality of that portion of the material used in the project.

aa. "Required compressive strength" (f'c) is the mean compressive strength of concrete required to meet structural criteria. The required strength is the mean concrete strength for tests of properly batched concrete at the age specified herein.

bb. "Service life" is the Owner's stated expectation for the number of years that the structure will function without needing major concrete rehabilitation. Service life is defined as the number of years before major restoration is necessary given minimal maintenance to the structure during its life. Major restoration is defined as extensive areas that require extensive repairs using a jack hammer or other destructive means to prepare the concrete for rehabilitation. Service life is further defined as the summation of the corrosion initiation period (Ti) and the corrosion propagation period (Tp) for a given concrete system.

c. "Service Life Modeling" in the context of this document refers to a methodology using a rational numerical approach to predict the time before the chloride ion contamination will reach a level of reinforcing that is likely to result in the initiation of steel corrosion.

d. "Specified Effective Diffusion Coefficient" (D_{spec}) is, in the STADIUM® methodology, the calculated effective diffusion coefficient at which the chloride ion content is within 10 percent (50 ppm) of the chloride threshold, at the steel cover depth, for the given exposure.

e. "Splash zone" is the portion of the structure just above the tidal zone. This portion of the structure is predominantly dry, but is likely to intermittently wet by wave action and wind driven spray. For the purposes of this specification, the splash zone is defined as follows:

(1) for locations protected by seawalls or otherwise sheltered from open-ocean waves, the 2 meters 6 feet area just above the tidal zone;

(2) for unprotected locations, the 6 meters 20 feet area just above the tidal zone.

ff. "Submerged zone" is defined as the submerged portion of the structure. For the purposes of this specification, any element or portion thereof that is located below Mean Lower Low Water (MLLW). In areas with minimal tides, it would be defined as that portion of the element below Mean Sea Level (MSL).

gg. "Supplemental Corrosion Protection" includes (but not limited to) fusion-bonded epoxy-coated steel reinforcing, galvanized steel reinforcing, stainless reinforcing, corrosion inhibitors, barrier coatings to the concrete surface, and cathodic protection.
hh. "Supplementary cementing materials" (SCM) include coal fly ash, granulated blast-furnace slag, natural or calcined pozzolans, and ultra-fine coal ash when used in such proportions to replace the portland cement that result in considerable improvement to sustainability, durability and in some cases a reduction in initial cost.

ii. "Test Section" is a slab or wall separate from the main structure and constructed prior to main construction as an all-inclusive demonstration of methods and materials. The adequacy of the Test Section must be approved by the owner's representative prior to construction of the project.

jj. "Tidal zone" is defined as the portion of the structure regularly wetted by wave action. For the purposes of this specification, any element or portion thereof that is located between Mean Lower Low Water (MLLW) and Mean Higher High Water (MHHW) is in the tidal zone. In areas with minimal tides, this would be defined as the area located between Mean Sea Level (MSL) and Mean High Water (MHW).

kk. "Tolerance Limit" is defined for each transport parameter as the characteristic value that will be surpassed in 1 of 10 batches, at a 90 percent confidence level. This definition is provided for reference only, additional documentation and evaluation is needed prior to it being suggested as prescriptive criteria.

ll. "Transport properties" refers to the properties that characterize the rate of chloride penetration into a concrete element. These properties include for the STADIUM® methodology: volume of permeable voids (phi), ionic diffusion coefficient ($D_{ch}$), aging factor, and moisture transport coefficient (MTC). These properties include for the fib Bulletin 34 methodology: chloride migration coefficient.

mm. "Transport property testing" refers to the testing procedures that characterize the rate of chloride penetration into a concrete element. These properties are used as input data for the service life modeling.

nn. "Volume of Permeable Voids" (phi) is the porosity of the concrete as determined by ASTM C642.

1.3 SUBMITTALS

**************************************************************************

NOTE: Review Submittal Description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving
Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

1.4 MODIFICATION OF REFERENCES

Accomplish work in accordance with ACI publications except as modified herein. Consider the advisory or recommended provisions to be mandatory, as though the word "shall" had been substituted for the words "should" or "could" or "may," wherever they appear. Interpret reference to the "Building Official," the "Structural Engineer," and the "Architect/Engineer" to mean the Contracting Officer.

1.5 DELIVERY, PLACING, STORAGE, AND HANDLING OF CONCRETE

Follow ACI 301M, ACI 301, ACI 304R, and ASTM A934/A934M requirements and recommendations. Do not deliver concrete until vapor barrier, forms, reinforcement, embedded items, and chamfer strips are in place and ready for concrete placement. Store reinforcement of different sizes and shapes in separate piles or racks raised above the ground. Protect materials from contaminants such as grease, oil, and dirt. Ensure materials can be accurately identified after bundles are broken and tags removed.

1.6 CONCRETE QUALITY CONTROL

*****************************************************************************************

NOTE: Service Life Modeling

Use of service life modeling predicts the performance of the concrete mixture when placed and cured properly. Concrete sampling during production and (if necessary) from the completed structure provides additional data to predict the service life. This methodology enhances the Navy's confidence that the structure will perform without major repairs for the defined service life. It is recommended that every significant structure employ this section inclusive of service life modeling.

The Owner, the Engineer of Record, and/or the Contracting Officer shall determine if this approach is applicable. Additional information is provided in TR-NAVFAC ESC-CI-1215.

The goal is to provide quality concrete with the specified concrete cover to protect the steel, which provides the primary protection mechanism against chemical deterioration and corrosion related damage. All other corrosion protection strategies are considered to be supplemental and include (but are not limited to): barrier coatings to the concrete surface, fusion-bonded epoxy-coated steel, corrosion inhibitors, galvanized, stainless, MMFX, Z-bar reinforcing and cathodic protection. All of which may provide some life extension but by how
much is considered to be speculation for real structures exposed to chloride environments. If the available materials in the region of the project are inadequate to meet the requirements for shrinkage, compressive strength, constructability and service life then the Contractor shall prepare a recommendation for review by the agency's Subject Matter Expert in Concrete Materials and approval by the Contracting Officer and Engineer of Record on a case-by-case basis to use supplemental corrosion protection to meet project requirements.

Two methodologies for predicting the service life of concrete structures are acceptable to the Navy: STADIUM® and the methodology described in fib Bulletin 34 Model Code for Service Life Design. Service life modeling is a tool to be used with engineering judgment to aid in the design, material selection, and construction methods to produce a durable structure.

Where they are available, specify only ACI certified personnel. Check the American Concrete Institute (ACI) website for local availability: https://www.concrete.org/certification.

**************************************************************************

The objective of the concrete quality control program is for the Contractor to outline the procedures that will be used to construct a structure that will obtain the design service life. The Contractor shall develop and submit for approval a concrete quality control program in accordance with the guidelines of ACI 121R and as specified herein. The plan shall include approved laboratories. The Contractor shall provide direct oversight for the concrete qualification program inclusive of service life modeling, associated sampling and testing. If concrete cylinders tested during production indicate inadequate strength, excessive ion-transport properties, or inadequate mixing, then the owner may require the Contractor to extract concrete core samples from the hardened concrete for analysis at Contractor's expense to assure that the quality of the concrete as placed and cured will satisfy the defined service life.

Develop and submit for approval a concrete quality control program in accordance with the guidelines of ACI 121R and able to meet the defined service life using the methodology herein. Maintain a copy of ACI SP-15 and CRSI 10MSP at the project site.

1.6.1 Quality Control Personnel

The contractor shall submit for approval an organizational chart defining the quality control hierarchy, the responsibilities of the various positions, including the names and qualifications of the individuals in those positions.

Submit American Concrete Institute certification for the following:

a. CQC personnel responsible for inspection of concrete operations.

b. Lead Foreman or Journeyman of the Concrete Placing, Finishing, and
Curing Crews.

c. Field Testing Technicians: ACI Concrete Field Testing Technician, Grade I.
d. Laboratory Testing Technicians: ACI Concrete Strength Testing Technician and Laboratory Testing Technician, Grade I or II.
e. If using STADIUM® for service life modeling: STADIUM® certified laboratory and users of STADIUM® software.
f. Petrographer: Bachelor of Science degree in geology or petrography, trained in petrographic examination of concrete aggregate according to ASTM C294 and ASTM C295/C295M and trained in identification of the specific deleterious processes and tests identified in this specification. Resume shall detail the education, training and experience related to the project-specific test methods and deleterious materials and shall be submitted at least 20 days before petrographic and deleterious materials examination is to commence.

g. Concrete Batch Plant Operator: National Ready Mix Concrete Association (NRMCA) Plant Manager Certification at the Plant Manager level.

1.6.1.1 Quality Manager Qualifications

The quality manager shall hold a current license as a professional engineer in a U.S. state or territory with experience on at least five similar projects. Evidence of extraordinary proven experience may be considered by the Contracting Officer as sufficient to act as the Quality Manager.

1.6.1.2 Field Testing Technician and Testing Agency

Submit data on qualifications of proposed testing agency and technicians for approval by the Contracting Officer prior to performing testing on concrete.

a. Work on concrete under this contract shall be performed by an ACI Concrete Field Testing Technician Grade I qualified in accordance with ACI SP-2 or equivalent. Equivalent certification programs shall include requirements for written and performance examinations as stipulated in ACI SP-2.

b. Testing agencies that perform testing services on reinforcing steel shall meet the requirements of ASTM E329.

c. Testing agencies that perform testing services on concrete materials shall meet the requirements of ASTM C1077.

d. Testing agencies or engineering companies that characterize the transport properties of the concrete and/or conduct service life modeling analysis shall be pre-approved by the Contracting Officer with concurrence of the agency's Subject Matter Expert in Concrete Materials.

1.6.2 Laboratory Qualifications for Concrete Qualification Testing

The concrete testing laboratory shall have the necessary equipment and experience to accomplish required testing. The laboratory shall meet the requirements of ASTM C1077 and be Cement and Concrete Reference Laboratory (CCRL) inspected. If STADIUM® is used, the laboratory shall be a STADIUM®
certified laboratory. If the fib Bulletin 34 methodology is used, the laboratory shall be equipped and experienced in the use of the NT Build 492 test.

1.6.3 Laboratory Accreditation

Laboratory and testing facilities shall be provided by and at the expense of the Contractor. The laboratories performing the tests shall be accredited in accordance with ASTM C1077, including ASTM C78/C78M and ASTM C1260. The accreditation shall be current and shall include the required test methods, as specified.

a. Aggregate Testing and Mix Proportioning: Aggregate testing and mixture proportioning studies shall be performed by an accredited laboratory and under the direction of a licensed/registered civil engineer in a U.S. state or territory, who shall sign all reports and designs.

b. Acceptance Testing: Furnish all materials, labor, and facilities required for molding, curing, testing, and protecting test specimens at the site and in the laboratory. Furnish and maintain boxes or other facilities suitable for storing and curing the specimens at the site while in the mold within the temperature range stipulated by ASTM C31/C31M.

c. Contractor Quality Control: All sampling and testing shall be performed by an approved, onsite, independent, accredited laboratory.

1.7 CONCRETE DURABILITY

1.7.1 Service Life Design

Unless otherwise specified, the concrete structures shall be designed for a 75-year service life. The total service life is the summation of the corrosion initiation period (Ti) and the corrosion propagation period (Tp).

The modeling for the corrosion initiation period (Ti) shall use a full probabilistic approach. The corrosion initiation time shall meet a target reliability index of 1.3. The corrosion propagation period can be determined using a deterministic approach.

The modeling of the corrosion initiation time shall be in accordance with one of the following methodologies:

a. STADIUM® software: Only certified STADIUM® laboratories and users can perform the testing and modeling.

b. fib Bulletin 34 Model Code for Service Life Design (2006): The model used for the corrosion initiation time shall be as per Appendix B2. The choice of each input parameter shall be documented in the Durability Modeling Report; it shall be demonstrated how the choice of input parameters is reasonable and applicable to the project. Calculations shall be checked, the Contracting Officer may request a copy of the calculations for review. Testing of the concrete transport property, the chloride migration coefficient, shall be in accordance with the NT Build 492 test method.

Deterioration mechanisms other than chloride-induced corrosion shall be considered and mitigated using the deemed-to-satisfy or avoidance approach as described in fib Bulletin 34.
The Durability Modeling Report shall present the service life design including the corrosion initiation time modeling.

1.7.2 Concrete Mixture Proportions

At least 60 days prior to concrete placement, submit concrete mixture proportions, ingredient material certificates and test data, and trial batch test data for each class of concrete proposed for use on the project. Submittal shall clearly indicate where each mixture will be used when more than one mixture design is submitted. Obtain approval from Contracting Officer prior to placement.

1.7.3 Concrete Design Requirements

Proportion concrete mixtures to meet the requirements listed in Table 1 in accordance with the procedures outlined in ACI 201.2R and ACI 211.1.

The mixture proportions for concrete shall be developed by the Contractor to produce the required compressive strength (f'c), drying shrinkage, and constructability for mixtures that have the potential to accomplish a structure with the design service life.

1.7.4 Concrete Mixture Qualifications

1.7.4.1 Previously Approved Concrete Mixtures

For identical concrete mixtures previously approved for use within the past 18 months, the previous mixture qualification submittal may be re-submitted without further trial batch testing if accompanied by:
a. A copy of the prior approvals indicating the project name, project number, and location.

b. Ingredient material test data conducted within 6 months of the submittal date.

c. Copies of the previously approved trial batch test data, including concrete transport properties and tests required in Table 1.

d. A log containing at least 15 sequential test results with the calculated mean and standard deviation of the production concrete for air content, compressive strength and concrete transport properties.

If the Contractor changes material type, class, sources, or suppliers; chemical composition; and/or mix proportions, the Contractor shall provide a written opinion of the significance of the change(s). The change(s) may require additional testing at the discretion of the Contracting Officer in consultation with the agency's Subject Matter Expert in Concrete Materials.

1.7.4.2 New Concrete Mixtures

a. Submit complete ingredient material test data, including applicable reference specifications. Submit additional data regarding concrete aggregates if the source of aggregate changes.

b. Submit copies of test reports by independent test lab conforming to ASTM C1077 showing that the mixture has been successfully tested to produce concrete with the properties specified and that mixture will be suitable for the job conditions as described. Test reports shall be submitted along with the concrete mixture proportions. Obtain approval before concrete placement.

c. Test a minimum of one trial batch of production concrete to establish the specified transport properties. If batching facilities are located such that the haul-time will exceed 30 minutes, a simulated haul time shall be included in the trial batch.

If the concrete mixture for construction is proposed to contain corrosion inhibitors then laboratory testing shall be accomplished and tested for transport properties with and without the corrosion inhibitor because they are known to distort the results of the service life modeling when compared to mixtures without corrosion inhibitors. The Contractor shall obtain approval from the Contracting Officer for use of corrosion inhibitors.

(1) Test and report fresh concrete property tests of each trial batch as follows:

(a) Slump in accordance with ASTM C143/C143M.

(b) Air content in accordance with ASTM C231/C231M or ASTM C173/C173M.

(c) Unit weight in accordance with ASTM C138/C138M.

(d) Temperature in accordance with ASTM C1064/C1064M.

(2) Cast specimens, test, and report hardened concrete property tests
of each trial batch as follows:

(a) Compressive strength at 3, 7, 28, 56 and 90 days in accordance with ASTM C39/C39M. Use of unbonded caps in accordance with ASTM C1231/C1231M is permitted.

(b) Drying shrinkage may be determined from one batch.

(c) Tensile strength (if required) may be determined using specimens cast from one batch.

(d) Freeze-thaw durability factor (if required) shall be determined as the mean of three test specimens cast from one batch.

(e) Initial chloride ion content may be determined from one batch.

(f) Spacing factor may be determined from one batch.

(g) Scaling resistance may be determined from one batch.

(3) Moist cure concrete intended for cast-in-place applications in accordance with the standard moist curing conditions described in ASTM C192/C192M unless otherwise specified. Moist cure concrete intended for precast applications in the manner proposed for use on the project.

(4) If using STADIUM® methodology: Cast twelve 100 by 200 mm 4 by 8 inch cylinders, test and report ion transport properties as follows:

(a) Determine the porosity at 28-days and 90-days of standard moist curing. Calculate the mean porosity and standard deviation at each test age.

(b) Determine the $D_{oh}$ at 28-days and 90-days of standard moist curing. Calculate the mean $D_{oh}$ and standard deviation at each test age.

(c) Determine the MTC at 28-days of standard moist curing.

(d) Calculate the aging coefficient as the ratio of the mean 90-day, or longer, $D_{oh}$ to the mean 28-day standard moist cure $D_{oh}$.

(e) Retain unused specimens in storage. These specimens may be tested later to refine the actual aging factor. This is advisable in the event that any production concrete falls short of the service life as it will provide evidence to better predict the service life.

(5) If using the fib Bulletin 34 methodology: Cast three 100 by 200 mm 4 by 8 inch cylinders from the same concrete batch, test and report ion transport properties as follows:

(a) Determine the chloride migration coefficient at 28 days as per NT Build 492 test procedure.

(6) Special handling will be necessary for shipments of transport property specimens. These cylinders shall be wrapped completely with slightly damp paper towels with distilled water only.
wrapped cylinders shall be placed in either a vacuum package or double layers of sealed plastic bags. Package the test cylinders to prevent damage and ship to an approved testing laboratory.

d. The Contractor shall forward a Durability Modeling report prepared by the consultant that conducts the service life assessment of the proposed concrete system for each concrete mixture. As a minimum, the report shall contain:

1. The concrete mixture proportions.

2. The concrete cover to reinforcing steel. The cover to all reinforcing bars shall be clearly delineated with allowance for placement tolerances per ACI 117.

3. The environmental exposure conditions used for each type of concrete element.

4. The concrete transport properties and materials characteristics that, for the specified exposure zones, satisfies the minimum required service life of the structural element.

5. A narrative describing the modeling process including assumptions and recommendations to accomplish the service life using quality concrete and specified cover. In the event that locally available materials cannot be shown to accomplish the service life then the Contractor shall prepare a proposal for review by the agency's Subject Matter Expert in Concrete Materials and approval by the Contracting Officer to use alternative sources of materials and/or supplemental corrosion protection methods.

6. A cover letter signed and stamped by a registered Professional Engineer certifying compliance with the present specification, including required average compressive strength (f'cr), drying shrinkage, transport properties, and constructability, for mixtures that have the potential to accomplish a structure with the design service life.

7. If using the STADIUM® methodology: Letter regarding the certificate of completion for the STADIUM® training.

8. The UFGS Laboratory Certification letter for the accredited laboratory.

e. For concrete mixtures that are proposed to contain corrosion inhibitors, the Contractor shall submit 28-day values for transport properties (D_{oh} for STADIUM® or chloride migration coefficient for fib Bulletin 34) from at least three batches of the mixture with and without the admixture making appropriate adjustments to maintain constant water to cementitious ratio. The purpose is to establish a correlation with respect to an adjusted value for production tested values.

f. At the option of the Contractor, a revised service life submittal may be provided as a value engineering proposal using refined characteristic properties calculated from production data. Extensions to corrosion propagation period may be reviewed by the agency's Subject Matter Expert in Concrete Materials and approved by the Contracting Officer based on evidence provided by the Contractor on a case-by-case
1.7.5 Project Environment

1.7.5.1 Location Details

The values of Table 2 define the location and exposure conditions to be used in service life modeling. The Engineer of Record shall define these values. Alternatively, the use of default values in accordance with the STADIUM® or fib Bulletin 34 methodologies may be approved by the Engineer of Record.

1.7.5.2 Exposure Conditions by Element

The Contractor shall use the service life model and exposure conditions listed above to provide concrete system(s) that meet or exceed the service life requirement. Evaluate the service life of each element for its severest service condition.

1.7.6 Concrete Qualification Program

1.7.6.1 Fresh Concrete Properties

a. Air Content: Concrete that is air entrained shall conform to the air limits specified in ACI 301M ACI 301 for exposure and the aggregate size used and tested in accordance with ASTM C231/C231M. Variations outside the limits specified shall not be reason to reject the concrete in locations not subject to freeze-thaw conditions.
b. Slump: The concrete mixture shall be proportioned to have, at the point of deposit, a maximum slump of 100 mm 4 inches as determined by ASTM C143/C143M when admixtures that affect slump are not used. Where an ASTM C494/C494M, Type F or G admixture is used, the slump after the addition of the admixture shall not exceed 200 mm 8 inches. Slump tolerances shall comply with the requirements of ACI 117.

c. Self-Consolidating Concrete: When self-consolidating concrete is proposed for use, the mixture shall be proportioned and tested for qualification using:

(1) ASTM C1611/C1611M slump flow shall not be greater than 609.6 mm 24 inches, with visual stability index not greater than 1.

(2) ASTM C1621/C1621M Passing ability using the J-ring. Spread within 25.4 mm 1 inch less than the slump flow.

(3) Passing ability using the L-Box between 4 and 8 seconds

(4) ASTM C1610/C1610M, static segregation shall be less than 4.0 percent.

For process control sampling, the slump flow limit as determined by ASTM C1611/C1611M shall be no greater than 609.6 mm 24 inches and the visual stability index limit shall be no greater than 1.0.

d. Underwater concrete: When the concrete is intended for placement under water using the tremie technique, the concrete shall be proportioned to be cohesive and flow with minimal out segregation. Viscosity modifying admixtures are permitted for underwater concrete. Proportioning guidance in ACI 304R shall be considered. Concrete mixtures shall be qualified for tremie placement methods based on a trial placement approved by the Contracting Officer.

1.7.6.2 Hardened Concrete Properties

**************************************************************************
NOTE: Navy waterfront structures typically take a year or more to complete. With time, all concrete continues to gain strength. The Engineer of Record is encouraged to design the structural elements based on the compressive strength that will be achieved at 56 or 90 days rather than at 28 days. Doing so will better allow the Contractor to develop and place concrete mixtures with less portland cement. Excessive use of cement leads to more cracks and shorter-lived structures. Embracing this approach will result in structures that are less expensive, greener, and more sustainable.
**************************************************************************

a. Compressive Strength: The structural engineer shall specify the minimum compressive strength results at [28] [56] days. Determine compressive strength (f'cr) for qualification of concrete mixtures and for quality acceptance testing. A compressive strength test result is defined as the mean of three properly conducted tests on 100 by 200 mm 4 by 8 inch cylinders in accordance with ASTM C39/C39M. Alternatively and for concrete mixtures containing a maximum size aggregate greater than 25.4 mm 1 inch, a strength test result shall be defined as the mean of two
properly conducted 28-day tests on 150 by 300 mm 6 by 12 inch cylindrical specimens in accordance with ASTM C39/C39M. In addition:

(1) Specified Compressive Strength: For structural concrete elements exposed in a marine environment, the minimum specified [28] [56] day design strength is denoted as (f'c). Strength of concrete containing 35 percent or more fly ash shall be specified at a minimum of 56 days.

(2) Required Average Strength: The concrete shall be proportioned such that the minimum required average compressive strength (f'cr) exceeds the specified design strength (f'c) as per ACI 301M ACI 301.

(3) The average compressive strength may not exceed the specified strength at the same age by more than 20 percent unless approved by the Engineer of Record.

(4) Strength of any individual concrete placement shall be considered satisfactory if both the following requirements are met:

(a) The arithmetic mean of any three consecutive lot strength tests is between 1.0 and 1.2 f'c, and;

(b) No individual strength test result is less than 0.90 f'c.

(5) In the event that a placement is represented by single sampling lot, strength shall be considered satisfactory if either:

(a) The mean of the initial test is between 1.0 and 1.2 f'c, or;

(b) The mean of the initial test and retest is between 1.0 and 1.2 f'c, and neither strength test result is less than 0.90 f'c.

(6) For underwater concrete, cast compressive strength samples by placing concrete in four 5-gallon buckets below water using similar placement as the project. Permanently mark buckets as "3 days," "7 days," "[28] [56] days," and "Extra." Include date and station. Provide specimen sets at every [76.5 cubic meters] [100 cubic yards] of concrete for the first [382.3 cubic meters] [500 cubic yards], then every [382.3 cubic meters] [500 cubic yards] thereafter with a minimum of one set per day of underwater concrete placement.

(a) Retrieve buckets at specified intervals and extract three cores from each bucket. Conduct compressive strength test in accordance with ASTM C42/C42M.

(b) Strength of underwater concrete shall be satisfactory if the compressive strength result from extracted cores at the age of the specified strength is between 0.85 and 1.2 f'c with no individual strength test result less than 0.75 f'c.

b. Drying Shrinkage: Determine drying shrinkage for qualification of concrete mixtures prior to the fabrication of the Test Section and from samples made during the fabrication of the Test Section (see the paragraph TEST SECTION). No test results shall exceed 0.05 percent. A drying shrinkage test result shall be the mean value from three or more individual specimens constituting a test set. If an individual specimen's measurements deviate from the mean value by more than 0.009
percent length change the specimen's measurements shall be discarded and a new average established. Casting more than three specimens for each set is permitted. Test procedures and test specimens shall conform to the following:

Drying shrinkage specimens, typically 75 by 75 by 285.8 mm or 3 by 3 by 11.25 inch prisms for 25.4 mm or 1 inch maximum size aggregate or smaller, shall be fabricated, cured, dried, and measured at 28 days in the manner delineated in ASTM C157/C157M. Mixtures containing 50 percent or more supplementary cementing materials shall meet the shrinkage criteria at 56 days.

c. Tensile strength: Determine splitting-tensile strength of concrete only for qualification of concrete mixtures. Determine and report the splitting-tensile strength result of each class of concrete in accordance with ASTM C496/C496M as the mean of three properly conducted tests at the age specified for f'c and again at 90-days age for information only.

d. Freeze-thaw durability: Determine the freeze-thaw durability factor of concrete for qualification of concrete mixtures, if required by environmental conditions. Determine and report the freeze-thaw durability factor of each class of concrete in accordance with ASTM C666/C666M Method-A. Start testing after [28] days of moist curing. The minimum acceptable durability factor after 300 cycles of rapid freezing and thawing is 90 percent.

e. Acid Soluble Chloride Ion Content: Determine the chloride ion content only for qualification of concrete mixtures. Determine acid soluble chloride ion content in accordance with ASTM C1152/C1152M. The limits for allowable acid-soluble chloride ion concentrations in hardened concrete are listed in Table 1.

f. Scaling resistance: Determine the scaling resistance only for qualification of concrete mixtures. Determine scaling resistance in accordance with ASTM C672/C672M. The limits are listed in Table 1.

g. The use of silica fume is discouraged. Silica fume shall only be used for OCONUS projects where Class F fly ash and GGBF slag are not available, and when approved by the Contracting Officer. If justified by service life modeling the mixture may contain a maximum of 7 percent silica fume by mass of total cementitious materials. Concrete mixtures containing any percentage of silica fume shall be evaluated at every [76.5] cubic meters or [100] cubic yards of concrete for the first [382.3] cubic meters or [500] cubic yards thereof to ensure that the silica fume is properly dispersed in hardened concrete samples. A qualified laboratory shall microscopically examine a sectioned sample and document the results. Provide at the Contractor's expense the services of a manufacturer's technical representative, experienced in mixing, proportioning, placement procedures, and curing of concrete containing silica fume.

h. Transport Properties if using STADIUM®: Determine ion transport properties of the concrete in accordance with test procedures outlined by SIMCO, maker of STADIUM® software. Ion Transport properties are required as inputs for service life modeling and include: the volume of permeable voids (porosity); the ion diffusion coefficient (D_{sh}); the moisture transport coefficient (MTC), and an aging factor. A brief description of the test procedures is provided below. See TR-NAVFAC ESC-CI-1215 for further details.
(1) Porosity: The volume of permeable voids (porosity) of concrete is determined in accordance with ASTM C642. Porosity is determined for qualification of concrete mixtures and for quality acceptance testing.

(2) Ion Diffusion Coefficient ($D_{oh}$): This test is a modified version of ASTM C1202 and uses an electrical field to migrate chloride ions through a vacuum saturated concrete specimen for approximately 14 days. The electrical charge flowing through the concrete is related to the diffusion coefficient of ionic species in cementitious materials. A test is defined as the average of two specimens run together and whose results are analyzed together to produce a single $D_{oh}$ value. The service life modeling software uses the cementitious materials proportions and porosity measurements to analyze the electrical measurements and determine the $D_{oh}$. The $D_{oh}$ is determined for qualification of concrete mixtures and for quality acceptance testing.

(3) Moisture Transport Test: This modified version of the ASTM C1585 test determines the drying rate of pre-saturated cementitious materials by measuring the evaporative mass loss of concrete slices with different thickness exposed to constant temperature and relative humidity environment. The moisture transport coefficient (MTC) is then determined by analyzing the mass loss data using the service life modeling software. This test is only used for qualification of concrete mixtures, not for production concrete.

(4) Aging factor: The aging factor is a necessary value to estimate the change in diffusion coefficient over time. The aging factor is defined as the ratio of the ultimate $D_{oh}$ to the 28-day $D_{oh}$ per TR-NAVFAC ESC-CI-1215. Since we cannot wait for two or more years to characterize project concrete, a surrogate aging factor is used in this specification. This surrogate aging factor is calculated as the ratio of 90-day, or longer, $D_{oh}$ to the 28-day $D_{oh}$. The aging factor is determined only for qualification of concrete mixtures in compliance with TR-NAVFAC ESC-CI-1215.

i. Transport Properties if using fib Bulletin 34: Determine the transport properties of the concrete in accordance with test procedures outlined by fib Bulletin 34. Transport properties are required as inputs for service life modeling and include: the chloride migration coefficient measured as per the NT Build 492 test procedure. The NT Build 492 test is performed at 28 maturity days on a 50 mm 2 inch thick sample sliced from a standard test cylinder. The sample is immersed in a saline solution to which a voltage is applied to accelerate the penetration of chlorides through the concrete for a period of generally 24 hours. At this time, the sample is split in half across its diameter and the depth of the chloride penetration is measured at seven points along the fractured surface. This data is used to calculate the rate at which chlorides penetrate the concrete. This rate is called the chloride migration coefficient and is a direct input value into the service life modeling. One NT Build 492 test is defined as the average of three specimens run together and whose results are averaged together to produce a single chloride migration coefficient value. The chloride migration coefficient is determined for qualification of concrete mixtures and for quality acceptance testing.
1.7.6.3 Reinforcing Steel Corrosion Properties

The corrosion properties of the reinforcing steel used for service life modeling shall be as follows unless otherwise approved by the Contracting Officer after review by the agency's Subject Matter Expert in Concrete Materials:

*See TR-NAVFAC ESC-CI-1215

** All other reinforcement not listed require approval of agency's Subject Matter Expert in Concrete Materials

1.7.6.4 Supplemental Corrosion Protection

If the available materials in the region of the project cannot practically be made to meet the service life based on testing and service life modeling without the use of supplemental corrosion protection, then the Contractor shall prepare a recommendation on how to accomplish the service life using imported materials and/or supplemental corrosion protection. With input from the agency's Subject Matter Expert in Concrete Materials, the Contracting Officer shall consider approval of the Contractor's recommendation on a case-by-case basis.

1.7.7 Mass Concrete Temperature Control Plans

a. Thirty days minimum prior to concrete placement, submit for approval a mass concrete temperature control plan that includes:

(1) Location and identification of temperature monitoring sensors.

(2) Product data for automated temperature sensors and recording equipment.

(3) Cooling pipe layout diagram with sizes and materials, if used.

(4) Proposed insulation materials and associated R-values.

(5) Anticipated form removal schedule and curing procedures.

(6) Maximum allowable concrete placement temperature for the range of anticipated ambient temperatures based on thermal modeling.
(7) Monitoring procedures and contingency plans.

Concrete placement temperature shall be based on results of thermal modeling for the element incorporating: the heat of hydration and specific heat capacity for the concrete mixture, solar gain, and heat transfer to the environment through formwork, insulation, and cooling techniques.

Mass concrete temperature control shall be monitored using automated temperature recording devices that allow wireless transmission of data to an on-site host computer for real-time monitoring of temperatures.

Temperature control sensor layout for each placement shall be provided with individual sensor ID identified.

Minimum sensor requirements include at least two sensors for each placement located as follows:

(1) The geometric center of the element cross-section.

(2) Within 76.2 mm 3 inches of the side forms at mid-height.

(3) Within 76.2 mm 3 inches of the top surface located directly above the center sensors.

(4) Within 76.2 mm 3 inches from the top corner at the intersection of side forms.

(5) Ambient temperature sensors placed in a shaded location.

Procedures for installing, protecting sensors during placement, and testing sensors a minimum of 24 hours prior to concrete placement shall be provided. Initiate sensor recording at least 2 hours prior to placement. Verify function of all sensors prior to and upon completion of concrete placing operations. Provide additional sensors for placements greater than 305.8 cubic meters 400 cubic yards at each location.

Submit procedures for controlling concrete temperatures within the following limits:

(1) Maximum temperature shall be less than 70 degrees C 158 degrees F.

(2) Maximum temperature differential between the mean of all functioning center sensor temperatures to any individual surface or corner sensor shall be less than 20 degrees C 36 degrees F.

(3) Temperature control procedures shall remain in effect until the differential between the ambient low temperature and mean of all functioning center sensor temperatures is less than 20 degrees C 36 degrees F.

(4) An additional submittal shall be provided for the Contracting Officer's approval in the event the Contractor fails to control temperatures within the limits listed above. The submittal shall include documentation of any cracks that develop, identify revisions to control procedures to prevent future cracking, and procedures to seal or otherwise mitigate defects.
b. **Mass Concrete Mock-up**: For concrete mixtures intended for mass concrete, cast thirty-one 100 by 200 mm 4 by 8 inch cylinder specimens in accordance with ASTM C192/C192M, three 75 by 75 by 285.8 mm 3 by 3 by 11.25 inch concrete prisms in accordance with ASTM C157/C157M, and at least one semi-adiabatic cube from a trial batch.

The semi adiabatic cube shall have a minimum dimension of 3 feet per side, and shall be insulated all sides with a minimum R-value of 30. Install pairs of thermocouples at the center of mass, the middle of each side, the top surface, and the top corner. Automatically record the temperature of each sensor hourly for one week. Additional cubes may be cast to calibrate active cooling system performance.

(1) Conduct compressive strength development testing at 3, 7, [28] [56], and 90 days age using three specimens per age in accordance with ASTM C39/C39M, and develop a compressive strength prediction equation for the concrete mixture in accordance with ASTM C1074.

(2) Conduct tensile strength tests at 3, 7, [28] [56], and 90 days on two specimens per age in accordance with ASTM C496/C496M, and develop a tensile strength prediction equation for the concrete mixture in accordance with ASTM C1074.

(3) Conduct elastic modulus tests at 3, 7, [28] [56], and 90 days on two specimens per age in accordance with ASTM C469/C469M, and develop an elastic modulus prediction equation for the concrete mixture in accordance with ASTM C1074.

Conduct coefficient of thermal expansion testing in accordance with COE CRD-C 39 after 28 days of moist curing. Test specimens in a saturated condition.

Report all test results and predictive equations in the mock-up submittal. The predictive equations may be used by the Contractor to establish the duration of temperature control and form removal based on the allowable temperature differential between the concrete core and ambient low temperature.

### 1.8 CONCRETE

#### 1.8.1 Drawings

Fabrication Drawings for concrete formwork, reinforcement materials, precast elements, wall forms, and bulkhead forms must indicate concrete pressure calculations with both live and dead loads, along with material types. Provide design calculations by a registered Civil or Structural Engineer for the formwork.

#### 1.8.1.1 Formwork

Prior to commencing work, submit drawings for approval showing details of formwork including, but not limited to: joints, supports, studding and shoring, and sequence of form and shoring removal. Reproductions of contract drawings are unacceptable.

Design, fabricate, erect, support, brace, and maintain formwork so that it is capable of supporting without failure all vertical and lateral loads that may reasonably be anticipated to be applied to the formwork.
ACI 347R. Include design calculations indicating arrangement of forms, sizes, species, and grades of supports (lumber), panels, and related components. Indicate placement schedule, construction, and location and method of forming control joints. Include locations of inserts, pipe work, conduit, sleeves, and other embedded items. Furnish drawings and descriptions of shoring and reshoring methods proposed for slabs, beams, and other horizontal concrete members.

1.8.1.2 Reinforcing Steel

ACI SP-66. Provide bending and cutting diagrams, assembly diagrams, splicing placement and laps of bars, shapes, dimensions, and details of bar reinforcing, accessories, and concrete cover. Do not scale dimensions from structural drawings to determine lengths of reinforcing bars. Only complete drawings will be accepted.

1.8.1.3 Precast Elements

**************************************************************************
NOTE: Modify requirements based on the scope of the project.
**************************************************************************

Submit drawings and design calculations indicating complete information for the fabrication, handling, and erection of the precast elements. Drawings shall not be reproductions of contract drawings.

1.8.1.4 Joints

Submit a plan indicating the type and location of each construction joint. Final joint locations are subject to Government approval.

1.8.2 Pre-Construction Submittals

1.8.2.1 Curing Concrete Elements

Submit proposed materials and methods for curing concrete elements.

1.8.2.2 Concrete Curing Plan

Submit proposed materials, methods, and duration for curing and cooling concrete elements in accordance with ACI 308.1.

Minimum moist curing duration shall be seven days.

Begin curing immediately after placement. Protect concrete from premature drying, excessively hot temperatures, and mechanical injury; and maintain minimal moisture loss at a relatively constant temperature for the period necessary for hydration of the cement and hardening of the concrete. The materials and methods of curing are subject to approval by the Contracting Officer.

1.8.2.3 Form Removal Schedule

Submit schedule for form removal indicating element and minimum length of time for form removal. Submit technical literature of forming material or liner, form release agent, form ties, and gasketing to prevent leakage at form and construction joints. Provide a full description of materials and
methods to be used to patch form-tie holes.

1.8.2.4 Concrete Placement and Compaction

a. Submit technical literature for equipment and methods proposed for use in placing concrete. Include concrete pumping or conveying equipment including type, size and material for pipe, valve characteristics, and the maximum length and height concrete will be pumped. No adjustments shall be made to the mixture design to facilitate pumping.

b. Submit technical literature for equipment and methods proposed for vibrating and compacting concrete. Submittal shall include technical literature describing the equipment including vibrator diameter, length, frequency, amplitude, centrifugal force, and manufacturer's description of the radius of influence under load. Where flat work is to be cast, provide similar information relative to the proposed compacting screed or other method to ensure dense placement.

1.8.2.5 Concrete Report

Provide a Report inclusive of materials and methods used, test results, and the field test strength (fcr) for concrete that shows compliance with the structural and service life requirements.

1.8.2.6 Coatings

Coatings are considered to be "supplemental corrosion protection". Surface preparation and installation of any coatings on concrete shall be conducted in strict compliance with written manufacturer instructions. Submit the product data and written manufacturer instructions. A manufacturer representative shall train installers, witness initial installation, and certify that the installation was conducted in accordance with the instructions.

1.8.2.7 Preconstruction Testing of Materials

All sampling and testing shall be performed by, and at the expense of, the Contractor. Use an approved commercial laboratory or, for cementitious materials and chemical admixtures, a laboratory maintained by the manufacturer of the material. No material shall be used until notice of acceptance has been given. The Contractor will not be entitled to any additional payment or extension of time due to failure of any material to meet project requirements, or for any additional sampling or testing required. Additional tests may be performed by the Government at the discretion of the Contracting Officer; such Government testing will not relieve the Contractor of any testing responsibilities.

1.8.2.8 Material Safety Data Sheets

Submit Material Safety Data Sheets (SDS) for all materials that are regulated for hazardous health effects. Prominently post the SDS at the construction site.

1.8.2.9 Mixture Designs

Provide a detailed report of materials and methods used, test results, and the field test strength (fcr) for marine concrete required to meet structural and durability requirements.
1.8.3 Sampling
The Contractor shall be responsible for conducting concrete production process control sampling and testing in compliance with this specification.

1.8.3.1 Ingredient Material Sampling
a. Cementitious material mill certificates and test reports shall be provided for each shipment. Record the date delivered and quantity of material represented by the certificate.

b. Conduct and log aggregate moisture content at a minimum frequency of twice daily for each day's production. Use of moisture sensors in storage bins is recommended practice, but does not satisfy this requirement.

c. Aggregate sampling for gradation and dry-rodded unit weight shall be conducted for each 100 tons delivered for use on the project, or portion thereof.

1.8.4 Reporting

1.8.4.1 Daily Inspection Reports
Contractor shall prepare daily inspection reports for all inspection activities such as base preparation, formwork preparation, reinforcement installation, concrete placement log, and temperature control activities. Submit sample forms and describe the procedure used to organize, archive, and retrieve inspection records in the Quality Program submittal.

1.8.4.2 Sampling Logs
Contractor shall maintain a concrete placement log as an electronic spreadsheet or database identifying each placement date, placement location, volume of concrete, batch ticket numbers, lot identification code, fresh concrete properties, compressive strength results, transport properties, inspection comments, and acceptance status. Contractor shall provide/transmit the concrete testing log to the Contracting Officer weekly. The Contractor shall provide copies of supporting documents for any placement requested by the Contracting Officer immediately upon request.

1.8.4.3 Quality Control Data
The Contractor shall prepare, maintain, and report separate quality control charts illustrating the slump, temperature, air content, compressive strength test results, and transport property results for each lot of each concrete mixture used on the project.

1.8.4.4 Quality Team Meetings
The contractor shall conduct regular quality control team meetings to review plans for future placements, review test results, and discuss dispensation of non-conforming materials. The quality team shall include the Contractor's quality manager, the project manager, the project superintendent, the Contracting Officer, and representatives of the testing agency and concrete producer, or approved substitutes. It is recommended that the meetings be held on a weekly or bi-weekly basis during the service life modeling submittal phases and then monthly, as the construction progresses. The transition from the weekly or bi-weekly meetings to the
monthly meetings shall be with the Contracting Officer's approval. The Contractor shall prepare quality control team meeting minutes for each meeting. The minutes shall include the date of each meeting, attendees, key discussion points, findings, recommendations, assigned tasks, assigned personnel, task completion dates and status of each task.

1.8.4.5 Non-conforming materials

The exact location of non-conforming concrete as placed shall be identified and the Contracting Officer and Engineer of Record shall be notified immediately. There are numerous possible indicators that the as-placed concrete is non-conforming including (but not limited to) excessive compressive strength, inadequate compressive strength, excessive slump, transport properties out of limits, excessive voids and honeycombing, and concrete delivery records that indicate excessive time between mixing and placement and/or excessive water was added to the mixture during delivery and placement. Any of these indicators alone are sufficient reason for the Contracting Officer to request additional sampling, testing, and service life modeling to quantify the concrete properties. If justified, cores may be extracted for testing, and an investigation into the cause for non-conformance shall be conducted. The investigation may include statistical analysis of the test data collected to date; appropriateness of the pre-defined QAL based on statistical analysis of production data; the impact of the non-conforming material on the structure strength and/or service life; and recommendations for concrete production process improvements, mitigation, or remediation, as appropriate.

Investigations into non-conforming materials shall be conducted at the Contractor's expense. The Contractor shall be responsible for the investigation and shall make written recommendations to adequately mitigate or remediate the non-conforming material. The Contracting Officer may accept, accept with reduced payment, require mitigation, or require removal and replacement of non-conforming material at no additional cost to the Government.

1.8.5 Test Reports

Concrete Test Reports shall be identified by a sequential report identification code. Each report shall identify the placement date, placement location, weather, name of testing technician, time of sampling, batch ticket number, fresh concrete test results, and hardened concrete test results.

1.8.5.1 Concrete Mixture Requirements

a. Submit copies of test reports conforming to ASTM C1077 showing that the mixture has been successfully tested to produce concrete with the properties specified and that mixture will be suitable for the job conditions. Test reports shall be submitted along with the concrete mixture proportions. Obtain approval before concrete placement.

b. Fully describe the processes and methodology whereby mixture proportions were developed and tested and how proportions will be adjusted during progress of the work to achieve, as closely as possible, the designated levels of relevant properties.

c. Submit copies of the Durability Modeling Report with laboratory analysis and modeling results indicating contract-goal service life
will be met.

1.8.5.2 Supplementary Cementing Materials

Submit test results in accordance with ASTM C618 and the physical and chemical analysis in accordance with applicable ASTM standards such as ASTM C311/C311M for fly ash. Submit test results performed within 6 months of submittal date. Update this report during construction as necessary to assure that the supplementary cementing materials used on the projects meets the ASTM criteria and the report on file is never older than 6 months.

1.8.5.2.1 Ground Granulated Blast-Furnace Slag

Submit test results in accordance with ASTM C989/C989M for ground granulated blast-furnace slag. Submit test results performed within 6 months of submittal date. Update this report during construction as necessary to assure that the report on file is never older than 6 months.

1.8.5.2.2 Ultra Fine Fly Ash or Pozzolan

Submit test results in accordance with ASTM C618 as a Class F fly ash or Class N pozzolan with the following additional requirements:

a. The strength activity index at 28 days shall be at least 95 percent of the control.

b. The average particle size shall not exceed 6 microns.

c. The sum SiO₂ plus Al₂O₃ plus Fe₂O₃ shall be greater than 77 percent.

Submit test results performed within 6 months of submittal date. Update this report during construction as necessary to assure that the report on file is never older than 6 months.

1.8.5.3 Silica Fume

Submit test results in accordance with ASTM C1240 for silica fume. Data shall be based upon tests performed within 6 months of submittal. Update this report during construction as necessary to assure that the report on file is never older than 6 months.

1.8.5.4 Aggregates

Aggregate samples shall be obtained in accordance with ASTM D75/D75M and shall be representative of the materials to be used for the project. Submit test results for aggregate quality in accordance with ASTM C33/C33M, and the combined gradation curve proposed for use in the work and used in the mixture qualification, and ASTM C295/C295M for results of petrographic examination. Confirm that the potential for alkali-silica reaction are within allowable limits by conducting tests in accordance with ASTM C1260. Submit results of all tests during progress of the work in tabular and graphical form as noted above, describing the cumulative combined aggregate grading and the percent of the combined aggregate retained on each sieve. Submit test results performed within 12 months of submittal date.

1.8.5.5 Admixtures

Submit test results in accordance with ASTM C494/C494M and ASTM C1017/C1017M for concrete admixtures, ASTM C260/C260M for air-entraining admixture, and
manufacturer's literature and test reports for corrosion inhibitors and anti-washout admixture. Submitted data shall be based upon tests performed within 6 months of submittal. Submit certified copies of test results for the specific lots or batches to be used on the project. Test results shall be not more than 6 months old prior to use in the work. Chemical admixtures that have been in storage at the project site for longer than 6 months or that has been subjected to freezing will be retested at the expense of the Contractor.

1.8.5.6 Portland Cement

Portland cement[, ground granulated blast furnace (GGBF) slag[,] [and pozzolan] will be accepted on the basis of manufacturer's certification of compliance, accompanied by mill test reports showing that the material in each shipment meets the requirements of the specification under which it is furnished. Mill test reports shall be no more than one month old, prior to use in the work. No cementitious material shall be used until notice of acceptance has been given by the Contracting Officer. Cementitious material may be subjected to check testing by the Government from samples obtained at the mill, at transfer points, or at the project site. If tests prove that a cementitious material that has been delivered is unsatisfactory, it shall be promptly removed at Contractor's expense from the site of the work. Cementitious material that has not been used within 6 months after testing shall be retested at the Contractor's expense and shall be rejected if test results are not satisfactory. Submit test results in accordance with ASTM C150/C150M portland cement and/or ASTM C595/C595M and ASTM C1157/C1157M for blended cement.

1.8.5.7 Testing During Construction

During construction, the Contractor is responsible for sampling and testing aggregates, cementitious materials, and concrete as specified herein. The Government will sample and test concrete and ingredient materials as considered appropriate. Provide facilities and labor as may be necessary for procurement of representative test samples. Testing by the Government will in no way relieve the Contractor of the specified testing requirements.

1.8.5.8 Test Section

a. Horizontal Placements. No more than 90 days prior to construction, construct a Test Section 3048 mm by 3048 mm by 203.2 mm 10 by 10 feet by 8 inches thick near the job site, but not as part of the structure. The Test Section shall meet all specification requirements and be acceptable to the Contracting Officer in all respects, including but not limited to delivery time, placement, consolidation, curing and surface texture. Use the Test Section to develop and demonstrate to the satisfaction of the Contracting Officer the proposed techniques of mixing, hauling, placing, consolidating, finishing, curing, initial saw cutting, start-up procedures, testing methods, plant operations, and the preparation of the construction joints. The mixing plant shall be operated and equipment calibrated prior to start of placing the Test Section. Use the same equipment, materials, and construction techniques on the Test Section as will be used in all subsequent work. Concrete production, placing, consolidating, curing, construction of joints, and all testing shall be in accordance with applicable provisions of this specification. At a minimum of three days after completion of the Test Section, extract a sufficient number of concrete cores 100 by 200 mm 4 by 8 inch to conduct tests to evaluate; strength, homogeneity, consolidation, segregation, air void spacing factor, and
transport properties. Test Results that are unacceptable Test Section will necessitate construction of an additional Test Section at no additional cost to the Government.

b. Vertical Placements. No more than 90 days prior to construction, construct a Test Section that represents the vertical placements, (if applicable) near the job site, but not as part of the structure. Test Section shall meet all specification requirements and being acceptable to the Contracting Officer in all respects, including but not limited to delivery time, placement, consolidation, curing and surface texture. Use the Test Section to develop and demonstrate to the satisfaction of the Contracting Officer the proposed techniques of mixing, hauling, placing, consolidating, finishing, curing, initial saw cutting, start-up procedures, testing methods, plant operations, and the preparation of the construction joints. The mixing plant shall be operated and equipment calibrated prior to start of placing the Test Section. Use the same equipment, materials, and construction techniques on the Test Section as will be used in all subsequent work. Concrete production, placing, consolidating, curing, construction of joints, and all testing shall be in accordance with applicable provisions of this specification. At a minimum of three days after completion of the Test Section, extract a sufficient number of concrete cores to evaluate strength, homogeneity, consolidation, segregation, air void spacing factor, and transport properties. If any of the test results are unacceptable, the Contracting Officer may require that a new Test Section be accomplished at no additional cost to the Government.

1.8.5.9 Acceptability of Work

The materials and the structure itself will be accepted on the basis of tests made by the Contractor and shall be in compliance with the criteria herein. The Government may make check tests at its expense to validate the results of the Contractor's testing. Testing performed by the Government will in no way relieve the Contractor from the specified testing requirements.

PART 2 PRODUCTS

**************************************************************************
NOTE: Delete any reference to any products which are not to be used on the project. Coordinate all product requirements with the appropriate agency's Contracting Officer.
**************************************************************************

2.1 CEMENTITIOUS MATERIALS

**************************************************************************
NOTE: Edit these paragraphs as appropriate for the particular project. Guidance for use of cementitious materials should be sought from the agency's Subject Matter Expert in Concrete Materials. Consideration should be given to the use of fly ash or GGBF slag for partial replacement of portland cement up to 50 percent. Type III cement should not be specified. Laboratory mixtures, proportioning studies, and tests during the design stage of the project should be inclusive of service
life modeling.

**************************************************************************
NOTE: Supplementary Cementitious Materials (SCM)

When granulated slag, coal fly ash, and natural pozzolans are used as cementing materials for replacement of portland cement in a concrete mixture, and if by doing so the sustainability, durability and the initial cost of the concrete mixture show considerable improvement then these materials are called "supplementary cementitious materials" (SCM).

The Engineer of Record is encouraged to specify the use of supplementary cementing materials. For example, 50 percent replacement of the portland cement using Class F fly ash has been successfully demonstrated to offer the required compressive strength ($f'_c$), drying shrinkage, lower permeability, constructability, and the potential to accomplish a structure with the design service life while being less expensive with a smaller carbon footprint.

Cementitious materials shall be portland cement or cement blended with supplementary cementing materials. New submittals are required when the cementitious materials change sources or types.

The Contractor shall provide cementitious materials meeting the requirements of the applicable specification, and as modified herein. Provide mill certificates and test results conducted within six-months of the submittal date as part of the concrete mixture qualification submittal.

Provide a single manufacturer of cementitious material for each type of cement and supplementary cementing materials supplied to the project.

2.1.1 Portland Cement

**************************************************************************
NOTE: Use Type II or Type V cement in project locations with Environmental Severity Classifications (ESC) of C3 thru C5 or where deicing salts are used on the structure. See UFC 1-200-01 for determination of ESC for project locations.

Provide portland cement conforming to ASTM C150/C150M, Type [I] [II] [V], low alkali [including false set requirements] with tri-calcium aluminates (C3A) content less than 10 percent and a maximum cement-alkali content of 0.80 percent Na2Oe (sodium oxide) equivalent. Type III cement shall be used only with concurrence of the agency's Subject Matter Expert in Concrete Materials. When HVFA mixtures are specified they should be blended with Type II portland cement. HVFA is encouraged instead of using Type V cement in high-sulfate areas. Low alkali cement may be required if the proposed aggregates are found to be expansive.
ASTM C150/C150M cements shall be combined with supplementary cementing materials in the concrete mixture.

2.1.2 Blended Cements

Blended cement shall conform to ASTM C595/C595M, Type IP or IS, including the optional requirement for mortar expansion [and sulfate soundness] and consist of a mixture of ASTM C150/C150M Type I, or Type II cement and a supplementary cementing material. The slag added to the Type IS blend shall be ASTM C989/C989M ground granulated blast-furnace slag. The pozzolan added to the Type IP blend shall be ASTM C618 Class F and shall be interground with the cement clinker. The manufacturer shall state in writing that the amount of pozzolan in the finished cement will not vary more than plus or minus 5 mass percent of the finished cement from lot-to-lot or within a lot. The percentage and type of mineral admixture used in the blend shall not change from that submitted for the aggregate evaluation and mixture proportioning.

2.1.3 Pozzolan

2.1.3.1 Fly Ash

**************************************************************************
NOTE: Class C fly ash is not permitted.
Use loss on ignition not exceeding 3 percent for frost areas to reduce carbon interference with air entraining admixture.
**************************************************************************

Fly ash shall conform to ASTM C618, Class F, including the optional requirements for uniformity and effectiveness in controlling Alkali-Silica reaction and shall have a loss on ignition not exceeding 3 percent. Class F fly ash for use in mitigating Alkali-Silica Reactivity shall have a Calcium Oxide (CaO) content of less than 8 percent and a total equivalent alkali content less than 1.5 percent. Add with cement.

2.1.3.2 Raw or Calcined Natural Pozzolan

Natural pozzolan shall be raw or calcined and conform to ASTM C618, Class N, including the optional requirements for uniformity and effectiveness in controlling Alkali-Silica reaction and shall have an on ignition loss not exceeding 3 percent. Class N pozzolan for use in mitigating Alkali-Silica Reactivity shall have a Calcium Oxide (CaO) content of less than 13 percent and total equivalent alkali content less than 3 percent.

2.1.3.3 Ultra Fine Fly Ash and Ultra Fine Pozzolan

Ultra Fine Fly Ash (UFFA) and Ultra Fine Pozzolan (UFP) shall conform to ASTM C618, Class F or N, and the following additional requirements:

a. The strength activity index at 28 days of age shall be at least 95 percent of the control specimens.

b. The average particle size shall not exceed 6 microns.

c. The sum of SiO2 + Al2O3 + Fe2O3 shall be greater than 77 percent.
2.1.4 Ground Granulated Blast-Furnace (GGBF) Slag

Ground Granulated Blast-Furnace Slag shall conform to ASTM C989/C989M, [Grade 100 or Grade 120]. Add with cement.

2.1.5 Silica Fume

**************************************************************************
NOTE: Silica Fume shall only be used for OCONUS projects where Class F fly ash and GGBF slag are not available, and when approved by the Contracting Officer. Guidance for use of silica fume should be sought from the agency's Subject Matter Expert in Concrete Materials.
**************************************************************************

Silica fume shall conform to ASTM C1240, including the optional limits on reactivity with cement alkalis. Silica fume may be furnished as a dry, densified material or as slurry. Proper mixing is essential to accomplish proper distribution of the silica fume and avoid agglomerated silica fume which can react with the alkali in the cement resulting in premature and extensive concrete damage. Supervision at the batch plant, finishing, and curing is essential. Provide at the Contractor's expense the services of a manufacturer's technical representative, experienced in mixing, proportioning, placement procedures, and curing of concrete containing silica fume. This representative must be present on the project prior to and during at least the first 4 days of concrete production and placement using silica fume. A High Range Water Reducer (HRWR) shall be used with silica fume. Finishing may be more difficult. Proper curing is essential because there is a tendency for plastic shrinkage cracking.

2.1.6 Supplementary Cementitious Materials (SCM) Content

The concrete mix shall always contain supplementary cementing materials whether or not the aggregates are found to be reactive in accordance with the paragraph AGGREGATES. Concrete mixtures shall be designed and proportioned to meet the requirements for strength, constructability, shrinkage, and service life.

**************************************************************************
NOTE: This specification requires that the structural requirements (f'c) be met and concrete strength is between 1.0 f'c and 1.2 f'c. If the prequalified mixture as approved by the Engineer of Record should produce a higher design strength (fcr), that strength shall be used instead of f'c. Maintain required w/cm ratio regardless of strength requirements.
**************************************************************************

2.2 AGGREGATES

**************************************************************************
NOTE: The largest possible aggregate size that meets the nominal maximum size requirements of ACI 318 should be used. Larger aggregates permit a leaner mixture with low paste content while maintaining workability.
**************************************************************************
NOTE: In some tropical locations where standard aggregate such as gravel or manufactured aggregates are not readily available, the use of coral aggregate is acceptable. The specific gravity of any coralline material must not be less than 2.40. Specify coral aggregates with higher specific gravity wherever available. Wash aggregates dredged from the ocean or lagoons with fresh water to remove as much salt as possible. Include bracketed paragraph where coral will be used as an aggregate.

Comply with ASTM C33/C33M Class 4S, except as modified herein.

The quantities to be retained on each sieve may be adjusted only where available aggregates are elongated or slivered and cause interference with mix mobility, or available aggregate gradations do not comply with the 18-8 requirement. When necessary to satisfy local conditions and when permitted, the combined aggregate percentages may be changed to not more than 22 percent nor less than 6 percent retained on any individual sieve. The combined aggregates in the mixture (coarse, intermediate, and fine) shall be well graded with no more than 18 percent nor less than 8 percent of the combined aggregate retained on any individual sieve, unless satisfactory performance can be demonstrated. The 300 micrometers No. 50 sieve may have less than 8 percent retained; sieves finer than 300 micrometers No. 50 shall have less than 8 percent retained, and the coarsest sieve may have less than 8 percent retained. Use intermediate sizes for blending where necessary, to provide a well graded combined aggregate.

a. Provide gradation of individual aggregate sizes using standard concrete aggregate sieves including 37.5 mm 1-1/2 inches, 25 mm one inch, 19 mm 3/4 inch, 12.5 mm 1/2 inch, 9.5 mm 3/8 inch, 4.75 mm No. 4, 2.36 mm No. 8, 1.18 mm No. 16, 600 micrometers No. 30, 300 micrometers No. 50, and 150 micrometers No. 100.

b. Provide aggregates for exposed concrete from one source. Aggregate reactivity shall be limited per the paragraph AGGREGATES. Provide aggregate containing no deleterious material properties as identified by ASTM C295/C295M.

c. Where a size designation is indicated, that designation indicates the nominal maximum size of the coarse aggregate.

d. Aggregate tests shall be conducted within 6 months from the date of concrete mixture submittal.

e. Provide ASTM C1260 or ASTM C1567 test results conducted within 6 months of the submittal date showing the proposed coarse and fine aggregates are either: innocuous to alkali silica reaction; or that reactivity has been mitigated by the proposed cementitious materials as modified herein. Fine and coarse aggregates to be used in all concrete shall be evaluated and tested for alkali-aggregate reactivity. Both coarse aggregate size groups shall be tested.

f. Should the test data indicate a potential for alkali-aggregate reaction, aggregates shall be rejected or procedures from AASHTO R 80
shall be followed.

g. Coral may be used as a coarse aggregate when conventional concrete aggregate is not available. Coral aggregate must be washed to eliminate chloride ions from the aggregate. Specific gravity of coral must be at least 2.40.

2.3 WATER

Water shall comply with the requirements of ASTM C94/C94M and ASTM C1602/C1602M, except that the chloride and sulfate limits as tested in accordance with ASTM D512 and ASTM D516 shall not exceed 500 parts per million chloride ion and not more than 1000 parts per million of sulfate ion as S04. Water shall be free from injurious amounts of oils, acids, alkalis, salts, and organic materials. Where non-potable water or water from reprocessed concrete is proposed for use in the work, submit results of tests in accordance with ASTM C1602/C1602M. Submit test results in accordance with ASTM D512 and ASTM D516.

2.4 ADMIXTURES

a. Provide certifications that chemical admixtures comply with the requirements shown in Table 4 and are compatible with each other. Use admixtures in accordance with manufacturer’s recommendations, as appropriate for the climatic conditions and construction needs.

b. Do not use calcium chloride or admixtures containing chloride ion content in more than trace amounts from impurities in admixture ingredients or potable water. Provide maximum concentrations of corrosion-inducing chemicals as shown in Table 4. For concrete that may be in contact with prestressing steel tendons, the concentration shall not exceed 60 percent of the limits given in Table 4. For the concentration in grout for prestressing ducts, do not exceed 25 percent of the limits in Table 4.

</table>

* Limits refer to water-soluble chemicals

** Limits are expressed as a percentage of the mass of the total cementitious materials.

c. Provide anti-washout or viscosity modifying admixtures for underwater concrete placement. Provide certification that the admixture is compatible with the cementitious materials and other chemical admixtures in the proposed concrete mixture. The anti-washout or viscosity modifying admixture shall require approval by the Contracting Officer and have a proven record of performance with a minimum of five similar projects. Test per COE CRD-C 61 to determine cumulative mass...
loss shall be performed once for each 267.6 cubic meters 350 cubic yards of underwater concrete and results submitted to Contracting Officer for approval prior to continued use.

d. The total alkali contribution of chemical admixtures shall not increase the total sodium-oxide equivalent content of the concrete mixture by more than 0.3 kg/m³ 0.5 lb/yd³.

2.4.1 Air Entraining

Provide air entraining admixtures conforming to ASTM C260/C260M.

2.4.2 Accelerating

ASTM C494/C494M, Type C.

2.4.3 Retarding

ASTM C494/C494M, Type B, D, or G.

2.4.4 Water Reducing

**************************************************************************
NOTE: The use of high range water reducers can be used to reduce the water-cementitious materials ratio which will produce a more dense concrete matrix and improve resistance to chloride ion penetration in the concrete.
**************************************************************************

ASTM C494/C494M, Type A, E, or F.

High Range Water Reducer (HRWR) shall be ASTM C494/C494M, Type F and ASTM C1017/C1017M.

2.4.5 Corrosion Inhibitors

Corrosion inhibitors are considered "supplemental corrosion projection". Adjust the quantity of concrete mixing water for the mass of water in the admixture. Accelerating and set adjusted versions are acceptable. Concrete setting time and mixture workability shall be evaluated. The use of supplemental corrosion protection shall not be used in lieu of the fundamental requirement to meet the defined service life using quality concrete with specified concrete cover over the steel reinforcing. Changes to the corrosion propagation period that is calculated for quality concrete due to the use of supplemental corrosion protection materials may be approved by the Contracting Officer based on evidence provided by the Contractor and reviewed by the agency's Subject Matter Expert in Concrete Materials on a case-by-case basis.

2.5 NON-SHRINK GROUT

ASTM C1107/C1107M.

2.6 MATERIALS FOR FORMS

Provide wood, plywood, or steel. Use plywood or steel forms where a smooth form finish is required. Lumber shall be square edged or tongue-and-groove boards, free of raised grain, knotholes, or other surface defects.
Plywood: APA PS 1, B-B concrete form panels or better. Steel form surfaces shall not contain irregularities, dents, or sags.

2.6.1 Form Ties and Form-Facing Material

a. Provide a form tie system that does not leave mild steel after break-off or removal any closer than 50 mm 2 inches from the exposed surface. Do not use wire alone. Form ties and accessories shall not reduce the effective cover of the reinforcement.

b. Form-facing material shall be structural plywood or other material that can absorb air and some of the high water-cementitious materials ratio surface paste that may be trapped in pockets between the form and the concrete. Maximum reuse is three times. Provide forms with a form treatment to prevent bond of the concrete to the forms. Use a controlled permeability form liner in strict accordance with the manufacturer's recommendations.

2.7 REINFORCEMENT

2.7.1 Prestressing Steel

******************************************************************************
NOTE: Use prestressing in fender and bearing piles and deck soffits wherever possible. Post-tensioning of pile caps and decks is recommended where feasible. Do not mix coated prestressing strands and plain prestressing strands. This will produce a large corrosion cell between the plain strand and any defect in the coated strand.
******************************************************************************

Use seven-wire stress-relieved or low-relaxation strand conforming to ASTM A416/A416M, Grade 270. Use of indented seven-wire stress-relieved or low-relaxation strand conforming to ASTM A882/A882M, Grade 270; or epoxy-filled seven-wire stress-relieved or low-relaxation strand conforming to ASTM A886/A886M, Grade 270 shall be permitted in lieu of prestressing steel conforming to ASTM A416/A416M. Use prestressing steel free of grease, oil, wax, paint, soil, dirt, and loose rust. Do not use prestressing strands or wire having kinks, bends, or other defects.

2.7.2 Reinforcing Bars

******************************************************************************
NOTE: It is intended that plain steel rebar with specified concrete cover of 75 mm 3.0 inches shall normally be specified according to applicable codes. Predictive modeling can confirm that the candidate concrete mixture, type of steel and concrete cover will yield the required service life for the particular structural element under consideration. For the purpose of predicting the service life of the concrete, the design shall meet the owner's design life without relying on a barrier such as epoxy or zinc coating of the steel rebar or passive cathodic protection for additional life extension. The use of galvanized rebar and epoxy-coated rebar are acceptable for use, but it is
difficult to justify a specific life extension from either without conclusive research data.

ASTM A706/A706M bars are mainly used in seismic design or for welding. Do not mix coated rebar and plain reinforcing bars. This may produce a large corrosion cell between the plain bar and any defect in the coated bar.

**************************************************************************

ACI 301M ACI 301 unless otherwise specified and shall meet the design yield strength and ductility requirements. Deformed reinforcing bars meeting the requirements of ASTM A615/A615M with the bars marked A, Grade ASTM A276/A276M stainless steel bars; ASTM A767/A767M Class 1 galvanized; prefabricated epoxy coated, ASTM A934/A934M; ASTM A955/A955M stainless steel bars; ASTM A1035/A1035M MMFX2 bars; ASTM A1055/A1055M Z bars; ASTM A706/A706M; or other approved reinforcing material shall be permitted for use in the cast-in-place concrete system.

The reinforcing selected shall match the structural properties of the reinforcing specified. Alternative reinforcing bars shall have similar structural properties to the specified reinforcing and may be used with the Contracting Officer's approval.

2.7.2.1 Reinforcement and Protective Coating

If applicable, provide coating manufacturer's and coating applicator's test data sheets certifying that applied coating meets the requirements of the concrete system specified on the Plans. Extensions to the corrosion propagation period may be approved by the Contracting Officer based on evidence provided by the Contractor and reviewed by the agency's Subject Matter Expert in Concrete Materials on a case-by-case basis.

2.7.3 Mechanical Reinforcing Bar Connectors

ACI 301M ACI 301. Provide 125 percent minimum yield strength of the reinforcement bar. Coat connectors in accordance with the requirements of the reinforcing bars.

2.7.4 Welded Wire Fabric

2.7.5 Wire

Comply with ASTM A1064/A1064M carbon steel.

2.8 ACCESSORY MATERIALS

2.8.1 Polyvinylchloride Waterstops

COE CRD-C 572.

2.8.2 Materials for Curing Concrete

2.8.2.1 Impervious Sheeting

ASTM C171; waterproof paper, clear or white polyethylene sheeting, or
polyethylene-coated burlap.

2.8.2.2 Pervious Sheeting

AASHTO M 182 or carpet covering the free surface and kept continuously wet throughout the curing period.

2.8.2.3 Liquid Membrane-Forming Compound

Comply with ASTM C309, white-pigmented, Type 2, Class B.

2.8.3 Liquid Chemical Sealer-Hardener Compound

Provide magnesium fluosilicate compound which when mixed with water seals and hardens the surface of the concrete. Do not use on exterior slabs exposed to freezing conditions. Compound shall not reduce the adhesion of resilient flooring, tile, paint, roofing, waterproofing, or other material applied to concrete.

2.8.4 Expansion/Contraction Joint Filler

Comply with ASTM D1751 or ASTM D1752, 13 mm 1/2 inch thick unless otherwise indicated.

2.8.5 Joint Sealants

2.8.5.1 Horizontal Surfaces

**************************************************************************

NOTE: For horizontal surfaces subject to jet fuel, specify section 32 01 19.61 SEALING OF JOINTS IN RIGID PAVEMENT.

**************************************************************************

Horizontal surfaces are defined as all surfaces with a 3 percent maximum slope. ASTM D6690 or ASTM C920, Type M, Class 25, Use T.

2.8.5.2 Vertical Surfaces

**************************************************************************

NOTE: Specify ASTM C920 for vertical surfaces greater than 3 percent slope and not subject to jet fuel, gasoline, fuel oil, etc. For vertical surfaces greater than 3 percent slope and subject to jet fuel, specify FS SS-S-200, no sag.

**************************************************************************

Vertical surfaces are defined as all surfaces with a slope greater than 3 percent. ASTM C920, Type M, Grade NS, Class 25, Use T. FS SS-S-200, no sag.

PART 3 EXECUTION

3.1 FORMS

a. Provide formwork with clean-out openings to permit inspection and removal of debris. Formwork shall be gasketed or otherwise rendered sufficiently tight to prevent leakage of paste or grout under heavy, high-frequency vibration. Use a release agent that does not cause surface dusting. Limit reuse of plywood to no more than three times.
Reuse may be further limited by the Contracting Officer if it is found that the pores of the plywood are clogged with paste so that the wood does not absorb air and some of the high water-cementitious materials ratio paste that may be trapped in pockets between the form and the concrete.

b. Comply with ACI 301M ACI 301. Concrete for footings may be placed in excavations without forms upon inspection and approval by the Contracting Officer. Excavation width shall be a minimum of 100 mm 4 inches greater than indicated. Set forms rigidly, mortar-tight, and true to line and grade. Chamfer above grade exposed joints, edges, and external corners of concrete 20 mm 0.75 inch unless otherwise indicated. Forms submerged in water shall be watertight.

c. Patch form tie holes with a no shrink patching material in accordance with the manufacturer's recommendations and subject to approval.

3.1.1 Coating

Before concrete placement, coat the contact surfaces of forms with a no staining mineral oil, no staining form coating compound, or two coats of nitrocellulose lacquer. Do not use mineral oil on forms for surfaces to which adhesive, paint, or other finish material is to be applied.

3.1.2 Removal of Forms and Supports

After placing concrete, forms shall remain in place for the time periods specified in ACI 347R, except for concrete placed underwater, forms shall remain in place a minimum of 48 hours. Prevent concrete damage during form removal.

3.1.2.1 Special Requirements for Reduced Time Period

Forms may be removed earlier than specified if ASTM C39/C39M test results of field-cured samples from a representative portion of the structure or other approved and calibrated non-destructive testing techniques show that the concrete has reached a minimum of 85 percent of the design strength.

3.1.3 Reshoring

Do not allow construction loads to exceed the superimposed load that the structural member, with necessary supplemental support, is capable of carrying safely and without damage. Reshore concrete elements where forms are removed prior to the specified time period. Do not permit elements to deflect or accept loads during form stripping or reshoring. Forms on columns, walls, or other load-bearing members may be stripped after 2 days if loads are not applied to the members. After forms are removed, slabs and beams over 3 meters 10 feet in span and cantilevers over 1.2 meters 4 feet shall be reshored for the remainder of the specified time period in accordance with paragraph REMOVAL OF FORMS AND SUPPORTS. Perform reshoring operations to prevent subjecting concrete members to overloads, eccentric loading, or reverse bending. Reshoring elements shall have the same load-carry capabilities as original shoring and shall be spaced similar to original shoring. Firmly secure and brace reshoring elements to provide solid bearing and support.

3.2 PLACING REINFORCEMENT AND MISCELLANEOUS MATERIALS

ACI 301M ACI 301. Remove rust, scale, oil, grease, clay, or foreign
substances from reinforcing that would reduce the epoxy coating bond from reinforcing. Do not tack weld. Inspect and verify proper reinforcement grade, quantity, spacing, and clearance requirements prior to concrete placement. Inspect placed steel reinforcing for coating damage prior to placing concrete. Repair all visible damage.

3.2.1 Coated Reinforcing

The use of supplemental corrosion protection shall not be used in lieu of the fundamental requirement to meet the defined service life. Extensions to corrosion propagation period may be approved by the Contracting Officer based on evidence provided by the Contractor and reviewed by the agency's Subject Matter Expert in Concrete Materials on a case-by-case basis.

Record coating lot on each shipping notice and carefully identify and retag bar bundles from bending plant. Provide systems for handling coated bars that have padded contact areas, nylon slings, etc., to keep bars free of dirt and grit. Carefully handle and install bars to minimize job site patching including lifting and supporting bundled coated bars with strong back, multiple supports, or platform bridge to prevent sagging and abrasion. When possible, assemble reinforcement as tied cages prior to final placement into the forms. Bundling bands shall be padded where in contact with bars. Do not drop or drag bars or bundles. Store coated bars both in shop and in field, aboveground, on wooden or padded cribbing with adequate protective blocking between layers. Schedule deliveries of coated bars to the job site to avoid the need for long term storage. Protect from direct sunlight and weather. Bars to be stored longer than 12 hours at the job site shall be covered with opaque polyethylene sheeting or other suitable equivalent protective material.

Inspect for defects and provide required repairs prior to assembly. After assembly, reinspect and provide final repairs. Excessive nicks and scrapes that expose steel shall be cause for rejection.

a. Immediately prior to application of the patching material, any rust and debonded coating shall be manually removed from the reinforcement by suitable techniques employing devices such as wire brushes and emery paper. Care shall be exercised during this surface preparation so that the damaged areas are not enlarged more than necessary to accomplish the repair. Damaged areas shall be clean of dirt, debris, oil, and similar materials prior to application of the patching material.

b. Repair and patching shall be done in accordance with the patching material manufacturer's recommendations. These recommendations, including cure times, shall be available at the job site at all times.

c. Allow adequate time for the patching materials to cure in accordance with the manufacturer's recommendation prior to concrete placement.

d. Rinse placed reinforcing bars with ASTM C1602/C1602M compliant water to remove chloride contamination prior to placing concrete.

3.2.2 Reinforcement Supports

Place reinforcement and secure with non-corrodible chairs, spacers, and hangers. Metal hangers may be used, but shall be of similar material to the reinforcing. Support reinforcement on the ground with concrete or other non-corrodible material, having a compressive strength equal to or greater than the concrete being placed and having permeability equal or
less than the concrete being placed.

Coated reinforcing bars supported from formwork shall rest on coated wire bar supports, or on bar supports made of dielectric material or other acceptable material. Wire bar supports shall be coated with dielectric material, compatible with concrete, for a minimum distance of 50 mm 2 inches from the point of contact with the coated reinforcing bars. Reinforcing bars used as support bars shall be coated with the same material as the reinforcing. Spreader bars, where used, shall be coated. Non-coated combination bar clips and spreaders used in construction with coated reinforcing bars shall be made corrosion resistant or coated with dielectric material. Coated bars shall be tied with plastic-coated tie wire or other materials acceptable to the Contracting Officer.

3.2.3 Splicing

As indicated. For splices not indicated, comply with ACI 301M ACI 301. Do not splice at points of maximum stress. Overlap welded wire fabric the spacing of the cross wires, plus 50 mm 2 inches. Welded splices shall comply with AWS D1.4/D1.4M and be approved prior to use.

3.2.4 Future Bonding

Plug exposed, threaded, mechanical reinforcement bar connectors with a greased bolt. Bolt threads shall match the connector. Countersink the connector in the concrete. Caulk the depression after the bolt is installed.

3.2.5 Cover

**************************************************************************
NOTE: Uniform, high quality concrete cover over the steel reinforcement is critically important for long-term durability.
**************************************************************************

As a minimum, comply with ACI 318M ACI 318 for concrete cover over the steel reinforcement. The cover may be greater than that required by ACI 318M ACI 318 based on the results from service life modeling. Use allowable tolerances for the placement of the steel as defined in the service life modeling. When predicting service life, the cover thickness must be modelled considering the specified cover and construction tolerances per ACI 117.

3.2.6 Setting Miscellaneous Material and Prestress Anchorages

Place and secure anchors, bolts, pipe sleeves, conduits, and other such items in position before concrete placement. Plumb anchor bolts and check location and elevation. Temporarily fill voids in sleeves with readily removable material to prevent the entry of concrete. Electrically isolate exposed steel work and its anchor systems from the primary steel reinforcement with at least 50 mm 2 inches of concrete. Coat exposed steel work to reduce corrosion. Take particular care to ensure against corrosion on edges and horizontal surfaces. Use epoxy coatings for protection of carbon steel plates and fittings.

3.2.7 Construction Joints

Locate joints to least impair strength. Continue reinforcement across
joints unless otherwise indicated. Final joint locations are subject to Government approval or substantiating calculations from the Contractor.

3.2.8 Expansion Joints and Contraction Joints

Provide expansion joint at edges of interior floor slabs on grade abutting vertical surfaces, and as indicated. Make expansion joints 13 mm 1/2 inch wide unless indicated otherwise. Fill expansion joints not exposed to weather with preformed joint filler material. Completely fill joints exposed to weather with joint filler material and joint sealant. Do not extend reinforcement or other embedded metal items bonded to the concrete through any expansion joint unless an expansion sleeve is used. Place contraction joints, either formed or saw cut or cut with a jointing tool, to the indicated depth after the surface has been finished. Sawed joints shall be completed within 4 to 12 hours after concrete placement. Protect joints from intrusion of foreign matter.

3.2.9 Waterstop Splices

Fusion weld in the field.

3.2.10 Pits and Trenches

Place bottoms and walls monolithically or provide waterstops and keys.

3.3 Batching, Measuring, Mixing, and Transporting Concrete

**ASTM C94/C94M, ACI 301M ACI 301, and ACI 304R, except as modified herein.**

Batching equipment shall be such that the concrete ingredients are consistently measured within the following tolerances: 1 percent for cement and water, 2 percent for aggregate, and 3 percent for admixtures. Furnish mandatory batch tickets imprinted with mix identification, batch size, batch design and measured weights, moisture in the aggregates, and time batched for each load of ready mix concrete. When a pozzolan is batched cumulatively with the cement, it shall be batched after the cement has entered the weight hopper.

3.3.1 Measuring

Make measurements at intervals as specified in paragraphs SAMPLING and TESTING.

Adjust batch proportions to replicate the mixture design using methods provided in the approved quality assurance plan. Base the adjustments on results of tests of materials at the batch plant for use in the work. Maintain a full record of adjustments and the basis for each.

3.3.2 Mixing

Comply with ASTM C94/C94M and ACI 301M ACI 301. If time of discharge exceeds time required by ASTM C94/C94M, submit a request along with description of precautions to be taken.

3.3.3 Transporting

Comply with ACI 304R.
3.4 PLACING CONCRETE

Comply with ACI 304R and ACI 304.2R. Place concrete as soon as practicable after the forms and the reinforcement have been inspected and approved. Do not place concrete when weather conditions prevent proper placement and consolidation; in uncovered areas during periods of precipitation; or in standing water. Prior to placing concrete, remove dirt, construction debris, water, snow, and ice from within the forms. Deposit concrete as close as practicable to the final position in the forms. Do not exceed a free vertical drop of one m 3 feet from the point of discharge. Place concrete in one continuous operation from one end of the structure towards the other or lifts for vertical construction. Position grade stakes on 6 m 20 foot centers maximum for exterior slabs.

3.4.1 Vibration

**************************************************************************

NOTE: The requirement for vibrator spacing shall be considered in the reinforcing steel design by the engineer of record. ACI SP-66 requires that bar bundling be done by the design engineer. It is very important to provide space for placement and consolidation of concrete.

**************************************************************************

Comply with the requirements of ACI 309R[ and ASTM A934/A934M for epoxy-coated bar] using vibrators with a minimum frequency of 9000 vibrations per minute (VPM). Use only high cycle or high frequency vibrators. Motor-in-head 60 cycle vibrators may not be used. For walls and deep beams, use a minimum of two vibrators with the first to melt down the mixture and the second to thoroughly consolidate the mass. Provide a spare vibrator at the casting site whenever concrete is placed. Place concrete in 500 mm 18 inch maximum vertical lifts. Insert and withdraw vibrators approximately 500 mm 18 inches apart. Penetrate at least 200 mm 8 inches into the previously placed lift with the vibrator when more than one lift is required. Extract the vibrator using a series of up and down motions to drive the trapped air out of the concrete and from between the concrete and the forms.

For slab construction, use vibrating screeds designed to consolidate the full depth of the concrete. Where beams and slabs intersect, use an internal vibrator to consolidate the beam. Do not vibrate concrete placed with anti-washout admixtures. Vibrators shall be equipped with rubber vibrator heads.

3.4.2 Cold Weather

Comply with ACI 306R. Do not allow concrete temperature to decrease below 10 degrees C 50 degrees F. Obtain approval prior to placing concrete when ambient temperature is below 4 degrees C 40 degrees F or when concrete is likely to be subjected to freezing temperatures within 24 hours. Placement of concrete shall be halted whenever the ambient temperature drops below 5 degrees C 40 degrees F. When the ambient temperature is less than 10 degrees C 50 degrees F the temperature of the concrete when placed shall be not less than 10 degrees C 50 degrees F or more than 25 degrees C 75 degrees F. Heating of the mixing water or aggregates may be necessary to regulate the concrete placing temperature. An accelerating admixture may be used when the ambient temperature is below 10 degrees C 50 degrees F. Covering and other means shall be provided for maintaining the concrete at
a temperature of at least 10 degrees C 50 degrees F for not less than 7 days after placing, and at a temperature above freezing for the remainder of the curing period.

3.4.3 Hot Weather

Comply with ACI 305R. Maintain required concrete temperature using Figure 2.1.5, "Effect of Concrete Temperatures, Relative Humidity, and Wind Velocity on the Rate of Evaporation of Surface Moisture From Concrete" in ACI 305R to prevent the evaporation rate from exceeding one kg per square meter 0.2 pound of water per square foot of exposed concrete per hour. If necessary, cool ingredients before mixing or use other suitable means to control concrete temperature and prevent rapid drying of newly placed concrete. Shade the fresh concrete as soon as possible after placing. Start curing when the surface of the fresh concrete is sufficiently hard to permit curing without damage. If the evaporation rate exceeds 0.5 kg per square meter 0.1 pound of water per square foot per hour, fog spray the exposed concrete surfaces until active moist curing is applied. Provide water hoses, pipes, spraying equipment, and water hauling equipment, where job site is remote to water source, to maintain a moist concrete surface throughout the curing period. Provide burlap cover or other suitable, permeable material with fog spray or continuous wetting of the concrete when weather conditions prevent the use of either liquid membrane curing compound or impervious sheets. For vertical surfaces, protect forms from direct sunlight and add water to top of structure once concrete is set.

3.4.4 Prevention of Plastic Shrinkage Cracking

During weather with low humidity, and particularly with high temperature and appreciable wind, develop and institute measures to prevent plastic shrinkage cracks from developing. If plastic shrinkage cracking occurs, halt further placement of concrete until protective measures are in place to prevent further cracking. Periods of high potential for plastic shrinkage cracking can be anticipated by use of Figure 2.1.5 of ACI 305R. In addition to the protective measures concrete placement shall be further protected by erecting shades and windbreaks and by applying fog sprays of water, the addition of monomolecular films, or wet covering. When such water treatment is stopped, curing procedures shall be immediately commenced. The methods and materials to remove or repair areas affected by plastic shrinkage cracks shall be suggested by the Contractor, reviewed by the agency's Subject Matter Expert in Concrete Materials, and approved by the Contracting Officer. Cracks shall never be troweled over or filled with cement slurry.

3.4.5 Mass Concrete

All mass concrete elements shall be placed per the requirements of the Mass Concrete Temperature Control Plan.

3.4.6 Depositing Concrete Under Water

ACI 301M ACI 301 methods and equipment used shall prevent the washing of the cement from the mixture, minimize the formation of laitance, prevent the flow of water through the concrete before it has hardened, and minimize disturbance to the previously placed concrete. Tremies, if used, shall be watertight and sufficiently large to permit a free flow of concrete. Keep the discharge end continuously submerged in fresh concrete. Keep the shaft full of concrete to a level well above the water surface. Discharge and spread the concrete by raising the tremie to maintain a uniform flow.
Place concrete without interruption until the top of the fresh concrete is at the required height.

3.5 SURFACE FINISHES EXCEPT FLOOR, SLAB, AND PAVEMENT

3.5.1 Defects

Repair formed surfaces by removing minor honeycombs, pits greater than 600 square mm one square inch surface area or 6 mm 0.25 inch maximum depth, or otherwise defective areas. Provide edges perpendicular to the surface and patch with non-shrink grout. Patch tie holes and defects when the forms are removed. Concrete with extensive honeycomb including exposed steel reinforcement, cold joints, entrapped debris, separated aggregate, or other defects that affect the serviceability or structural strength will be rejected, unless correction of defects is approved. Obtain approval of corrective action prior to repair. The surface of the concrete shall not vary more than the allowable tolerances of ACI 347R. Exposed surfaces shall be uniform in appearance and finished to a smooth form finish unless otherwise indicated.

3.5.2 Formed Surfaces

3.5.2.1 Tolerances

Comply with ACI 117 and as indicated.

3.5.2.2 As-Cast Rough Form

Provide for surfaces not exposed to public view. Patch holes and defects and level abrupt irregularities. Remove or rub off fins and other projections exceeding 6 mm 0.25 inch in height.

3.5.2.3 As-Cast Form

Provide form facing material producing a smooth, hard, uniform texture on the concrete. Arrange facing material in an orderly and symmetrical manner and keep seams to a practical minimum. Support forms as necessary to meet required tolerances. Material with raised grain, torn surfaces, worn edges, patches, dents, or other defects that will impair the texture of the concrete surface shall not be used. Patch tie holes and defects and completely remove fins.

3.6 FINISHES FOR HORIZONTAL CONCRETE SURFACES

3.6.1 Finish

Comply with ACI 301M ACI 301. Place, consolidate, and immediately strike off concrete to obtain proper contour, grade, and elevation before bleedwater appears. Permit concrete to attain a set sufficient for floating and supporting the weight of the finisher and equipment. If bleedwater is present prior to floating the surface, drag excess water off or remove by absorption with porous materials. Do not use dry cement to absorb bleedwater.

3.6.1.1 Scratched

Use for surfaces intended to receive bonded applied cementitious applications. After the concrete has been placed, consolidated, struck off, and leveled, the surface shall be roughened with stiff brushes of
3.6.1.2 Floated

Exterior slabs where not otherwise specified. After the concrete has been placed, consolidated, struck off, and leveled, do not work the concrete further, until ready for floating. Whether floating with a wood, magnesium, or composite hand float, with a bladed power trowel equipped with float shoes, or with a powered disc, float shall begin when the surface has stiffened sufficiently to permit the operation.

3.6.1.3 Broomed

Perform a floated finish, then draw a broom or burlap belt across the surface to produce a coarse scored texture. Permit surface to harden sufficiently to retain the scoring or ridges. Broom transverse to traffic or at right angles to the slope of the slab.

3.6.1.4 Pavement

Screed the concrete with a template advanced with a combined longitudinal and crosswise motion. Maintain a slight surplus of concrete ahead of the template. After screeding, float the concrete longitudinally. Use a straightedge to check slope and flatness; correct and refloat as necessary. Obtain final finish by a burlap drag. Drag a strip of clean, wet burlap from 900 to 3000 mm wide and 600 mm longer 3 to 10 feet wide and 2 feet longer than the pavement width across the slab. Produce a fine, granular, sandy textured surface without disfiguring marks. Round edges and joints with an edger having a radius of 3 mm 1/8 inch.

3.6.1.5 Concrete Toppings Placement

Remove dirt, laitance, and loose aggregate by means of a stiff wire broom. Keep the base wet for a period of 12 hours preceding the application of the topping. Remove excess water prior to the topping placement. Do not allow temperature differential between the completed base and the topping to exceed 6 degrees C 10 degrees F at the time of placing. Place the topping and finish as specified for pavement.

3.7 CURING AND PROTECTION

Comply with ACI 301M ACI 301 and ACI 308.1 unless otherwise specified. Prevent concrete from drying by misting surface of concrete. Begin curing immediately following final set. Avoid damage to concrete from vibration created by blasting, pile driving, movement of equipment in the vicinity, disturbance of formwork or protruding reinforcement, by rain or running water, adverse weather conditions, and any other activity resulting in ground vibrations. Protect concrete from injurious action by sun, rain, flowing water, frost, mechanical injury, tire marks, and oil stains. Do not allow concrete to dry out from time of placement until the expiration of the specified curing period. Do not use membrane-forming compound on surfaces where appearance would be objectionable, on any surface to be painted, where coverings are to be bonded to the concrete, or on concrete to which other concrete is to be bonded. If forms are removed prior to the expiration of the curing period, provide another curing procedure specified herein for the remaining portion of the curing period. Provide moist curing for those areas receiving liquid chemical sealer-hardener or epoxy coating.
NOTE: When the use of alkali-reactive aggregates is permitted, add the following paragraph.

Furnish ASTM C39/C39M test results to verify the anticipated rate of strength development for the proposed concrete design mixture. Submit an increased curing period and minimum time to strip formwork based upon the reduced rate of strength development.

3.7.1 Wet Curing

Wet cure marine concrete using ASTM C1602/C1602M compliant water for a minimum of 7 days. Do not allow construction loads to exceed the superimposed load that the structural member, with necessary supplemental support, is capable of carrying in current condition safely and without damage.

Leaving the forms in place for seven days is a suitable alternative to wet curing.

3.7.1.1 Ponding or Immersion

Continually immerse the concrete throughout the seven-day curing period. Water shall not be \(11 \text{ degrees C} \) \(20 \text{ degrees F} \) less than the temperature of the concrete. For temperatures between \(4 \text{ and 10 degrees C} \) \(40 \text{ and 50 degrees F} \), increase the curing period by 50 percent.

3.7.1.2 Fog Spraying or Sprinkling

Apply water uniformly and continuously throughout the curing period. For temperatures between \(4 \text{ and 10 degrees C} \) \(40 \text{ and 50 degrees F} \), increase the curing period by 50 percent.

3.7.1.3 Pervious Sheeting

Completely cover surface and edges of the concrete with two thicknesses of wet sheeting. Overlap sheeting 150 mm 6 inches over adjacent sheeting. Sheeting shall be at least as long as the width of the surface to be cured. During application, do not drag the sheeting over the finished concrete or over sheeting already placed. Wet sheeting thoroughly and keep continuously wet throughout the curing period.

3.7.1.4 Impervious Sheeting

Wet the entire exposed surface of the concrete thoroughly with a fine spray of water and cover with impervious sheeting throughout the curing period. Lay sheeting directly on the concrete surface and overlap edges 300 mm 12 inches minimum. Provide sheeting not less than 450 mm 18 inches wider than the concrete surface to be cured. Secure edges and transverse laps to form closed joints. Repair torn or damaged sheeting or provide new sheeting. Cover or wrap columns, walls, and other vertical structural elements from the top down with impervious sheeting; overlap and continuously tape sheeting joints; and introduce sufficient water to soak the entire surface prior to completely enclosing.

3.7.2 Liquid Membrane-Forming Curing Compound
NOTE: Stay in place forms and moist curing are the preferred method for curing concrete. Use of a liquid membrane-forming curing compound is only permitted when approved by the Contracting Officer.

Seal or cover joint openings prior to application of curing compound. Prevent curing compound from entering the joint. Apply in accordance with the recommendations of the manufacturer immediately after any water sheen that may develop after finishing has disappeared from the concrete surface. Provide and maintain compound on the concrete surface throughout the curing period. Do not use this method of curing where the use of Figure 2.1.5, "Effect of Concrete Temperatures, Relative Humidity, and Wind Velocity on the Rate of Evaporation of Surface Moisture From Concrete" in ACI 305R indicates that hot weather conditions will cause an evaporation rate exceeding one kg per square meter per hour 0.2 pound of water per square foot per hour.

3.7.2.1 Application

Mechanically agitate curing compound thoroughly during use. Use approved power-spraying equipment to uniformly apply two coats of compound in a continuous operation. The total coverage for the two coats shall be 5 square meters maximum per l 200 square feet maximum per gallon of undiluted compound unless otherwise recommended by the manufacturer's written instructions. The compound shall form a uniform, continuous, coherent film that will not check, crack, or peel. Immediately apply an additional coat of compound to areas where the film is defective. Respray concrete surfaces subjected to rainfall within 3 hours after the curing compound application.

3.7.2.2 Protection of Treated Surfaces

Prohibit pedestrian and vehicular traffic and other sources of abrasion at least 72 hours after compound application. Maintain continuity of the coating for the entire curing period and immediately repair any damage.

3.7.3 Liquid Chemical Sealer-Hardener

Apply the sealer-hardener in accordance with manufacturer's recommendations. Seal or cover joints and openings in which joint sealant is to be applied as required by the joint sealant manufacturer. The sealer-hardener shall not be applied until the concrete has been moist cured and has aged for a minimum of 30 days. Apply a minimum of two coats of sealer-hardener.

3.7.4 Curing Periods

NOTE: Add the following if concrete will be underwater: [Cure land-cast elements for a minimum of 7 days prior to submerging].

Moist cure concrete using ASTM C1602/C1602M compliant water for a minimum of 7 days. Continue additional curing for a total period of 21 days. Begin curing immediately after placement. Protect concrete from premature drying, excessively hot temperatures, and mechanical injury; and maintain minimal moisture loss at a relatively constant temperature for the period.
necessary for hydration of the cement and hardening of the concrete. The materials and methods of curing shall be subject to approval by the Contracting Officer.

3.8 FIELD QUALITY CONTROL

**************************************************************************
NOTE: Consider the size and complexity of job to determine if all tests are required.
**************************************************************************

3.8.1 Fresh Concrete Properties

For each concrete mixture, the Contractor shall take samples in accordance with ASTM C172/C172M, test and record the slump, and temperature. If the slump deviates from the previous batch by more than 25.4 mm 1 inch, air content shall also be determined. Adjustment of air content and/or slump with chemical admixture is permitted provided the water to cementitious material ratio is not exceeded.

3.8.1.1 Slump Tests

ASTM C143/C143M. Take concrete samples during concrete placement. The maximum slump may be increased as specified with the addition of an approved high range water reducing (HRWR) admixture provided that the water-cementitious ratio is not exceeded. Perform tests at commencement of concrete placement, when test cylinders are made, and for each batch (minimum) or every 40 cubic meters 50 cubic yards (maximum) of concrete. If concrete does not pass slump test, adjust using a HRWR and test every concrete batch until two consecutive batches meet slump without adjustment.

3.8.1.2 Temperature Tests

a. Test the concrete delivered and the concrete in the forms. Perform tests in hot or cold weather conditions below 10 degrees C and above 27 degrees C below 50 degrees F and above 80 degrees F for each batch (minimum) or every 40 cubic meters 50 cubic yards (maximum) of concrete, until the specified temperature is obtained, and whenever test cylinders and slump tests are made.

b. Determine temperature of each concrete sample in accordance with ASTM C1064/C1064M. Temperatures must comply with the Concrete Temperature Control Plans.

3.8.1.3 Air Content Tests

ASTM C231/C231M or ASTM C173/C173M. Perform tests at commencement of concrete placement each day, when test cylinders are made, and if slump test varies by more than 25.4 mm 1 inch from previous results or concrete does not pass slump test.

3.8.1.4 Unit Weight Test

ASTM C138/C138M. Take concrete samples during concrete placement. Perform tests at commencement of concrete placement, when test cylinders are made, and for each batch (minimum) or every 38.2 cubic meters 50 cubic yards (maximum) of concrete.
3.8.2 Hardened Concrete Properties

NOTE: The Engineer of Record must specify the frequency of testing during the construction phase. Sufficient testing must be done to maintain confidence that the concrete, as delivered and placed, remains consistent. For example: sample and test every 75 cubic meters 100 cubic yards for the first 382 cubic meters 500 cubic yards, then every 382 cubic meters 500 cubic yards once confidence is established in uniformity. However, this is only a guideline, and the owner and Engineer of Record should agree on the frequency of sampling as best suits the particulars of each project and budget.

For example, a sampling interval for a new pier may be as follows:

- During the first week of casting piles
- During the second week of casing piles
- Midway through the casting of all piles
- During the final week of casting piles
- At the first pile cap and every tenth bent thereafter
- During the two first concrete deck pours
- During the final concrete deck pour

Sample and test each lot at [75] cubic meters [100] cubic yards for the first [382] cubic meters [500] cubic yards, then every [382] cubic meters [500] cubic yards thereafter.

Cast and cure specimens in accordance with ASTM C172/C172M, ASTM C31/C31M, and applicable requirements of ACI 305R and ACI 306R.

For each lot, record the date and time sampled, the batch ticket code, cylinder ID code the location of placement, total volume of concrete represented by the sample, and fresh concrete properties; ASTM C143/C143M for slump or ASTM C1611/C1611M for slump flow and visual stability index (VSI), ASTM C231/C231M for air content, ASTM C1064/C1064M for temperature, and ASTM C138/C138M unit weight.

For each lot sample, cast twelve 150 by 300 mm 6 by 12 inch cylinder specimens for strength and seven 100 by 200 mm 4 by 8 inch cylinder specimens for transport property testing. Special handling will be necessary for shipments of transport property specimens. These cylinders shall be wrapped completely with slightly dampened paper towels with water only. The wrapped cylinders shall be placed in either a vacuum package or double layers of sealed plastic bags. Package cylinders to prevent damage and ship to the approved testing laboratory.

In the event the results of cylinder tests fail to satisfy transport properties, then an additional pair of specimens shall be tested. In the event quality acceptance test results and retest results fail to meet the quality acceptance criteria, the entire lot shall be considered non-conforming material, refer to the paragraph REPAIR, REHABILITATION and REMOVAL.
3.8.2.1 Compressive Strength Tests

NOTE: When the same mix design is used for multiple elements such as slabs, beams, and walls, the design element type may be specified in addition to the mix design to better identify deficient concrete.

ACI 214R tests for strength - conduct strength tests of concrete during construction in accordance with the following procedures:

a. Test cylinders in accordance with ASTM C39/C39M. Test three cylinders at 3 days, three cylinders at 7 days, and three cylinders at the age when the compressive strength requirement was specified. Hold the remaining three cylinders in storage. If one specimen in a test shows evidence of improper sampling, molding or testing, discard the specimen and consider the strength of the remaining cylinder to be the test result. If more than one specimen shows excess defects, the Contracting Officer may allow the entire test to be discarded. Test results shall not exceed the specified compressive strength by more than 20 percent for the age specified.

b. If the average strength test results are less than the specified strength (f’c) extract three core samples from the structure in accordance with ASTM C42/C42M, from the area that correlates to the low test results. These extracted cores shall not contain steel reinforcing. Repair core holes with non-shrink grout. Match color and finish of adjacent concrete. For concrete not meeting strength criteria, the Contractor shall prepare a remediation strategy for the review by the Contracting Officer.

c. Strength test reports shall be provided within 7 days of test completion.

3.8.2.2 Transport Property Tests

If using STADIUM®: Test cylinder concrete for porosity and ion diffusion coefficient at 28 days. Calculate the $D_{eff}$ with the determined ionic diffusion coefficient ($D_{oh}$) and volume of permeable voids (porosity).

If using fib Bulletin 34: Test cylinder concrete for chloride migration coefficient at 28 days.

Concrete representative of the tested concrete with values non-conforming with the quality acceptance values determined in the service life modeling will require retesting using spare samples. If the retest exceeds the quality acceptance limit, this shall be grounds to stop concrete placement and to review quality control issues.

The Contractor shall monitor the transport properties throughout the duration of the project and prepare an as-built report documenting the transport property test results. The report shall include a chart or table of the effective diffusion coefficient ($D_{eff}$) or measured chloride ion migration coefficient versus the specified value over the duration of the placement for each concrete, indicate the concrete placed outside of the tolerance limits, describe any mitigation measures taken to ensure the service life specified, and estimate the service life of the various concretes, as placed.
3.8.2.3 Chloride Ion Concentration

Comply with ACI 318M Table 1. Determine water soluble chloride ion concentration. Perform test once for each mix design.

3.8.2.4 Anti-Washout Admixture

Comply with COE CRD-C 61. Determine cumulative mass loss. Perform test once for each 267.6 cubic meters 350 cubic yards of underwater concrete.

3.8.2.5 Non-Destructive Tests

Use of a rebound hammer to obtain data on the strength of the concrete surface shall be in accordance with ASTM C805/C805M. Test results from the rebound hammer and other non-destructive testing may be helpful in selecting areas to extract concrete cores for destructive testing.

3.8.3 Core Samples and Compressive Strength Testing

Obtain and test cores in accordance with ASTM C42/C42M.

If concrete in the structure is dry under service conditions, air dry cores (temperature 16 to 27 degrees C 60 to 80 degrees F, relative humidity less than 60 percent) for 7 days before testing and test dry. Otherwise, test the cores, after moisture conditioning, in accordance with ASTM C42/C42M.

Acceptance criteria for cylinder compressive strength are provided in paragraph ACCEPTANCE OF CONCRETE STRENGTH.

Take at least three representative cores from each member or area of concrete in place that is considered potentially strength deficient. Impair the strength of the structure as little as possible. If, before testing, extracted cores show evidence of having been damaged subsequent to or during removal from the structure, take replacement cores.

Fill core holes with low slump concrete or mortar of a strength equal to or greater than the original concrete.

The Contracting Officer will evaluate and validate core tests in accordance with the specified procedures.

3.8.4 Acceptance of Concrete Strength

3.8.4.1 Standard Molded and Cured Strength Specimens

The acceptance of concrete strengths shall be based on averages of results from three consecutive compressive strength tests. When the averages of all sets of three consecutive compressive strength test results are between 1.0 and 1.2 times the field test strength (fcr), and no individual strength test falls below fcr by more than 3.45 MPa 500 psi, the strength of the concrete is satisfactory. These criteria also apply when accelerated strength testing is specified unless another basis for acceptance is specified.

3.8.4.2 Non-Destructive Tests

Non-destructive tests may be used when permitted to evaluate concrete where standard molded and cured cylinders have yielded results not meeting the
3.8.4.3 Extracted Core Tests

When the average compressive strengths of the representative cores are between 0.85 fcr and 1.2 fcr and if no single core is less than 0.75 fcr, the strength of concrete is satisfactory.

3.8.5 Inspection

ACI 311.4R. Inspect concrete placed under water with qualified divers.

3.9 REPAIR, REHABILITATION AND REMOVAL

Before the Owner accepts the structure and final payment is made the Contractor shall inspect the structure for cracks, damage, and substandard concrete placements that may adversely affect the service life of the structure. A report documenting these defects shall be prepared that includes recommendations for repair, removal, and/or remediation, which will be reviewed by the agency's Subject Matter Expert in Concrete Materials and submitted to the Contracting Officer for approval before any corrective work is accomplished.

3.9.1 Crack Repair

Prior to final acceptance, all cracks in excess of 0.50 mm 0.02 inches wide shall be documented and repaired. The proposed method and materials to repair the cracks shall be submitted to the Contracting Officer for approval. The proposal shall address the amount of movement expected in the crack due to temperature changes and loading.

3.9.2 Repair of Weak Surfaces

Weak surfaces are defined as mortar-rich, rain-damaged, uncured, or containing exposed voids or deleterious materials. Concrete surfaces with weak surfaces less than 6 mm 1/4 inch thick shall be diamond ground to remove the weak surface. Surfaces containing weak surfaces greater than 6 mm 1/4 inch thick shall be removed and replaced or mitigated in a manner acceptable to the Contracting Officer.

3.9.3 Failure of Quality Assurance Test Results

**************************************************************************
NOTE: Test results accomplished on concrete samples during concrete production that fall short of the acceptance criteria alert the Contractor to something in the production and placement process that has drifted out of calibration or that an error has been made. The goal is to track down the problem and correct it as quickly as possible. Unless the concrete producer makes a large error in batching or in placing, the chance that hardened concrete needs to be removed is remote. Removal and replacement is a last resort.

For those areas adversely affected by substandard concrete new numerical service life modeling simulations can be helpful to evaluate the effectiveness of the proposed remediation strategies.
Proposed mitigation efforts by the Contractor to restore the service life shall be reviewed by the agency's Subject Matter Expert in Concrete Materials and approved by the Contracting Officer prior to proceeding.

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for reinforced concrete exposed to marine and chloride environments for projects with no specific requirements for service life design. In addition, use this guide specification for projects with concrete exposed to weather in locations with Environmental Severity Classifications (ESC) of C4 and C5 and where deicing salts are used on the structure. See UFC 1-200-01 for determination of the ESC for project locations.

This guide specification provides prescriptive requirements for marine concrete. It contains specific requirements for quality control (actions taken by the Contractor) and quality assurance (actions that may be taken by the Government). This guide specification is for projects where service life modeling is not required or deemed beneficial by the Government. If it is determined that concrete service life modeling is required, then Section 03 31 29 MARINE CONCRETE WITH SERVICE LIFE MODELING should be used.

This guide specification should be considered for projects that meet the following conditions:

- Required service life: equal to or less than 60 years; and
- Volume of concrete works: equal to or less than 10,000 cubic yard; and
- Monetary construction value of the entire project: equal to or less than $15M; and
- Service life modeling is not required by the Government.

Other criteria to consider when evaluating the
applicability of service life design include:

- Mission Criticality based on the Mission Dependency Index (MDI) Score. For example, a MDI score between 1 to 54 should assess if service life modeling is beneficial. MDI scores greater than 54 should incorporate service life modeling unless there is a specific determination made by the Government not to.

- Consequences of failure: UFC 3-301-01 Risk Categories I, II, or III should assess if service life modeling is beneficial. Higher risk categories should incorporate service life modeling unless there is a specific determination made by the Government not to.

The criteria listed above are provided as guidance to the specifier as to the applicability of this guide specification. Specific project characteristics should be evaluated and the decision to implement service life modeling will ultimately depend upon the project specific requirements and the determination of the Owner, Engineer of Record, and/or Contracting Officer.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

**************************************************************************
** NOTE: Development team of this section considered the International Green Construction Code, which is "the first model code that includes sustainability measures for the entire construction project and its site - from design through construction, certificate of occupancy and beyond. The new code is expected to make buildings more efficient, reduce waste, and have a positive impact on health, safety, and community welfare."
**************************************************************************

**************************************************************************
** NOTE: The following information shall be shown on

SECTION 03 31 30 Page 6
the project drawings:

1. Design assumptions.

2. Assumed temperature range when temperature stresses are a factor in design.

3. Material strengths used in design, f'c.

4. Yield strength of reinforcement required 414 mPa 60,000 psi or other grade as available.

5. Details of concrete sections, showing dimensions, reinforcement cover, and required camber.

6. Joint details, showing locations and dimensions.

7. Details and locations of critical construction joints, including water stop locations and splices, keys, and dowels when required, and location of fiber-reinforced concrete elements.

1.2 DEFINITIONS

a. "Atmospheric zone" is any portion of the waterfront structure above the splash zone.

b. "Buried zone" is any portion of the structure permanently buried in soil.

c. "Cementitious material" as used herein shall include portland cement and any pozzolanic material such as fly ash, natural pozzolans, ground granulated blast-furnace slag and silica fume.

d. "Concrete System" is the term describing a structural element comprised of concrete, reinforcing steel and concrete cover.

e. "Design strength" (f'c) is the specified compressive strength of concrete at time(s) specified by Contracting Officer to meet structural design criteria. Typical duration is 28 days; however, the Contracting Officer and Engineer of Record are encouraged to consider specifying strength at 56 or 90 days. For concrete mixtures containing 35 percent fly ash or more, the duration shall be a minimum of 56 days.

f. "Field test strength" (fcr) is the required compressive strength of concrete to meet structural and durability criteria. Determine (fcr) during mixture proportioning process.

g. "High-volume fly ash concrete" has a minimum of 35 percent Class F fly ash as a partial replacement to portland cement.

h. "Marine concrete" is all concrete that will be in contact with seawater or brackish water, tidal variations, splash, or spray from water in navigable waterways. Piles driven on land that extend below the water table that contains saltwater or brackish water shall be designed as marine concrete. Components of a marine structure that are permanently buried in soil shall be considered marine concrete. In addition, structures may need to be designed using these criteria even though they are not adjacent to the waterfront. For example, structures located several hundred yards from the waterfront often deteriorate prematurely due to salt spray and salt fog brought to the structure by prevailing winds. An assessment of existing structures near the construction site can be an excellent indicator for the Engineer of Record and Owner to decide if the proposed structure should follow the guidelines for marine concrete.

i. "Mass Concrete" is any concrete system that approaches a maximum temperature of 70 degrees C 158 degrees F within the first 72 hours of placement. In addition, it includes all concrete elements with a section thickness of 1 meter 3 feet or more regardless of temperature.

j. "Mixture proportioning" is the process of designing concrete mixture proportions to enable it to meet the strength, durability and constructability requirements and of the project while minimizing the initial and life-cycle cost.

k. "Mixture proportions" are the masses or volumes of individual ingredients used to make a unit measure (cubic yard or meter) of concrete.

l. "Pozzolan" is a siliceous or siliceous and aluminous material, which in
itself possesses little or no cementitious value but will, in finely
divided form and in the presence of moisture, chemically react with
calcium hydroxide at ordinary temperatures to form compounds possessing
cementitious properties.

m. "Process control sampling" is sampling and testing conducted by the
Contractor to monitor the quality of materials or processes. Process
control sampling is intended to indicate the quality of materials at
critical steps in production that allow intervention prior to using a
material on the project.

n. "Quality Acceptance Limit" (QAL) is the limiting value of a test result
that indicates acceptable material quality. Quality acceptance limits
are based on design criteria that may be either upper-bound limits
where smaller values indicate acceptable material, such as $D_{oh}$; or
lower-bound limits where larger values indicate acceptable material,
such as compressive strength.

o. "Quality acceptance sampling" is sampling and testing conducted by the
Contractor, or an independent testing agency, to evaluate the quality
of materials used on the project. Quality acceptance sampling is
conducted at regular intervals identified as "lots" to represent the
quality of that portion of the material used in the project.

p. "Required compressive strength" ($f'c$) is the mean compressive strength
of concrete required to meet structural criteria. The required
strength is the mean concrete strength for tests of properly batched
cement at the age specified herein.

q. "Service life" is the Owner's stated expectation for the number of
years that the structure will function without needing major concrete
rehabilitation. A service life of 75 years for pile supported piers,
wharves and bridges is a reasonable objective. Service life is defined
as the number of years before major restoration is necessary given
minimal maintenance to the structure during its life. Major
restoration is defined as extensive areas that require extensive
repairs using a jack hammer or other destructive means to prepare the
concrete for rehabilitation. Service life is further defined as the
summation of the corrosion initiation period ($T_i$) and the corrosion
propagation period ($T_p$) for a given concrete system.

r. "Service Life Modeling" in the context of this document refers to a
methodology to predict the length of time in service at which a defined
level of deterioration will occur. Service life modeling is not
required in this specification.

s. "Splash zone" is the portion of the structure just above the tidal
zone. This portion of the structure is predominantly dry, but is
likely to intermittently wet by wave action and wind driven spray. For
the purposes of this specification, the splash zone is defined as
follows:

(1) for locations protected by seawalls or otherwise sheltered from
open-ocean waves, the 2 meters 6 feet area just above the tidal
zone;

(2) for unprotected locations, the 6 meters 20 feet area just above
the tidal zone.
t. "Submerged zone" is defined as the submerged portion of the structure. For the purposes of this specification, any element or portion thereof that is located below Mean Lower Low Water (MLLW). In areas with minimal tides, it would be defined as that portion of the element below Mean Sea Level (MSL).

u. "Supplemental Corrosion Protection" includes (but is not limited to) fusion-bonded epoxy-coated steel reinforcing, galvanized steel reinforcing, stainless reinforcing, corrosion inhibitors, barrier coatings to the concrete surface, and cathodic protection.

v. "Supplementary cementing materials" (SCM) include coal fly ash, granulated blast-furnace slag, natural or calcined pozzolans, and ultra-fine coal ash when used in such proportions to replace the portland cement that result in considerable improvement to sustainability, durability and in some cases a reduction in initial cost.

w. "Test Section" is a slab or wall separate from the main structure and constructed prior to main construction as an all inclusive demonstration of methods and materials. The adequacy of the Test Section must be approved by the owner's representative prior to construction of the project.

x. "Tidal zone" is defined as the portion of the structure regularly wetted by wave action. For the purposes of this specification, any element or portion thereof that is located between Mean Lower Low Water (MLLW) and Mean Higher High Water (MHHW) is in the tidal zone. In areas with minimal tides, this would be defined as the area located between Mean Sea Level (MSL) and Mean High Water (MHW).

1.3 SUBMITTALS

**************************************************************************
NOTE: Review Submittal Description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.
The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.

**************************************************************************
Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

1.4 MODIFICATION OF REFERENCES

Accomplish work in accordance with ACI publications except as modified herein. Consider the advisory or recommended provisions to be mandatory, as though the word "shall" had been substituted for the words "should" or "could" or "may," wherever they appear. Interpret reference to the "Building Official," the "Structural Engineer," and the "Architect/Engineer" to mean the Contracting Officer.
1.5 DELIVERY, PLACING, STORAGE, AND HANDLING OF CONCRETE

Follow ACI 301M ACI 301, ACI 304R, and ASTM A934/A934M requirements and recommendations. Do not deliver concrete until vapor barrier, forms, reinforcement, embedded items, and chamfer strips are in place and ready for concrete placement. Store reinforcement of different sizes and shapes in separate piles or racks raised above the ground. Protect materials from contaminants such as grease, oil, and dirt. Ensure materials can be accurately identified after bundles are broken and tags removed.

1.6 CONCRETE QUALITY CONTROL

**************************************************************************
NOTE: The goal is to provide quality concrete with the specified concrete cover to protect the steel, which provides the primary protection mechanism against chemical deterioration and corrosion related damage. All other corrosion protection strategies are considered to be supplemental and include (but are not limited to): barrier coatings to the concrete surface, fusion-bonded epoxy-coated steel, corrosion inhibitors, galvanized, stainless, MMFX, Z-bar reinforcing and cathodic protection. All of which may provide some life extension but by how much is difficult to predict on a numerical basis for real structures exposed to chloride environments. If the available materials in the region of the project are inadequate to meet the requirements for shrinkage, compressive strength, constructability and service life then the Contractor shall prepare a recommendation for review by the agency's Subject Matter Expert in Concrete Materials and approval by the Contracting Officer and Engineer of Record on a case-by-case basis to use supplemental corrosion protection to meet project requirements.

Where they are available, specify only ACI certified personnel. Check the American Concrete Institute (ACI) website for local availability:
**************************************************************************

The objective of the concrete quality control program is for the Contractor to outline the procedures that will be used to construct a structure that will meet the project criteria. The Contractor shall develop and submit for approval a concrete quality control program in accordance with the guidelines of ACI 121R and as specified herein. The plan shall include approved laboratories. The Contractor shall provide direct oversight for the concrete qualification program inclusive of associated sampling and testing. If concrete cylinders tested during production indicate inadequate strength, excessive chloride ion penetration, or inadequate mixing, then the owner may require the Contractor to extract concrete core samples from the hardened concrete for analysis at Contractor's expense to assure that the quality of the concrete as placed and cured will satisfy the project criteria.

Develop and submit for approval a concrete quality control program in
accordance with the guidelines of ACI 121R. Maintain a copy of ACI SP-15 and CRSI 10MSP at the project site.

1.6.1 Quality Control Personnel

The contractor shall submit for approval an organizational chart defining the quality control hierarchy, the responsibilities of the various positions, including the names and qualifications of the individuals in those positions.

Submit American Concrete Institute certification for the following:

a. CQC personnel responsible for inspection of concrete operations.

b. Lead Foreman or Journeyman of the Concrete Placing, Finishing, and Curing Crews.

c. Field Testing Technicians: ACI Concrete Field Testing Technician, Grade I.

d. Laboratory Testing Technicians: ACI Concrete Strength Testing Technician and Laboratory Testing Technician, Grade I or II.

e. Petrographer: Bachelor of Science degree in geology or petrography, trained in petrographic examination of concrete aggregate according to ASTM C294 and ASTM C295/C295M and trained in identification of the specific deleterious processes and tests identified in this specification. Resume shall detail the education, training and experience related to the project-specific test methods and deleterious materials and shall be submitted at least 20 days before petrographic and deleterious materials examination is to commence.

f. Concrete Batch Plant Operator: National Ready Mix Concrete Association (NRMCA) Plant Manager Certification at the Plant Manager level.

1.6.1.1 Quality Manager Qualifications

The quality manager shall hold a current license as a professional engineer in a U.S. state or territory with experience on at least five similar projects. Evidence of extraordinary proven experience may be considered by the Contracting Officer as sufficient to act as the Quality Manager.

1.6.1.2 Field Testing Technician and Testing Agency

Submit data on qualifications of proposed testing agency and technicians for approval by the Contracting Officer prior to performing testing on concrete.

a. Work on concrete under this contract shall be performed by an ACI Concrete Field Testing Technician Grade 1 qualified in accordance with ACI SP-2 or equivalent. Equivalent certification programs shall include requirements for written and performance examinations as stipulated in ACI SP-2.

b. Testing agencies that perform testing services on reinforcing steel shall meet the requirements of ASTM E329.

c. Testing agencies that perform testing services on concrete materials shall meet the requirements of ASTM C1077.
1.6.2 **Laboratory Qualifications** for Concrete Qualification Testing

The concrete testing laboratory shall have the necessary equipment and experience to accomplish required testing. The laboratory shall meet the requirements of ASTM C1077, and be Cement and Concrete Reference Laboratory (CCRL) inspected.

1.6.3 **Laboratory Accreditation**

Laboratory and testing facilities shall be provided by and at the expense of the Contractor. The laboratories performing the tests shall be accredited in accordance with ASTM C1077, including ASTM C78/C78M and ASTM C1260. The accreditation shall be current and shall include the required test methods, as specified.

a. Aggregate Testing and Mix Proportioning: Aggregate testing and mixture proportioning studies shall be performed by an accredited laboratory and under the direction of a licensed/registered civil engineer in a U.S. state or territory, who shall sign all reports and designs.

b. Acceptance Testing: Furnish all materials, labor, and facilities required for molding, curing, testing, and protecting test specimens at the site and in the laboratory. Furnish and maintain boxes or other facilities suitable for storing and curing the specimens at the site while in the mold within the temperature range stipulated by ASTM C31/C31M.

c. Contractor Quality Control: All sampling and testing shall be performed by an approved, onsite, independent, accredited laboratory.

1.7 **CONCRETE DURABILITY**

1.7.1 **Concrete Mixture Proportions**

At least 60 days prior to concrete placement, submit concrete mixture proportions, ingredient material certificates and test data, and trial batch test data for each class of concrete proposed for use on the project. Submittal shall clearly indicate where each mixture will be used when more than one mixture design is submitted. Obtain approval from Contracting Officer prior to placement.

1.7.2 **Concrete Design Requirements**

Proportion concrete mixtures to meet the requirements listed in Table 1 in accordance with the procedures outlined in ACI 201.2R and ACI 211.1.

The mixture proportions for concrete shall be developed by the Contractor to produce the required compressive strength (f'c), drying shrinkage, durability, and constructability. The amount of cementitious material in the mixture can be minimized as long as the concrete still meets the mixture design requirements for durability and strength.

The mixture proportions and Water-Cementitious Materials Ratio for marine concrete shall be developed by the Contractor to produce the design strength (f'c) and to provide durability, workability, and mixture consistency to facilitate placement, compaction into the forms and around reinforcement without segregation or bleeding. The requirements for durability specified in Table 1 and Table 2 below shall be incorporated in...
The use of silica fume is discouraged. Silica fume shall only be used for OCONUS (outside continental United States) projects where Class F fly ash and ground granulated blast furnace (GGBF) slag are not available, and when approved by the Contracting Officer. If needed, the mixture may contain a maximum of 7 percent silica fume by mass of total cementing material. Concrete mixtures containing any percentage of silica fume shall be evaluated at every [76.5] cubic meters ([100] cubic yards) of concrete for the first [382.3] cubic meters ([500] cubic yards), then every [382.3] cubic meters ([500] cubic yards) thereafter to ensure that the silica fume is properly dispersed in hardened concrete samples. A qualified laboratory shall microscopically examine a sectioned sample and document the results. Provide at the Contractor's expense the services of a manufacturer's technical representative, experienced in mixing, proportioning, placement procedures, and curing of concrete containing silica fume.

The concrete mixture shall contain one of the CCM/SCM listed in Table 3, or a linear combination thereof. The minimum amount of portland cement is 50 percent of the total mass of cementitious material.

Air content: Concrete shall be air entrained and shall conform to the air limits specified in ACI 301M ACI 301 for exposure and the aggregate size used and tested in accordance with ASTM C231/C231M. The average spacing factor for three consecutive tests shall not exceed 0.008 in with no individual test exceeding 0.010 in as determined by ASTM C457/C457M. Variations outside the limits specified shall not be reason to reject the concrete in locations not subject to freeze-thaw conditions.

Slump: The concrete mixture shall be proportioned to have, at the point of deposit, a maximum slump of 100 mm 4 inches as determined by ASTM C143/C143M when admixtures that affect slump are not used. Where an ASTM C494/C494M, Type F or G admixture is used, the slump after the addition of the admixture shall not exceed 200 mm 8 inches. Slump tolerances shall comply with the requirements of ACI 117.

1.7.3 Concrete Mixture Qualifications

1.7.3.1 Previously Approved Concrete Mixtures

For identical concrete mixtures previously approved for use within the past 18 months, the previous mixture qualification submittal may be re-submitted without further trial batch testing if accompanied by:

a. A copy of the prior approvals indicating the project name, project number, and location.

b. Ingredient material test data conducted within 12 months of the submittal date.

c. Copies of the previously approved trial batch test data.

d. A log containing at least 15 sequential test results with the calculated mean and standard deviation of the production concrete for air content, and compressive strength.

If the Contractor changes material type, class, sources, or suppliers; chemical composition; and/or mix proportions, the Contractor shall provide a written opinion of the significance of the change(s). The change(s) may require additional testing at the discretion of the Contracting Officer in consultation with the agency's Subject Matter Expert in Concrete Materials.

1.7.3.2 New Concrete Mixtures

a. Submit complete ingredient material test data, including applicable reference specifications. Submit additional data regarding concrete aggregates if the source of aggregate changes.

b. Submit copies of test reports by independent test lab conforming to ASTM C1077 showing that the mixture has been successfully tested to produce concrete with the properties specified and that mixture will be suitable for the job conditions as described. Test reports shall be submitted along with the concrete mixture proportions. Obtain approval before concrete placement.

c. Test a minimum of one trial batch of production concrete. If batching facilities are located such that the haul-time will exceed 30 minutes, a simulated haul time shall be included in the trial batch.

(1) Test and report fresh concrete property tests of each trial batch as follows:

(a) Slump in accordance with ASTM C143/C143M.

(b) Air content in accordance with ASTM C231/C231M or ASTM C173/C173M.

(c) Unit weight in accordance with ASTM C138/C138M.

(d) Temperature in accordance with ASTM C1064/C1064M.
(2) Cast specimens, test, and report hardened concrete property tests of each trial batch as follows:

(a) Compressive strength at 3, 7, 28, 56 and 90 days in accordance with ASTM C39/C39M. Use of unbonded caps in accordance with ASTM C1231/C1231M is permitted.

(b) Drying shrinkage.

(c) Tensile strength (if required).

(d) Freeze-thaw durability factor (if required) shall be determined as the mean of six test specimens comprised of at least two specimens cast from each batch.

(e) Initial chloride ion content.

(f) Spacing factor in accordance with ASTM C457/C457M.

(g) Chloride ion penetrability in accordance with ASTM C1202.

(3) Moisture cure concrete intended for cast-in-place applications in accordance with the standard moist curing conditions described in ASTM C192/C192M unless otherwise specified. Moisture cure concrete intended for precast applications in the manner proposed for use on the project.

d. For concrete mixtures that are proposed to contain corrosion inhibitors, the Contractor shall submit the chloride ion penetration values from at least one batch of the mixture with and without the admixture making appropriate adjustments to maintain constant water to cementitious materials ratio. The purpose is to establish a correlation with respect to an adjusted value for production chloride ion penetration.

1.7.4 Concrete Qualification Program

1.7.4.1 Fresh Concrete Properties

a. Air Content: The mixture shall be proportioned and tested for qualification.

b. Slump: The mixture shall be proportioned and tested for qualification.

c. Self-Consolidating Concrete: When self-consolidating concrete is proposed for use, the mixture shall be proportioned and tested for qualification using:

   (1) ASTM C1611/C1611M slump flow shall not be greater than 610 mm 24 inches, with visual stability index not greater than 1.

   (2) ASTM C1621/C1621M Passing ability using the J-ring. Spread within 25 mm 1 inch less than the slump flow.

   (3) Passing ability using the L-Box between 4 and 8 seconds

   (4) ASTM C1610/C1610M, static segregation shall be less than 4.0 percent.
For process control sampling, the slump flow limit as determined by ASTM C1611/C1611M shall be no greater than 610 mm 24 inches and the visual stability index limit shall be no greater than 1.0.

d. Underwater concrete: When the concrete is intended for placement under water using the tremie technique, the concrete shall be proportioned to be cohesive and flow with minimal segregation. Viscosity modifying admixtures are permitted for underwater concrete. Proportioning guidance in ACI 304R shall be considered. Concrete mixtures shall be qualified for tremie placement methods based on a trial placement approved by the Contracting Officer.

1.7.4.2 Hardened Concrete Properties

**************************************************************************
NOTE: Navy waterfront structures typically take a year or more to complete. With time all concrete continues to gain strength. The Engineer of Record is encouraged to design the structural elements based on the compressive strength that will be achieved at 56 or 90 days rather than at 28 days. Doing so will better allow the Contractor to develop and place concrete mixtures with less portland cement. Excessive use of cement leads to more cracks and shorter-lived structures. Embracing this approach will result in structures that are less expensive, greener and more sustainable.
**************************************************************************

a. Compressive Strength: The structural engineer shall specify the minimum compressive strength results at [28] [56] days. Determine compressive strength \( f'c \) for qualification of concrete mixtures and for quality acceptance testing. A compressive strength test result is defined as the mean of three properly conducted tests on 100 by 200 mm 4 by 8 inch cylinders in accordance with ASTM C39/C39M. Alternatively and for concrete mixtures containing a maximum size aggregate greater than 25.4 mm 1 inch, a strength test result shall be defined as the mean of two properly conducted 28-day tests on 150 by 300 mm 6 by 12 inch cylindrical specimens in accordance with ASTM C39/C39M. In addition:

(1) Specified Compressive Strength: For structural concrete elements exposed in a marine environment, the minimum specified [28] [56] day design strength is denoted as \( f'c \). Strength of concrete containing 35 percent or more fly ash shall be specified at a minimum of 56 days.

(2) Required Average Strength: The concrete shall be proportioned such that the minimum required average compressive strength \( f'cr \) exceeds the specified design strength \( f'c \) as per ACI 301M ACI 301.

(3) The average compressive strength may not exceed the specified strength at the same age by more than 20 percent unless approved by the Engineer of Record.

(4) Strength of any individual concrete placement shall be considered satisfactory if both the following requirements are met:

(a) The arithmetic mean of any three consecutive lot strength
tests is between 1.0 and 1.2 f'c, and;

(b) No individual strength test result is less than 0.90 f'c.

(5) In the event that a placement is represented by single sampling lot, strength shall be considered satisfactory if either:

(a) The mean of the initial test is between 1.0 and 1.2 f'c, or;

(b) The mean of the initial test and retest is between 1.0 and 1.2 f'c, and neither strength test result is less than 0.90 f'c.

(6) For underwater concrete, cast compressive strength samples by placing concrete in four 5-gallon buckets below water using similar placement as the project. Permanently mark buckets as "3 days," "7 days," "[28] [56] days," and "Extra." Include date and station. Provide specimen sets at every [76.5 cubic meters] [100 cubic yards] of concrete for the first [382.3 cubic meters] [500 cubic yards], then every [382.3 cubic meters] [500 cubic yards] thereafter with a minimum of one set per day of underwater concrete placement.

(a) Retrieve buckets at specified intervals and extract three cores from each bucket. Conduct compressive strength test in accordance with ASTM C42/C42M.

(b) Strength of underwater concrete shall be satisfactory if the compressive strength result from extracted cores at the age of the specified strength is between 0.85 and 1.2 f'c with no individual strength test result less than 0.75 f'c.

b. Drying Shrinkage: Determine drying shrinkage for qualification of concrete mixtures prior to the fabrication of the Test Section and from samples made during the fabrication of the Test Section (see the paragraph TEST SECTION). No test results shall exceed the limits in Table 1. A drying shrinkage test result shall be the mean value from three or more individual specimens constituting a test set. If an individual specimen's measurements deviate from the mean value by more than 0.009 percent length change, the specimen's measurements shall be discarded and a new average established. Casting more than three specimens for each set is permitted. Test procedures and test specimens shall conform to the following:

Drying shrinkage specimens, typically 75 by 75 by 285.8 mm 3 by 3 by 11.25 inch prisms for 25.4 mm 1 inch maximum size aggregate or smaller, shall be fabricated, cured, dried, and measured at 28 days in the manner delineated in ASTM C157/C157M. Mixtures containing 50 percent or more supplementary cementing materials shall meet the shrinkage criteria at 56 days.

c. Tensile strength: Determine splitting-tensile strength of concrete only for qualification of concrete mixtures. Determine and report the splitting-tensile strength result of each class of concrete in accordance with ASTM C496/C496M as the mean of three properly conducted tests at the age specified for f'c and again at 90-days age for information only.

d. Freeze-thaw durability: Determine the freeze-thaw durability factor of concrete for qualification of concrete mixtures, if required by
environmental conditions. Determine and report the freeze-thaw durability factor of each class of concrete in accordance with ASTM C666/C666M Method-A. Start testing after [28] days of moist curing. The minimum acceptable durability factor shall be as per Table 1.

e. Acid Soluble Chloride Ion Content: Determine the chloride ion content only for qualification of concrete mixtures. Determine acid soluble chloride ion content in accordance with ASTM C1152/C1152M. The limits for allowable acid-soluble chloride ion concentrations in hardened concrete are listed in Table 1.

f. Chloride Ion Penetrability: Determine the resistance of concrete to the penetration of chloride ions in accordance with ASTM C1202 during the prequalification phase. The average of three samples shall meet the limit specified Table 1.

1.7.4.3 Supplemental Corrosion Protection

Requirements for the use of supplemental corrosion protection, if any, shall be indicated on the plans.

1.7.5 Mass Concrete Temperature Control Plans

a. Thirty days minimum prior to concrete placement, submit for approval a mass concrete temperature control plan that includes:

   (1) Location and identification of temperature monitoring sensors.

   (2) Product data for automated temperature sensors and recording equipment.

   (3) Cooling pipe layout diagram with sizes and materials, if used.

   (4) Proposed insulation materials and associated R-values.

   (5) Anticipated form removal schedule and curing procedures.

   (6) Maximum allowable concrete placement temperature for the range of anticipated ambient temperatures based on thermal modeling.

   (7) Monitoring procedures and contingency plans.

Concrete placement temperature shall be based on results of thermal modeling for the element incorporating: the heat of hydration and specific heat capacity for the concrete mixture, solar gain, and heat transfer to the environment through formwork, insulation, and cooling techniques.

Mass concrete temperature control shall be monitored using automated temperature recording devices that allow wireless transmission of data to an on-site host computer for real-time monitoring of temperatures.

Temperature control sensor layout for each placement shall be provided with individual sensor ID identified.

Minimum sensor requirements include at least two sensors for each placement located as follows:
(1) The geometric center of the element cross-section.

(2) Within 76.2 mm 3 inches of the side forms at mid-height.

(3) Within 76.2 mm 3 inches of the top surface located directly above the center sensors.

(4) Within 76.2 mm 3 inches from the top corner at the intersection of side forms.

(5) Ambient temperature sensors placed in a shaded location.

Procedures for installing, protecting sensors during placement, and testing sensors a minimum of 24 hours prior to concrete placement shall be provided. Initiate sensor recording at least 2 hours prior to placement. Verify function of all sensors prior to and upon completion of concrete placing operations. Provide additional sensors for placements greater than 305.8 cubic meters 400 cubic yards at each location.

Submit procedures for controlling concrete temperatures within the following limits:

(1) Maximum temperature shall be less than 70 degrees C 158 degrees F.

(2) Maximum temperature differential between the mean of all functioning center sensor temperatures to any individual surface or corner sensor shall be less than 20 degrees C 36 degrees F.

(3) Temperature control procedures shall remain in effect until the differential between the ambient low temperature and mean of all functioning center sensor temperatures is less than 20 degrees C 36 degrees F.

(4) An additional submittal shall be provided for the Contracting Officer's approval in the event the Contractor fails to control temperatures within the limits listed above. The submittal shall include documentation of any cracks that develop, identify revisions to control procedures to prevent future cracking, and procedures to seal or otherwise mitigate defects.

b. Mass Concrete Mock-up: For concrete mixtures intended for mass concrete, cast thirty-one 100 by 200 mm 4 by 8 inch cylinder specimens in accordance with ASTM C192/C192M, three 75 by 75 by 285.8 mm 3 by 3 by 11.25 inch concrete prisms in accordance with ASTM C157/C157M, and at least one semi-adiabatic cube from a trial batch.

The semi adiabatic cube shall have a minimum dimension of 3 feet per side, and shall be insulated all sides with a minimum R-value of 30. Install pairs of thermocouples at the center of mass, the middle of each side, the top surface, and the top corner. Automatically record the temperature of each sensor hourly for one week. Additional cubes may be cast to calibrate active cooling system performance.

(1) Conduct compressive strength development testing at 3, 7, [28] [56], and 90 days age using three specimens per age in accordance with ASTM C39/C39M, and develop a compressive strength prediction equation for the concrete mixture in accordance with ASTM C1074.
(2) Conduct tensile strength tests at 3, 7, [28] [56], and 90 days on two specimens per age in accordance with ASTM C496/C496M, and develop a tensile strength prediction equation for the concrete mixture in accordance with ASTM C1074.

(3) Conduct elastic modulus tests at 3, 7, [28] [56], and 90 days on two specimens per age in accordance with ASTM C469/C469M, and develop an elastic modulus prediction equation for the concrete mixture in accordance with ASTM C1074.

Conduct coefficient of thermal expansion testing in accordance with COE CRD-C 39 after 28 days of moist curing. Test specimens in a saturated condition.

Report all test results and predictive equations in the mock-up submittal. The predictive equations may be used by the Contractor to establish the duration of temperature control and form removal based on the allowable temperature differential between the concrete core and ambient low temperature.

1.8 CONCRETE

1.8.1 Drawings

Fabrication Drawings for concrete formwork, reinforcement materials, precast elements, wall forms, and bulkhead forms must indicate concrete pressure calculations with both live and dead loads, along with material types. Provide design calculations by a registered Civil or Structural Engineer for the formwork.

1.8.1.1 Formwork

Prior to commencing work, submit drawings for approval showing details of formwork including, but not limited to: joints, supports, studding and shoring, and sequence of form and shoring removal. Reproductions of contract drawings are unacceptable.

Design, fabricate, erect, support, brace, and maintain formwork so that it is capable of supporting without failure all vertical and lateral loads that may reasonably be anticipated to be applied to the formwork.

ACI 347R. Include design calculations indicating arrangement of forms, sizes, species, and grades of supports (lumber), panels, and related components. Indicate placement schedule, construction, and location and method of forming control joints. Include locations of inserts, pipe work, conduit, sleeves, and other embedded items. Furnish drawings and descriptions of shoring and reshoring methods proposed for slabs, beams, and other horizontal concrete members.

1.8.1.2 Reinforcing Steel

ACI SP-66. Provide bending and cutting diagrams, assembly diagrams, splicing placement and laps of bars, shapes, dimensions, and details of bar reinforcing, accessories, and concrete cover. Do not scale dimensions from structural drawings to determine lengths of reinforcing bars. Only complete drawings will be accepted.
1.8.1.3 Precast Elements

**************************************************************************
NOTE: Modify requirements based on the scope of the project.
**************************************************************************
Submit drawings and design calculations indicating complete information for the fabrication, handling, and erection of the precast elements. Drawings shall not be reproductions of contract drawings.

1.8.1.4 Joints
Submit a plan indicating the type and location of each construction joint. Final joint locations are subject to Government approval.

1.8.2 Pre-Construction Submittals
1.8.2.1 Curing Concrete Elements
Submit proposed materials and methods for curing concrete elements.

1.8.2.2 Concrete Curing Plan
Submit proposed materials, methods, and duration for curing and cooling concrete elements in accordance with ACI 308.1.

Minimum moist curing duration shall be seven days.

Begin curing immediately after placement. Protect concrete from premature drying, excessively hot temperatures, and mechanical injury; and maintain minimal moisture loss at a relatively constant temperature for the period necessary for hydration of the cement and hardening of the concrete. The materials and methods of curing are subject to approval by the Contracting Officer.

1.8.2.3 Form Removal Schedule
Submit schedule for form removal indicating element and minimum length of time for form removal. Submit technical literature of forming material or liner, form release agent, form ties, and gasketing to prevent leakage at form and construction joints. Provide a full description of materials and methods to be used to patch form-tie holes.

1.8.2.4 Concrete Placement and Compaction

a. Submit technical literature for equipment and methods proposed for use in placing concrete. Include concrete pumping or conveying equipment including type, size and material for pipe, valve characteristics, and the maximum length and height concrete will be pumped. No adjustments shall be made to the mixture design to facilitate pumping.

b. Submit technical literature for equipment and methods proposed for vibrating and compacting concrete. Submittal shall include technical literature describing the equipment including vibrator diameter, length, frequency, amplitude, centrifugal force, and manufacturer's description of the radius of influence under load. Where flat work is to be cast, provide similar information relative to the proposed compacting screed or other method to ensure dense placement.
1.8.2.5 Concrete Report

Provide a Report inclusive of materials and methods used, test results, and the field test strength (fcr) for concrete that shows compliance with the structural and durability requirements.

1.8.2.6 Coatings

Coatings are considered to be "supplemental Corrosion Projection". Surface preparation and installation of any coatings on concrete shall be conducted in strict compliance with written manufacturer instructions. Submit the product data and written manufacturer instructions. A manufacturer representative shall train installers, witness initial installation, and certify that the installation was conducted in accordance with the instructions.

1.8.2.7 Preconstruction Testing of Materials

All sampling and testing shall be performed by, and at the expense of, the Contractor. Use an approved commercial laboratory or, for cementitious materials and chemical admixtures, a laboratory maintained by the manufacturer of the material. No material shall be used until notice of acceptance has been given. The Contractor will not be entitled to any additional payment or extension of time due to failure of any material to meet project requirements, or for any additional sampling or testing required. Additional tests may be performed by the Government at the discretion of the Contracting Officer; such Government testing will not relieve the Contractor of any testing responsibilities.

1.8.2.8 Material Safety Data Sheets

Submit Material Safety Data Sheets (SDS) for all materials that are regulated for hazardous health effects. Prominently post the SDS at the construction site.

1.8.2.9 Mixture Designs

Provide a detailed report of materials and methods used, test results, and the field test strength (fcr) for marine concrete required to meet structural and durability requirements.

1.8.3 Sampling

The Contractor shall be responsible for conducting concrete production process control sampling and testing in compliance with this specification.

1.8.3.1 Ingredient Material Sampling

a. Cementitious material mill certificates and test reports shall be provided for each shipment. Record the date delivered and quantity of material represented by the certificate.

b. Conduct and log aggregate moisture content at a minimum frequency of twice daily for each day's production. Use of moisture sensors in storage bins is recommended practice, but does not satisfy this requirement.

c. Aggregate sampling for gradation and dry-rodded unit weight shall be
conducted for each 100 tons delivered for use on the project, or portion thereof.

1.8.4 Reporting

1.8.4.1 Daily Inspection Reports

Contractor shall prepare daily inspection reports for all inspection activities such as base preparation, formwork preparation, reinforcement installation, concrete placement log, and temperature control activities. Submit sample forms and describe the procedure used to organize, archive, and retrieve inspection records in the Quality Program submittal.

1.8.4.2 Sampling Logs

Contractor shall maintain a concrete placement log as an electronic spreadsheet or database identifying each placement date, placement location, volume of concrete, batch ticket numbers, lot identification code, fresh concrete properties, compressive strength results, transport properties, inspection comments, and acceptance status. Contractor shall provide/transmit the concrete testing log to the Contracting Officer weekly. The Contractor shall provide copies of supporting documents for any placement requested by the Contracting Officer immediately upon request.

1.8.4.3 Quality Control Data

The Contractor shall prepare, maintain, and report separate quality control charts illustrating the slump, temperature, plastic air content, compressive strength, and chloride ion penetration test results for each lot of each concrete mixture used on the project.

1.8.4.4 Quality Team Meetings

The contractor shall conduct regular quality control team meetings to review plans for future placements, review test results, and discuss dispensation of non-conforming materials. The quality team shall include the Contractor's quality manager, the project manager, the project superintendent, the Contracting Officer, and representatives of the testing agency and concrete producer, or approved substitutes. It is recommended that the meetings be held on a weekly or bi-weekly basis during the service life modeling submittal phases and then monthly, as the construction progresses. The transition from the weekly or bi-weekly meetings to the monthly meetings shall be with the Contracting Officer's approval.

The Contractor shall prepare quality control team meeting minutes for each meeting. The minutes shall include the date of each meeting, attendees, key discussion points, findings, recommendations, assigned tasks, assigned personnel, task completion dates, and status of each task.

1.8.4.5 Non-conforming materials

The exact location of non-conforming concrete as placed shall be identified and the Contracting Officer and Engineer of Record shall be notified immediately. There are numerous possible indicators that the as-placed concrete is non-conforming including (but not limited to) excessive compressive strength, inadequate compressive strength, excessive slump, chloride ions penetration out of limits, excessive voids and honeycombing, and concrete delivery records that indicate excessive time between mixing and placement and/or excessive water was added to the mixture during
delivery and placement. Any of these indicators alone are sufficient reason for the Contracting Officer to request additional sampling, testing, and service life modeling to quantify the concrete properties. If justified, cores may be extracted for testing, and an investigation into the cause for non-conformance shall be conducted. The investigation may include statistical analysis of the test data collected to date; appropriateness of the pre-defined QAL based on statistical analysis of production data; the impact of the non-conforming material on the structure strength and/or service life; and recommendations for concrete production process improvements, mitigation, or remediation, as appropriate.

Investigations into non-conforming materials shall be conducted at the Contractor's expense. The Contractor shall be responsible for the investigation and shall make written recommendations to adequately mitigate or remediate the non-conforming material. The Contracting Officer may accept, accept with reduced payment, require mitigation, or require removal and replacement of non-conforming material at no additional cost to the Government.

1.8.5 Test Reports

Concrete Test Reports shall be identified by a sequential report identification code. Each report shall identify the placement date, placement location, weather, name of testing technician, time of sampling, batch ticket number, fresh concrete test results, and hardened concrete test results.

1.8.5.1 Concrete Mixture Requirements

a. Submit copies of test reports conforming to ASTM C1077 showing that the mixture has been successfully tested to produce concrete with the properties specified and that mixture will be suitable for the job conditions. Test reports shall be submitted along with the concrete mixture proportions. Obtain approval before concrete placement.

b. Fully describe the processes and methodology whereby mixture proportions were developed and tested and how proportions will be adjusted during progress of the work to achieve, as closely as possible, the designated levels of relevant properties.

1.8.5.2 Supplementary Cementing Materials

Submit test results in accordance with ASTM C618 and the physical and chemical analysis in accordance with applicable ASTM standards such as ASTM C311/C311M for fly ash. Submit test results performed within 6 months of submittal date. Update this report during construction as necessary to assure that the supplementary cementing materials used on the projects meets the ASTM criteria and the report on file is never older than 6 months.

1.8.5.2.1 Ground Granulated Blast-Furnace Slag

Submit test results in accordance with ASTM C989/C989M for ground granulated blast-furnace slag. Submit test results performed within 6 months of submittal date. Update this report during construction as necessary to assure that the report on file is never older than 6 months.

1.8.5.2.2 Ultra Fine Fly Ash or Pozzolan

Submit test results in accordance with ASTM C618 as a Class F fly ash or
Class N pozzolan with the following additional requirements:

a. The strength activity index at 28 days shall be at least 95 percent of the control.

b. The average particle size shall not exceed 6 microns.

c. The sum $\text{SiO}_2$ plus $\text{Al}_2\text{O}_3$ plus $\text{Fe}_2\text{O}_3$ shall be greater than 77 percent.

Submit test results performed within 6 months of submittal date. Update this report during construction as necessary to assure that the report on file is never older than 6 months.

1.8.5.3 Silica Fume

Submit test results in accordance with ASTM C1240 for silica fume. Data shall be based upon tests performed within 6 months of submittal. Update this report during construction as necessary to assure that the report on file is never older than 6 months.

1.8.5.4 Aggregates

Aggregate samples shall be obtained in accordance with ASTM D75/D75M and shall be representative of the materials to be used for the project. Submit test results for aggregate quality in accordance with ASTM C33/C33M, and the combined gradation curve proposed for use in the work and used in the mixture qualification, and ASTM C295/C295M for results of petrographic examination. Confirm that the potential for alkali-silica reaction are within allowable limits by conducting tests in accordance with ASTM C1260. Submit results of all tests during progress of the work in tabular and graphical form as noted above, describing the cumulative combined aggregate grading and the percent of the combined aggregate retained on each sieve. Submit test results performed within 12 months of submittal date.

1.8.5.5 Admixtures

Submit test results in accordance with ASTM C494/C494M and ASTM C1017/C1017M for concrete admixtures, ASTM C260/C260M for air-entraining admixture, and manufacturer's literature and test reports for corrosion inhibitors and anti-washout admixture. Submitted data shall be based upon tests performed within 6 months of submittal. Submit certified copies of test results for the specific lots or batches to be used on the project. Test results shall be not more than 6 months old prior to use in the work. Chemical admixtures that have been in storage at the project site for longer than 6 months or that has been subjected to freezing will be restested at the expense of the Contractor.

1.8.5.6 Portland Cement

Portland cement[, ground granulated blast furnace (GGBF) slag,][ and pozzolan] will be accepted on the basis of manufacturer's certification of compliance, accompanied by mill test reports showing that the material in each shipment meets the requirements of the specification under which it is furnished. Mill test reports shall be no more than 1 month old, prior to use in the work. No cementitious material shall be used until notice of acceptance has been given by the Contracting Officer. Cementitious material may be subjected to check testing by the Government from samples obtained at the mill, at transfer points, or at the project site. If tests prove that a cementitious material that has been delivered is
unsatisfactory, it shall be promptly removed at Contractor's expense from the site of the work. Cementitious material that has not been used within 6 months after testing shall be retested at the Contractor's expense and shall be rejected if test results are not satisfactory. Submit test results in accordance with ASTM C150/C150M portland cement and/or ASTM C595/C595M and ASTM C1157/C1157M for blended cement.

1.8.5.7 Testing During Construction

During construction, the Contractor is responsible for sampling and testing aggregates, cementitious materials, and concrete as specified herein. The Government will sample and test concrete and ingredient materials as considered appropriate. Provide facilities and labor as may be necessary for procurement of representative test samples. Testing by the Government will in no way relieve the Contractor of the specified testing requirements.

1.8.5.8 Test Section

a. Horizontal Placements. No more than 90 days prior to construction, construct a Test Section 3048 mm by 3048 mm by 203.2 mm 10 by 10 feet by 8 inches thick near the job site, but not as part of the structure. The Test Section shall meet all specification requirements and be acceptable to the Contracting Officer in all respects, including but not limited to delivery time, placement, consolidation, curing and surface texture. Use the Test Section to develop and demonstrate to the satisfaction of the Contracting Officer the proposed techniques of mixing, hauling, placing, consolidating, finishing, curing, initial saw cutting, start-up procedures, testing methods, plant operations, and the preparation of the construction joints. The mixing plant shall be operated and equipment calibrated prior to start of placing the Test Section. Use the same equipment, materials, and construction techniques on the Test Section as will be used in all subsequent work. Concrete production, placing, consolidating, curing, construction of joints, and all testing shall be in accordance with applicable provisions of this specification. At a minimum of three days after completion of the Test Section, extract a sufficient number of concrete cores 100 by 200 mm 4 by 8 inch to conduct tests to evaluate strength, air void spacing factor, homogeneity, consolidation, segregation, and chloride ion penetration properties. Test Results that are unacceptable Test Section will necessitate construction of an additional Test Section at no additional cost to the Government.

b. Vertical Placements. No more than 90 days prior to construction, construct a Test Section that represents the vertical placements, (if applicable) near the job site, but not as part of the structure. Test Section shall meet all specification requirements and being acceptable to the Contracting Officer in all respects, including but not limited to delivery time, placement, consolidation, curing and surface texture. Use the Test Section to develop and demonstrate to the satisfaction of the Contracting Officer the proposed techniques of mixing, hauling, placing, consolidating, finishing, curing, initial saw cutting, start-up procedures, testing methods, plant operations, and the preparation of the construction joints. The mixing plant shall be operated and equipment calibrated prior to start of placing the Test Section. Use the same equipment, materials, and construction techniques on the Test Section as will be used in all subsequent work. Concrete production, placing, consolidating, curing, construction of joints, and all testing shall be in accordance with applicable provisions of this specification. At a minimum of three days after
completion of the Test Section, extract a sufficient number of concrete cores to evaluate strength, air void spacing factor, homogeneity, consolidation, segregation, and chloride ion penetration properties. If any of the test results are unacceptable, the Contracting Officer may require that a new Test Section be accomplished at no additional cost to the Government.

1.8.5.9 Acceptability of Work

The materials and the structure itself will be accepted on the basis of tests made by the Contractor and shall be in compliance with the criteria herein. The Government may make check tests at its expense to validate the results of the Contractor's testing. Testing performed by the Government will in no way relieve the Contractor from the specified testing requirements.

PART 2 PRODUCTS

**************************************************************************
NOTE: Delete any reference to any products that are not to be used on the project. Coordinate all product requirements with the appropriate agency's Contracting Officer.
**************************************************************************

2.1 CEMENTITIOUS MATERIALS

**************************************************************************
NOTE: Edit these paragraphs as appropriate for the particular project. Guidance for use of cementitious materials should be sought from the agency's Subject Matter Expert in Concrete Materials. Consideration should be given to the use of fly ash or GGBF slag for partial replacement of portland cement up to 50 percent. Type III cement should not be specified.
**************************************************************************

**************************************************************************
NOTE: Supplementary Cementitious Materials (SCM)

When granulated slag, coal fly ash, and natural pozzolans are used as cementing materials for replacement of portland cement in a concrete mixture, and if by doing so the sustainability, durability and the initial cost of the concrete mixture show considerable improvement then these materials are called "supplementary cementitious materials" (SCM).

The Engineer of Record is encouraged to specify the use of supplementary cementing materials. For example, 50 percent replacement of the portland cement using Class F fly ash has been successfully demonstrated to offer the required compressive strength (f'cr), drying shrinkage, lower permeability, constructability, and the potential to accomplish a structure with the design service life while being less expensive with a smaller carbon
footprint.

Cementitious materials shall be portland cement or cement blended with supplementary cementing materials. New submittals are required when the cementitious materials change sources or types.

The Contractor shall provide cementitious materials meeting the requirements of the applicable specification, and as modified herein. Provide mill certificates and test results conducted within six-months of the submittal date as part of the concrete mixture qualification submittal.

Provide a single manufacturer of cementitious material for each type of cement and supplementary cementing materials supplied to the project.

2.1.1 Portland Cement

NOTE: Use Type II or Type V cement in project locations with Environmental Severity Classifications (ESC) of C3 thru C5 or where deicing salts are used on the structure. See UFC 1-200-01 for determination of ESC for project locations.

Provide portland cement conforming to ASTM C150/C150M, Type [I] [II] [V], low alkali [including false set requirements] with tri-calcium aluminates (C3A) content less than 10 percent and a maximum cement-alkali content of 0.80 percent Na2Oe (sodium oxide equivalent). Type III cement shall be used only with concurrence of the agency's Subject Matter Expert in Concrete Materials. When HVFA mixtures are specified, they should be blended with Type II portland cement. HVFA is required instead of using Type V cement in high-sulfate areas. Low alkali cement may be required if the proposed aggregates are found to be expansive.

ASTM C150/C150M cements shall be combined with supplementary cementing materials in the concrete mixture.

2.1.2 Blended Cements

Blended cement shall conform to ASTM C595/C595M, Type IP or IS, including the optional requirement for mortar expansion [and sulfate soundness] and consist of a mixture of ASTM C150/C150M Type I, or Type II cement and a supplementary cementing material. The slag added to the Type IS blend shall be ASTM C989/C989M ground granulated blast-furnace slag. The pozzolan added to the Type IP blend shall be ASTM C618 Class F and shall be interground with the cement clinker. The manufacturer shall state in writing that the amount of pozzolan in the finished cement will not vary more than plus or minus 5 mass percent of the finished cement from lot-to-lot or within a lot. The percentage and type of mineral admixture used in the blend shall not change from that submitted for the aggregate evaluation and mixture proportioning.

2.1.3 Pozzolan

2.1.3.1 Fly Ash

NOTE: Class C fly ash is not permitted.
Use loss on ignition not exceeding 3 percent for frost areas to reduce carbon interference with air entraining admixture.

Fly ash shall conform to ASTM C618, Class F, including the optional requirements for uniformity and effectiveness in controlling Alkali-Silica reaction and shall have a loss on ignition not exceeding [3][6] percent. Class F fly ash for use in mitigating Alkali-Silica Reactivity shall have a Calcium Oxide (CaO) content of less than 8 percent and a total equivalent alkali content less than 1.5 percent. Add with cement.

2.1.3.2 Raw or Calcined Natural Pozzolan

Natural pozzolan shall be raw or calcined and conform to ASTM C618, Class N, including the optional requirements for uniformity and effectiveness in controlling Alkali-Silica reaction and shall have a loss on ignition not exceeding 3 percent. Class N pozzolan for use in mitigating Alkali-Silica Reactivity shall have a Calcium Oxide (CaO) content of less than 13 percent and total equivalent alkali content less than 3 percent.

2.1.3.3 Ultra Fine Fly Ash and Ultra Fine Pozzolan

Ultra Fine Fly Ash (UFFA) and Ultra Fine Pozzolan (UFP) shall conform to ASTM C618, Class F or N, and the following additional requirements:

a. The strength activity index at 28 days of age shall be at least 95 percent of the control specimens.

b. The average particle size shall not exceed 6 microns.

c. The sum of SiO2 + Al2O3 + Fe2O3 shall be greater than 77 percent.

2.1.4 Ground Granulated Blast-Furnace (GGBF) Slag

Ground Granulated Blast-Furnace Slag shall conform to ASTM C989/C989M, [Grade 100 or Grade 120]. Add with cement.

2.1.5 Silica Fume

NOTE: Silica Fume shall only be used for OCONUS projects where Class F fly ash and GGBF slag are not available, and when approved by the Contracting Officer. Guidance for use of silica fume should be sought from the agency's Subject Matter Expert in Concrete Materials.

Silica fume shall conform to ASTM C1240, including the optional limits on reactivity with cement alkalis. Silica fume may be furnished as a dry, densified material or as slurry. Proper mixing is essential to accomplish proper distribution of the silica fume and avoid agglomerated silica fume, which can react with the alkali in the cement resulting in premature and extensive concrete damage. Supervision at the batch plant, finishing, and curing is essential. Provide at the Contractor's expense the services of a manufacturer's technical representative, experienced in mixing, proportioning, placement procedures, and curing of concrete containing...
2.1.6 Supplementary Cementitious Materials (SCM) Content

The concrete mix shall always contain supplementary cementing materials whether or not the aggregates are found to be reactive in accordance with the paragraph AGGREGATES. Concrete mixtures shall be designed and proportioned to meet the requirements for strength, constructability, shrinkage, and durability.

**************************************************************************
NOTE: This specification requires that the structural requirements (f’c) be met and concrete strength is between 1.0 f’c and 1.2 f’c. If the prequalified mixture as approved by the Engineer of Record should produce a higher design strength (fcr), that strength shall be used instead of f’c. Maintain required w/cm ratio regardless of strength requirements.
**************************************************************************

2.2 AGGREGATES

**************************************************************************
NOTE: The largest possible aggregate size that meets the nominal maximum size requirements of ACI 318 should be used. Larger aggregates permit a leaner mixture with low paste content while maintaining workability.
**************************************************************************

**************************************************************************
NOTE: In some tropical locations where standard aggregate such as gravel or manufactured aggregates are not readily available, the use of coral aggregate is acceptable. The specific gravity of any coralline material must not be less than 2.40. Specify coral aggregates with higher specific gravity wherever available. Wash aggregates dredged from the ocean or lagoons with fresh water to remove as much salt as possible. Include bracketed paragraph where coral will be used as an aggregate.
**************************************************************************

Comply with ASTM C33/C33M Class 4S, except as modified herein.

The quantities to be retained on each sieve may be adjusted only where available aggregates are elongated or slivered and cause interference with mix mobility, or available aggregate gradations do not comply with the 18-8 requirement. When necessary to satisfy local conditions and when permitted, the combined aggregate percentages may be changed to not more than 22 percent nor less than 6 percent retained on any individual sieve. The combined aggregates in the mixture (coarse, intermediate, and fine) shall be well graded with no more than 18 percent nor less than 8 percent of the combined aggregate retained on any individual sieve, unless
satisfactory performance can be demonstrated. The 300 micrometers No. 50 sieve may have less than 8 percent retained; sieves finer than 300 micrometers No. 50 shall have less than 8 percent retained, and the coarsest sieve may have less than 8 percent retained. Use intermediate sizes for blending where necessary, to provide a well graded combined aggregate.

a. Provide gradation of individual aggregate sizes using standard concrete aggregate sieves including 37.5 mm 1-1/2 inches, 25 mm one inch, 19 mm 3/4 inch, 12.5 mm 1/2 inch, 9.5 mm 3/8 inch, 4.75 mm No. 4, 2.36 mm No. 8, 1.18 mm No. 16, 600 micrometers No. 30, 300 micrometers No. 50, and 150 micrometers No. 100.

b. Provide aggregates for exposed concrete from one source. Aggregate reactivity shall be limited per the paragraph AGGREGATES. Provide aggregate containing no deleterious material properties as identified by ASTM C295/C295M.

c. Where a size designation is indicated, that designation indicates the nominal maximum size of the coarse aggregate.

d. Aggregate tests shall be conducted within 6 months from the date of concrete mixture submittal.

e. Provide ASTM C1260 or ASTM C1567 test results conducted with 6 months of the submittal date showing the proposed coarse and fine aggregates are either: innocuous to alkali silica reaction; or that reactivity has been mitigated by the proposed cementitious materials as modified herein. Maximum allowable expansion is 0.08 percent at 14 days per ASTM C1260. If this is not met, then maximum allowable expansion for the proposed concrete mixture/s shall be 0.08 percent at 14 days per ASTM C1567. All aggregate sources shall be tested. Also, provide documentation that the aggregate has no history of chemical deterioration in concrete. Fine and coarse aggregates to be used in all concrete shall be evaluated and tested for alkali-aggregate reactivity. Both coarse aggregate size groups shall be tested.

f. Should the test data indicate a potential risk of alkali-aggregate reaction, the aggregate(s) shall be rejected or procedures from AASHTO R 80 shall be followed.

[ g. Coral may be used as a coarse aggregate when conventional concrete aggregate is not available. Coral aggregate must be washed to eliminate chloride ions from the aggregate. Specific gravity of coral must be at least 2.40.

]2.3 WATER

Water shall comply with the requirements of ASTM C94/C94M and ASTM C1602/C1602M, except that the chloride and sulfate limits as tested in accordance with ASTM D512 and ASTM D516 shall not exceed 500 parts per million chloride ion and not more than 1000 parts per million of sulfate ion as SO4. Water shall be free from injurious amounts of oils, acids, alkalis, salts, and organic materials. Where non-potable water or water from reprocessed concrete is proposed for use in the work, submit results of tests in accordance with ASTM C1602/C1602M. Submit test results in accordance with ASTM D512 and ASTM D516.
2.4 ADMIXTURES

a. Provide certifications that chemical admixtures comply with the requirements shown in Table 4 and are compatible with each other. Use admixtures in accordance with manufacturer's recommendations, as appropriate for the climatic conditions and construction needs.

b. Do not use calcium chloride or admixtures containing chloride ion content in more than trace amounts from impurities in admixture ingredients or potable water. Provide maximum concentrations of corrosion-inducing chemicals as shown in Table 4. For concrete that may be in contact with prestressing steel tendons, the concentration shall not exceed 60 percent of the limits given in Table 4. For the concentration in grout for prestressing ducts, do not exceed 25 percent of the limits in Table 4.

* Limits refer to water-soluble chemicals
** Limits are expressed as a percentage of the mass of the total cementitious materials.

c. Provide anti-washout or viscosity modifying admixtures for underwater concrete placement. Provide certification that the admixture is compatible with the cementitious materials and other chemical admixtures in the proposed concrete mixture. The anti-washout or viscosity modifying admixture shall require approval by the Contracting Officer and have a proven record of performance with a minimum of five similar projects. Test per COE CRD-C 61 to determine cumulative mass loss shall be performed once for each 267.6 cubic meters 350 cubic yards of underwater concrete and results submitted to Contracting Officer for approval prior to continued use.

d. The total alkali contribution of chemical admixtures shall not increase the total sodium-oxide equivalent content of the concrete mixture by more than 0.3 kg/m3 0.5 lb/yd3.

2.4.1 Air Entraining

Provide air entraining admixtures conforming to ASTM C260/C260M

2.4.2 Accelerating

ASTM C494/C494M, Type C.

2.4.3 Retarding

ASTM C494/C494M, Type B, D, or G.
2.4.4 Water Reducing

**************************************************************************
NOTE: The use of high range water reducers can be used to reduce the water-cementitious materials ratio which will produce a more dense concrete matrix and improve resistance to chloride ion penetration in the concrete.
**************************************************************************

ASTM C494/C494M, Type A, E, or F.

High Range Water Reducer (HRWR) shall be ASTM C494/C494M, Type F and ASTM C1017/C1017M.

2.4.5 Corrosion Inhibitors

Corrosion inhibitors are considered "supplemental corrosion projection". If used, adjust the quantity of concrete mixing water for the mass of water in the admixture. Accelerating and set adjusted versions are acceptable. Concrete setting time and mixture workability shall be evaluated.

2.5 NON-SHRINK GROUT

ASTM C1107/C1107M.

2.6 MATERIALS FOR FORMS

Provide wood, plywood, or steel. Use plywood or steel forms where a smooth form finish is required. Lumber shall be square edged or tongue-and-groove boards, free of raised grain, knotholes, or other surface defects.

Plywood: APA PS 1, B-B concrete form panels or better. Steel form surfaces shall not contain irregularities, dents, or sags.

2.6.1 Form Ties and Form-Facing Material

a. Provide a form tie system that does not leave mild steel after break-off or removal any closer than 50 mm 2 inches from the exposed surface. Do not use wire alone. Form ties and accessories shall not reduce the effective cover of the reinforcement.

b. Form-facing material shall be structural plywood or other material that can absorb air and some of the high water-cementitious materials ratio surface paste that may be trapped in pockets between the form and the concrete. Maximum reuse is three times. Provide forms with a form treatment to prevent bond of the concrete to the forms. Use a controlled permeability form liner in strict accordance with the manufacturer's recommendations.

2.7 REINFORCEMENT

2.7.1 Prestressing Steel

**************************************************************************
NOTE: Use prestressing in fender and bearing piles and deck soffits wherever possible. Post-tensioning of pile caps and decks is recommended where
**************************************************************************
feasible. Do not mix coated prestressing strands and plain prestressing strands. This will produce a large corrosion cell between the plain strand and any defect in the coated strand.

Use seven-wire stress-relieved or low-relaxation strand conforming to ASTM A416/A416M, Grade 270. Use of indented seven-wire stress-relieved or low-relaxation strand conforming to ASTM A882/A882M, Grade 270; or epoxy-filled seven-wire stress-relieved or low-relaxation strand conforming to ASTM A886/A886M, Grade 270 shall be permitted in lieu of prestressing steel conforming to ASTM A416/A416M. Use prestressing steel free of grease, oil, wax, paint, soil, dirt, and loose rust. Do not use prestressing strands or wire having kinks, bends, or other defects.

2.7.2 Reinforcing Bars

NOTE: It is intended that plain steel rebar with specified concrete cover of 75 mm 3.0 inches shall normally be specified according to applicable codes.

ASTM A706/A706M bars are mainly used in seismic design or for welding. Do not mix coated rebar and plain reinforcing bars. This may produce a large corrosion cell between the plain bar and any defect in the coated bar.

ACI 301M unless otherwise specified and shall meet the design yield strength and ductility requirements. Deformed reinforcing bars meeting the requirements of ASTM A615/A615M with the bars marked A, Grade ASTM A276/A276M stainless steel bars; ASTM A767/A767M Class 1 galvanized; prefabricated epoxy coated, ASTM A934/A934M; ASTM A955/A955M stainless steel bars; ASTM A1035/A1035M MMFX2 bars; ASTM A1055/A1055M Z bars; ASTM A706/A706M; or other approved reinforcing material shall be permitted for use in the cast-in-place concrete system.

The reinforcing selected shall match the structural properties of the reinforcing specified. Alternative reinforcing bars shall have similar structural properties to the specified reinforcing and may be used with the Contracting Officer's approval.

2.7.2.1 Reinforcement and Protective Coating

If applicable, provide coating manufacturer's and coating applicator's test data sheets certifying that applied coating meets the requirements of the concrete system specified on the Plans.

2.7.3 Mechanical Reinforcing Bar Connectors

ACI 301M ACI 301. Provide 125 percent minimum yield strength of the reinforcement bar. Coat connectors in accordance with the requirements of the reinforcing bars.

2.7.4 Welded Wire Fabric

2.7.5 Wire

Comply with ASTM A1064/A1064M carbon steel.

2.8 ACCESSORY MATERIALS

2.8.1 Polyvinylchloride Waterstops

COE CRD-C 572.

2.8.2 Materials for Curing Concrete

2.8.2.1 Impervious Sheeting

ASTM C171; waterproof paper, clear or white polyethylene sheeting, or polyethylene-coated burlap.

2.8.2.2 Pervious Sheeting

AASHTO M 182 or carpet covering the free surface and kept continuously wet throughout the curing period.

2.8.2.3 Liquid Membrane-Forming Compound

Comply with ASTM C309, white-pigmented, Type 2, Class B.

2.8.3 Liquid Chemical Sealer-Hardener Compound

Provide magnesium fluosilicate compound which when mixed with water seals and hardens the surface of the concrete. Do not use on exterior slabs exposed to freezing conditions. Compound shall not reduce the adhesion of resilient flooring, tile, paint, roofing, waterproofing, or other material applied to concrete.

2.8.4 Expansion/Contraction Joint Filler

Comply with ASTM D1751 or ASTM D1752, 13 mm 1/2 inch thick unless otherwise indicated.

2.8.5 Joint Sealants

2.8.5.1 Horizontal Surfaces

**************************************************************************
NOTE: For horizontal surfaces subject to jet fuel, specify section 32 01 19.61 SEALING OF JOINTS IN RIGID PAVEMENT.
**************************************************************************

Horizontal surfaces are defined as all surfaces with a 3 percent maximum slope. ASTM D6690 or ASTM C920, Type M, Class 25, Use T.

2.8.5.2 Vertical Surfaces

**************************************************************************
NOTE: Specify ASTM C920 for vertical surfaces greater than 3 percent slope and not subject to jet fuel, gasoline, fuel oil, etc. For vertical
**surfaces greater than 3 percent slope and subject to jet fuel, specify FS SS-S-200, no sag.**

Vertical surfaces are defined as all surfaces with a slope greater than 3 percent. ASTM C920, Type M, Grade NS, Class 25, Use T. FS SS-S-200, no sag.

**PART 3 EXECUTION**

**3.1 FORMS**

a. Provide formwork with clean-out openings to permit inspection and removal of debris. Formwork shall be gasketed or otherwise rendered sufficiently tight to prevent leakage of paste or grout under heavy, high-frequency vibration. Use a release agent that does not cause surface dusting. Limit reuse of plywood to no more than three times. Reuse may be further limited by the Contracting Officer if it is found that the pores of the plywood are clogged with paste so that the wood does not absorb air and some of the high water-cementitious materials ratio paste that may be trapped in pockets between the form and the concrete.

b. Comply with ACI 301M ACI 301. Concrete for footings may be placed in excavations without forms upon inspection and approval by the Contracting Officer. Excavation width shall be a minimum of 100 mm 4 inches greater than indicated. Set forms rigidly, mortar-tight, and true to line and grade. Chamfer above grade exposed joints, edges, and external corners of concrete 20 mm 0.75 inch unless otherwise indicated. Forms submerged in water shall be watertight.

c. Patch form tie holes with a no shrink patching material in accordance with the manufacturer's recommendations and subject to approval.

**3.1.1 Coating**

Before concrete placement, coat the contact surfaces of forms with a no staining mineral oil, no staining form coating compound, or two coats of nitrocellulose lacquer. Do not use mineral oil on forms for surfaces to which adhesive, paint, or other finish material is to be applied.

**3.1.2 Removal of Forms and Supports**

After placing concrete, forms shall remain in place for the time periods specified in ACI 347R, except for concrete placed underwater, forms shall remain in place a minimum of 48 hours. Prevent concrete damage during form removal.

**3.1.2.1 Special Requirements for Reduced Time Period**

Forms may be removed earlier than specified if ASTM C39/C39M test results of field-cured samples from a representative portion of the structure or other approved and calibrated non-destructive testing techniques show that the concrete has reached a minimum of 85 percent of the design strength.

**3.1.3 Reshoring**

Do not allow construction loads to exceed the superimposed load that the structural member, with necessary supplemental support, is capable of
carrying safely and without damage. Reshore concrete elements where forms are removed prior to the specified time period. Do not permit elements to deflect or accept loads during form stripping or reshoring. Forms on columns, walls, or other load-bearing members may be stripped after 2 days if loads are not applied to the members. After forms are removed, slabs and beams over 3 meters 10 feet in span and cantilevers over 1.2 meters 4 feet shall be reshored for the remainder of the specified time period in accordance with paragraph REMOVAL OF FORMS AND SUPPORTS. Perform reshoring operations to prevent subjecting concrete members to overloads, eccentric loading, or reverse bending. Reshoring elements shall have the same load-carry capabilities as original shoring and shall be spaced similar to original shoring. Firmly secure and brace reshoring elements to provide solid bearing and support.

3.2 PLACING REINFORCEMENT AND MISCELLANEOUS MATERIALS

ACI 301M ACI 301. Remove rust, scale, oil, grease, clay, or foreign substances from reinforcing that would reduce the epoxy coating bond from reinforcing. Do not tack weld. Inspect and verify proper reinforcement grade, quantity, spacing, and clearance requirements prior to concrete placement. Inspect placed steel reinforcing for coating damage prior to placing concrete. Repair all visible damage.

3.2.1 Coated Reinforcing

If coated reinforcement is used, record coating lot on each shipping notice and carefully identify and retag bar bundles from bending plant. Provide systems for handling coated bars that have padded contact areas, nylon slings, etc., to keep bars free of dirt and grit. Carefully handle and install bars to minimize job site patching including lifting and supporting bundled coated bars with strong back, multiple supports, or platform bridge to prevent sagging and abrasion. When possible, assemble reinforcement as tied cages prior to final placement into the forms. Bundling bands shall be padded where in contact with bars. Do not drop or drag bars or bundles. Store coated bars both in shop and in field, aboveground, on wooden or padded cribbing with adequate protective blocking between layers. Schedule deliveries of coated bars to the job site to avoid the need for long term storage. Protect from direct sunlight and weather. Bars to be stored longer than 12 hours at the job site shall be covered with opaque polyethylene sheeting or other suitable equivalent protective material.

Inspect for defects and provide required repairs prior to assembly. After assembly, reinspect and provide final repairs. Excessive nicks and scrapes that expose steel shall be cause for rejection.

a. Immediately prior to application of the patching material, any rust and debonded coating shall be manually removed from the reinforcement by suitable techniques employing devices such as wire brushes and emery paper. Care shall be exercised during this surface preparation so that the damaged areas are not enlarged more than necessary to accomplish the repair. Damaged areas shall be clean of dirt, debris, oil, and similar materials prior to application of the patching material.

b. Repair and patching shall be done in accordance with the patching material manufacturer's recommendations. These recommendations, including cure times, shall be available at the job site at all times.

c. Allow adequate time for the patching materials to cure in accordance
with the manufacturer's recommendation prior to concrete placement.

d. Rinse placed reinforcing bars with ASTM C1602/C1602M compliant water to remove chloride contamination prior to placing concrete.

3.2.2 Reinforcement Supports

Place reinforcement and secure with non-corrodible chairs, spacers, and hangers. Metal hangers may be used, but shall be of similar material to the reinforcing. Support reinforcement on the ground with concrete or other non-corrodible material, having a compressive strength equal to or greater than the concrete being placed and having permeability equal or less than the concrete being placed.

Coated reinforcing bars supported from formwork shall rest on coated wire bar supports, or on bar supports made of dielectric material or other acceptable material. Wire bar supports shall be coated with dielectric material, compatible with concrete, for a minimum distance of 50 mm 2 inches from the point of contact with the coated reinforcing bars. Reinforcing bars used as support bars shall be coated with the same material as the reinforcing. Spreader bars, where used, shall be coated. Non-coated combination bar clips and spreaders used in construction with coated reinforcing bars shall be made corrosion resistant or coated with dielectric material. Coated bars shall be tied with plastic-coated tie wire or other materials acceptable to the Contracting Officer.

3.2.3 Splicing

As indicated. For splices not indicated, comply with ACI 301M ACI 301. Do not splice at points of maximum stress. Overlap welded wire fabric the spacing of the cross wires, plus 50 mm 2 inches. Welded splices shall comply with AWS D1.4/D1.4M and be approved prior to use.

3.2.4 Future Bonding

Plug exposed, threaded, mechanical reinforcement bar connectors with a greased bolt. Bolt threads shall match the connector. Countersink the connector in the concrete. Caulk the depression after the bolt is installed.

3.2.5 Cover

**************************************************************************
NOTE: Uniform, high quality concrete cover over the steel reinforcement is critically important for long-term durability.
**************************************************************************

Provide concrete cover thickness as shown on the Plans. If no concrete cover is specified, as a minimum, comply with ACI 318M ACI 318 for concrete cover over the steel reinforcement. Use ACI 117 to determine allowable tolerances for the placement of the steel.

3.2.6 Setting Miscellaneous Material and Prestress Anchorages

Place and secure anchors, bolts, pipe sleeves, conduits, and other such items in position before concrete placement. Plumb anchor bolts and check location and elevation. Temporarily fill voids in sleeves with readily removable material to prevent the entry of concrete. Electrically isolate...
exposed steel work and its anchor systems from the primary steel reinforcement with at least 50 mm 2 inches of concrete. Coat exposed steel work to reduce corrosion. Take particular care to ensure against corrosion on edges and horizontal surfaces. Use epoxy coatings for protection of carbon steel plates and fittings.

3.2.7 Construction Joints

Locate joints to least impair strength. Continue reinforcement across joints unless otherwise indicated. Final joint locations are subject to Government approval or substantiating calculations from the Contractor.

3.2.8 Expansion Joints and Contraction Joints

Provide expansion joint at edges of interior floor slabs on grade abutting vertical surfaces, and as indicated. Make expansion joints 13 mm 1/2 inch wide unless indicated otherwise. Fill expansion joints not exposed to weather with preformed joint filler material. Completely fill joints exposed to weather with joint filler material and joint sealant. Do not extend reinforcement or other embedded metal items bonded to the concrete through any expansion joint unless an expansion sleeve is used. Place contraction joints, either formed or saw cut or cut with a jointing tool, to the indicated depth after the surface has been finished. Sawed joints shall be completed within 4 to 12 hours after concrete placement. Protect joints from intrusion of foreign matter.

3.2.9 Waterstop Splices

Fusion weld in the field.

3.2.10 Pits and Trenches

Place bottoms and walls monolithically or provide waterstops and keys.

3.3 Batching, Measuring, Mixing, and Transporting Concrete

ASTM C94/C94M, ACI 301M ACI 301, and ACI 304R, except as modified herein. Batching equipment shall be such that the concrete ingredients are consistently measured within the following tolerances: 1 percent for cement and water, 2 percent for aggregate, and 3 percent for admixtures. Furnish mandatory batch tickets imprinted with mix identification, batch size, batch design and measured weights, moisture in the aggregates, and time batched for each load of ready mix concrete. When a pozzolan is batched cumulatively with the cement, it shall be batched after the cement has entered the weight hopper.

3.3.1 Measuring

Make measurements at intervals as specified in paragraphs SAMPLING and TESTING.

Adjust batch proportions to replicate the mixture design using methods provided in the approved quality assurance plan. Base the adjustments on results of tests of materials at the batch plant for use in the work. Maintain a full record of adjustments and the basis for each.

3.3.2 Mixing

Comply with ASTM C94/C94M and ACI 301M ACI 301. If time of discharge
exceeds time required by ASTM C94/C94M, submit a request along with description of precautions to be taken.

3.3.3 Transporting

Comply with ACI 304R.

3.4 PLACING CONCRETE

Comply with ACI 304R and ACI 304.2R. Place concrete as soon as practicable after the forms and the reinforcement have been inspected and approved. Do not place concrete when weather conditions prevent proper placement and consolidation; in uncovered areas during periods of precipitation; or in standing water. Prior to placing concrete, remove dirt, construction debris, water, snow, and ice from within the forms. Deposit concrete as close as practicable to the final position in the forms. Do not exceed a free vertical drop of one m 3 feet from the point of discharge. Place concrete in one continuous operation from one end of the structure towards the other or lifts for vertical construction. Position grade stakes on 6 m 20 foot centers maximum for exterior slabs.

3.4.1 Vibration

**************************************************************************
NOTE: The requirement for vibrator spacing shall be considered in the reinforcing steel design by the engineer of record. ACI SP-66 requires that bar bundling be done by the design engineer. It is very important to provide space for placement and consolidation of concrete.
**************************************************************************

Comply with the requirements of ACI 309R [and ASTM A934/A934M for epoxy-coated bar] using vibrators with a minimum frequency of 9000 vibrations per minute (VPM). Use only high cycle or high frequency vibrators. Motor-in-head 60 cycle vibrators may not be used. For walls and deep beams, use a minimum of two vibrators with the first to melt down the mixture and the second to thoroughly consolidate the mass. Provide a spare vibrator at the casting site whenever concrete is placed. Place concrete in 500 mm 18 inch maximum vertical lifts. Insert and withdraw vibrators approximately 500 mm 18 inches apart. Penetrate at least 200 mm 8 inches into the previously placed lift with the vibrator when more than one lift is required. Extract the vibrator using a series of up and down motions to drive the trapped air out of the concrete and from between the concrete and the forms.

For slab construction, use vibrating screeds designed to consolidate the full depth of the concrete. Where beams and slabs intersect, use an internal vibrator to consolidate the beam. Do not vibrate concrete placed with anti-washout admixtures. Vibrators shall be equipped with rubber vibrator heads.

3.4.2 Cold Weather

Comply with ACI 306R. Do not allow concrete temperature to decrease below 10 degrees C 50 degrees F. Obtain approval prior to placing concrete when ambient temperature is below 4 degrees C 40 degrees F or when concrete is likely to be subjected to freezing temperatures within 24 hours. Placement of concrete shall be halted whenever the ambient temperature drops below 5
degrees C 40 degrees F. When the ambient temperature is less than 10 degrees C 50 degrees F the temperature of the concrete when placed shall be not less than 10 degrees C 50 degrees F or more than 25 degrees C 75 degrees F. Heating of the mixing water or aggregates may be necessary to regulate the concrete placing temperature. An accelerating admixture may be used when the ambient temperature is below 10 degrees C 50 degrees F. Covering and other means shall be provided for maintaining the concrete at a temperature of at least 10 degrees C 50 degrees F for not less than 7 days after placing, and at a temperature above freezing for the remainder of the curing period.

3.4.3 Hot Weather

Comply with ACI 305R. Maintain required concrete temperature using Figure 2.1.5, "Effect of Concrete Temperatures, Relative Humidity, and Wind Velocity on the Rate of Evaporation of Surface Moisture From Concrete" in ACI 305R to prevent the evaporation rate from exceeding one kg per square meter 0.2 pound of water per square foot of exposed concrete per hour. If necessary, cool ingredients before mixing or use other suitable means to control concrete temperature and prevent rapid drying of newly placed concrete. Shade the fresh concrete as soon as possible after placing. Start curing when the surface of the fresh concrete is sufficiently hard to permit curing without damage. If the evaporation rate exceeds 0.5 kg per square meter 0.1 pound of water per square foot per hour, fog spray the exposed concrete surfaces until active moist curing is applied. Provide water hoses, pipes, spraying equipment, and water hauling equipment, where job site is remote to water source, to maintain a moist concrete surface throughout the curing period. Provide burlap cover or other suitable, permeable material with fog spray or continuous wetting of the concrete when weather conditions prevent the use of either liquid membrane curing compound or impervious sheets. For vertical surfaces, protect forms from direct sunlight and add water to top of structure once concrete is set.

3.4.4 Prevention of Plastic Shrinkage Cracking

During weather with low humidity, and particularly with high temperature and appreciable wind, develop and institute measures to prevent plastic shrinkage cracks from developing. If plastic shrinkage cracking occurs, halt further placement of concrete until protective measures are in place to prevent further cracking. Periods of high potential for plastic shrinkage cracking can be anticipated by use of Figure 2.1.5 of ACI 305R. In addition to the protective measures concrete placement shall be further protected by erecting shades and windbreaks and by applying fog sprays of water, the addition of monomolecular films, or wet covering. When such water treatment is stopped, curing procedures shall be immediately commenced. The methods and materials to remove or repair areas affected by plastic shrinkage cracks shall be suggested by the Contractor, reviewed by the agency’s Subject Matter Expert in Concrete Materials, and approved by the Contracting Officer. Cracks shall never be troweled over or filled with cement slurry.

3.4.5 Mass Concrete

All mass concrete elements shall be placed per the requirements of the Mass Concrete Temperature Control Plan.

3.4.6 Depositing Concrete Under Water

ACI 301M ACI 301 methods and equipment used shall prevent the washing of
the cement from the mixture, minimize the formation of laitance, prevent the flow of water through the concrete before it has hardened, and minimize disturbance to the previously placed concrete. Tremies, if used, shall be watertight and sufficiently large to permit a free flow of concrete. Keep the discharge end continuously submerged in fresh concrete. Keep the shaft full of concrete to a level well above the water surface. Discharge and spread the concrete by raising the tremie to maintain a uniform flow. Place concrete without interruption until the top of the fresh concrete is at the required height.

3.5 SURFACE FINISHES EXCEPT FLOOR, SLAB, AND PAVEMENT

3.5.1 Defects

Repair formed surfaces by removing minor honeycombs, pits greater than 600 square mm one square inch surface area or 6 mm 0.25 inch maximum depth, or otherwise defective areas. Provide edges perpendicular to the surface and patch with non-shrink grout. Patch tie holes and defects when the forms are removed. Concrete with extensive honeycomb including exposed steel reinforcement, cold joints, entrapped debris, separated aggregate, or other defects that affect the serviceability or structural strength will be rejected, unless correction of defects is approved. Obtain approval of corrective action prior to repair. The surface of the concrete shall not vary more than the allowable tolerances of ACI 347R. Exposed surfaces shall be uniform in appearance and finished to a smooth form finish unless otherwise indicated.

3.5.2 Formed Surfaces

3.5.2.1 Tolerances

Comply with ACI 117 and as indicated.

3.5.2.2 As-Cast Rough Form

Provide for surfaces not exposed to public view. Patch holes and defects and level abrupt irregularities. Remove or rub off fins and other projections exceeding 6 mm 0.25 inch in height.

3.5.2.3 As-Cast Form

Provide form facing material producing a smooth, hard, uniform texture on the concrete. Arrange facing material in an orderly and symmetrical manner and keep seams to a practical minimum. Support forms as necessary to meet required tolerances. Material with raised grain, torn surfaces, worn edges, patches, dents, or other defects that will impair the texture of the concrete surface shall not be used. Patch tie holes and defects and completely remove fins.

3.6 FINISHES FOR HORIZONTAL CONCRETE SURFACES

3.6.1 Finish

Comply with ACI 301M ACI 301. Place, consolidate, and immediately strike off concrete to obtain proper contour, grade, and elevation before bleedwater appears. Permit concrete to attain a set sufficient for floating and supporting the weight of the finisher and equipment. If bleedwater is present prior to floating the surface, drag excess water off or remove by absorption with porous materials. Do not use dry cement to
3.6.1.1 Scratched

Use for surfaces intended to receive bonded applied cementitious applications. After the concrete has been placed, consolidated, struck off, and leveled, the surface shall be roughened with stiff brushes or rakes before final set.

3.6.1.2 Floated

Exterior slabs where not otherwise specified. After the concrete has been placed, consolidated, struck off, and leveled, do not work the concrete further, until ready for floating. Whether floating with a wood, magnesium, or composite hand float, with a bladed power trowel equipped with float shoes, or with a powered disc, float shall begin when the surface has stiffened sufficiently to permit the operation.

3.6.1.3 Broomed

Perform a floated finish, then draw a broom or burlap belt across the surface to produce a coarse scored texture. Permit surface to harden sufficiently to retain the scoring or ridges. Broom transverse to traffic or at right angles to the slope of the slab.

3.6.1.4 Pavement

Screed the concrete with a template advanced with a combined longitudinal and crosswise motion. Maintain a slight surplus of concrete ahead of the template. After screeding, float the concrete longitudinally. Use a straightedge to check slope and flatness; correct and refloat as necessary. Obtain final finish by a burlap drag. Drag a strip of clean, wet burlap from 900 to 3000 mm wide and 600 mm longer than the pavement width across the slab. Produce a fine, granular, sandy textured surface without disfiguring marks. Round edges and joints with an edger having a radius of 3 mm 1/8 inch.

3.6.1.5 Concrete Toppings Placement

Remove dirt, laitance, and loose aggregate by means of a stiff wire broom. Keep the base wet for a period of 12 hours preceding the application of the topping. Remove excess water prior to the topping placement. Do not allow temperature differential between the completed base and the topping to exceed 6 degrees C 10 degrees F at the time of placing. Place the topping and finish as specified for pavement.

3.7 CURING AND PROTECTION

Comply with ACI 301M ACI 301 and ACI 308.1 unless otherwise specified. Prevent concrete from drying by misting surface of concrete. Begin curing immediately following final set. Avoid damage to concrete from vibration created by blasting, pile driving, movement of equipment in the vicinity, disturbance of formwork or protruding reinforcement, by rain or running water, adverse weather conditions, and any other activity resulting in ground vibrations. Protect concrete from injurious action by sun, rain, flowing water, frost, mechanical injury, tire marks, and oil stains. Do not allow concrete to dry out from time of placement until the expiration of the specified curing period. Do not use membrane-forming compound on surfaces where appearance would be objectionable, on any surface to be
painted, where coverings are to be bonded to the concrete, or on concrete
to which other concrete is to be bonded. If forms are removed prior to the
expiration of the curing period, provide another curing procedure specified
herein for the remaining portion of the curing period. Provide moist
curing for those areas receiving liquid chemical sealer-hardener or epoxy
coating.

**************************************************************************

NOTE: When the use of alkali-reactive aggregates is
permitted, add the following paragraph.
**************************************************************************

Furnish ASTM C39/C39M test results to verify the anticipated rate of
strength development for the proposed concrete design mixture. Submit an
increased curing period and minimum time to strip formwork based upon the
reduced rate of strength development.

3.7.1 Wet Curing

Wet cure marine concrete using ASTM C1602/C1602M compliant water for a
minimum of 7 days. Do not allow construction loads to exceed the
superimposed load that the structural member, with necessary supplemental
support, is capable of carrying in current condition safely and without
damage.

Leaving the forms in place for seven days is a suitable alternative to wet
curing.

3.7.1.1 Ponding or Immersion

Continually immerse the concrete throughout the seven-day curing period.
Water shall not be 11 degrees C 20 degrees F less than the temperature of
the concrete. For temperatures between 4 and 10 degrees C 40 and 50
degrees F, increase the curing period by 50 percent.

3.7.1.2 Fog Spraying or Sprinkling

Apply water uniformly and continuously throughout the curing period. For
temperatures between 4 and 10 degrees C 40 and 50 degrees F, increase the
curing period by 50 percent.

3.7.1.3 Pervious Sheeting

Completely cover surface and edges of the concrete with two thicknesses of
wet sheeting. Overlap sheeting 150 mm 6 inches over adjacent sheeting.
Sheeting shall be at least as long as the width of the surface to be
cured. During application, do not drag the sheeting over the finished
concrete or over sheeting already placed. Wet sheeting thoroughly and keep
continuously wet throughout the curing period.

3.7.1.4 Impervious Sheeting

Wet the entire exposed surface of the concrete thoroughly with a fine spray
of water and cover with impervious sheeting throughout the curing period.
Lay sheeting directly on the concrete surface and overlap edges 300 mm 12
inches minimum. Provide sheeting not less than 450 mm 18 inches wider than
the concrete surface to be cured. Secure edges and transverse laps to form
closed joints. Repair torn or damaged sheeting or provide new sheeting.
Cover or wrap columns, walls, and other vertical structural elements from
the top down with impervious sheeting; overlap and continuously tape sheeting joints; and introduce sufficient water to soak the entire surface prior to completely enclosing.

3.7.2 Liquid Membrane-Forming Curing Compound

******************************************************************************
NOTE: Stay in place forms and moist curing are the preferred method for curing concrete. Use of a liquid membrane-forming curing compound is only permitted when approved by the Contracting Officer.
******************************************************************************

Seal or cover joint openings prior to application of curing compound. Prevent curing compound from entering the joint. Apply in accordance with the recommendations of the manufacturer immediately after any water sheen that may develop after finishing has disappeared from the concrete surface. Provide and maintain compound on the concrete surface throughout the curing period. Do not use this method of curing where the use of Figure 2.1.5, "Effect of Concrete Temperatures, Relative Humidity, and Wind Velocity on the Rate of Evaporation of Surface Moisture From Concrete" in ACI 305R indicates that hot weather conditions will cause an evaporation rate exceeding one kg pf water per square meter per hour 0.2 pound of water per square foot per hour.

3.7.2.1 Application

Mechanically agitate curing compound thoroughly during use. Use approved power-spraying equipment to uniformly apply two coats of compound in a continuous operation. The total coverage for the two coats shall be 5 square meters maximum per L 200 square feet maximum per gallon of undiluted compound unless otherwise recommended by the manufacturer's written instructions. The compound shall form a uniform, continuous, coherent film that will not check, crack, or peel. Immediately apply an additional coat of compound to areas where the film is defective. Respray concrete surfaces subjected to rainfall within 3 hours after the curing compound application.

3.7.2.2 Protection of Treated Surfaces

Prohibit pedestrian and vehicular traffic and other sources of abrasion at least 72 hours after compound application. Maintain continuity of the coating for the entire curing period and immediately repair any damage.

3.7.3 Liquid Chemical Sealer-Hardener

Apply the sealer-hardener in accordance with manufacturer's recommendations. Seal or cover joints and openings in which joint sealant is to be applied as required by the joint sealant manufacturer. The sealer-hardener shall not be applied until the concrete has been moist cured and has aged for a minimum of 30 days. Apply a minimum of two coats of sealer-hardener.

3.7.4 Curing Periods

******************************************************************************
NOTE: Add the following if concrete will be underwater: [Cure land-cast elements for a minimum of 7 days prior to submerging].
******************************************************************************
Moist cure concrete using ASTM C1602/C1602M compliant water for a minimum of 7 days. Continue additional curing for a total period of 21 days. Begin curing immediately after placement. Protect concrete from premature drying, excessively hot temperatures, and mechanical injury; and maintain minimal moisture loss at a relatively constant temperature for the period necessary for hydration of the cement and hardening of the concrete. The materials and methods of curing shall be subject to approval by the Contracting Officer.

3.8 FIELD QUALITY CONTROL

NOTE: Consider the size and complexity of job to determine if all tests are required.

3.8.1 Fresh Concrete Properties

For each concrete mixture, the Contractor shall take samples in accordance with ASTM C172/C172M, test and record the slump, and temperature. If the slump deviates from the previous batch by more than 25.4 mm 1 inch, air content shall also be determined. Adjustment of air content and/or slump with chemical admixture is permitted provided the water to cementitious material ratio is not exceeded.

3.8.1.1 Slump Tests

ASTM C143/C143M. Take concrete samples during concrete placement. The maximum slump may be increased as specified with the addition of an approved high range water reducing (HRWR) admixture provided that the water-cementitious ratio is not exceeded. Perform tests at commencement of concrete placement, when test cylinders are made, and for each batch (minimum) or every 40 cubic meters 50 cubic yards (maximum) of concrete. If concrete does not pass slump test, adjust using a HRWR and test every concrete batch until two consecutive batches meet slump without adjustment.

3.8.1.2 Temperature Tests

a. Test the concrete delivered and the concrete in the forms. Perform tests in hot or cold weather conditions below 10 degrees C and above 27 degrees C below 50 degrees F and above 80 degrees F for each batch (minimum) or every 40 cubic meters 50 cubic yards (maximum) of concrete, until the specified temperature is obtained, and whenever test cylinders and slump tests are made.

b. Determine temperature of each concrete sample in accordance with ASTM C1064/C1064M. Temperatures must comply with the Concrete Temperature Control Plans.

3.8.1.3 Air Content Tests

ASTM C231/C231M or ASTM C173/C173M. Perform tests at commencement of concrete placement each day, when test cylinders are made, and if slump test varies by more than 25.4 mm 1 inch from previous results or concrete does not pass slump test.
3.8.1.4 Unit Weight Test

**ASTM C138/C138M.** Take concrete samples during concrete placement. Perform tests at commencement of concrete placement, when test cylinders are made, and for each batch (minimum) or every 38.2 cubic meters 50 cubic yards (maximum) of concrete.

3.8.2 Hardened Concrete Properties

**************************************************************************

NOTE: The Engineer of Record must specify the frequency of testing during the construction phase. Sufficient testing must be done to maintain confidence that the concrete, as delivered and placed, remains consistent. For example: sample and test every 75 cubic meters 100 cubic yards for the first 382 cubic meters 500 cubic yards, then every 382 cubic meters 500 cubic yards once confidence is established in uniformity. However, this is only a guideline, and the owner and Engineer of Record should agree on the frequency of sampling as best suits the particulars of each project and budget.

For example, a sampling interval for a new pier may be as follows:

- During the first week of casting piles
- During the second week of casing piles
- Midway through the casting of all piles
- During the final week of casting piles
- At the first pile cap and every tenth bent thereafter
- During the two first concrete deck pours
- During the final concrete deck pour

**************************************************************************

Sample and test each lot at [75] cubic meters [100] cubic yards for the first [382] cubic meters [500] cubic yards, then every [382] cubic meters [500] cubic yards thereafter.

Cast and cure specimens in accordance with ASTM C172/C172M, ASTM C31/C31M, and applicable requirements of ACI 305R and ACI 306R.

For each lot, record the date and time sampled, the batch ticket code, cylinder ID code the location of placement, total volume of concrete represented by the sample, and fresh concrete properties; ASTM C143/C143M for slump or ASTM C1611/C1611M for slump flow and visual stability index (VSI), ASTM C231/C231M for air content, ASTM C1064/C1064M for temperature, and ASTM C138/C138M unit weight.

For each lot sample, cast twelve 150 by 300 mm 6 by 12 inch cylinder specimens for strength and three 100 by 200 mm 4 by 8 inch cylinder specimens for chloride ion penetration testing. These cylinders shall be wrapped completely with slightly damped paper towels with water only. The wrapped cylinders shall be placed in either a vacuum package or double layers of sealed plastic bags. Package cylinders to prevent damage and ship to the approved testing laboratory.

In the event quality acceptance test results and retest results fail to
meet the quality acceptance criteria, the entire lot shall be considered non-conforming material, refer to the paragraph REPAIR, REHABILITATION and REMOVAL.

3.8.2.1 Compressive Strength Tests

**************************************************************************
NOTE: When the same mix design is used for multiple elements such as slabs, beams, and walls, the design element type may be specified in addition to the mix design to better identify deficient concrete.
**************************************************************************

ACI 214R tests for strength - conduct strength tests of concrete during construction in accordance with the following procedures:

a. Test cylinders in accordance with ASTM C39/C39M. Test three cylinders at 3 days, three cylinders at 7 days, and three cylinders at the age when the compressive strength requirement was specified. Hold the remaining three cylinders in storage. If one specimen in a test shows evidence of improper sampling, molding or testing, discard the specimen and consider the strength of the remaining cylinder to be the test result. If more than one specimen shows excess defects, the Contracting Officer may allow the entire test to be discarded. Test results shall not exceed the specified compressive strength by more than 20 percent for the age specified.

b. If the average strength test results are less than the specified strength (f'c) extract three core samples from the structure in accordance with ASTM C42/C42M, from the area that correlates to the low test results. These extracted cores shall not contain steel reinforcing. Repair core holes with non-shrink grout. Match color and finish of adjacent concrete. For concrete not meeting strength criteria, the Contractor shall prepare a remediation strategy for the review by the Contracting Officer.

c. Strength test reports shall be provided within 7 days of test completion.

3.8.2.2 Chloride Ion Penetration Test

Test cylinder concrete for chloride ion penetration at 56 days. Concrete representative of the tested concrete with values greater than the quality acceptance values determined in Table 1, will require retesting using spare samples. If the retest exceeds the quality acceptance limit, this shall be grounds to stop concrete placement and to review quality control issues.

3.8.2.3 Chloride Ion Concentration

Comply with ACI 318M Table 1. Determine water soluble chloride ion concentration. Perform test once for each mix design.

3.8.2.4 Anti-Washout Admixture

Comply with COE CRD-C 61. Determine cumulative mass loss. Perform test once for each 267.6 cubic meters 350 cubic yards of underwater concrete.
3.8.2.5 Non-Destructive Tests

Use of a rebound hammer to obtain data on the strength of the concrete surface shall be in accordance with ASTM C805/C805M. Test results from the rebound hammer and other non-destructive testing may be helpful in selecting areas to extract concrete cores for destructive testing.

3.8.3 Core Samples and Compressive Strength Testing

Obtain and test cores in accordance with ASTM C42/C42M.

If concrete in the structure is dry under service conditions, air dry cores (temperature 16 to 27 degrees C 60 to 80 degrees F, relative humidity less than 60 percent) for 7 days before testing and test dry. Otherwise, test the cores, after moisture conditioning, in accordance with ASTM C42/C42M.

Acceptance criteria for cylinder compressive strength are provided in paragraph ACCEPTANCE OF CONCRETE STRENGTH.

Take at least three representative cores from each member or area of concrete in place that is considered potentially strength deficient. Impair the strength of the structure as little as possible. If, before testing, extracted cores show evidence of having been damaged subsequent to or during removal from the structure, take replacement cores.

Fill core holes with low slump concrete or mortar of a strength equal to or greater than the original concrete.

The Contracting Officer will evaluate and validate core tests in accordance with the specified procedures.

3.8.4 Acceptance of Concrete Strength

3.8.4.1 Standard Molded and Cured Strength Specimens

The acceptance of concrete strengths shall be based on averages of results from three consecutive compressive strength tests. When the averages of all sets of three consecutive compressive strength test results are between 1.0 and 1.2 times the field test strength (fcr), and no individual strength test falls below fcr by more than 3.45 MPa 500 psi, the strength of the concrete is satisfactory. These criteria also apply when accelerated strength testing is specified unless another basis for acceptance is specified.

3.8.4.2 Non-Destructive Tests

Non-destructive tests may be used when permitted to evaluate concrete where standard molded and cured cylinders have yielded results not meeting the criteria.

3.8.4.3 Extracted Core Tests

When the average compressive strengths of the representative cores are between 0.85 fcr and 1.2 fcr and if no single core is less than 0.75 fcr, the strength of concrete is satisfactory.

3.8.5 Inspection

ACI 311.4R. Inspect concrete placed under water with qualified divers.
3.9 REPAIR, REHABILITATION AND REMOVAL

Before the Owner accepts the structure and final payment is made the Contractor shall inspect the structure for cracks, damage, and substandard concrete placements that may adversely affect the service life of the structure. A report documenting these defects shall be prepared that includes recommendations for repair, removal and/or remediation which, will be reviewed by the agency's Subject Matter Expert in Concrete Materials and submitted to the Contracting Officer for approval before any corrective work is accomplished.

3.9.1 Crack Repair

Prior to final acceptance, all cracks in excess of 0.50 mm 0.02 inches wide shall be documented and repaired. The proposed method and materials to repair the cracks shall be submitted to the Contracting Officer for approval. The proposal shall address the amount of movement expected in the crack due to temperature changes and loading.

3.9.2 Repair of Weak Surfaces

Weak surfaces are defined as mortar-rich, rain-damaged, uncured, or containing exposed voids or deleterious materials. Concrete surfaces with weak surfaces less than 6 mm 1/4 inch thick shall be diamond ground to remove the weak surface. Surfaces containing weak surfaces greater than 6 mm 1/4 inch thick shall be removed and replaced or mitigated in a manner acceptable to the Contracting Officer.

3.9.3 Failure of Quality Assurance Test Results

**************************************************************************
NOTE: Test results accomplished on concrete samples during concrete production that fall short of the acceptance criteria alert the Contractor to something in the production and placement process that has drifted out of calibration or that an error has been made. The goal is to track down the problem and correct it as quickly as possible. Unless the concrete producer makes a large error in batching or in placing, the chance that hardened concrete needs to be removed is remote. Removal and replacement is a last resort.
**************************************************************************

Proposed mitigation efforts by the Contractor to restore the original design intent shall be reviewed by the agency's Subject Matter Expert in Concrete Materials and approved by the Contracting Officer prior to proceeding.

NOTE: This guide specification covers the requirements for cast-in-place architectural concrete. Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1 GENERAL

1.1 REFERENCES

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.
References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

AMERICAN CONCRETE INSTITUTE (ACI)

ACI 211.2 (1998; R 2004) Standard Practice for Selecting Proportions for Structural Lightweight Concrete

ACI 301M (2016) Metric Specifications for Structural Concrete

ACI 318 (2019; R 2022) Building Code Requirements for Structural Concrete (ACI 318-19) and Commentary (ACI 318R-19)

ACI 318M (2014; ERTA 2015) Building Code Requirements for Structural Concrete & Commentary

ACI 347R (2014; Errata 1 2017) Guide to Formwork for Concrete

ASTM INTERNATIONAL (ASTM)

1.2 SYSTEM DESCRIPTION

All materials, procedures, and requirements specified in Section 03 30 00 CAST-IN-PLACE CONCRETE fully apply to cast-in-place architectural concrete, except as otherwise specified.

1.2.1 Concrete Mix Design

NOTE: If it is determined that the concrete mix requires plasticizers, the requirements will be added in this paragraph. Slumps for plasticized concrete may range as high as 250 mm 10 inches.
Design the concrete mix in accordance with ACI 211.1 and ACI 211.2 including consideration of the finishes required.

1.2.2 Formwork Design

Design formwork conforming to ACI 301MACI 301 and ACI 347R.

1.3 SUBMITTALS

**************************************************************************

NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.

SD-04: The materials used in architectural concrete vary from one project to another. For most projects, samples for all materials are not required. A list of suggested samples is given below:

Form Ties
Form Liners
Cement Colors
Coarse Aggregates
Reinforcing Chairs
Sample panels should not be required for small projects.
Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-02 Shop Drawings

Detail Drawings.

SD-04 Samples

Materials

Panels

1.4 QUALITY ASSURANCE

1.4.1 Detail Drawings

Submit detail drawings conforming to ACI SP-66 and ACI 318M ACI 318. Show location of cast-in-place elements in the work, building elevations, formwork fabrication details, reinforcements, embedments, dimensions, concrete strength, interface with adjacent materials, and special placing instructions, in sufficient detail to cover fabrication, placement, stripping, and finishing.

1.4.2 Panels

Provide sample panels 1.8 m 6 feet long and 1.2 m 4 feet high with the thickness to match building conditions for each type of architectural concrete and finish, located where directed. Panel forms include a typical joint between form panels, form tie conditions and finishes. Protect panels from weather, and other damage until acceptance of work. Use sample panels as job standards throughout construction. Submit a sample panel for approval.

PART 2 PRODUCTS

2.1 MATERIALS

Submit samples of materials listed below, indicating sizes, shapes, finishes, color, and pertinent accessories: [____].

2.1.1 Aggregates

******************************************************************************
NOTE: If a specific type or size of aggregate is required for a desired finish, whether it be for a facing mix or the entire thickness, the additional requirements will be added in this paragraph.
******************************************************************************

Provide aggregates conforming to [____].
2.1.2 Reinforcing Steel

Provide galvanized reinforcing steel if clearance to an exterior face is 25 mm 1 inch or less.

2.1.3 Tie Wire

Provide soft monel or 18-8 stainless steel tie wire.

2.1.4 Plates, Angles, Anchors, and Embedments

Provide plates, angles, anchors, and embedments conforming to ASTM A36/A36M, and prime paint with inorganic zinc primer.

2.1.5 Formwork

Use approved formwork for special effects.

2.1.6 Form Release Agents

Provide manufacturer's standard form release agents that are nonstaining, nonpetroleum based, and compatible with surface sealer finish coating.

2.1.7 Surface Sealer

Provide surface sealer consisting of methyl methacrylate polymer acrylic emulsion, clear color.

PART 3 EXECUTION

3.1 FORMWORK ERECTION

Erect formwork in accordance with the detail drawings to ensure that the finished concrete members conform accurately to the indicated dimensions, lines, elevations, and finishes. Deflection exceeding 1/360th of each component span or distance between adjacent supports is not acceptable. Cumulative deflections and tolerance is not acceptable. Install form lines as necessary to provide the required finish. Coat forms with form release agents before reinforcement is placed. Provide formwork conforming to ACI 301MACI 301 and ACI 347R.

3.2 CONCRETE FINISHES

**************************************************************************
NOTE: The types of possible finishes for concrete faces are virtually limitless. The requirements for the project will be specified in this paragraph.
**************************************************************************

Concrete finishes must conform to the approved finishes. Accomplish finishing at the time of concrete placement or immediately after formwork removal, as follows:

a. Smooth finish: (1) As cast using flat smooth nonporous forms. (2) As cast using fluted, sculptured, board finish or textured form liners.

b. Textured finish: (1) Textured form liners applied to inside of forms. (2) Distress finish by breaking off portion of face of raised portion of unit.
c. Exposed aggregate finish: (1) Finish obtained by applying even coat of retardant to face of form, removing forms after concrete hardens, and exposing coarse aggregate to a depth of [_____] mm inches by washing and brushing or lightly sandblasting away surface mortar. (2) Finish obtained by treating surface of unit with brushes which have been immersed in acid solution.

Use the following procedures for cast-in-place concrete elements which are to have a finish other than the surface produced from standard formwork: [______].

3.3 JOINT SEALING

Perform joint sealing as specified in Section 07 92 00 JOINT SEALANTS.

3.4 CLEANING

No sooner than 72 hours after joints are sealed, wash down, clean with soap and apply water with a soft bristle brush to faces and other exposed surfaces of cast-in-place concrete, then wash down again with clean water, or clean by other approved procedures. Consider discolorations which cannot be removed by these procedures defective work. Perform cleaning work when temperature and humidity conditions are such that surfaces dry rapidly. Take care during cleaning operations to protect adjacent surfaces from damage.

3.5 SURFACE SEALING

After cleaning, give indicated exterior exposed architectural concrete surfaces one coat of surface sealer, spray apply unless otherwise approved. Protect adjacent surfaces to prevent damage from the surface sealer.

3.6 PROTECTION OF WORK

Protect work against damage from subsequent operations.

3.7 DEFECTIVE WORK

Repair or replace defective work, as directed, using approved procedures.

2.1 SYSTEM DESCRIPTION
   - 2.1.1 Design of Preplaced Aggregate
   - 2.1.2 Maximum Water-Cement Ratio (W/C)
2.2 MATERIALS
   - 2.2.1 Cementitious Materials
     - 2.2.1.1 Portland Cement
     - 2.2.1.2 Pozzolan
     - 2.2.1.3 [Ground Granulated Blast-Furnace Slag]
   - 2.2.2 Aggregates
     - 2.2.2.1 Listed Sources
     - 2.2.2.2 Fine-Aggregate Grading
     - 2.2.2.3 Coarse-Aggregate Grading
     - 2.2.2.4 Coarse-Aggregate Particle Shape
     - 2.2.2.5 Concrete Aggregate Sources
       - 2.2.2.5.1 List of Sources
       - 2.2.2.5.2 Selection of Source
     - 2.2.2.6 Coarse-Aggregate Quality
   - 2.2.3 Chemical Admixtures
2.2.3.1 Air-Entraining Admixture
2.2.3.2 Grout Fluidifier
2.2.3.3 Water-Reducing or Retarding Admixtures
2.2.4 Curing Materials
2.2.4.1 Impervious-Sheet Curing Materials
2.2.4.2 Membrane-Forming Curing Compound
2.2.4.3 Burlap
2.2.5 Water
2.2.6 Nonshrink Grout

2.3 GROUT MIXTURE PROPORTIONING
2.3.1 Quality of Mixture
2.3.2 Air Content
2.3.3 Grout Flow

2.4 EQUIPMENT
2.4.1 Capacity
2.4.2 Batching Equipment
2.4.2.1 Scales
2.4.2.2 Batching Tolerances
2.4.2.2.1 Tolerances on Mass
2.4.2.2.2 Volumetric Tolerances
2.4.2.3 Grout Mixer
2.4.2.4 Agitator Tank
2.4.2.5 Grout Pump
2.4.3 Grout Pipe System
2.4.3.1 Delivery Pipes
2.4.3.2 Grout Insert Pipes
2.4.3.3 Sounding Wells

PART 3 EXECUTION

3.1 PREPARATION FOR PLACEMENT
3.1.1 Embedded Items
3.1.2 Concrete on Earth Foundations
3.1.3 Concrete on Rock Foundations
3.1.4 Underwater Placement
3.1.5 Concrete Surfaces
3.1.6 Construction Joint Treatment
3.1.6.1 Joint Preparation
3.1.6.2 Air-Water Cutting
3.1.6.3 High-Pressure Water Jet
3.1.6.4 Wet Sandblasting
3.1.6.5 Waste Disposal
3.2 COARSE-AGGREGATE AND GROUT PLACEMENT
3.2.1 Coarse-Aggregate Washing and Screening
3.2.2 Transporting and Placing Coarse Aggregate
3.2.3 Cold-Weather Placing of Preplaced-Aggregate Concrete
3.2.4 Hot-Weather Placing of Preplaced-Aggregate Concrete
3.2.5 Grout Mixing and Pumping
3.2.5.1 Charging Sequence
3.2.5.2 Mixing Time
3.2.5.3 Pumping Procedure
3.2.5.4 Blocked Pipes
3.2.5.5 Placing Temperature
3.3 FINISHING
3.3.1 Formed Top Surface
3.3.2 Screeded or Trowelled Surface
3.4 CURING AND PROTECTION
3.4.1 Duration
3.4.2 Moist Curing
3.4.3 Curing with Membrane-Forming Curing Compound
   3.4.3.1 Pigmented Curing Compound
   3.4.3.2 Nonpigmented Curing Compound
   3.4.3.3 Application
3.4.4 Impervious-Sheet Curing
3.4.5 Cold-Weather Curing and Protection
3.4.6 Appearance

3.5 TESTING AND QUALITY VERIFICATION FOR CONTRACTOR QUALITY CONTROL

3.5.1 General
3.5.2 Testing and Inspection Requirements
   3.5.2.1 Fine Aggregate
      3.5.2.1.1 Grading
      3.5.2.1.2 Corrective Action for Fine-Aggregate Grading
      3.5.2.1.3 Moisture Content Testing
      3.5.2.1.4 Moisture Content Corrective Action
   3.5.2.2 Coarse Aggregate
      3.5.2.2.1 Grading
      3.5.2.2.2 Corrective Action for Grading
   3.5.2.3 Quality of Aggregates
      3.5.2.3.1 Frequency of Quality Tests
      3.5.2.3.2 Corrective Action for Aggregate Quality
   3.5.2.4 Scales
      3.5.2.4.1 Accuracy in Determination of Mass
      3.5.2.4.2 Scales Corrective Action
   3.5.2.5 Grout Plant Control
   3.5.2.6 Grout Mixture
      3.5.2.6.1 Air-Content Testing
      3.5.2.6.2 Air-Content Corrective Action
   3.5.2.7 Test for Grout Flow
      3.5.2.7.1 Tests
      3.5.2.7.2 Grout Flow Corrective Action
      3.5.2.7.3 Temperature
      3.5.2.7.4 Compressive-Strength Specimens
   3.5.2.8 Inspection Before Pumping Grout
   3.5.2.9 Grout Pumping
      3.5.2.9.1 Placing Inspection
      3.5.2.9.2 Pumping Corrective Action
   3.5.2.10 Curing
      3.5.2.10.1 Moist-Curing Inspections
      3.5.2.10.2 Moist-Curing Corrective Action
      3.5.2.10.3 Membrane-Curing Inspection
      3.5.2.10.4 Membrane-Curing Corrective Action
      3.5.2.10.5 Sheet-Curing Inspection
      3.5.2.10.6 Sheet-Curing Corrective Action

ATTACHMENTS:

concrete aggregates sources

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for furnishing, hauling, and preplacing aggregate concrete incidental to the drilling and the grouting. This section was originally developed for USACE Civil Works projects.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1  GENERAL

NOTE: The content of this specification is such that guidance given in EM 1110-2-2000, "Standard Practice for Concrete", is applicable.

1.1  UNIT PRICES

NOTE: If Section 01 20 00 PRICE AND PAYMENT PROCEDURES is included in the project specifications, this paragraph title (UNIT PRICES) should be deleted from this section and the
remaining appropriately edited subparagraphs below should be inserted into Section 01 20 00.

1.1.1 Payment

Payment will be made for all costs associated with unloading, handling, and storage of all aggregate, cement, [pozzolan,] fluidifier, and chemical admixture used in the work, including all costs of labor and the use of all equipment, tools, 150 by 300 mm 6 by 12 inch cylinder molds, and other materials required to complete the work, excluding cost of reinforcement and embedded parts which are specified to be paid for separately.

1.1.2 Measurement

Preplaced-Aggregate Concrete will be measured for payment based on the actual volume placed within the paylines of the structures as indicated.

1.1.3 Unit of Measure

Unit of measure: cubic meter yard.

1.2 REFERENCES

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

1.3 SUBMITTALS

NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

1.4 QUALITY ASSURANCE

The individuals who sample and test concrete or the constituents of concrete as required in this specification have demonstrated a knowledge and ability to perform the necessary test procedures equivalent to the ACI minimum guidelines for certification of Concrete Field Testing Technicians, Grade I. The individuals who perform the inspection of concrete construction have demonstrated a knowledge and ability equivalent to the ACI minimum guidelines for certification of [Concrete Transportation Construction Inspector (CTCI)] [Concrete Construction Inspector (CCI)], Level II.

1.4.1 Government Preconstruction Sampling and Testing

1.4.1.1 Aggregates

********************************************************************************************
NOTES: The Designer should consult the appropriate DM, identify the sources for aggregates, and include them in the Aggregate Sources Template attached to the end of this section. Contact the Division Laboratory for information to fill in the blanks below.
********************************************************************************************

The aggregate sources listed at the end of this section have been tested and, at the time testing was performed, were capable of producing materials
of a quality required for this project, provided suitable processing is performed. The Contractor may furnish materials from a listed source or from a source not listed. Deliver samples from any source of coarse aggregate and any source of fine aggregate, consisting of not less than [70] [_____] kg [150] [_____] pounds of each coarse aggregate and [35] [_____] kg [75] [_____] pounds taken under the supervision of the Contracting Officer in accordance with COE CRD-C 100 to [_____] within 15 days after notice to proceed. Sampling and shipment of samples is at the Contractor's expense. [_____] days will be required to complete evaluation of the aggregates. Testing will be performed by and at the expense of the Government in accordance with COE CRD-C 114 or ASTM test methods. The cost of testing one source for each size of aggregate will be borne by the Government. If the Contractor selects more than one source for each aggregate size or selects a substitute source for any size aggregate after the original source was tested, the cost of that additional testing will be borne by the Contractor. Tests to which aggregate may be subjected are listed in paragraph QUALITY OF AGGREGATES in PART 3. Provide material from the proposed source meeting the quality requirements of this paragraph. The Government's test data and other information on aggregate quality of those sources listed at the end of this section are included in the Design Memorandum and are available for review in the district office. Quality Assurance testing of aggregates by the Government does not relieve the Contractor of quality control requirements as outlined in paragraph TESTING AND QUALITY VERIFICATION FOR CONTRACTOR QUALITY CONTROL in PART 3.

1.4.1.2 Cementitious Materials, Admixtures, and Curing Compound

**************************************************************************
NOTE: When the optional sentence below is deleted, the corresponding manufacturer's certification should be used. EM 1110-2-2000, "Standard Practice for Concrete", provides guidance in selecting the options for Government or for Contractor testing.
**************************************************************************

At least 60 days in advance of concrete placement, notify the Contracting Officer of the source of materials, along with sampling location, brand name, type, and quantity to be used in the manufacture and/or curing of the concrete. [Sampling and testing will be performed by and at the expense of the Government except as otherwise specified. Do not use material until notice has been given by the Contracting Officer that test results are satisfactory. Submit samples of materials for Government testing and approval. The Government will sample and test other chemical admixtures, curing compounds, and cementitious materials].

a. Chemical Admixtures - Retest chemical admixtures that have been in storage at the project site for longer than 6 months or that have been subjected to freezing at the expense of the Contractor when directed by the Contracting Officer and reject if test results are not satisfactory. Chemical admixtures will be accepted based on compliance with the requirements in paragraph CHEMICAL ADMIXTURES in PART 2.

[ b. Cement and Pozzolan - If cement or pozzolan is to be obtained from more than one source, state the estimated amount to be obtained from each source and the proposed schedule of shipments in the initial notification.]

**************************************************************************
NOTE: Delete this paragraph if materials are to be
accepted on the basis of a manufacturer's certification of compliance and mill test reports. See the appropriate DM or consult the Materials Engineer to select prequalified sources, (1) and (2), sealed bins, (3) and (4), or both options, (1), (2), (3), and (4). Selection of the sealed bin method, subparagraphs (3) and (4), must be fully justified in the appropriate DM.

**************************************************************************

(1) Prequalified Cement Sources: Deliver and use cement directly from a mill of a producer designated as a qualified source. Samples of cement for check testing will be taken at the project site or concrete-producing plant by a representative of the Contracting Officer for testing at the expense of the Government. A list of prequalified cement sources is available from Director, U.S. Army Engineer Waterways Experiment Station (USACE-WES), 3909 Halls Ferry Road, Vicksburg, MS 39180-6199, ATTN: CEWES-SC.

(2) Prequalified Pozzolan Sources: Deliver and use pozzolan directly from a producer designated as a qualified source. Samples of pozzolan for check testing will be taken at the project site by a representative of the Contracting Officer for testing at the expense of the Government. A list of prequalified pozzolan sources is available from the Director, USACE-WES, 3909 Halls Ferry Road, Vicksburg, MS 39180-6199, ATTN: CEWES-SC.

(3) Nonprequalified Cement Sources: Cement, if not from a prequalified source, will be sampled at the source and stored in sealed bins pending completion of testing. Sampling, testing, and the shipping inspection from the point of sampling, when the point is other than at the site of the work, will be made by or under the supervision of the Government and at its expense. Do not use cement until notice has been given by the Contracting Officer that test results are satisfactory. In the event of failure, the cement may be resampled and tested at the Contractor's request and expense. When the point of sampling is other than at the site of the work, the fill gates of the sampled bin and conveyances used in shipment will be sealed under Government supervision and kept sealed until shipment from the bin has been completed. If tested cement is rehandled at transfer points, the extra cost of inspection is at the Contractor's expense. The cost of testing cement excess to project requirements is also at the expense of the Contractor. The charges for testing cement at the expense of the Contractor will be deducted from the payments due the Contractor at a rate of [_____] dollars per ton of cement represented by the tests.

**************************************************************************

NOTE: To fill in the blank for cost of testing excess cement, contact the Structures Laboratory, Concrete Technology Division, WES.

**************************************************************************

(4) Nonprequalified Pozzolan Sources: Pozzolan, if not from a prequalified source, will be sampled at the source and stored in sealed bins pending completion of certain tests. Pozzolan will also be sampled at the site when determined necessary. All sampling and testing will be by and at the expense of the
Government. Release for shipment and approval for use will be based on compliance with 7-day lime-pozzolan strength requirements and other physical and chemical and uniformity requirements for which tests can be completed by the time the 7-day lime-pozzolan strength test is completed. Release for shipment and approval for use on the above basis will be contingent on continuing compliance with the other requirements of the specifications. If a bin fails, the contents may be resampled and tested at the Contractor's expense. In this event, the pozzolan may be sampled as it is loaded into cars, trucks, or barges provided they are kept at the source until released for shipment. Unsealing and resealing of bins and sealing of shipping conveyances will be done by or under the supervision of the Government. Shipping conveyances will not be accepted at the site of the work unless received with all seals intact. If pozzolan is damaged in shipment, handling, or storage, promptly remove it from the site of the work. Retest pozzolan that has not been used within 6 months after testing at the expense of the Contractor when directed by the Contracting Officer and reject if the test results are not satisfactory. If tested pozzolan is rehandled at transfer points, the extra cost of inspection is at the Contractor's expense. The cost of testing excess pozzolan is at the Contractor's expense at a rate of [_____] cents per ton of pozzolan represented by the test. The amount will be deducted from payment to the Contractor.]

1.4.2 Construction Testing by Government

The Government will sample and test aggregates, grout, and preplaced-aggregate concrete to determine compliance with the specifications. Provide facilities and labor as may be necessary for procurement of representative test samples. Samples of aggregates will be obtained at the point of placement in accordance with COE CRD-C 100. Grout will be sampled after the agitator and tested for flow in accordance with ASTM C939/C939M and air content in accordance with ASTM C231/C231M. Unconfined compressive strength test specimens will be made and cured in accordance with ASTM C943 and tested in accordance with ASTM C39/C39M.

PART 2 PRODUCTS

2.1 SYSTEM DESCRIPTION

Provide steel bars, welded steel wire fabric and accessories for concrete reinforcement in compliance with Section 03 30 00 CAST-IN-PLACE CONCRETE. Provide concrete formwork complying with Section 03 30 00 CAST-IN-PLACE CONCRETE.

2.1.1 Design of Preplaced Aggregate

**************************************************************************
NOTE: Consult the Structural Design Engineer and the appropriate DM to fill in the blanks.
**************************************************************************

Specified compressive strength is as follows:
2.1.2 Maximum Water-Cement Ratio (W/C)

NOTE: Consult EM 1110-2-2000 and the appropriate DM to fill in the blanks and to select the appropriate W/C. When cementitious materials other than portland cement are used, see paragraph GROUT MIXTURE PROPORTIONING in PART 2 for definitions of W/C.

Maximum W/C is as follows:

<table>
<thead>
<tr>
<th>WATER-CEMENT RATIO, BY MASS</th>
<th>STRUCTURE OR PORTION OF STRUCTURE</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.40</td>
<td>[_____]</td>
</tr>
<tr>
<td>0.45</td>
<td>[_____]</td>
</tr>
<tr>
<td>0.50</td>
<td>[_____]</td>
</tr>
<tr>
<td>0.55</td>
<td>[_____]</td>
</tr>
<tr>
<td>0.60</td>
<td>[_____]</td>
</tr>
<tr>
<td>0.65</td>
<td>[_____]</td>
</tr>
</tbody>
</table>

These W/Cs may cause higher strengths than required by above paragraph.

2.2 MATERIALS

2.2.1 Cementitious Materials

NOTE: See the appropriate DM to select the proper requirements for the Cementitious Materials Options. Other cementitious materials may be added if specifically recommended and approved in the concrete materials DM.

Delete the requirements for certificates for air-entraining admixtures, other chemical admixtures, curing compounds, portland cement, and
Provide cementitious materials that is portland cement or portland cement in combination with pozzolan [or [____]] and conforming to appropriate specifications listed below. Do not use cementitious materials until notice of acceptance has been given by the Contracting Officer. Cementitious materials will be subject to check testing from samples obtained at the mill, at transfer points, or at the project site, as scheduled by the Contracting Officer, and such sampling will be by or under the supervision of the Government at its expense. Promptly remove material not meeting specifications from the site of work. Submit manufacturer's certification of compliance, accompanied by mill test reports attesting that materials meet the requirements of the specification under which they are furnished. Provide certification and mill test reports that are from samples taken from the particular lot furnished. Submit certificate of compliance for the following: Impervious-Sheet Curing Materials, Air-Entraining Admixture, Nonshrink Grout, Grout Fluidifier, and Membrane-Forming Curing Compound.

2.2.1.1 Portland Cement

ASTM C150/C150M, Type I or II, except that the maximum amount of tricalcium aluminate (C3A) in Type I cement consisting of 15 percent [including the heat of hydration at 7 days] [including false set requirements] [low alkali when used with aggregates listed at the end of this section which require it.] [In lieu of low-alkali cement, the Contractor may use a combination of portland cement that does not meet the low-alkali requirement with a pozzolan or slag provided the following requirement is met. The expansion of the proposed combination when tested in accordance with ASTM C441/C441M must be equal to or less than the expansion of a low-alkali cement meeting the requirements of ASTM C150/C150M when tested in general conformance with ASTM C441/C441M. Run the expansion tests concurrently at an independent laboratory that is nationally recognized to perform such tests. The Government reserves the right to confirm the test results and to adjust the percentage of pozzolan or slag in the combination to suit other requirements.]

2.2.1.2 Pozzolan

Provide pozzolan conforming to ASTM C618, Class [C], [F], [N], with the optional requirements for multiple factor, drying shrinkage, and uniformity [and [moderate] [severe] sulfate resistance requirements] of Table 2A. Table 1A requirement for maximum alkalis applies when used with aggregates listed at the end of this section to require low-alkali cement.

2.2.1.3 [Ground Granulated Blast-Furnace Slag]

Provide ground granulated blast-furnace slag conforming to ASTM C989/C989M, Grade [____].]

2.2.2 Aggregates

**************************************************************************

NOTE: This note may be disregarded for regions where Alkali-Silica Reactivity (ASR) is not a concern. Some aggregate sources may exhibit an ASR
Potential. ASR is a potentially deleterious reaction between alkalis present in concrete and some siliceous aggregates, reference EM 1110-2-2000 paragraph 2-3b(6) and appendix D. Where ASR is known or suspected to pose a concern for concrete durability, it is recommended that aggregates proposed for use in concrete be evaluated to determine ASR potential and an effective mitigation. EM 1110-2-2000, provides recommendations for evaluating and mitigating ASR in concrete mixtures. Aggregate evaluations may not be practical for projects requiring small quantities of concrete (less than 200 cubic meters 250 cubic yards).

Section 32 13 14.13 CONCRETE PAVING FOR AIRFIELDS AND OTHER HEAVY DUTY PAVEMENTS, paragraph Alkali-Silica Reactivity, provides a specification method for the Contractor to evaluate and mitigate ASR in concrete mixtures. The expansion limits specified in Section 32 13 14.13 are requirements for pavements and exterior slab construction. For structural concrete applications the measured expansion must be less than 0.10 percent. It may not be economical or practical to specify different test limit requirements for use on the same project. In which case the lower limit required by the application should be used.

The designer may use the specification method in Section 32 13 14.13 by incorporating the relevant paragraphs into this specification, or may use the following requirements (retain either the 0.10 or the 0.08 percent expansion limits as appropriate) included in the paragraph below. Delete the following paragraph if not required in the project.

Alkali-Silica Reactivity: Test and evaluate fine and coarse aggregates proposed for use in concrete for alkali-aggregate reactivity in accordance with ASTM C1260. Evaluate the fine and coarse aggregates separately and in combination, matching the Contractor's proposed mix design proportioning. All results of the separate and combination testing must have a measured expansion less than 0.10 (0.08) percent at 16 days after casting. Should the test data indicate an expansion of 0.10 (0.08) percent or greater, reject the aggregate(s) or perform additional testing using ASTM C1260 and ASTM C1567. Perform the additional testing using ASTM C1260 and ASTM C1567 using the low alkali portland cement in combination with ground granulated blast furnace (GGBF) slag, or Class F fly ash. Use GGBF slag in the range of 40 to 50 percent of the total cementitious material by mass. Use Class F fly ash in the range of 25 to 40 percent of the total cementitious material by mass.

2.2.2.1 Listed Sources

NOTE: The list of sources and required tests and test limits will be taken from the concrete materials DM.
Concrete aggregates may be furnished from any source capable of meeting the quality requirements as stated in paragraph QUALITY OF AGGREGATES in PART 3. The sources listed at the end of this section were evaluated during the design phase of the project in [_____] and were found at that time capable of meeting the quality requirements when suitably processed. No guarantee is given or implied that any of the listed sources are currently capable of producing aggregates that meet the required quality specified above. A Design Memorandum containing the results of the Government investigation and test results is available for review in the [_____] district office. Contact [_____] at [_____] to arrange for review of the memorandum. Consider the test results and conclusions valid only for the sample tested and do not take them as an indication of the quality of all material from a source nor for the amount of processing required.

2.2.2.2 Fine-Aggregate Grading

Provide grading and uniformity of the fine aggregate conforming to the following requirements as delivered to the grout mixer:

<table>
<thead>
<tr>
<th>U.S. STANDARD SIEVE SIZE</th>
<th>PERCENT BY MASS, PASSING</th>
</tr>

In addition to the grading limits specified above, provide fine aggregate with a fineness modulus of not less than 1.30 nor more than 2.10. Control the grading of the fine aggregate so that the fineness moduli of at least four of any five consecutive test samples does not vary more than 0.15 from the average fineness modulus of all samples previously taken.

2.2.2.3 Coarse-Aggregate Grading

Provide grading of the coarse aggregate conforming to the following requirements:

2.2.2.4 Coarse-Aggregate Particle Shape

The quantity of flat and elongated particles of the coarse aggregate, as defined and determined by ASTM D4791, must not exceed 25 percent.

2.2.2.5 Concrete Aggregate Sources

**************************************************************************
NOTE: If an aggregate source is provided by the Government, the appropriate paragraphs from Section 03 70 00 MASS CONCRETE should be used.
**************************************************************************

2.2.2.5.1 List of Sources

The concrete aggregates sources may be selected from sources listed at the end of this section.

2.2.2.5.2 Selection of Source

After the award of the contract, designate in writing only one source or combination of sources from which to furnish aggregates. If the Contractor proposes to furnish aggregates from a source or from sources not listed at the end of this section, designate only a single source or single combination of sources for aggregates. If a source for coarse or fine aggregates does not meet the quality requirements stated in paragraph QUALITY OF AGGREGATES in PART 3, the Contractor may not submit for approval other nonlisted sources but furnish the coarse or fine aggregate, as the case may be, from sources listed at the end of this section at no additional cost to the Government.

2.2.2.6 Coarse-Aggregate Quality

**************************************************************************
NOTES: The tests selected should be those which are applicable to the concrete to be used in the project. These tests may include those listed below in addition to others not listed. See Chapter 2 of EM 1110-2-2000 for discussion of tests.
**************************************************************************
A list of properties and test values are unique to each project and should be taken from the concrete materials design memorandum. Delete the quality tests not required in the DM.

Use the petrographic examination to identify deleterious substances in aggregates. List deleterious substances individually with respective limits.

Depending upon the quality of aggregates available, some tests may not be required. Refer to EM 1110-2-2000 for the purpose of each test.

Deliver aggregates to the mixer that meet the following requirements:

</table>
2.2.3 Chemical Admixtures

Use chemical admixtures, when required or permitted, conforming to the appropriate specification listed.

2.2.3.1 Air-Entraining Admixture

Provide air-entraining admixture conforming to ASTM C260/C260M.

2.2.3.2 Grout Fluidifier

Provide grout fluidifier conforming to ASTM C937.

2.2.3.3 Water-Reducing or Retarding Admixtures

Provide water-reducing or retarding admixtures meeting the requirements of ASTM C494/C494M, Type A, B, or D, except that the 6-month and 1-year compressive strength tests are waived.

2.2.4 Curing Materials

2.2.4.1 Impervious-Sheet Curing Materials

Provide impervious-sheet curing materials conforming to ASTM C171, type optional, except do not use polyethylene film.

2.2.4.2 Membrane-Forming Curing Compound

Furnish membrane-forming curing compound that meets the requirements of ASTM C309, Type 1-D or 2, except use a styrene acrylate or chlorinated rubber compound meeting Class B requirements for surfaces that are to be painted. Select curing compound that is compatible with any subsequent paint specified. Use nonpigmented compound containing a fugitive dye and has the reflective requirements in ASTM C309 waived.

2.2.4.3 Burlap

Use burlap for curing that conforms to AASHTO M 182.

2.2.5 Water

Use water for mixing and curing that is fresh, clean, potable, and free of injurious amounts of oil, acid, salt, or alkali, except that nonpotable water may be used if it meets the requirements of COE CRD-C 400.
2.2.6 Nonshrink Grout

Furnish nonshrink grout conforming to ASTM C1107/C1107M and is a commercial formulation suitable for the application proposed.

2.3 GROUT MIXTURE PROPORTIONING

Submit determined grout mixture proportions for review, including the quantities of all ingredients per cubic meter yard and stating the grading of the fine aggregate size that will be used in the manufacture of each quantity of concrete. Include test reports from a laboratory complying with ASTM C1077 which show that proportions thus selected will produce preplaced-aggregate concrete of the qualities indicated. Provide grout mixture proportioning meeting the following requirements:

2.3.1 Quality of Mixture

For each portion of the structure, select mixture proportions so that the strength and water-cement ratio requirements listed in paragraph DESIGN OF PREPLACED AGGREGATE in PART 1 are met. State the source of materials and proportions of portland cement, [pozzolan], fluidifier, fine aggregate, and water. Determine the grout proportions for the preplaced-aggregate concrete in accordance with ASTM C938. Use grout proportions for the preplaced-aggregate concrete meeting the specified strength as determined by specimens molded in accordance with ASTM C943 and tested in accordance with ASTM C39/C39M. Convert the maximum water-cement ratios required in paragraph MAXIMUM WATER-CEMENT RATIO (W/C) in PART 1 to a ratio by mass of water to cement plus pozzolan or GGBF slag by mass equivalency as described in ACI 211.1. In the case where GGBF slag is used, include the mass of the slag in the equations for the term P, which is used to denote the mass of pozzolan. If pozzolan is used in the concrete mixture, use pozzolan with a minimum pozzolan content that is 15 percent of the total cementitious material. Make no substitution in the source or type of materials used in the work without additional tests to show that the new quality of materials and concrete are satisfactory.

2.3.2 Air Content

The air content of the grout mixture as determined by ASTM C231/C231M within 15 minutes after mixing must be 9.0 plus or minus 1.0 percent.

2.3.3 Grout Flow

Use grout flow of 18.0 plus or minus 2.0 seconds when sampled from the agitator and test in accordance with ASTM C939/C939M.

2.4 EQUIPMENT

Submit data on the pumping equipment and methods for pumping and delivering the grout for preplaced-aggregate concrete for review by the Contracting Officer, including the methods for transporting, handling, and depositing the coarse aggregate, the location, arrangement, and size of the pipe and inserts, sequence of pumping, method of withdrawal of injection pipe, and the rate of grout injection. Also include methods for venting of air from under embedded projections.

2.4.1 Capacity

************************************************************************************************
Provide mixing and pumping equipment with a capacity of at least [_____] cubic meters yards per hour.

2.4.2 Batching Equipment

Mechanically batch all materials by mass except the water and admixture which may be batched by volume.

2.4.2.1 Scales

Use equipment for determining mass conforming to the applicable requirements of NIST HB 44, except that the accuracy must be plus or minus 0.2 percent of scale capacity. Provide standard test reference masses and any other auxiliary equipment required for checking the operating performance of each scale or other measuring devices. Make tests at the frequency required in paragraph TESTING AND QUALITY VERIFICATION FOR CONTRACTOR QUALITY CONTROL in PART 3, in the presence of a Government representative.

2.4.2.2 Batching Tolerances

2.4.2.2.1 Tolerances on Mass

<table>
<thead>
<tr>
<th>MATERIAL</th>
<th>PERCENT OF REQUIRED MASS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cementitious materials</td>

<td>Aggregate</td>
<td>plus or minus 2</td>
</tr>
<tr>
<td>Water</td>
<td>plus or minus 1</td>
</tr>
<tr>
<td>Chemical admixture</td>
<td>0 to plus 6</td>
</tr>
</tbody>
</table>

2.4.2.2.2 Volumetric Tolerances

For volumetric batching equipment, the following tolerances apply to the required volume of material being batched: Water: plus or minus 1 percent. Chemical admixtures: Zero to plus 6 percent.

2.4.2.3 Grout Mixer

Provide a machine especially designed for the mixing of grout, capable of mixing grout mechanically to a uniform consistency. Maintain the mixer in satisfactory operating condition and kept free of hardened grout. Should any grout mixer at any time produce unsatisfactory results, promptly discontinue its use until the condition is corrected. Provide the grout
mixer with an acceptable device to lock the discharge mechanism until the required mixing time has elapsed. Use of revolving-drum concrete mixers will not be permitted. Submit Grout-mixer data including the make, type, and capacity of grout mixers, grout agitators, tank, pump, and pipe system proposed for producing the grout for preplaced-aggregate concrete.

2.4.2.4 Agitator Tank

Furnish agitator tank that has at least the same capacity as the mixer and equip to agitate the grout effectively and continuously. Pass all grout entering the tank through a wire sieve. A sieve size less than $4.75 \text{ mm}$ No. 4 and greater than $9.5 \text{ mm}$ is not permitted.

2.4.2.5 Grout Pump

Furnish grout pump that operates by positive displacement or progressive cavity. Equip the pump with a by-pass line connecting the discharge and inlet or provide circulation into the agitator for continuous operation if line blockage or temporary shutdown of grouting operation occurs. Install a pressure gauge on the pump discharge line to indicate incipient line blockage or a plugged insert pipe. Provide standby pumping equipment.

2.4.3 Grout Pipe System

2.4.3.1 Delivery Pipes

Provide main delivery line carrying grout from the grout pump to the vicinity of the insert pipes of such diameters that grout velocity at the planned operating rate will range between 0.6 and 1.2 meters 2 and 4 feet per second. All pipe fittings must be watertight. Provide unions for quick disconnect to facilitate pipe cleanup when required. A manifold system, in which more than one grout insert is operative at the same time, will not be permitted.

2.4.3.2 Grout Insert Pipes

Provide pipes that are $[19] [25] [40] \text{ mm} [3/4] [1] [1-1/2] \text{ inch}$ in diameter conforming to ASME B36.10M Schedule 40. Standard pipe couplings may be used if the couplings are to be withdrawn not more than $4.5 \text{ m} 15 \text{ feet}$ through the preplaced aggregate. Where pipe couplings are required for greater depths of preplaced aggregate, use flush-coupled pipe conforming to ASME B36.10M Schedule 160. Make connections between grout delivery hoses and insert pipes using quick-opening fittings. Quick-disconnect pneumatic fittings will not be permitted for this purpose. Provide valves in the pipe system that are plug or ball type, quick-opening, and which can be easily taken apart and cleaned. Stem lubricate valves over $25 \text{ mm} 1 \text{ inch}$ in diameter.

2.4.3.3 Sounding Wells

Provide sounding wells that are $50 \text{ mm} 2 \text{ inch}$ diameter steel pipe provided with milled (not burned) $13 \text{ mm} 1/2$-inch open slots $150 \text{ mm} 6$ inches long with $300 \text{ mm} 12$ inches between slots. Ream the pipe and remove burrs before installation. Equip the sounding line with a $25 \text{ mm} 1$ inch diameter float having a mass so as to sink in water, yet float on the grout surface within the slotted pipe.
PART 3   EXECUTION

3.1   PREPARATION FOR PLACEMENT

3.1.1   Embedded Items

Before placement of coarse aggregate for preplaced-aggregate concrete, take care to determine that all embedded items are firmly and securely fastened in place as indicated on the drawings, or required. Provide embedded items that are free of oil and other foreign matter such as loose coatings or rust, paint, and scale. The embedding of wood in concrete will be permitted only when specifically authorized or directed. Fill voids in sleeves, inserts, and anchor slots temporarily with readily removable materials to prevent the entry of grout into voids. Welding, including tack welding, will not be permitted on embedded metals within 600 mm 2 feet of the surface of the preplaced-aggregate concrete.

3.1.2   Concrete on Earth Foundations

**************************************************************************
NOTE: The Designer should insert the appropriate Section number and title below.
**************************************************************************

Use earth surfaces upon which preplaced-aggregate concrete is to be placed that are clean, damp, and free from debris, frost, ice, and standing or running water. Prior to placement of coarse aggregate, satisfactorily compact the earth foundation in accordance with the provisions of [Section 31 00 00 EARTHWORK] [______].

3.1.3   Concrete on Rock Foundations

Use rock surfaces upon which coarse aggregate for preplaced-aggregate concrete is to be placed that are clean, free from oil, standing or running water, ice, mud, drummy rock, coating, debris, and loose, semidetached, or unsound fragments. Clean joints in rock to a satisfactory depth, as determined by the Contracting Officer, and to firm rock on the sides. Immediately before the coarse aggregate is placed, clean all rock surfaces thoroughly by the use of air-water jets or sandblasting as defined in paragraph CONSTRUCTION JOINT TREATMENT below.

3.1.4   Underwater Placement

Place coarse aggregate for underwater preplaced-aggregate concrete on rock surfaces which are clean, free from drummy rock, coatings, debris, and loose semidetached or unsound fragments.

3.1.5   Concrete Surfaces

Use concrete surfaces on which coarse aggregate is to be placed or preplaced-aggregate concrete surfaces between stages that are clean and free from foreign material. Remove excessive accumulation of fine material on the surface with high-pressure water jets or other approved methods.

3.1.6   Construction Joint Treatment

3.1.6.1   Joint Preparation

   a. If grout in a preplaced-aggregate placement is not brought to the
surface in order to form a construction joint, stop the intrusion grout rise **300 mm 12 inches** below the aggregate surface. Do not allow dirt and debris to collect on the aggregate surface or to filter down to the grout surface. Pull the insert pipes just above the grout surface before the grout stiffens and rodded clear. When pumping is ready to resume, work the insert pipes back to near contact with the hardened grout surface and then slowly resume pumping for a few minutes.

b. Prepare preplaced-aggregate concrete in which the grout has been brought to the surface and any other concrete surfaces to which preplaced-aggregate concrete is to be bonded for receiving the next lift or adjacent preplaced-aggregate concrete by cleaning with air-water cutting, sandblasting, high-pressure water jet, or other approved method. Air-water cutting will not be permitted on formed surfaces or surfaces congested with reinforcing steel. Regardless of the method used, the resulting surfaces must be free from all laitance and inferior concrete so that clean, well-bonded coarse aggregate is exposed uniformly throughout the lift surface. Do not undercut the edges of the coarse aggregate. Wash clean the surface again as the last operation prior to placing the next lift.

3.1.6.2 Air-Water Cutting

Perform air-water cutting of a construction joint at the proper time and only on horizontal construction joints. Use an air pressure in the jet of **690 kPa 100 psi plus or minus 70 kPa 10 psi**, and use a sufficient water pressure to bring the water into effective influence of the air pressure. When approved by the Contracting Officer, a retarder complying with the requirements of **COE CRD-C 94** may be applied to the surface of the lift to prolong the period of time during which air-water cutting is effective. Prior to receiving approval, furnish samples of the material to be used and demonstrate the method to be used in applications. After cutting, wash and rinse the surface as long as there is any trace of cloudiness of the wash water. Where necessary to remove accumulated laitance, coatings, stains, debris, and other foreign material, high-pressure water jet or sandblasting will be required as the last operation before placing the next lift.

3.1.6.3 High-Pressure Water Jet

A stream of water under a pressure of not less than **20.7 MPa 3,000 psi** may be used for cleaning. Delay its use until the concrete is sufficiently hard so that only the surface skin or mortar is removed, and there is no undercutting of coarse-aggregate particles. If the water jet is incapable of a satisfactory cleaning, clean the surface by sandblasting.

3.1.6.4 Wet Sandblasting

This method may be used when the concrete has reached sufficient strength to prevent undercutting of the coarse-aggregate particles. Then wash the surface of the concrete thoroughly to remove all loose materials.

3.1.6.5 Waste Disposal

Use a method in disposing of waste water employed in cutting, washing, and rinsing of concrete surfaces such that the waste water does not stain, discolor, or affect exposed surfaces of the structures, or damage the environment of the project area. The method of disposal is subject to approval.
3.2 COARSE-AGGREGATE AND GROUT PLACEMENT

3.2.1 Coarse-Aggregate Washing and Screening

Wash, screen, and immediately saturate coarse aggregate before placement. Washing of the aggregate in the forms will not be permitted. If more than one size of coarse aggregate is used, weigh, batch, and mix the aggregate in the proper proportions onto the wash screen. The wash screen may be a vibrating deck or revolving.

3.2.2 Transporting and Placing Coarse Aggregate

Transport coarse aggregate to the forms and place in substantially horizontal layers by means which will prevent objectionable segregation and breakage. Remove foreign material and excessive accumulation of fine material on the lift surface before placing the next lift. Place coarse aggregate under water continuously in each stage or lift until placement in that stage or lift is completed. When the coarse aggregate is to be placed in the dry, there must be no vertical drop greater than 1.5 m 5 feet except where suitable equipment is provided to prevent breakage and segregation and where specifically authorized. Vehicle traffic on top of preplaced-coarse aggregate is not permitted.

3.2.3 Cold-Weather Placing of Preplaced-Aggregate Concrete

When the cold-weather placing of preplaced-aggregate concrete is likely to be subjected to freezing temperatures before the expiration of the curing period, place concrete in accordance with the approved procedures. Submit for approval the proposed materials, methods, and protection if preplaced-aggregate concrete is to be placed under cold-weather conditions. Use an ambient temperature of the space adjacent to the preplaced-aggregate concrete placement and surfaces to receive preplaced-aggregate concrete that is above 0 degrees C 32 degrees F. Use a placing temperature of the preplaced aggregate concrete having a minimum dimension less than 300 mm 12 inches between 13 and 24 degrees C 55 and 75 degrees F when measured in accordance with ASTM C1064/C1064M. Use a placing temperature of the preplaced-aggregate concrete having a minimum dimension greater than 300 mm 12 inches between 10 and 21 degrees C 50 and 70 degrees F. Heating of the mixing water or aggregates will be required to regulate the concrete-placing temperatures. Ensure materials entering the grout mixer are free from ice, snow, or frozen lumps. Do not mix salt, chemicals, or other materials with the grout to prevent freezing. Provide forms that are free of frost, and use aggregate, when deposited in the form, that is free of ice, snow, and frozen lumps.

3.2.4 Hot-Weather Placing of Preplaced-Aggregate Concrete

*************************************************************************************************************************
NOTE: See the appropriate DM for the proper placing temperature.
*************************************************************************************************************************

Properly perform hot-weather placing of preplaced-aggregate concrete and finish per the approved procedures. Submit for review and approval by the Contracting Officer the proposed materials and methods, if preplaced-aggregate concrete is to be placed under hot-weather conditions. Preplaced-aggregate concrete temperature exceeding [_____] degrees C F when measured in accordance with ASTM C1064/C1064M is not acceptable. Cooling of the mixing water may be required to obtain an adequate placing.
temperature. A retarder meeting the requirements of paragraph WATER-REDUCING OR RETARDING ADMIXTURES in PART 2, may be used to facilitate placing and finishing. Cool steel forms and reinforcement prior to concrete placement when steel temperatures are greater than 49 degrees C 120 degrees F.

3.2.5 Grout Mixing and Pumping

3.2.5.1 Charging Sequence

The order of placing material in the mixer is as follows:

a. Water, or premixed water and fluidifier, if the fluidifier is in a liquid form.

b. Cement, or preblended cement and fluidifier, if the fluidifier is in a powder form.

c. Remaining ingredients.

3.2.5.2 Mixing Time

After all solids are in the mixer, mix each batch for at least 2 minutes. Provide the mixer with an acceptable device to lock the discharge mechanism until the required mixing time has elapsed. Do not charge the mixer in excess of the capacity recommended by the manufacturer nor operate it at a speed in excess of the manufacturer's recommendation.

3.2.5.3 Pumping Procedure

Before starting to mix and pump grout, disconnect the grout hoses from inserts or from inlet points and flush the lines with water. Clear excess water from the pumps and lines. At the start of grouting, with the grout delivery lines disconnected at the inserts, pump and waste grout until grout exiting the line is the same uniform consistency as that being discharged from the mixer. The coarse aggregate within the forms must be in a moist condition at the time of intrusion. Start the intrusion at the lowest point in the aggregate. Perform uniform pumping and at the rate that will permit the grout to fill all voids and avoid displacing the aggregate. After being discharged into the agitator tank, continuously agitate each batch of grout until that batch is fully discharged into the pump. Properly arrange and space insert pipes to ensure a relatively level uniform grout surface. Initially the outlet end of the intrusion lines must penetrate the aggregate mass to within 50 mm 2 inches of the base of the aggregate, unless otherwise directed. Raise the outlets as the grout rises, and after grouting has progressed sufficiently to so permit, extend the outlets into the grout no less than 300 mm 12 inches. Provide satisfactory means for venting the underside of embedded projections with procedures previously submitted in accordance with paragraph SUBMITTALS. Continue grouting until grout of the specified quality is returned from the vent pipes, thereby indicating completeness of grout injection. During the intrusion procedure, externally vibrate the forms in the vicinity of the grout surface. Provide sounding wells or other approved means of accurately locating the grout surface without interrupting the intrusion procedure for observation and regulation of the level of the grout. Provide continuous agitation of grout during any shutdown of the intrusion procedure. When there is a lapse in the operation of intrusion in excess of 15 minutes, recirculate the grout through the pump, or agitator and pump. Flush the grout delivery lines with clean water if they become
blocked. Disconnect them from grout insert pipe before the flushing operation is performed and do not reconnect to grout insert pipe after flushing until pumping is resumed and grout appears. Do not use grout after appreciable stiffening of the grout mixture has occurred. [When placed underwater, begin intrusion while aggregates are being placed and follow closely behind aggregate placement unless otherwise approved. Do not bring the grout surface closer than 300 mm 1 foot of the lowest point of the aggregate lift prior to topping out.]

3.2.5.4 Blocked Pipes

Exercise care to avoid blocking grout insert pipes by avoiding interruptions in pumping; however, when a pipe becomes blocked, withdraw it immediately until the end is at least 600 mm 2 feet above the level of the grout before an attempt is made to unblock it by washing out the line. Do not attempt washing with the end of the grout line inserted in the grout.

3.2.5.5 Placing Temperature

Do not place intrusion grout when the ambient temperature is below 2 degrees C 35 degrees F, unless specifically approved by the Contracting Officer. Do not subject preplaced-aggregate concrete, without special protection, to freezing temperatures before grout reaches a unconfined compressive strength of 3500 kPa 500 psi. Grout which is intruded during cold weather must have a temperature of not less than 5 degrees C 40 degrees F nor more than 15 degrees C 60 degrees F. Heating of the mixing water or fine aggregate will not be permitted until the temperature of the grout has decreased to 7 degrees C 45 degrees F. All methods and equipment for heating are subjected to approval.

3.3 FINISHING

**************************************************************************
NOTE: Consult the appropriate DM for those surfaces to receive a trowel finish, abrasive aggregate finish, or broom finish. Be sure those special finishes are shown.
**************************************************************************

An ambient temperature of spaces adjacent to surfaces being finished less than 10 degrees C 50 degrees F is not permitted. In hot weather when the rate of evaporation of surface moisture, as determined by use of Figure 2.1.5 of ACI 305R, may reasonably be expected to exceed 1 kg/square meter 0.2 psf per hour, make provisions for windbreaks, shading, fog spraying, or wet covering with a light-colored material in advance of placement. Take such protective measures as quickly as finishing operations will allow. Provide a float finish for all unformed surfaces that are not to be covered by additional concrete or backfill. Provide additional finishing as specified below and true to the elevation shown in the drawings. Bring surfaces to receive additional concrete or backfill to the elevation shown in the drawings and leave true and regular. Slope exterior surfaces for drainage unless otherwise shown in the drawing or as directed.

3.3.1 [Formed Top Surface

Use a venting form constructed of muslin to produce the finished surface. Place the venting form on top of the aggregate and back up by fly screen, diamond metal lath, and sheeting boards spaced from 13 to 25 mm 1/2 to 1 inch apart. Tie down the form against uplift pressure.]
3.3.2 [Screeded or Trowelled Surface]

Bring the grout up to flood the aggregate surface and any remove diluted surface grout by brooming. Following this, work a thin layer of pea gravel or 9.5 to 12.5 mm 3/8 to 1/2 inch crushed aggregate down into the surface by tamping and raking. When the surface is sufficiently hardened to permit working, screed, float, or trowel the surface to the specified finish.

3.4 CURING AND PROTECTION

Submit curing medium and methods to be used, for review and approval. Provide curing and protection conforming to the following requirements:

3.4.1 Duration

Determine the length of the curing period by the type of cementitious material, as specified below. Cure concrete by an approved method.

<table>
<thead>
<tr>
<th>CONCRETE CURING PERIOD</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type I portland cement</td>
</tr>
<tr>
<td>Type II portland cement</td>
</tr>
<tr>
<td>Portland cement blended with 25 percent or less fly-ash</td>
</tr>
<tr>
<td>Portland cement blended with more than 25 percent Fly-ash</td>
</tr>
</tbody>
</table>

Immediately after placement, protect preplaced-aggregate concrete from premature drying, extremes in temperatures, rapid temperature change, and mechanical damage. Make all materials and equipment needed for adequate curing and protection available and at the placement site to the start of grouting. Protect preplaced-aggregate concrete from the damaging effects of rain for 12 hours and from flowing water for 14 days. Fire or excessive heat, including welding, is not permitted near or in direct contact with concrete or concrete embedments at any time.

3.4.2 Moist Curing

Maintain preplaced-aggregate concrete that is moist-cured continuously, not periodically, wet for the entire curing period. If water or curing materials stain or discolor concrete surfaces that are to be permanently exposed, clean them as required in paragraph APPEARANCE, below. Where wooden form sheathing is left in place during curing, keep the sheathing wet at all times. Where steel forms are left in place during curing, carefully break the forms loose from the hardened concrete and continuously apply curing water into the void to continuously saturate the entire concrete surface. Horizontal surfaces may be moist cured by ponding, by covering with a minimum uniform thickness of 50 mm 2 inches of continuously saturated sand, or by covering with saturated nonstaining burlap or cotton mats. Rinse burlap and cotton mats to remove soluble substances before using. Furnish water for curing in compliance with the requirements of paragraph WATER in Part 2.
3.4.3 Curing with Membrane-Forming Curing Compound

Concrete may be cured with an approved membrane-forming curing compound in lieu of moist curing, except that membrane curing will not be permitted on any surface to which a grout-cleaned finish is to be applied or other concrete is to be bonded, on any surface containing protruding steel reinforcement, on an abrasive aggregate finish, or any surface maintained at curing temperature by use of free steam. A styrene acrylate or chlorinated rubber compound may be used for surfaces that are to be painted. Select curing compound that is compatible with any subsequent paint specified.

3.4.3.1 Pigmented Curing Compound

A pigmented curing compound meeting the requirements of paragraph MEMBRANE-FORMING CURING COMPOUND in PART 2, may be used on surfaces that will not be exposed to view when the project is completed.

3.4.3.2 Nonpigmented Curing Compound

A nonpigmented curing compound containing a fugitive dye may be used on surfaces that will be exposed to view when the project is completed. Concrete cured with nonpigmented curing compound must be shaded from the sun for the first 3 days when the ambient temperature is 32 degrees C 90 degrees F or higher.

3.4.3.3 Application

Apply the curing compound to formed surfaces immediately after the forms are removed and prior to any patching or other surface treatment except the cleaning of loose sand, mortar, and debris from the surface. Thoroughly moisten the surfaces with water, and apply the curing compound as soon as free water disappears. Apply the curing compound to unformed surfaces as soon as free water has disappeared. Apply the curing compound in a two-coat continuous operation by approved motorized power-spraying equipment operating at a minimum pressure of 520 kPa 75 psi, at a uniform coverage of not more than 10 square meters/L 400 square feet/gallon for each coat, and apply the second coat perpendicular to the first coat. Respray concrete surfaces that have been subjected to rainfall within 3 hours after curing compound has been applied by the method and at the coverage specified. Adequately protect all concrete surfaces on which the curing compound has been applied for the duration of the entire curing period from pedestrian and vehicular traffic and from any other cause that will disrupt the continuity of the curing membrane.

SECTION 03 37 00 Page 30
3.4.5 Cold-Weather Curing and Protection

When the daily outdoor low temperature is less than 0 degrees C 32 degrees F, maintain the temperature of the concrete above 5 degrees C 40 degrees F for the first 7 days after placing. In addition, during the period of protection removal, control the air temperature adjacent to the concrete surfaces so that concrete near the surface will not be subjected to a temperature differential of more than 15 degrees C 25 degrees F. Determine this by observation of ambient and concrete temperatures indicated by suitable temperatures measuring devices furnished by the Government as required and installed adjacent to the concrete surface and 50 mm 2 inches inside the surface of the concrete. Install thermometers at such locations as may be directed.

3.4.6 Appearance

Clean permanently exposed surfaces, if stained or otherwise discolored, by a method that does not harm the concrete and that is approved.

3.5 TESTING AND QUALITY VERIFICATION FOR CONTRACTOR QUALITY CONTROL

Submit statements attesting that the concrete testing technicians and the concrete inspectors meet the specified requirements, also Contractor quality control test results and inspection reports daily and weekly as required. With the testing and quality verification, conform to the following requirements.

3.5.1 General

Perform the inspection and tests described below, and based upon the results of these inspections and tests, take the action required and submit reports as required. When, in the opinion of the Contracting Officer, the preplaced-aggregate concreting operations are out of control, cease aggregate and intrusion grouting. Perform tests using an onsite laboratory and conforming with ASTM C1077. The Government will inspect the laboratory, equipment, and test procedures prior to start of concreting operations and at least once per year thereafter for conformance with ASTM C1077.

3.5.2 Testing and Inspection Requirements

3.5.2.1 Fine Aggregate

3.5.2.1.1 Grading

At least once during each shift when the grout plant is operating, perform one sieve analysis and fineness modulus determination in accordance with ASTM C136/C136M and COE CRD-C 104 for the fine aggregate. The grading must conform to requirements in paragraph FINE-AGGREGATE GRADING in PART 2. The location at which samples are taken may be selected by the Contractor as the most advantageous for control. However, the Contractor is responsible for delivering fine aggregate to the mixer within specification limits.

3.5.2.1.2 Corrective Action for Fine-Aggregate Grading

When the amount passing on any sieve is outside the specification limits, resample and retest the fine aggregate immediately. If there is another failure on any sieve, report the fact immediately to the Contracting Officer.
3.5.2.1.3 Moisture Content Testing

Perform at least four tests for moisture content in accordance with ASTM C566 during each 8-hour period of mixing plant operation. Select random times for the tests within the 8-hour period. Make an additional test whenever the grout flow is out of control or excessive variation in consistency is reported by the placing foreman. Use the results of tests for moisture content to adjust the added water in the control of the grout mixing.

3.5.2.1.4 Moisture Content Corrective Action

Whenever the moisture content of the fine aggregate changes by 0.5 percent or more, adjust the scale settings for the fine-aggregate batcher and water batcher (directly or by means of a moisture compensation device), if necessary to maintain the specified flow.

3.5.2.2 Coarse Aggregate

3.5.2.2.1 Grading

At least once during each shift in which the coarse aggregate is being placed in the forms, perform a sieve analysis in accordance with ASTM C136/C136M for each size of coarse aggregate. Furnish coarse aggregates conforming to the requirements found in paragraph COARSE-AGGREGATE GRADING in PART 2. The location at which samples are taken may be selected by the Contractor as the most advantageous for production control. Maintain a test record of samples of aggregate taken at the same locations showing the results of the current test as well as the average results of the five most recent tests including the current test. The Contractor may adopt limits for control which are coarser than the specification limits for samples taken at locations other than as delivered to the forms to allow for degradation during handling.

3.5.2.2.2 Corrective Action for Grading

When the amount passing any sieve is outside the specification limits, immediately resample and retest the coarse aggregate. If the second sample fails on any sieve, report that fact to the Contracting Officer. Where two consecutive averages of five tests are outside specification limits, consider the operation out of control and report it to the Contracting Officer. Stop aggregate placement and take immediate steps to correct the grading.

3.5.2.3 Quality of Aggregates

**************************************************************************
NOTES: Depending upon the quality of aggregates available, some tests may not be required. Refer to EM 1110-2-2000 for the purpose of each test.

Use the petrographic examination to identify deleterious substances in aggregates. List deleterious substances individually with respective limits.
**************************************************************************

Submit aggregate quality test results, at least 30 days prior to start of
preplaced-aggregate concrete placement. Provide quality of aggregates meeting the following requirements.

3.5.2.3.1 Frequency of Quality Tests

Thirty days prior to the start of preplaced-aggregate concrete placement perform all tests for aggregate quality listed on the following page. In addition, after the start of concrete placement, perform tests for aggregate quality in accordance with the frequency schedule. Take samples of fine aggregate tested after the start of concrete placement immediately prior to entering the grout mixer. Take samples of coarse aggregate tested after the start of concrete placement immediately prior to entering the forms.

3.5.2.3.2 Corrective Action for Aggregate Quality

If the result of a quality test fails to meet the requirements for quality
immediately prior to start of preplaced-aggregate concreting operations, change production procedures or change materials and perform additional tests until the material meets the quality requirements prior to proceeding with either mixture proportioning studies or starting preplaced-aggregate concreting operations. After preplaced-aggregate concreting operations commences, whenever the result of a test for quality fails the requirements, rerun the test immediately. If the second test fails the quality requirement, report the fact to the Contracting Officer and take immediate steps to rectify the situation.

3.5.2.4 Scales

3.5.2.4.1 Accuracy in Determination of Mass

Check the accuracy of the scales by reference masses prior to start of grouting operations and at least once every 3 months for conformance with the applicable requirements of paragraph BATCHING EQUIPMENT in PART 2. Also make such tests as directed whenever there are variations in properties of the fresh grout that could result from batching errors.

3.5.2.4.2 Scales Corrective Action

When the accuracy of determination of mass does not comply with specification requirements, do not perform grouting until necessary adjustments or repairs have been made. Correct discrepancies in recording accuracies immediately and report to the Contracting Officer.

3.5.2.5 Grout Plant Control

Continuously control the measurement of all constituent materials including cementitious materials, aggregate, water, and admixtures. Adjust the fine aggregate mass and amount of added water as necessary to compensate for free moisture in the fine aggregate. Adjust the amount of air-entraining agent to control air content within specified limits. Prepare a report indicating type and source of cement used, type and source of pozzolan used, amount and source of admixtures used, aggregate source, the required aggregate and water in mass per cubic meter, amount of water as free moisture in the fine aggregate, and the batch aggregate and mass of water per cubic meter for each mixture batched during grouting operations.

3.5.2.6 Grout Mixture

3.5.2.6.1 Air-Content Testing

Make air-content tests when test specimens are fabricated. In addition, make at least two tests for air content on randomly selected batches of each separate grout mixture produced during each 8-hour period of grout production. Make additional tests when excessive variation in consistency is reported by the placing foreman or Government quality assurance representative. Make tests in accordance with ASTM C231/C231M. Plot test results on control charts which will at all times be readily available to the Government. Keep copies of the current control charts in the field by the Contractor's quality control representatives and plot results as tests are made. When a single test result reaches the upper or lower action limit, make a second test immediately. Average the results of the two tests. Use this average as the air content of the batch to plot on the control chart for air content and on the control chart for range and to determine the need for any remedial action. Plot the result of each test, or average as noted in the previous sentence, on a separate chart for each
mixture on which an average line is set at the midpoint of the specified air-content range from paragraph AIR CONTENT in PART 2. Set an upper warning limit and a lower warning limit line 1.0 percentage point above and below the average line. Set an upper action limit and a lower action limit line 1.5 percentage points above and below the average line, respectively. Plot the range between each two consecutive tests on a control chart for range where an upper warning limit is set at 2.0 percentage points and up upper action limit is set at 3.0 percentage points. Samples for air content may be taken at the mixer; however, the Contractor is responsible for delivering the grout to the placement site at the stipulated flow. If the Contractor's materials or transportation methods cause flow loss between the mixer and the placement, take correlation samples at the placement site as required by the Contracting Officer and control the air content at the mixer as directed.

3.5.2.6.2 Air-Content Corrective Action

Whenever points on the control chart for percent air reach either warning limit, make an adjustment immediately in the amount of air-entraining admixture batched. As soon as is practical after each adjustment, make another test to verify the result of the adjustment. Whenever a point on the control chart range reaches the warning limit, recalibrate the admixture dispenser to ensure that it is operating accurately and with good reproducibility. Whenever a point on either control chart reaches an action limit line, consider the air content out of control and immediately halt the concreting operation until the air content is under control. make additional air-content tests when grout mixing is restarted. All this will be at no extra cost to the Government.

3.5.2.7 Test for Grout Flow

3.5.2.7.1 Tests

Make at least two tests on randomly selected batches of grout mixture during each shift's production in accordance with ASTM C939/C939M. Make additional tests when excessive variation in flow of grout mixture is reported by the grout foreman or Government inspector. Plot test results on control charts which will at all times be readily available to the Government. Keep copies of the current control charts in the field by the Contractor's quality control representatives and plot results as tests are made. When a single-flow test reaches or goes beyond the upper or lower action limit, make a second test immediately on the same batch of concrete. Average the results of the two tests. Use this average as the flow of the batch to plot on the control chart for flow and the chart for range and to determine the need for any remedial action. Set an upper warning limit at 1 second below the maximum allowable flow on separate control charts for flow used for each type of mixture, and set upper and lower action limit lines at the maximum and minimum allowable flows, respectively. Plot the range between each consecutive flow test for each type of mixture on a single control chart for range on which an upper action limit is set at 2 seconds. Take samples for flow at the agitator; however, the Contractor is responsible for delivering the grout to the placement site at the stipulated flow. If the Contractor's materials or transportation methods cause flow loss between mixer and the placement, takecorrelation samples at the placement site as required by the Contracting Officer and control the flow at the mixer as directed.
3.5.2.7.2 Grout Flow Corrective Action

Whenever points on the control chart for flow reach the upper warning limit, make an adjustment immediately in the batch weights of water and fine aggregate. The adjustments are to be made so that the total water content does not exceed that amount allowed by the maximum W/C specified, based upon aggregates which are in a saturated surface-dry condition. When a single flow reaches the upper or lower action limit, do not deliver further grout to the placing site until proper adjustments have been made. Immediately after each adjustment, make another test to verify the correctness of the adjustment. Whenever two consecutive flow tests, made during a period when there was no adjustment of batch weights, produce a point on the control chart for range at or above the upper action limit, halt the grouting operation immediately, and take appropriate steps to bring the flow under control. Also, make additional flow tests as directed. All this will be at no additional cost to the Government.

3.5.2.7.3 Temperature

Measure the temperature of the grout when compressive strength specimens are fabricated. Measure temperature in accordance with ASTM C1064/C1064M. Report the temperature along with the compressive strength data.

3.5.2.7.4 Compressive-Strength Specimens

Make at least one set of test specimens each day on each different preplaced-aggregate concrete mixture placed during the day. Make additional sets of test cylinders, as directed by the Contracting Officer, when the mixture proportions are changed or when low strengths have been detected. Develop a random grout sampling plan and obtain approval prior to the start of construction. Assure that sampling is done in a completely random and unbiased manner. Provide a set of test specimens for concrete with a 28-day specified strength, in accordance with paragraph DESIGN OF PREPLACED AGGREGATE in Part 1, consisting of six cylinders, three to be tested at 7 days and three at 28 days. Provide a set of test specimens for concrete with a 90-day strength, in accordance with the same paragraph, consisting of nine cylinders, three tested at 7 days, three at 28 days, and three at 90 days. Mold and cure specimens in accordance with ASTM C943 and test in accordance with ASTM C39/C39M. Report all compressive-strength tests immediately to the Contracting Officer. Keep quality control charts for individual strength tests, moving average for strength, and moving average for range for each mixture, that are similar to those found in ACI 214R.

3.5.2.8 Inspection Before Pumping Grout

Inspect foundation or construction joints, forms, and embedded items for quality in sufficient time prior to each grout placement to certify to the Contracting Officer that they are ready to receive grout. Report the results of each inspection in writing.

3.5.2.9 Grout Pumping

3.5.2.9.1 Placing Inspection

The placing foreman will supervise all placing operations, will determine that the correct quality of grout is placed in each location as directed by the Contracting Officer, and is responsible for measuring and recording grout temperatures and ambient temperature hourly during placing...
operations, weather conditions, time of grout placement, amount of grout placed, and method of placement.

3.5.2.9.2 Pumping Corrective Action

Do not permit grouting operations to begin until it has been verified that an adequate number of vibrators in working order and with competent operators are available. If any batch of grout fails to meet the temperature requirements, take immediate steps to improve temperature controls. Submit data on the size, frequency, and amplitude of the external vibrators for review.

3.5.2.10 Curing

3.5.2.10.1 Moist-Curing Inspections

At least once each shift and once per day on nonwork days, inspect all areas subject to moist curing. Note and record surface moisture condition.

3.5.2.10.2 Moist-Curing Corrective Action

When a daily inspection report lists an area of inadequate curing, take immediate corrective action, and extend the required curing period for such areas by 1 day.

3.5.2.10.3 Membrane-Curing Inspection

Do not apply curing compound until the Contractor's authorized representative has verified that the compound is properly mixed and ready for spraying. At the end of each operation, estimate the quantity of compound used by measurement of the container and the area of concrete surface covered and compute the rate of coverage in square meters/L square feet/gallon. Note whether or not coverage is uniform.

3.5.2.10.4 Membrane-Curing Corrective Action

When the coverage rate of the curing compound is less than that specified or when the coverage is not uniform, spray the entire surface again.

3.5.2.10.5 Sheet-Curing Inspection

At least once each shift and once per day on nonwork days, inspect all areas being cured using material sheets. Note and record the condition of the covering and the tightness of the laps and tapes.

3.5.2.10.6 Sheet-Curing Corrective Action

When a daily inspection report lists any tears, holes, or laps or joints that are not completely closed, promptly repair the tears and holes or replace the sheets, close the joints, and extend the required curing period for those areas by 1 day.

3.5.2.11 Cold-Weather Protection and Sealed Insulation Curing

At least once each shift and once per day on nonwork days, inspect all areas subject to cold-weather protection. Inspect the protection system for holes, tears, unsealed joints, or other deficiencies that could result in damage to the concrete. Take special attention at edges, corners, and thin sections. Note, correct, and report any deficiencies.
3.5.2.12 Cold-Weather Protection Corrective Action

When a daily inspection report lists any holes, tears, unsealed joints, or other deficiencies, correct the deficiency immediately and extend the period of protection 1 day.

3.5.3 Reports

Informally report all results of tests or inspections conducted as they are completed and in writing daily. Prepare a weekly report for the updating of control charts covering the entire period from the start of the construction season through the current week. During periods of cold-weather protection, make reports of pertinent temperatures daily. These requirements do not relieve the Contractor of the obligation to report certain failures immediately as required in preceding paragraphs. Confirm such reports of failures and the action taken in writing in the routine reports. The Contracting Officer has the right to examine all contractor quality control records.

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for materials, proportioning, application, and curing of shotcrete.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1 GENERAL

NOTE: The content of this specification is such that guidance given in EM 1110-2-2005, STANDARD PRACTICE FOR SHOTCRETE, is applicable.

1.1 SCOPE

1.1.1 Work Specified

This Specification covers the requirements for shotcrete as specified by the Contracting Officer. Included are the requirements for materials; proportioning; and application of [structural] [nonstructural] [fiber-reinforced][wet-mixture][dry-mixture] shotcrete.
NOTE: The successful use of shotcrete in structural sections requires careful planning, forming, skill, and continuous care in application. The nozzle size and rate of feed should be limited as necessary to permit full nozzle control and produce a uniform, dense application, even in tight places. For this reason, selecting structural as opposed to nonstructural will provide greater quality of placement as prescribed in the paragraph titled "QUALIFICATIONS".

Dry-mix shotcrete is shotcrete in which most of the mixing water is added at the nozzle. Dry-mix is commonly used for placing mixtures containing lightweight aggregates or refractory materials. Wet-mix shotcrete is shotcrete in which all the ingredients, including water, are mixed before introduction into the delivery hose; compressed air is introduced to the material flow at the nozzle. Compared to dry-mix, wet-mix shotcrete gives better assurance that the mixing water is thoroughly mixed with other ingredients. The paragraph titled "MIXTURE PROPORTIONS" requires the water-cementitious materials ratio (w/cm) for wet-mixture shotcrete to be submitted.

If you want to leave it up to the contractor to decide which type of shotcrete to use then delete both [wet-mixture][dry-mixture] options so the contractor is not limited.

Fibers can provide improved flexural and shear toughness, and impact resistance. For refractory shotcrete, stainless steel fibers increase resistance to thermal shock, temperature cycling damage, and crack development. Some specific applications where fiber-reinforced shotcrete can be cost effective are slope protection, ground support in tunnels and mines, concrete repair, swimming pools, thin shell configurations, and refractory applications such as boilers, furnaces, coke ovens, and petrochemical linings. Synthetic fibers may reduce the susceptibility of shotcrete to plastic shrinkage cracking. In addition to reducing plastic shrinkage, steel fibers can also improve flexural toughness.

If fiber-reinforcing is selected, additional testing for fibers and shotcrete properties will be required. Additional qualifications described in the paragraph titled "QUALIFICATIONS" will also be required.

**************************************************************************

1.1.2 Unit of Measure

Unit of measure: [cubic meter yard][square meter feet].

1.3 DEFINITIONS

1.3.1 Accepted
Determined to be satisfactory by the Contracting Officer.

1.3.2 Contractor
The person, firm, or corporation with whom the Contracting Officer enters into an agreement for construction of the Work.

1.3.3 Fiber-Reinforced Shotcrete (FRS)
Shotcrete containing discontinuous discrete fibers.

1.3.4 Gun finish
Undisturbed final layer of shotcrete as applied from a nozzle without further finishing.

1.3.5 Overspray
Waste shotcrete material deposited away from intended receiving surface.

1.3.6 Permitted
Accepted by or acceptable to the Contracting Officer; usually pertains to a request by Contractor, or when specified in contract documents.

1.3.7 Predampening
In the dry-mixture process, adding water to the aggregate before mixing to bring its moisture content to a specified amount, usually 3 to 6 percent.

1.3.8 Rod finish
A sharp-edged cutting screed to be used to trim shotcrete forms or ground wires.

1.3.9 Shotcrete
Concrete or mortar conveyed through a hose and pneumatically projected at high velocity onto a surface to achieve compaction.

1.4 SUBMITTALS

********************************************************************************************************************
NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification
technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.

**************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

**SD-06 Test Reports**

[Preconstruction Testing]

Testing During Construction; G[, [_____]]

Aggregate

Water

Mixture Proportions; G[, [_____]]

Repair Of Shotcrete; G[, [_____]]

Resistance To Alkali-Silica Reaction

**SD-07 Certificates**

Qualifications; G[, [_____]]

Cement
1.5 QUALIFICATIONS

Submit qualifications and experience of the proposed workers including the supervisor, nozzlemen, and crew. For structural or FRS shotcrete, submit evidence of ACI certification of nozzlemen proposed for the Work.

**************************************************************************

NOTE: Requirements of the paragraphs titled "Structural Concrete" and "Nonstructural Concrete" are determined by the selection made in the paragraph titled "Work specified". Structural shotcrete and FRS require careful planning, forming, skill, and continuous care in application, hence why ACI certification is required.

**************************************************************************

1.5.1 Structural Concrete

Submit proof of experience for the Contractor and the shotcrete crew foreman to include at least five projects of similar size and complexity. Include a description of previous project's size, density of reinforcing materials, and volume of shotcrete placed.

1.5.2 Nonstructural Concrete

Submit proof that the Contractor and crew foreman have at least 3 years' experience in that type of shotcrete application.

1.6 [PRECONSTRUCTION TESTING]

**************************************************************************

NOTE: It is not practical to conduct laboratory trial mixtures for dry-mix shotcrete. There are also problems in duplicating as-shot conditions for the wet-mix shotcrete. Therefore, field trials and preconstruction testing, should be used for qualifying mixture proportions. Preconstruction testing procedures using the personnel, materials, and equipment to be used on the project are outlined in this paragraph Tests should be conducted under similar conditions expected to be experienced in the actual application.

**************************************************************************
1.6.1 [General Requirements]

a. [Testing of materials required as part of the preconstruction program must be conducted by the Contractor's testing agency. Agency selection must be acceptable to the Contracting Officer.]

b. Notify the Contracting Officer of the time and place of preconstruction testing and provide the Contracting Officer with copies of testing reports.

c. Construct preconstruction test panels for examination by the Contracting Officer prior to project shotcrete placement. Perform preparation and testing in compliance with ASTM C1140/C1140M. Provide mixture proportions meeting the requirements of the paragraph titled "MIXTURE PROPORTIONS".

d. Construct test panels for each proposed shotcrete mixture, each anticipated shooting orientation, and each proposed nozzleman.

e. Testing required as part of the preconstruction test program must be provided by the Contractor's testing agency.

f. Test specimens cored or sawed from the panels for compliance with the specified compressive strength in accordance with ASTM C1604/C1604M.

g. [Provide flexural strength in accordance with ASTM C78/C78M with beams obtained by ASTM C42/C42M]

**************************************************************************
** NOTE: Test flexural properties using ASTM C78/C78M when FRS is not specified. Welded-wire fabric has commonly been used in shotcrete tunnel linings to provide ductility to the shotcrete lining. Welded-wire reinforcement is increasingly being replaced by fibers. When fibers are used in panels, delete this provision and use the one below. **
**************************************************************************

h. [Prepare additional panels with the specified reinforcement. Core panels in accordance with ASTM C1140/C1140M. Provide cores containing reinforcement to the Contracting Officer for visual examination to determine acceptance. Provide cores for examination with a minimum diameter of 95 mm 3.75 in and are the full thickness of the panel.]

**************************************************************************
** NOTE: In preconstruction testing only, additional panels could be constructed with reinforcement. The **
**************************************************************************

SECTION 03 37 13 Page 12
reinforcement should be constructed to represent the
reinforcement that will be used in the actual
structure.

**************************************************************************

i. If the initial prequalification test panel is rejected, a second panel
may be shot and tested. If this panel is acceptable, Work may proceed.
If the second panel is not acceptable, change procedures, mixture
proportions, nozzlemen, or shotcrete equipment as necessary before
repeating the preconstruction testing. Do not proceed with Work until
preconstruction test results are satisfactory to Contracting Officer.]

1.6.2 [Preplacement Verification]

a. [Provide forms that are to line and grade and have adequate support to
remain rigid during shooting.

b. The formwork, substrata preparation, and cleanliness must be the same
as specified herein.

c. The reinforcement type, size, grade, amount, placement, cleanliness,
and other requirements must be the same as specified [herein][the same
size and spacing as the existing structure].

d. The placement of and clearance around reinforcement must permit
complete encasement of reinforcement with shotcrete.

e. The mixture proportions must be the same as the approved submittal [and
need not include admixtures].]

**************************************************************************

NOTE: Requirement e could also include admixtures,
refer the paragraph titled "Admixtures" for this
option.

**************************************************************************

1.7 TESTING DURING CONSTRUCTION

1.7.1 Quality Assurance

Provide submittals for the "Quality Control Plan", "Quality Control
Personnel Certifications", and Laboratory Qualifications for Concrete
Qualification Testing per section 03 30 00 CAST-IN-PLACE CONCRETE.

1.7.2 Testing Shotcrete

a. Compressive strength samples: [Obtain test specimens from job-site test
panels.][Use in-place shotcrete test specimens.][_____

**************************************************************************

NOTE: Test samples can be obtained from test panels
(1st choice) or cored from the structure being built
with shotcrete (2nd choice)

**************************************************************************

b. Test samples: Sample shotcrete in accordance with ASTM C1385/C1385M.
The Contractor is responsible for the curing and protection of test
panels on site prior to the time that they are transported to the
testing agency's laboratory.
c. [Only use test panels for flexural strength, flexural parameter, or toughness requirements.][____]

d. Air content of mixture: For wet-mixture shotcrete test air content at discharge from the truck chute in accordance with ASTM C231/C231M prior to placement.
   [For dry-mix shotcrete, test air content in hardened concrete using ASTM C457/C457M][____]

**************************************************************************
NOTE: Specifying air entrainment for dry-mixture shotcrete is not common but has been satisfactorily used for severe freezing-and-thawing exposures. For dry-mix shotcrete, air content is tested on hardened concrete.
**************************************************************************

e. Temperature of shotcrete mixture: Determine the temperature of the mixture using material sampled prior to discharge from the truck chute into the pump for wet-mixture shotcrete or the shotcrete machine for dry-mix shotcrete. Complete testing in accordance with ASTM C1064/C1064M.

1.7.3 [Test Panels]

a. [Construct a test panel for each mixture, each nozzleman, and each work day or for every [38 cubic meter 50 cubic yard][185 square meter 2000 square feet][____] placed, whichever results in the most panels. The face dimensions of a test panel must be a minimum of 400 x 400 m 16 x 16 in. with a minimum depth of 125 mm 5 in. For toughness testing in accordance with ASTM C1550, the face dimension must be 800 mm 30.5 in. in diameter and 75 mm 3 in. thick. The test panels will be shot in a [vertical][____] orientation.

**************************************************************************
NOTE: A test panel could be fabricated for each shooting position to be encountered in the structure such as horizontal, vertical, or overhead. If this is needed, then add those shooting positions to this paragraph
**************************************************************************

b. Condition test panels in accordance with ASTM C1140/C1140M until transported to the testing agency's laboratory.

c. Obtain test specimens from test panels using procedures outlined in ASTM C1140/C1140M or ASTM C1604/C1604M. Cores will be a nominal 75 mm 3 in. diameter.

d. Test shotcrete specimens for compliance in accordance with ASTM C1604/C1604M for compressive strength.

e. [Test boiled absorption and volume of permeable voids in accordance with ASTM C642.][____]

f. [Test flexural parameters in accordance with methods specified in the paragraph titled "flexural strength and properties"][____]
1.7.4  [Testing In-Place Shotcrete]

a.  [Obtain core specimens from locations designated by the Contracting Officer in accordance with ASTM C1140/C1140M.]

**************************************************************************
NOTE: Cores from the actual structure should be obtained and tested when the contracting officer suspects a lower strength or deficiency in quality. Test panels are the main quality control/assurance method; obtaining and testing cores are not typically done, unless the placement is in doubt.
**************************************************************************

b.  [Condition test specimens by soaking as specified in ASTM C1604/C1604M.]

c.  Test specimens in accordance with the paragraph titled "Testing Shotcrete".

1.7.5  [Testing Shotcrete Bond to Substrate]

[Conduct bond testing of the shotcrete to the substrate in accordance with ASTM C1583/C1583M.]

1.7.6  Reporting of Quality Assurance Test Results

Provide copies of any test results generated for quality assurance to the Contractor, Contracting Officer, and concrete supplier.

1.7.7  Action Required for Shotcrete Defects

Submit repair of shotcrete procedures for defects for the Contracting Officer's acceptance. Refer to the paragraph titled "REPAIR OF SHOTCRETE" for details.

PART 2   PRODUCTS

2.1  MATERIALS

2.1.1  Cement

Provide cement in compliance with [ASTM C150/C150M Type I][ASTM C595/C595M][ASTM C1157/C1157M][______].
Submit cement test reports showing manufacturing location, and compliance with applicable ASTM standards.

**************************************************************************
NOTE: Most shotcrete is produced with Type I or I-II cements conforming to ASTM C150 or ASTM C595. Other cementitious materials, such as blended hydraulic cements, should meet ASTM C1157. The type of cement used for a structure must consider the exposure requirements of the concrete being placed. Refer to ACI 318 or ACI 350 material durability requirements to determine cement requirements or supplementary cementitious requirements discussed in paragraph titled "Supplementary cementitious materials".
**************************************************************************
2.1.2 Supplementary Cementitious Materials

Provide supplementary cementitious materials (SCMs) complying with [ASTM C618 for fly ash and natural pozzolans] [ASTM C989/C989M for slag cement] [ASTM C1240 for silica fume].
[The types and dosages of supplementary cementing material must meet ACI 301 requirements][_____] .
[[A minimum of] [_____] percent of [_____] is required as supplementary cementing material][_____] .
Submit supplementary cementitious materials types, test reports showing manufacturing location, and compliance with applicable ASTM standards.

******************************************************************************

NOTE: SCMs can be used in shotcreting. SCMs can enhance workability or pumpability of some wet-mix shotcrete. They may provide more resistance to sulfate attack and to alkali-silica reactivity if reactive aggregates are used. The use of SCMs on an equal weight replacement for cement may result in slower early strength gain. Natural pozzolans and fly ash should meet the requirements of ASTM C618. Other pozzolans should meet the appropriate ASTM specifications. Both silica fume and metakaolin should meet the requirements of ASTM C1240.

Slag cement should meet the requirements of ASTM C989. There are three grades of slag. Generally, higher-grade slag will be finer and have greater strength development.

Silica fume comes in three forms: slurry, undensified, and densified. All three forms are acceptable for use in shotcrete. When using slurry, the water portion of the slurry should be compensated for in the w/cm; that is, the water in the slurry counts as mixing water for both dry-mix and wet-mix shotcrete. Undensified silica fume is mainly used in premixed dry-bag shotcrete products. Densified fume is best used in wet-mix shotcrete.

Specify if the SCM limits meet ACI 301 (Table 4.2.1.1) requirements or other alternative specifications.
Specify the type (Class F, or C fly ash; slag cement; silica fume; or other SCMs) and the minimum percent cement replacement requirements based on ACI 318 or ACI 350 requirements (if required).

******************************************************************************

2.1.3 Aggregate

Aggregates must comply with [ASTM C33/C33M][_____] for [normal weight][_____] aggregates. The combined aggregate gradation must comply with [grading No. 2 of ASTM C1436][_____] .
Submit aggregate source, producers' names, gradations, specific gravities, compliance with [ASTM C33/C33M][_____] , and evidence that this data is not more than 1 year old.
[Submit aggregate absorption in accordance with ASTM C127 for coarse aggregate and ASTM C128 for fine aggregate.]
2.1.4 Water

[Water must be potable][Water must be potable or nonpotable and comply with ASTM C1602/C1602M requirements. Wash water is not permitted unless accepted by Contracting Officer.][_____

[For nonpotable water, submit the source and reports confirming compliance with ASTM C1602/C1602M.]

2.1.5 Admixtures

Provide admixtures in compliance with ASTM C1141/C1141M or, for hydration control admixtures, with ASTM C494/C494M.[The following admixtures are also permitted [_____]][_____

Submit admixture types, brand names, producers, manufacturer's technical data sheets describing technical properties and performance in shotcrete and showing compatibility with each other and the project cementitious materials.

[Assess admixture in the prequalification test program described in the paragraph titled "PRECONSTRUCTION TESTING".]

2.1.6 Fibers

[Use the following types, material, and sizes of fibers:[_____]]. Provide FRS conforming to ASTM C1116/C1116M.
Submit compressive strength test results and, flexural strength and flexural parameters as specified in the paragraph titled "flexural strength and properties". Submit manufacturer's technical data sheets and data on fiber material, length or lengths, and fiber content used for the mixture.

**************************************************************************
NOTE: As discussed in the paragraph titled "work specified" notes, fibers can enhance the properties of shotcrete. The available types of fibers include steel, glass, synthetic, and natural fibers.

To select the type of fiber required for a job, obtain information about the fiber materials available for shotcrete in the designated area. Knowing what materials are available and the desired properties, follow the recommendations of ACI 506R, ACI 506.1 and ACI 544.1 to select the fiber to be used on the job.
**************************************************************************

2.1.7 Reinforcement

Follow the requirements included in the contract documents [as well as] [03 30 00 CAST-IN-PLACE CONCRETE] [_____] for non-fiber types of reinforcement.

Submit mill certificate showing conformance for reinforcing steel or welded wire reinforcement.

2.1.8 Curing Materials

2.1.8.1 Sheet Materials

Provide sheet materials for curing in compliance with ASTM C171.

2.1.8.2 Curing Compounds

Provide curing compounds in compliance with ASTM C309 or ASTM C1315. Provide volatile organic compounds (VOC) content in compliance with local air quality standards if those requirements are more stringent.

2.1.8.3 Architectural Finishes

Do not use curing materials that cause stains for shotcrete having an architectural finish.

2.1.9 [Packaged Shotcrete Materials]

[Provide packaged, preblended, dry combined materials complying with [ASTM C1480/C1480M][_____] .]

**************************************************************************
NOTE: Select this option to allow packaged Shotcrete Materials. Also, specify any standards, requirements, or limitations for those materials
**************************************************************************

SECTION 03 37 13 Page 18
2.2 SHOTCRETE PROPERTIES

2.2.1 Compressive Strength

The required compressive strength is [______].

**************************************************************************
NOTE: Specify the required compressive strength of concrete based on the design requirements. Per ACI 506.2, the 28-day compressive strength must not be less than 4000 psi (28 MPa). Assess the compressive strength in accordance with ACI 301.
**************************************************************************

[2.2.2 Flexural Strength and Properties

[The required flexural strength is [______].] Use [ASTM C78/C78M][ASTM C1609/C1609M][______] to test flexural strength.

The required residual strength using [ASTM C1609/C1609M][ASTM C1399/C1399M][______] is [______].

[The required toughness per [ASTM C1550][______] is [______].]

**************************************************************************
NOTE: In the first part of this paragraph specify the flexural strength value and test method required. Per ACI 506.2, flexural strength must not be less than 400 psi (2.8 MPa) at 28 days for FRS. ASTM C78/C78M is used for non-fiber reinforced concrete while ASTM C1609/1609M is a test method used for evaluating strength and other flexural parameters of FRS.

If you are specifying FRS, then specify your project requirements for residual strength, flexural toughness, or other mechanical properties if needed. For more information on test methods, properties, and requirements for FRS and fiber-reinforced concrete (FRC) in general, refer to ACI 544.9R and ACI 506.1R.
**************************************************************************

[2.2.3 Water-Cementitious Ratio

The maximum w/cm based on project service conditions is [______].

**************************************************************************
NOTE: Specify the maximum w/cm based on project service conditions. Refer to ACI 318 or 350 to determine project requirements. Guidance regarding freezing and thawing can be obtained from ASTM C33/C33M.

Note that paragraph titled "MIXTURE PROPORTIONS", only requires the submittal of water-cementitious materials ratio (w/cm) for wet-mixture shotcrete. Delete this paragraph for dry-mix shotcrete.
**************************************************************************
2.2.4 Air Content

The percent air content of concrete is [_____] plus or minus (±) 1.0 percent.

******************************************************************************************************************

NOTE: Air entrainment may be required where the shotcrete is exposed to freeze/thaw, seawater, or deicing salts. Specify minimum air void parameters based on project service conditions. Refer to ACI 318 or ACI 350 to determine project requirements. Guidance on the need for air entrainment to protect against freezing and thawing can be found in ASTM C33/C33M. Also, specify the frequency of air testing in the paragraph titled "Testing Shotcrete".

Per ACI 506.2, shotcrete placement reduces entrained air content such that shotcrete with a 7 percent or higher air content prior to shooting will have an entrained air content of approximately 3 to 4 percent after placement. Wet-mixture shotcrete exposed to moderate or severe freezing-and-thawing conditions should have an entrained air content of at least 6 to 7 percent prior to shooting. Obtaining greater than 4 percent air in the in-place material is difficult. For wet-mix shotcrete, air content is tested in plastic concrete. Specifying air entrainment for dry-mixture shotcrete is not common but has been satisfactorily used in severe freezing-and-thawing exposures. For dry-mix shotcrete, air content is tested on hardened concrete using methods such as Petrographic Examination.

******************************************************************************************************************

2.2.5 Chloride Content

[The maximum water-soluble chloride ion content based on project service conditions is [______]. Determine chloride content per [ASTM C1218/C1218M].]

******************************************************************************************************************

NOTE: For corrosion protection of the reinforcement in the shotcrete, the maximum water-soluble chloride-ion concentration in hardened shotcrete should not exceed a certain limit. This limit is based on the type of reinforcement used. Refer to ACI 318 or ACI 350 for recommended limits.

******************************************************************************************************************

2.2.6 Voids and Absorption Properties

Measure the voids and absorption properties using [ASTM C642][_____] and do not exceed [______].

Provide test reports for shotcrete boiled absorption and volume of permeable voids showing compliance with the specified properties.

******************************************************************************************************************

NOTE: The absorption test (ASTM C642) may be conducted on hardened shotcrete to provide an
overall indication of the quality of the shotcrete, especially in dry-mix shotcrete where the results are largely influenced by the w/cm. The absorption value and the volume of permeable voids are useful in identifying poorly compacted shotcrete or shotcrete with a weak or damaged microstructure.

Per ACI 506.2, typical values for quality shotcrete are a Maximum of 8 percent boiled absorption and 15 percent volume of permeable voids. Results vary depending on the absorptive characteristics of the aggregate. Lightweight aggregate has high absorption. The absorption of a shotcrete specimen is usually proportional to its w/cm. A low w/cm will yield a relatively low volume of permeable voids or low absorption values, which is an indication of a good quality shotcrete. A mixture shot too dry, however, will yield a relatively high volume of permeable voids or high absorption values due to the stiffness of the plastic shotcrete. Impact velocity is another important parameter that influences the porosity of the hardened shotcrete. Insufficient impact velocity will not provide adequate compaction, resulting in high permeability and high absorption values.

ASTM C457/C457M can also be used to determine parameters of the air-void system in hardened concrete.

**************************************************************************

2.2.7 Bond Strength

Perform testing for bond strength on a minimum of three core samples and the strength is the average of all samples. The average bond strength is [______].

**************************************************************************

NOTE: Bond strength is usually measured by shear or direct tension using a pull-off test (ASTM C1583/C1583M). Properly applied shotcrete with sufficient consolidation on a properly prepared substrate usually develops bond strength of over 145 psi (1 MPa).

**************************************************************************

2.2.8 Resistance to Alkali-Silica Reaction

[Use one of the three options below for qualifying concrete mixtures to reduce the potential of alkali-silica reaction.]

a. For each aggregate used in concrete, do not exceed 0.04 percent at 1 year for the expansion result determined in accordance with ASTM C1293.

b. For each aggregate used in concrete, do not exceed 0.10 percent at an age of 16 days for the expansion result of the aggregate and cementitious materials combination determined in accordance with ASTM C1567.

c. Alkali content in concrete must not exceed 2.35 kilograms per cubic
meters 4 pounds per cubic yard for moderately reactive aggregate or 1.78 kilograms per cubic meters 3 pounds per cubic yard for highly reactive aggregate. Determine reactivity determined by testing in accordance with ASTM C1293 and categorized in accordance with ASTM C1778.

2.3 MIXTURE PROPORTIONS

Proportion shotcrete mixture [by mass complying with ASTM C94/C94M][by volume complying with ASTM C685/C685M], to satisfy the specified properties. For FRS, proportion in compliance with ASTM C1116/C1116M. Submit shotcrete mixture proportions. Show constituent proportions by mass in the case of batching by weight or proportions by volume in the case of volumetric batching in submittals. For prepackaged materials meeting ASTM C1480/C1480M, submit suppliers' technical data showing compliance with requirements. Submit water-cementitious materials ratio (w/cm) for wet-mixture shotcrete only.

**************************************************************************
NOTE: Shotcrete mixtures are usually proportioned in accordance with ASTM C94/C94M or C685/C685M to attain a specified compressive strength. The main reasons for variations of in-place strength are the nature of the shotcrete process, type of delivery equipment, and quality of workmanship. This is especially true of dry-mix shotcrete, where the nozzleman is not only responsible for the proper placement technique but also regulates and controls the water content—a variable that can cause fluctuations in strength and durability. There is no recognized rational method of proportioning dry-mix shotcrete for strength or durability. Water is injected into the preproportioned cementitious material mixture stream at the nozzle by the nozzleman, so it is not possible to design dry-mix shotcrete based on w/cm. Dry-mix shotcrete has been proportioned based by weight, typically having a cementitious material to aggregate ratio of 1:4.
On the other hand, wet-mix shotcrete is typically proportioned using volumetric methods such as ACI 211.1 (just like regular types of concrete). Refer to ACI 506R for more details on proportioning shotcrete.
**************************************************************************

2.4 BATCHING, MIXING, AND DELIVERY

Batch, mix, and deliver wet-mixture shotcrete in accordance with ASTM C94/C94M, ASTM C685/C685M, or ASTM C1116/C1116M as applicable. For dry-mixture, batch, mix and deliver in accordance with ASTM C685/C685M or ASTM C1116/C1116M.
Use predampening or other methods suitable for prewetting the dry materials with packaged preblended material for dry-mixture shotcrete.
PART 3  EXECUTION

3.1  PREPARATION OF SURFACE TO RECEIVE SHOTCRETE

3.1.1  Earth

Prepare surfaces to line and grade. Dampen surfaces immediately prior to shooting. Standing water is not acceptable.

3.1.2  Concrete, Masonry, and Shotcrete

Remove all deteriorated, loose, unsound material or contaminants that will inhibit bonding. Dampen receiving surface and allow to dry to a saturated surface-dry (SSD) condition just prior to shotcrete application. Further surface preparations include:

a. Chipping surfaces to receive shotcrete to remove offsets causing abrupt changes in thickness.

b. Roughening receiving surfaces that have been saw cut.

3.1.3  Rock

Remove loose material, mud, or other foreign material that will inhibit bonding. Clean surface prior to shotcrete placement. Dampen surface in accordance with the paragraph titled "Earth".

3.1.4  Reinforcement

3.1.4.1  Surface Condition

The surface of the reinforcement must be free of overspray or other deleterious materials that inhibit development of bond with the shotcrete.

3.1.4.2  Reinforcement Laps

Laps must be noncontact and [separate with a clearance of at least three times the diameter of the largest reinforcing bar; three times the maximum size aggregate; or 50 mm 2 in., whichever is least][____]. Do not space bars spliced by noncontact lap splices in flexural members transversely farther apart than [the smaller of 1/5 the required lap splice length and 150 mm 6 in][____]. The use of contact lap splices necessary for support of the reinforcing is permitted when approved by the Contracting Officer. Place lapped bars in the same plane and parallel to the direction of shooting. Welded splices are permitted. Secure reinforcement to prevent movement. The use of mechanical splices is permitted when approved.

3.1.5  Forms

Use material of adequate thickness for formwork to resist movement during shooting. Reinforce, secure, and brace forms to minimize the effects of vibration during shooting. Construct forms to allow escape of placement air, overspray, and rebound. Use form-release coating material on removable forms unless the formed surface is to subsequently receive an additional coating.
3.2 JOINTS

3.2.1 Construction Joints

Taper construction joints at approximately 45 degrees from receiving surface. Form joints by cutting plastic shotcrete. Make joints at slab intersections at 90 degrees. Roughen shotcrete in the joint face while it is still plastic.

3.2.2 Control Joints

Place control joints as indicated in the Contract Document [Discontinue reinforcement at control joints] [______].

3.3 ALIGNMENT CONTROL

To establish thickness and plane of required surface, install taut ground wires or other means to guide the nozzleman. Install alignment control means at corners or offsets not established by forms.

3.4 APPLICATION

3.4.1 Placement Techniques

a. [Use the same shotcrete mixture and equipment that was used during prequalification testing for the production shotcrete.]

b. Use temporary coverings to protect adjacent surfaces from the deposit of overspray or impact from the nozzle stream.

c. Install sufficient lighting and ventilation to provide the shotcrete crew with a clear view of the shooting area. Suspend Work and adopt corrective measures if visibility is unsuitable for the application of quality shotcrete.

d. Provide a working surface that permits nozzlemen unobstructed access to the receiving surface. Place shotcrete first in corners, recesses, and other areas where rebound or overspray cannot easily escape.

e. Supply shotcrete material and air pressure at the nozzle uniformly, providing a steady, continuous flow of shotcrete with no detrimental surging or pulsing. Maintain the velocity and consistency of shotcrete exiting the nozzle at a uniform rate appropriate for the given job conditions so that satisfactory material consolidation and minimum rebound is achieved.

f. Place shotcrete perpendicular to the receiving surface with the nozzle held at such a distance to produce maximum consolidation of the shotcrete and full encapsulation of the reinforcement.

g. Shoot dry-mixture shotcrete material within 45 min after batching or, in the case of prepackaged material, within 45 min after predampening. Shoot wet-mixture shotcrete material within the time limits in ASTM C94/C94M.

h. Apply shotcrete using a circular or elliptical motion of the nozzle while building the required thickness.

i. Use sufficient material velocity, material consistency, and distance
from the end of the nozzle to the receiving surface to produce maximum consolidation of the shotcrete and full encapsulation of the reinforcing steel.

j. In corners, direct the nozzle to bisect the corner angle. Apply shotcrete so sagging or sloughing does not occur. Where there is potential for accumulated rebound or overspray material to be incorporated into the Work at congested areas of steel reinforcement, embedded obstructions, corners, and recesses, use a compressed air blow pipe to remove loose material from the Work.

k. Discontinue placement of shotcrete or shield the nozzle stream if wind causes separation of ingredients in the nozzle stream.

l. Do not reuse rebound or overspray in the Work.

m. Remove laitance from shotcrete surfaces that are to receive additional shotcrete layers.

n. Surface preparation prior to the shooting of shotcrete must comply with [the paragraph titled PREPARATION OF SURFACE TO RECEIVE SHOTCRETE][____].

**************************************************************************
NOTE: For repair jobs, refer to the section on repairs for surface preparation.
**************************************************************************

o. Do not apply shotcrete to surfaces with standing or flowing water.

p. Remove hardened overspray and rebound from adjacent surfaces, including exposed reinforcement.

3.4.2 Intermediate Surfaces

a. When applying more than one layer of shotcrete, use a cutting rod, brush with a stiff bristle, or other suitable equipment to remove all loose material, overspray, laitance, or other material that may compromise the bond of the subsequent layer of shotcrete. Conduct removal immediately after shotcrete reaches initial set.

b. Allow shotcrete to stiffen sufficiently before applying subsequent layers. If shotcrete has hardened, clean the surface of all loose material, laitance, overspray, or other material that may compromise the bond of subsequent layers. Bring the surface to a saturated surface-dry condition at the time of application of the next layer of shotcrete.

3.4.3 Encasement of Reinforcement

a. Place shotcrete to encase reinforcement and other embedments, and provide a minimum cover of [____].

**************************************************************************
NOTE: Refer to ACI 318 and ACI 350 for concrete cover requirements
**************************************************************************

b. Adjust air volume, material feed volume, and distance of the nozzle from
the Work as necessary to encase reinforcement.

c. Keep the front face of the reinforcement clean during shooting operations so that shotcrete builds up from behind to encase the reinforcement without the formation of shadows or voids.

d. Continuously remove accumulations of rebound and overspray using a compressed air blowpipe, or other suitable device, in advance of deposition of new shotcrete.

3.4.4 Hot Weather Shotcreting

Do not place shotcrete when shotcrete temperature is above [35°C 95°F][_____] unless PREQUALIFICATION TESTING shows that the required quality of materials can be achieved at higher temperatures. A temperature of reinforcement and receiving surfaces greater than [32°C 90°F][_____] prior to shotcrete placement is prohibited.

**************************************************************************
NOTE: If hot weather concrete needs to be considered, then a separate specification that covers hot weather concrete such as ACI 305.1 should be included in the project.
**************************************************************************

3.4.5 Cold Weather Shotcreting

Shooting may proceed when ambient temperature is [4°C 40°F][_____] and rising. Stop shooting when ambient temperature is [4°C 40°F][_____] and falling, unless measures are taken to protect the shotcrete. Shotcrete material temperature, when shot, less than [10°C 50°F][_____] is prohibited. Do not place shotcrete against frozen surfaces.

**************************************************************************
NOTE: If cold weather concrete needs to be considered, then a separate specification that covers cold weather concrete such as ACI 306.1 should be included in the project.
**************************************************************************

3.5 FINISH

[3.5.1 Gun Finish

Leave finished shotcrete surface as gun finish.

][3.5.2 Cutting Screed

After the surface has taken its initial set (crumbling slightly when cut), slice off excess material outside the forms and ground wires with a downward cutting motion using a sharp-edged cutting screed. Then remove ground wires and float the irregularities.

][3.5.3 Flash Coat

Apply a thin coat of shotcrete containing finer sand applied from a distance greater than normal to the surface as soon as possible after the screeding.
3.5.4  Float and Trowel Finish

Provide final surface finish using [wood float] [rubber float] [steel trowel]. Avoid troweling of thin sections of shotcrete unless both troweling and commencement of moisture curing take place within a relatively short period after placement of shotcrete.

3.5.5  Fiber-Reinforced Shotcrete

**************************************************************************
NOTE: Include this paragraph if the exposed fibers pose a safety hazard.
**************************************************************************

Finish the outer surface of the structure with a layer of nonfiber-reinforced shotcrete and provide an appropriate finish as denoted.

3.6  CURING

When the daily mean temperature is above 4°C 40°F, cure continuously for a minimum of 7 consecutive days or for the time necessary to attain 70 percent of the specified compressive or flexural strength, whichever period is less. If shotcrete is placed with daily mean temperatures 4°C 40°F or lower, provide cold weather protection until the shotcrete achieves 70 percent of the specified strength. Complete moist curing by one of the following methods:

a. Ponding or continuous sprinkling for a minimum of 7 days;

b. Covering with an absorptive mat or sand that is kept continuously wet;

c. Covering with impervious sheet material;

d. Use of curing compounds; apply twice the rate for formed surfaces as recommended by manufacturer if the surface is a gun finish.

Do not use natural curing in lieu of that specified in this paragraph unless the relative humidity of the air in contact with the shotcrete remains at or above 85 percent and such curing is authorized by Contracting Officer. Submit curing materials and curing procedures for shotcrete including product data sheets indicating conformance with specification requirements.

3.7  PROTECTION

Immediately after placement, protect shotcrete from premature drying or excessively hot or cold temperatures and mechanical injury. Maintain shotcrete protection to prevent freezing of the shotcrete and to ensure the necessary strength development for structural safety. Remove protection in such a manner that the maximum decrease in temperature measured at the surface of the shotcrete in a 24-hour period does not exceed the following:

a. 10°C 50°F for sections less than 300 mm 12 in. in the least dimension;

b. 4°C 40°F for sections from 300 to 900 mm 12 to 36 in. in the least dimension.
Protect surfaces not intended for shotcrete placement against deposit of rebound and overspray or impact from nozzle stream.

[3.8 TOLERANCES]

Provide dimensional tolerances of shotcrete in compliance with [ACI 117][the contract document][_____

**************************************************************************

NOTE: ACI 117 provides a guide for construction tolerances of concrete structures. Although shotcrete is concrete, ACI 117 specifically excludes shotcrete. Tolerances provide an indication of the finished product expected by the owner, but meeting tolerances may require additional effort and cost. Tolerances given by ACI 117.1R, for placement of reinforcing steel, cover over reinforcing steel, and overall alignment of cast-in-place structural members should be generally the same for shotcrete. Tolerances that require distinct values for shotcrete construction are cross-sectional dimensions, cover, and surface finish (or flatness). Therefore, specifying tolerances that can be consistently achieved are needed so that project expectations can be met at a reasonable cost. Specified tolerances should be based on use and function and can be the same as concrete, but are typically broader. Some finished surface tolerances may be waived to achieve proper coverage over existing reinforcement. For some structures, such as tunnels, only cover thickness is required and tolerances are not specified unless project-specific requirements dictate. Sometimes shotcrete tolerances are increased by a factor of 2 from those in ACI 117. Refer to ACI 506R for more details on shotcrete tolerances. Refer to ACI 318 or ACI 350 to determine project requirements.

**************************************************************************

[3.9 REPAIR OF SHOTCRETE]

3.9.1 General

a. Submit repair procedure for shotcrete defects for the Contracting Officer's acceptance. Include proposed materials, surface preparation, bonding procedures, and final surface finish.

b. Remove voids, shadows, sagging, or other defects in the hardened shotcrete using light-duty chipping hammers [maximum 8 kg 18 lb][_____] followed by high-pressure water blasting or grit blasting to remove bruised shotcrete surface.

c. Conduct removal of defective shotcrete without the creation of feather edges.
NOTE: Edges of the repair area should not be feather-edged. Common methods used for edge preparation include saw-cutting, chipping, grinding, sandblasting, hydro-milling, or other means to a depth of 1/2 to 1 in. (1.25 to 2.5 cm) normal to the surface of the member. Note: if saw-cutting or grinding is used, care should be taken to ensure reinforcing steel is not cut or damaged.

d. In the repair of core hole surfaces and saw cut edges, roughen the core hole or cut surface and predampen prior to repair.

3.9.2 Shotcrete Repair with Commercial Patching Products

Repair shotcrete with commercial patching products, including:

a. Portland cement mortar, modified with a latex bonding agent conforming to ASTM C1059/C1059M, Type II;

b. Packaged, dry concrete repair materials conforming to ASTM C928/C928M.

3.9.3 Removal of Stains, Rust, Efflorescence, and Surface Deposits

Remove stains, rust, efflorescence, and surface deposits considered objectionable by Contracting Officer by methods acceptable to the Contracting Officer.

3.10 ACCEPTANCE OF WORK

3.10.1 General

a. Remove and replace defective areas [larger than 31,000 square mm 48 square inches or 50 mm 2 inches deep][______]. Defects in shotcrete include honeycombing, laminations, dry patches, voids, or sand pockets. Remove defective areas in accordance with the procedures described in paragraph titled "REPAIR OF SHOTCRETE".

**************************************************************************

NOTE: Specify acceptance criteria for degree of reinforcement encasement or severity of defects. Shotcrete that exhibits laminations and voids, exceeding the specified quality, should be removed, replaced, or repaired. ACI 506.4R provides guidance for engineers, inspectors, contractors, and others involved in accepting, rejecting, or evaluating in-place dry-mix or wet-mix shotcrete.

**************************************************************************

b. Shotcrete Work that meets specifications will be accepted.

c. Shotcrete Work that has previously failed to meet one or more requirements, but has been repaired to bring it into compliance will be accepted.

d. The Contracting Officer will either accept or reject Shotcrete Work that fails to meet one or more requirements and that cannot be brought into compliance. Implement modifications to the mixture proportions or the shotcreting procedures to assure that remaining Work complies with the...
requirements.

e. The basis for acceptance or rejection of shotcrete properties is the specified compressive or flexural strength. When additional criteria, properties, or both are required in the contract documents, acceptance criteria includes compliance with those requirements.

3.10.2 Compliance with Test Properties

3.10.2.1 Compressive Strength

Consider the compressive strength adequate if the average of the three cores from a test panel or from in-place shotcrete exceeds 85 percent of the specified compressive strength and no single core is less than 75 percent of the specified compressive strength.

3.10.2.2 Flexural Strength

The average flexural strength of a set of three test beams from one panel must equal or exceed the specified flexural strength in the paragraph titled "flexural strength and properties".

3.10.2.3 Boiled Absorption and Volume of Permeable Voids

The average of tests on three specimens from a test panel, or from in-place shotcrete, must be less than or equal to the specified boiled absorption and specified volume of permeable void limits at the specified test age with no single test greater than the specified boiled absorption plus 1 percent.

3.10.2.4 Flexural Parameters

For FRS, provide flexural parameters and toughness requirements complying with the requirements specified in the paragraph titled "flexural strength and properties".

3.10.2.5 Bond

The average of the bond strength of the specified number of cores must exceed the specified minimum strength requirement of the paragraph titled "Bond strength", with no single core bond strength less than 75 percent of the specified strength.

3.10.2.6 Alkali-silica Reactivity

Provide concrete and concrete materials meeting one of the three requirements specified in the paragraph titled "Resistance to alkali-silica reaction"

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for furnishing, hauling, placing, and roller-compacting concrete for mass concrete construction. This section was originally developed for USACE Civil Works projects.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1 GENERAL

1.1 UNIT PRICES

NOTE: If Section 01 20 00 PRICE AND PAYMENT PROCEDURES is included in the project specifications, this paragraph title (UNIT PRICES) should be deleted from this section and the remaining appropriately edited subparagraphs below should be inserted into Section 01 20 00.

See appropriate Design Memorandum (DM) for concrete items that are to be measured by the neat line, batch or lump sum.
1.1.1  Roller-Compacted Concrete (RCC) in [_____]  

NOTE:  Repeat this bid item and its respective subparagaphs for each bid item of concrete, renumbering the bid items appropriately.

See the Design Memorandum on the use of the optional item on air entrainment.

If bedding concrete is to be paid for as a separate bid item, delete the optional words, "Bedding concrete and", below.

1.1.1.1  Payment

Payment will be made for costs associated with completing the concrete work for roller-compacted concrete placed in the [____], including all aggregate [, air-entraining admixture,] and the use of all equipment and tools to complete the concrete work. However, these costs will not include the cost of the cement, pozzolan, [water-reducing admixture,] and embedded parts that are specified to be paid for separately. [Bedding concrete and] bedding mortar [is] [are] incidental to the RCC and will be paid for as part of the RCC within the neat lines. [Joint materials, waterstops, sealants, and bond breakers are incidental to the concrete and will be paid for as part of the RCC.]  No payment will be made for concrete, as such, that is placed in structures of which payment is made as a lump sum.

1.1.1.2  Measurement

Roller-compacted concrete will be measured for payment on the basis of the actual volume of RCC within the pay lines of the structures as indicated on the drawings. Measure RCC placed against the sides of any excavation without the use of intervening forms only within the pay lines of the structure. No deductions will be made for rounded or beveled edges, space occupied by metal work, electrical conduits or reinforcing steel, nor for voids or embedded items that are either less than 0.14 cubic meter 5 cubic feet in volume or 0.09 square meter 1 square foot in cross section.

1.1.1.3  Unit of Measure

Unit of measure: cubic meter yard.

[1.1.2  Dental Concrete

1.1.2.1  Payment

Payment will be made for costs associated with placing dental concrete.

1.1.2.2  Measurement

Dental concrete will be measured for payment based upon the actual volume of dental concrete placed. The dental concrete volume in cubic meters yards will be computed from the mass weight of the material batched at the batch plant using the theoretical mass per meter weight per yard as determined from the design mixture. Any concrete which is wasted or placed in
violation of the specifications will not be measured for payment.

1.1.2.3  Unit of Measure

Unit of measure: cubic meter yard.

[1.1.3  Bedding Concrete

**************************************************************************

NOTE: If bedding concrete is to be paid for as a separate bid item, delete the optional wording "Bedding concrete and" in Bid Item "(1) Roller-Compacted Concrete (RCC) in [____"]", above.
**************************************************************************

1.1.3.1  Payment

Payment will be made for costs associated with placing bedding concrete.

1.1.3.2  Measurement

Bedding concrete will be measurement for payment based upon the actual volume of bedding concrete placed. The bedding concrete volume in cubic meters yards will be computed from the mass weight of the material batched at the batch plant using the theoretical mass/meter weight/yard as determined from the design mixture. Any concrete which is wasted or placed in violation of the specifications will not be measured for payment.

1.1.3.3  Unit of Measure

Unit of measure: cubic meter yard.

]1.1.4  Portland Cement

1.1.4.1  Payment

Payment will be made for costs associated with portland cement, including the cost of required unloading, hauling, handling, and storage at the site, of all portland cement used in the work for all of the concrete bid items.

1.1.4.2  Measurement

Portland cement will be measured for payment based upon the number of tons (metric) (2,000 pounds) of portland cement used, excluding amount specifically excepted, wasted, or used for the convenience of the Contractor. The quantity to be paid for will be determined by multiplying the approved batch mass in kg/cubic meter weight in pounds per cubic yard of portland cement in each type of concrete used by the number of cubic meters yards of concrete types placed within the pay lines of the structure, as determined in accordance with the concrete bid items, and dividing by 1000 2,000.

1.1.4.3  Unit of Measure

Unit of measure: tons (metric) (2,000 pounds).
1.1.5 Pozzolan

1.1.5.1 Payment

Payment will be made for costs associated with pozzolan, including the cost of required unloading, hauling, handling, and storage at the site, of all pozzolan used in the concrete bid items.

1.1.5.2 Measurement

Pozzolan will be measured for payment based upon the number of cubic meters or feet solid volume of pozzolan used unless specifically excepted, wasted, or used for the convenience of the Contractor. The quantity to be paid for will be determined by multiplying the approved batch mass in kg/cubic meter weight in pounds per cubic yard of pozzolan in each type of concrete used by the number of cubic meters or yards of concrete of the types placed within the pay lines of the structure, as determined in accordance with the concrete bid items, and dividing by the product of the average specific gravity of the pozzolan multiplied by 1000 kg/cubic meter or 62.4 pcf. The average specific gravity is the average of the test results for all material accepted during the period covered by the payment.

1.1.5.3 Unit of Measure

Unit of measure: cubic meter or foot solid volume.

1.1.6 Water-Reducing Admixture (WRA)

1.1.6.1 Payment

Payment will be made for costs associated with water-reducing admixture (WRA) at the applicable contract unit price per cubic yard of concrete containing water-reducing admixture for:

a. "Bid Item [_____]a., first [_____] cubic meters yards".

b. "Bid Item [_____]b., all over [_____] cubic meters yards".

1.1.6.2 Measurement

Water-reducing admixture (WRA) will be measured for payment based upon the actual volume of roller-compacted concrete containing the admixture and within the pay lines of the structures, as determined in accordance with the concrete bid items.

1.1.6.3 Unit of Measure

Unit of measure: cubic meter or yard.

1.1.7 RCC Test Section

**************************************************************************

NOTE: The Test Section may be paid for as a lump sum pay item provided test section requirement are clearly specified.

**************************************************************************
1.1.7.1 Payment

Payment will be made for costs associated with completing the roller-compacted test section, including equipment and tools needed to complete the test section.

1.1.7.2 Measurement

Roller-compacted concrete test section will be measurement for payment based upon the actual number of test sections taken.

1.1.7.3 Unit of Measure

Unit of measure: each.

1.3 SUBMITTALS

**************************************************************************
NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.

**************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-03 Product Data

Batch Plant; G[, [_____]]
Compaction Equipment; G[, [_____]]
Aggregate Production Schedule; G[, [_____]]
Regular Lift-Joint Treatment; G[, [_____]]
Curing and Protection; G[, [_____]]
Cold-Weather Protection; G[, [_____]]
1.4 QUALITY ASSURANCE

1.4.1 Preconstruction Government Testing

**************************************************************************
NOTE: Contact the division laboratory for guidance in filling in the blanks.
**************************************************************************

The aggregate sources listed in paragraph COMMERCIAL CONCRETE AGGREGATE SOURCES in PART 2, have been tested and, at the time testing was performed, were capable of producing materials of the quality required for this project, provided suitable processing is performed. Deliver samples from any source selected, whether listed or not listed, consisting of not less than [_____] kg pounds of each size coarse aggregate and [_____] kg pounds of fine aggregate, and taken under the supervision of the Contracting Officer in accordance with COE CRD-C 100, to [_____] within 15 days after Notice to Proceed. Sampling, shipment, and testing of samples is at the Contractor's expense. [_____] days will be required to complete evaluation of the aggregates. All quality assurance testing will be performed by the Government in accordance with the applicable COE CRD-C or ASTM test methods. Use material from the proposed source that meet the quality requirements of this paragraph for this project. The Government test data and other information on aggregate quality of those sources listed in PART 2 are included in the Design Memorandum and are available for review in the district office. Quality assurance testing of aggregates by the Government does not relieve the Contractor of quality control requirements.

1.4.2 Cementitious Materials and Admixtures

[At least [_____] days in advance of submitting samples for mixture proportioning studies,] [Not later than [_____] days after Notice to Proceed] notify the Contracting Officer of the source, brand name, type, and quantity of all materials (other than aggregates) to be used in the manufacture and curing of the concrete. Assist the Contracting Officer in obtaining samples of each material. Sampling and testing, as determined appropriate, will be performed by and at the expense of the Government. If cement or fly ash are to be obtained from more than one source, state the estimated amount of cement or fly ash to be obtained from each source and the proposed schedule of shipments in the notification. When pozzolan other than fly ash is used, it must be from one source.

1.4.3 Government Testing During Construction

The Government will sample and test cementitious materials, admixtures, aggregates, and concrete during construction as considered appropriate to determine compliance with the specifications. Provide facilities and labor as may be necessary for procurement of representative test samples. Samples of aggregates will be obtained at the point of batching in accordance with COE CRD-C 100. Slump and air content of conventional
concrete will be determined in accordance with ASTM C143/C143M and ASTM C231/C231M, respectively, except the point of sampling will be as specified in paragraph TESTS AND INSPECTIONS in PART 3. Compression test specimens of conventional concrete will be made and laboratory cured in accordance with ASTM C31/C31M and will be tested in accordance with ASTM C39/C39M. Consistency of the RCC will be determined by the Government using the modified Vebe apparatus in accordance with paragraph CONSISTENCY OF RCC above. Compression test specimens of RCC will be made and tested by the Government. Density of the compacted RCC will be checked by the Government as considered appropriate.

1.4.3.1 Aggregates Testing

Testing performed by the Government will not relieve the Contractor of its responsibility for testing under paragraph TESTS AND INSPECTIONS in PART 3. During construction, aggregates will be sampled for acceptance testing as delivered to the mixer to determine compliance with specification provisions. Provide necessary facilities and labor for the ready procurement of representative samples under Government supervision. The Government will test such samples at its expense using the specified COE CRD-C and ASTM methods.

1.4.3.2 Cementitious Materials

Cement or pozzolan will be sampled at the mill, shipping point, or site of the work by the Government. A list of prequalified cement sources and prequalified pozzolan sources is available from the Commander and Director, U.S. Army Engineer Waterways Experiment Station (CEWES-SC-MP), 3909 Halls Ferry Road, Vicksburg, MS 39180-6199. If tests prove that a material which has been delivered is unsatisfactory, promptly remove it from the site of the work. Cementitious materials that have not been used within 6 months after being tested will be retested by the Government at the expense of the Contractor when directed by the Contracting Officer.

1.4.3.3 Prequalified Cement Sources

Deliver and use cement directly from a mill of a producer designated as a prequalified source for the type of cement being used. Samples of cement for quality-assurance testing will be taken at the project site or cement-producing plant by the Contracting Officer for testing at the expense of the Government. Furnish a copy of the mill tests from the cement manufacturer for each lot.

1.4.3.4 Prequalified Pozzolan Sources

Deliver and use pozzolan directly from a producer designated as a prequalified source. Samples of pozzolan for check testing will be taken at the project site by the Contracting Officer for testing at the expense of the Government. Furnish a copy of the test results from the pozzolan manufacturer for each lot.

1.4.3.5 Nonprequalified Cement Sources

**************************************************************************

NOTE: The Contractor’s expense rate for excess testing of cement and Pozzolan by the Government can be obtained from the Structures Laboratory, U.S. Army Engineer Waterways Experiment Station (CEWES–SC–MP), 3909 Halls Ferry Road, Vicksburg, MS
Cement, if not from a prequalified source, will be sampled and tested by or under the supervision of the Government and at its expense. Do not use cement until notice has been given by the Contracting Officer that test results are satisfactory. In the event of failure, the cement may be resampled and tested at the request of the Contractor and at the Contractor's expense. The fill gate or gates of the sampled bin will be sealed and kept sealed until shipment from the bin has been completed. Sealing of the fill gate or gates and of conveyances used in shipment will be done by or under the supervision of the Government. Conveyances will not be accepted at the site of the work unless received with all seals intact. If tested cement is rehandled at transfer points, the extra cost of inspection will be at the Contractor's expense. The cost of testing cement excess to project requirements will also be at the Contractor's expense and will be deducted from payments due the Contractor at a rate of [_____] dollars per test.

1.4.3.6 Nonprequalified Pozzolan Sources

Pozzolan, if not from a prequalified source, will be sampled at the source or at the site of the work and will be stored in sealed bins pending completion of acceptance tests. Pozzolan may be resampled at the site when determined necessary. All sampling and testing will be performed by and at the expense of the Government. Release for shipment and approval for use will be based on compliance with 7-day lime-pozzolan strength requirements and other physical, chemical, and uniformity requirements for which tests can be completed by the time the 7-day lime-pozzolan strength test is completed. Release for shipment and approval for use on this basis will be contingent on continuing compliance with the other requirements of the specifications. If test results of a bin fail, the contents may be resampled and tested at the Contractor's expense. The Government will supervise or perform the unsealing and resealing of bins and shipping conveyances. If tested pozzolan is rehandled at transfer points, the extra cost of inspection will be at the Contractor's expense. The cost of testing excess pozzolan in excess of project requirements will be at the Contractor's expense at a rate of [_____] dollars per test. The amount will be deducted from payment to the Contractor.

1.4.3.7 Admixtures

Provide satisfactory facilities for ready procurement of adequate test samples. All sampling and testing of an admixture will be by and at the expense of the Government. Tests will be conducted on the same materials which will be shipped to the project.
1.5.1.2 Storage

Furnish cementitious materials in bulk. Immediately upon receipt at the site of the work, store all cementitious materials in a dry, weather-tight, and properly ventilated structure. All storage facilities must permit easy access for inspection and identification. Store sufficient materials for at least two operating days of continuous placement. In order that cement may not become unduly aged after delivery, use any cement that has been stored at the site for 60 days or more before using cement of lesser age.

1.5.2 Aggregate Storage

**************************************************************************
NOTE: Consult the materials engineer to select the appropriate optional phrase and to fill in the blank.
**************************************************************************

Store fine aggregate and each size of coarse aggregate in separate size groups adjacent to the batch plant and in such a manner as to prevent the intermixing of size groups or the inclusion of foreign materials in the aggregate. Maintain sufficient fine and coarse aggregate at the site for at least [30] [_____] operating days of continuous placement.

1.5.3 Chemical Admixtures

Do not use any admixture that has been in storage at the project site for longer than recommended by the manufacturer or that has been subjected to freezing in the work and remove from the site.

1.6 ENVIRONMENTAL REQUIREMENTS

**************************************************************************
NOTE: Make sure the climatological data is included if that optional sentence is included.
**************************************************************************

If unusual adverse weather, such as heavy rain, severe cold, high winds, heavy snow, etc., occurs or is forecast to occur during placement, suspend the placement operation until conditions improve. [A sample of available climatological data for this project based on historical information is contained herein for general information only. However, it is the responsibility of the Contractor to maintain the construction schedule at no additional cost to the Government.]

1.6.1 Cold-Weather Placement

In cold-weather placement, do not place the RCC when the ambient air temperature drops below 0 degrees C 32 degrees F. If the ambient air temperature does drop below 0 degrees C 32 degrees F, the surface of any recently placed (within the previous 72 hours) and exposed horizontal RCC surface must not remain exposed for more than 4 hours. Protect surfaces that will be exposed for longer times as specified in paragraph COLD-WEATHER PROTECTION in PART 3 as a measure to maintain RCC temperatures above 0 degrees C 32 degrees F until after the ambient air temperature rises to above 0 degrees C 32 degrees F and is expected to remain above 0 degrees C 32 degrees F until the end of the curing and protection period, or until covered by another lift.
1.6.2 Placing During Rain

Do not place RCC during rainfall of $2.5 \text{ mm/hr}$ or more. During periods of lesser rainfall, placement of RCC may continue if, in the opinion of the Contracting Officer, no damage to the RCC is occurring. Commence work only after excess free surface water and contaminated paste or RCC have been removed and the surface has gained sufficient strength (no less than 4 hours after the RCC placement was suspended) to prevent rutting, pumping, intermixing of rainwater with the RCC, or other damage to the RCC. When the RCC surface has been contaminated or damaged in any manner, wash the RCC to break up and remove laitance and/or mud-like coatings from the surface. Remove any undercut coarse aggregate. Remove and dispose of all waste in an approved manner.

1.6.3 Hot-Weather Placement

In hot-weather placement control the temperature of the RCC so that it does not exceed $[25] \ [_____] \text{ degrees C} \ [75.0] \ [_____] \text{ degrees F}$ when placed. Suspend placement as soon as the RCC temperature exceeds $[25] \ [_____] \text{ degrees C} \ [75] \ [_____] \text{ degrees F}$. Measures that can be taken to prevent temperatures exceeding $[25] \ [_____] \text{ degrees C} \ [75] \ [_____] \text{ degrees F}$ include, but are not limited to, chilling mixing water, sprinkling aggregate stockpiles, use of a canopy to shade the RCC placement areas, placing during nighttime and early morning hours, or restricting placements to cloudy days. Do not use any of these systems as reason for extension of completion dates specified in these specifications. In addition, to prevent potential damage to the RCC due to hot-weather related placement conditions, suspend all RCC operation between $[_____] \ [June 15th]$ and $[October 31st] \ [_____]$.

PART 2 PRODUCTS

2.1 RCC SYSTEM

Perform all work in accordance with EM 385-1-1. Provide RCC composed of cementitious materials, water, fine and coarse aggregates, and possibly admixtures. The cementitious material must be portland cement, or portland cement in combination with pozzolan. An admixture, when approved or directed, will be a water-reducing/retarding admixture. Air-entraining admixture will be used in the bedding concrete and other conventional concrete.

2.1.2 Mixture Proportions and Studies

RCC mixtures and all conventional concrete mixtures that interface with the
RCC (such as facing concrete and bedding mixtures) will be proportioned by the Contracting Officer [except that slipformed facing concrete mixture will be proportioned by the Contractor]. There will be one primary RCC mixture used for the mass of the dam [, ____], [and ____]. The primary mixture will contain approximately [____] to [____] kg pounds water, [____] kg pounds portland cement and [____] kg pounds pozzolan per cubic meter yard. [Secondary RCC mixtures requiring higher portland cement and pozzolan contents (approximately [____] to [____] kg pounds per cubic meter yard) will be used for [____] [, ____], [and ____].] There will also be a "bedding mortar" and "bedding concrete." The bedding mortar is a broomable mixture containing approximately 280 to 355 kg 475 to 600 pounds of portland cement and 135 to 180 kg 225 to 300 pounds pozzolan per cubic meter yard. The bedding mortar will have 9.5 mm 3/8-inch nominal maximum size aggregate and a slump, when placed, of 175 to 225 mm 7 to 9 inches. The bedding concrete, 75 to 100 mm 3 to 4 inch slump conventional concrete, must contain 19.0 mm 3/4-inch nominal maximum size aggregate and approximately [____] kg pounds of portland cement and pozzolan per cubic meter yard. The air content of the bedding concrete as delivered to the placement site must be between 4.5 and 7.5 percent. [Preliminary mixture proportioning studies are available for review in the District office.] Use concrete mixtures for [the upstream face] [, and ____], and other conventional concrete mixtures that contain from [____] to [____] kg pounds of cementitious materials and the slump must be between 25 and 100 mm 1 and 4 inches.

2.1.3 Proportioning Responsibility

The proportions of all materials entering the RCC and the conventional concrete will be furnished. The proportions will be changed as necessary by the Government. Adjustments will be made to the batch weights, including cement, pozzolan, and water, to maintain the necessary consistency to prevent segregation within the RCC and allow full compaction as determined. Frequent changes to the batch weights are considered usual and can be expected to occur frequently during the course of each day's placement depending on such variables as humidity, wind velocity, temperature, and cloud cover. Such changes will be as directed. The Contractor will be responsible for adjusting the added water to compensate for changes in aggregate moisture content and to adjust the amount of air-entraining admixture (if used) to keep the percent of air within the specified range.

2.1.4 Nominal Maximum Size of Aggregate

Use nominal maximum size of coarse aggregate in the various parts of the work in accordance with following:

<table>
<thead>
<tr>
<th>FEATURES</th>
<th>NOMINAL MAXIMUM SIZE AGGREGATE</th>
</tr>
</thead>
<tbody>
<tr>
<td>[RCC used in the main concrete gravity dam]</td>
<td>75 mm 3 inches</td>
</tr>
<tr>
<td>[RCC used in construction of the [____]]</td>
<td></td>
</tr>
<tr>
<td>[Conventional concrete for the upstream face]</td>
<td></td>
</tr>
<tr>
<td>[Conventional concrete for the [____]]</td>
<td></td>
</tr>
</tbody>
</table>
FEATURES | NOMINAL MAXIMUM SIZE AGGREGATE
---|---
[RCC used in the [_____]] | 37.5 mm 1-1/2 inch
[RCC used in the [_____]] | 19.0 mm 3/4 inch
[Conventional concrete for [_____]] | 4.75 mm No. 4
[Conventional concrete bedding mixture] | 19.0 mm 3/4 inch
[Bedding mortar] | 4.75 mm No. 4

Note: The nominal maximum size aggregate may be changed for applications requiring a special quality of concrete as directed.

2.1.5 Consistency of RCC

The Contracting Officer will determine at the placement site on a continuing basis the proper consistency necessary for adequate hauling, spreading, and compacting and will direct all necessary changes to achieve the proper RCC consistency. Changes will be directed based on visual examination of the RCC during the spreading and compaction process and on the Vebe time when it varies outside the range considered ideal for compaction, as determined by the Government using the modified Vebe apparatus, in accordance with COE CRD-C 53.

2.1.6 Materials for Mixture-Proportioning Studies

******************************************************************************
NOTE: Contact the Division Lab to fill in the blanks.
******************************************************************************

At least [_____] days in advance of the time when placing of concrete is expected to begin, deliver samples of representative materials proposed for this project and meeting all the requirements of this specification to [_____] by the Contractor at its expense. Take samples of aggregates under the supervision of the Contracting Officer in accordance with COE CRD-C 100, accompanied by test reports indicating conformance with grading and quality requirements hereinafter specified. Use samples of materials other than aggregates that are representative of those proposed for the project and submit accompanied by manufacturer's test reports indicating compliance with applicable specified requirements. Quantities of materials required are as follows:

<table>
<thead>
<tr>
<th>MATERIAL</th>
<th>QUANTITY</th>
</tr>
</thead>
<tbody>
<tr>
<td>75 mm 3 inches nominal maximum size coarse aggregate</td>
<td>[_____] kg pounds</td>
</tr>
<tr>
<td>37.5 mm 1-1/2 inch nominal maximum size coarse aggregate</td>
<td>[_____] kg pounds</td>
</tr>
<tr>

</tr>
<tr>
<td>Cement</td>
<td>[_____] kg pounds</td>
</tr>
<tr>
<td>Pozzolans</td>
<td>[_____] cu meters feet</td>
</tr>
<tr>
<td>Admixtures (each)</td>
<td>[_____] L gallons</td>
</tr>
</tbody>
</table>

Mixture-proportioning studies will be made by the Government at its expense.

2.2 MATERIALS

2.2.1 Cementitious Materials

******************************************************************************

NOTE: See the appropriate concrete aggregates DM or thermal study to select the proper requirements for cementitious materials options.

******************************************************************************

2.2.1.1 Portland Cement

Provide portland cement conforming to ASTM C150/C150M, Type [____], [low alkali when it is to be used with aggregates listed to require it in the paragraph COMMERCIAL CONCRETE AGGREGATE SOURCES below or when directed if a nonlisted source is permitted.] [the heat of hydration requirement at 7 days must be no greater than [____] calories per gram] [including false-set requirement]. [In lieu of low-alkali cement, the Contractor may use a combination of portland cement that does not meet the low-alkali requirement with a suitable pozzolan or ground granulated blast-furnace slag (GGBFS) provided the following requirement is met. The expansion of the proposed combination must be equal to or less than the expansion of a low-alkali cement meeting the requirements of ASTM C150/C150M when tested in conformance with ASTM C441/C441M. Perform these two tests concurrently at an independent certified laboratory at the Contractor's expense. The Government reserves the right to confirm the test results and to adjust the percentage of pozzolan or GGBFS in the combination to suit other requirements at no additional cost to the Government.] Furnish portland cement in bulk.

2.2.1.2 Pozzolan

Provide pozzolan conforming to ASTM C618, Class C or F, including low alkali [multiple factor,] [drying shrinkage,] [uniformity,][ and ][moderate] [severe] sulfate resistance requirements of Table 2A. Uniformity Requirements (for air content) applies to all fly ash. [Table 1A, Supplementary Optional Chemical Requirement for Maximum Alkalies, applies when it is to be used with aggregates listed to require low-alkali...]

SECTION 03 37 23 Page 22
cement]. Furnish pozzolan in bulk.

2.2.1.3 Ground Granulated Blast-Furnace (GGBF) Slag

Provide ground granulated blast-furnace slag conforming to ASTM C989/C989M, Grade 100 or Grade 120.

2.2.1.4 Temperature of Cementitious Materials

The temperature of the cementitious materials as delivered to the site must not exceed 65 degrees C 150 degrees F.

2.2.2 Admixtures

Furnish all liquid chemical admixtures in a solution of suitable viscosity and dilution for field use as determined by the Contracting Officer.

[2.2.2.1 Water-Reducing Admixture (WRA)]

Provide WRA meeting the requirements of ASTM C494/C494M, Type D, except that the 6-month and 1-year compressive strength tests are waived. The admixture may be added to the concrete mixture only when its use is approved or directed and after mixture proportioning studies.

]2.2.2.2 Air-Entraining Admixture

Provide air-entraining admixture conforming to ASTM C260/C260M.

2.2.3 Water

Use water for washing aggregates and for mixing and curing concrete that is free from injurious amounts of oil, acid, salt, alkali, organic matter, or other deleterious substances and complies with COE CRD-C 400.

2.2.4 Aggregates

******************************************************************************
NOTE: See the concrete materials DM to select the aggregate composition options.
This note may be disregarded for regions where Alkali-Silica Reactivity (ASR) is not a concern. Some aggregate sources may exhibit an ASR potential. ASR is a potentially deleterious reaction between alkalis present in concrete and some siliceous aggregates, reference EM 1110-2-2000 paragraph 2-3b(6) and appendix D. Use of cementitious materials meeting the low alkali requirement may be effective in some applications, and insufficient in others. In regions where imposing the low alkali requirement has not been effective in controlling ASR, additional effort for evaluation and mitigation may be required. In which case, the alternate procedures to proportion cementitious materials to meet the low alkali requirement in paragraph PORTLAND CEMENT should not be used with the following requirements. Where ASR is known or suspected to pose a concern for concrete durability, it is recommended that aggregates

SECTION 03 37 23 Page 23
proposed for use in concrete be evaluated to determine ASR potential and an effective mitigation. EM 1110-2-2000, provides recommendations for evaluating and mitigating ASR in concrete mixtures. Aggregate evaluations may not be practical for projects requiring small quantities of concrete (less than 200 cubic meters 250 cubic yards).

Section 32 13 14.13 CONCRETE PAVING FOR AIRFIELDS AND OTHER HEAVY DUTY PAVEMENTS, paragraph ALKALI-SILICA REACTIVITY, provides a specification method for the Contractor to evaluate and mitigate ASR in concrete mixtures. The expansion limits specified in Section 32 13 14.13 are requirements for pavements and exterior slab construction. For structural concrete applications the measured expansion must be less than 0.10 percent. It may not be economical or practical to specify different test limit requirements for use on the same project. In which case the lower limit required by the application should be used.

The designer may use the specification method in Section 32 13 14.13 by incorporating the relevant paragraphs into this specification, or may use the following requirements (retain either the 0.10 or the 0.08 percent expansion limits as appropriate).included in the set of brackets highlighted thus "[ ]".

**************************************************************************

2.2.4.1 Composition

[Use fine aggregate consisting of natural sand, manufactured sand, or a combination of natural and manufactured sands. Use coarse aggregate consisting of [gravel], [crushed gravel], [crushed stone], [air-cooled blast-furnace slag], or a combination thereof.] "[Test and evaluate fine and coarse aggregates proposed for use in concrete for alkali-aggregate reactivity in accordance with ASTM C1260. Evaluate the fine and coarse aggregates separately and in combination, which matches the Contractor's proposed mix design proportioning. All results of the separate and combination testing must have a measured expansion less than 0.10 (0.08) percent at 16 days after casting. Should the test data indicate an expansion of 0.10 (0.08) percent or greater, reject the aggregate(s) or perform additional testing using ASTM C1260 and ASTM C1567. Perform additional testing using ASTM C1260 and ASTM C1567 using the low alkali portland cement in combination with ground granulated blast furnace (GGBF) slag, or Class F fly ash. Use GGBF slag in the range of 40 to 50 percent of the total cementitious material by mass. Use Class F fly ash in the range of 25 to 40 percent of the total cementitious material by mass.]

2.2.4.2 Quality

**************************************************************************

NOTE: The tests selected should be those which are applicable to the concrete to be used in the project. These tests may include those listed below in addition to others not listed. See EM
1110-2-2000 for schedule of tests.

Only a limited number of laboratories are now running ASTM C123/C123M due to the toxic chemicals required. Recommend that ASTM C295/C295M/C295M be specified.

A list of properties and test values are unique to each project and should be taken from the concrete materials DM. Delete the quality tests not required in the DM.

Use the petrographic examination to identify deleterious substances in aggregates. List deleterious substances individually with respective limits.

Deliver aggregates to the mixer that meet the following requirements:

<table>

### 2.2.4.3 Grading

**************************************************************************
NOTE: See DM for appropriate fine aggregate options.
**************************************************************************

**a. Fine Aggregate** - The grading of the fine aggregate as delivered to the mixer for the RCC must be such that the individual percent retained on any sieve does not vary more than 3 percent from the percent retained on that sieve in a fixed grading selected by the Contractor after the first 30 days of concrete placement. The minimum percent retained on each of the 2.36 mm No. 8 through 75 µm No. 200 sieve sizes must be 5 percent. In addition to the grading limits, the fine aggregate, as delivered to the mixer, must have a fineness modulus of no less than 2.10 nor more than 2.75. Also control the grading of the fine aggregate so that the fineness moduli for at least four of five consecutive test samples of the fine aggregate as delivered to the mixer does not vary more than 0.10 from the fineness modulus of the fixed grading selected by the Contractor, and approved. Determine the fineness modulus in accordance with COE CRD-C 104. At the option of the Contractor, fine aggregate may be separated into two or more sizes or classifications, but control the uniformity of the grading of the separate sizes so that they may be combined throughout the job in fixed proportions established during the first 30 days of RCC placement. The grading of the fine aggregate for the bedding concrete and all other conventional concrete must conform to the requirements of [ASTM C33/C33M]. [Section 03 30 00 CAST-IN-PLACE CONCRETE] The fixed grading and the results of individual tests during the first 30 days must fall...
within the following limits:

<td></td>
</tr>
</tbody>
</table>
2.2.4.4 Particle Shape

Use particles of the fine aggregate and of the coarse aggregate that are generally spherical or cubical in shape. The quantity of flat and elongated particles at a length-to-width or width-to-thickness ratio greater than 3 in the separated size groups of coarse aggregate, as defined and determined by ASTM D4791, must not exceed 25 percent in any size group.

2.2.4.5 Moisture Content

Do not place fine aggregate in bins at the batch plant until it is in a stable state of moisture content. A stable moisture content is reached when the variation in the percent of total moisture tested in accordance with ASTM C566 and when sampled at the same location will not be more than 0.5 percent during one (1) hour of the two (2) hours prior to placing the material in the batch plant bins and the variation in moisture content when sampled at the same location must not be more than 2.0 percent during the last 8-hour period that the aggregate remains in the stockpile. Deliver coarse aggregate to the mixers with the least amount of free moisture and the least variation in free moisture practicable under the job conditions. Do not deliver the coarse aggregate to the mixer "dripping wet" under no conditions.

2.2.4.6 Commercial Concrete Aggregate Sources

**************************************************************************
NOTE: The list of sources and required tests will be taken from the concrete materials DM.
**************************************************************************

Concrete aggregates may be furnished from any source capable of meeting the quality requirements stated in paragraph QUALITY above. The following sources were evaluated during the design phase of the project in [_____] and were found at that time capable of meeting the quality requirements when suitably processed. No guarantee is given or implied that any of the following listed sources are currently capable of producing aggregates that meet the required quality stated above. A DM containing the results of the Government investigation and test results is available for review in the [_____] District Office. Contact [_____] at [_____] to arrange for review of the DM. Consider test results and conclusions valid only for the sample tested and do not take as an indication of the quality of all material from a source nor for the amount of processing required.

a. List of Sources

**************************************************************************
NOTE: The concrete materials DM will list those sources requiring low-alkali cement, which must be noted herein.
**************************************************************************

<table>
<thead>
<tr>
<th>FINE AGGREGATE</th>
<th>COARSE AGGREGATE</th>
</tr>
</thead>
<tbody>
<tr>
<td>F1: [_____] [1/]</td>
<td>C1: [_____] [1/]</td>
</tr>
<tr>
<td>F2: [_____]</td>
<td>C2: [_____]</td>
</tr>
</tbody>
</table>
b. **Selection of Source** - After the award of the contract, designate in writing only one source or combination of sources from which to furnish aggregates. If the Contractor proposes to furnish aggregates from a source or sources not listed above, he may designate only a single source or single combination of sources for aggregates. Regardless of the source selected, provide samples for quality-assurance testing as required by paragraphs PRECONSTRUCTION GOVERNMENT TESTING and MIXTURE PROPORTIONS AND STUDIES. If a source for coarse or fine aggregate so designated by the Contractor does not meet the quality requirements stated in paragraph QUALITY above, the Contractor may not submit for approval any other unlisted sources but must furnish the coarse or fine aggregate, as the case may be, from sources listed, provided it meets the requirements of the same paragraph, at no additional cost to the Government.

\[2.2.4.7\] **Government-Furnished Concrete Aggregate Source**

*NOTE: The specification writer should ascertain that restoration of the pit or quarry site is specified under other sections.*

a. **Location** - The deposits are [owned] [controlled] by the Government and are made available to the Contractor free of charge for production of aggregate required under this contract. Within the designated area, an adequate supply of material is available from which concrete aggregate meeting the requirement of these specifications can be produced with suitable processing. The Government guarantees that a sufficient amount of material of suitable quality for production of all of the concrete aggregate required is available within the deposit and that concrete aggregates of suitable quality can be produced with a properly designed and operated plant [without hand-picking or similar operations]. However, the amount of work involved or the amount of unsatisfactory materials required to be wasted to produce a sufficient quantity of suitable concrete aggregate is the responsibility of the Contractor, and the Government will not be held liable for costs resulting from such work or waste. Produce the concrete aggregate from the following sites as shown in the drawings:
b. Explorations - The deposits listed above have been explored by the Government to determine the character and extent of the materials available. The locations of the explorations are shown in the contract drawings. The logs of the exploratory holes are also shown in the drawings. Samples of materials secured are available for inspection at [______]. The results of explorations are furnished for information only. These data are the result of limited explorations and tests conducted by and for the Government and are accurate to the extent of the scope of the investigations conducted. The Government will not be responsible for any deduction, interpretation, or conclusion drawn therefrom by the Contractor.

2.3 PLANT AND EQUIPMENT

2.3.1 Concrete Plant

**************************************************************************
NOTE: See the concrete materials DM or EM 1110-2-2000 for the plant size requirements.
See EM 1110-2-2000 and the concrete materials DM for selection of automatic or semiautomatic plant and for use of the rescreening and washing plant.
**************************************************************************

Use concrete plant, conveying, placing, compaction, and cleanup systems with a capacity of at least [_____] cubic meters yards per hour. Use a batch or a continuous mixing concrete plant.

2.3.2 Location

Locate the concrete plant at the site of the work in the general area indicated in the drawings[, or locate offsite].

2.3.3 Bins and Silos

Provide separate bins, compartments, or silos for each size or classification of aggregate and for each of the cementitious materials. Provide compartments of ample size and constructed so that the various materials will be maintained separately under all working conditions.

2.3.4 Bulk Cement or Pozzolan

Separate all compartments containing bulk cement or pozzolan from each other by a free-draining air space. Equip cement and pozzolan bins with filters which allow air passage but preclude the venting of cement or pozzolan into the atmosphere. Clearly mark all filling ports with a permanent sign stating the contents.
2.3.5 **Batch Plant**

Submit details and data on the concrete plant ([_____] days prior to assembly) [not later than 30 days after Notice to Proceed] for review by the Contracting Officer. Final acceptance of any piece of plant is subject to satisfactory performance during operations. The batch plant should meet the following requirements.

2.3.5.1 **Batchers**

Weigh aggregate in separate weigh batchers with individual scales [or may be batched cumulatively]. Weigh bulk cement and other cementitious materials on a separate scale in a separate weigh batcher. Measure water by weight or by volume, but do not weigh or measure it cumulatively with another ingredient. Measure ice separately by weight. Batch admixtures separately and batch by weight or by volume in accordance with the manufacturers recommendations.

2.3.5.2 **Water Batcher**

Provide a suitable water-measuring and batching device that will be capable of measuring and batching the mixing water within the specified tolerances for each batch. Use mechanism for delivering water to the mixers that is free from leakage when the valves are closed. Interlock the filling and discharge valves for the water batcher so that the discharge valve cannot be opened before the filling valve is fully closed. When a water meter is used, provide a suitable strainer ahead of the metering device.

2.3.5.3 **Admixture Dispensers**

Provide a separate batcher or dispenser for each admixture. Equip each plant with the necessary calibration devices that will permit convenient checking of the accuracy of the dispensed volume of the particular admixture. Provide batching or dispensing devices capable of repetitively controlling the batching of the admixtures to the accuracy specified. Provide piping for liquid admixtures that is free from leaks and properly valved to prevent backflow or siphoning. Provide dispensing system which includes a device or devices that detect and indicate the presence or absence of the admixture or provide a convenient means of visually observing the admixture in the process of being batched or discharged. Ensure each system is capable of ready adjustment to permit varying the quantity of admixture to be batched. Interlock each dispenser with the batching and discharge operations so that each admixture is added separately to the batch in solution in a separate portion of the mixing water in a manner to ensure uniform distribution of the admixtures throughout the batch during the required mixing period. Store and handle admixtures in accordance with the manufacturer's recommendations.

2.3.5.4 **Moisture Control**

Provide plant that is capable of ready adjustment to compensate for the varying moisture content of the aggregates and to change the masses of the materials being batched. Provide a moisture meter complying with the provisions of **COE CRD-C 143** for measurement of moisture in the fine aggregate. Arrange sensing element so that the measurement is made near the batcher charging gate of the sand bin or in the sand batcher.
2.3.5.5 Scales

Provide adequate facilities for the accurate measurement and control of each of the materials entering each batch of concrete. Provide weighing equipment and controls conforming to the applicable requirements of NIST HB 44, except that the accuracy must be within 0.2 percent of the scale capacity. Provide standard test weights and any other auxiliary equipment required for checking the operating performance of each scale or other measuring device. Make tests at the frequency required in paragraph TESTS AND INSPECTIONS in PART 3 and in the presence of a Government inspector. Include a visible indicator that indicates the scale load at all stages of the weighing operation and shows the scale in balance at zero load with each weighing unit. Arrange weighing equipment so that the concrete plant operator can conveniently observe the indicators.

2.3.5.6 Operation and Accuracy

[The weighing operation of each material must start automatically when actuated by a single starter switch and end automatically when the designated amount of each material has been reached. These requirements can be met by providing an automatic batching system as defined in the NRMCA CPMB 100.] [The weighing operation of each material must begin automatically when actuated by one or more starter switches and end when the designated amount of each material has been reached. These requirements can be met by providing a semiautomatic or automatic batching system as defined by the NRMCA CPMB 100.] There must be equipment to permit the selection of [_____] preset mixtures each by the movement of not more than two switches or other control devices. Construct and arrange weigh batchers so that the sequence and timing of batcher discharge gates can be controlled to produce a ribboning and mixing of the aggregates, water, admixtures, and cementitious materials as the materials pass through the charging hopper into the mixer. Include provisions to facilitate the inspection of all operations at all times. Deliver materials from the batching equipment within the following limits of accuracy:

<table>
<thead>
<tr>
<th>MATERIAL</th>
<th>PERCENT OF REQUIRED MASS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cementitious materials</td>
<td>0 to +2</td>
</tr>
<tr>
<td>Water</td>
<td>±1</td>
</tr>
<tr>
<td>Aggregate smaller than 37.5 mm</td>
<td>±2</td>
</tr>
<tr>
<td>1-1/2 inch size</td>
<td></td>
</tr>
<tr>
<td>Aggregate larger than 37.5 mm</td>
<td>±3</td>
</tr>
<tr>
<td>1-1/2 inch size</td>
<td></td>
</tr>
<tr>
<td>Chemical admixtures</td>
<td>0 to +6</td>
</tr>
</tbody>
</table>

Note: When water or chemical admixtures are measured by volume, they must meet the same tolerance percent as stated in the chart.

2.3.5.7 Interlocks

Interlock batchers and mixers so that:

a. The charging device of each batcher cannot be actuated until all scales have returned to zero balance within plus or minus 0.2 percent of the scale capacity and each volumetric device has reset to start or has
signaled empty.

b. The charging device of each batcher cannot be actuated if the discharge device is open.

c. The discharge device of each batcher cannot be actuated if the charging device is open.

d. The discharge device of each batcher cannot be actuated until the indicated material is within the allowable tolerances.

e. Admixtures are batched automatically and separately with the water.

f. The mixers cannot be discharged until the required mixing time has elapsed.

2.3.5.8 Recorder

Provide an accurate recorder or recorders conforming to the following detailed requirements:

a. Produce a graphical or digital record on a single visible chart or tape of the weight or volume of each material in the batchers at the conclusion of the batching cycle. Produce the record prior to delivery of the materials to the mixer. After the batchers have been discharged, show the return to empty condition.

b. Completely house graphical recording or digital printout unit in a single cabinet that is capable of being locked.

c. Mark the chart or tape so that each batch may be permanently identified and so that variations in batch weights of each type of batch can be readily observed. Use chart or tape that is easily interpreted in increments not exceeding 0.5 percent of each batch weight.

d. Show time of day at intervals of no more than 15 minutes.

e. The recorder chart or tape will become the property of the Government.

f. Place the recorder in a position convenient for observation by the concrete plant operator and the Government inspector.

g. The recorded weights or volumes when compared to the weights or volumes actually batched must be accurate within plus or minus 2 percent.

2.3.5.9 Batch Counters

Include devices for automatically counting the total number of batches of all concrete batched and the number of batches of each preset mixture.

2.3.5.10 Rescreening Plant

Locate, arrange, and operate a rescreening plant in a manner that all coarse aggregate will be routed through the plant and that its operation will ensure delivery to the mixers of graded coarse aggregate free from variation and conforming to the size groups and grading of paragraph AGGREGATES above and with moisture content conforming to the provisions of paragraph TESTS AND INSPECTIONS in PART 3. Coarse aggregate may be rescreened and delivered to the batch plant bins one size group at a time.
or two or more adjacent size groups at a time. Simultaneous rescreening of nonadjacent size groups is not permitted. All material passing the bottom screen of the smallest size of coarse aggregate being screened must be wasted.

][2.3.5.11  Washing Plant

Wash all coarse aggregates immediately prior to entering the rescreening plant. The washing plant must contain adequate water nozzles and vibrating screens to remove foreign materials and coatings from aggregate particles. Use water for washing that meets the requirements of paragraph WATER above.

][2.3.5.12  Batch Plant Trial Operation

No less than 7 days prior to commencement of placing the test section, make a test of the batching and mixing plant in the presence of a representative of the Contracting Officer to check operational adequacy. Produce the number of full-scale concrete batches required in trial runs as directed, do not exceed 20, and proportion as directed by the Contracting Officer. Waste or use all concrete produced in these tests for purposes other than inclusion in structures covered by this specification. Correct all deficiencies found in plant operation to the satisfaction of the Contracting Officer prior to the start of concrete placing operations. No separate payment will be made to the Contractor for labor or materials required by provisions of this paragraph. Mixer uniformity testing, in accordance with paragraph TESTS AND INSPECTIONS in Part 3, will be performed by the government near the end of this trial operation period. Notify the Contracting Officer of the trial operation not less than 7 days prior to the start of the trial operation.

2.3.5.13  Protection

Protect weighing, indicating, recording, and control equipment against exposure to dust, moisture, and vibration so that there is no interference with proper operation of the equipment.

2.3.6  Continuous Mixing Plant(s)

******************************************************************************
NOTE: See the concrete materials DM or consult the materials engineer to fill in the blanks.
******************************************************************************

Provide a continuous mixing plant(s) that is capable of producing RCC of the same quality and uniformity as would be produced in a conventional batch plant and capable of producing a uniform continuous product (at both maximum and minimum production rates) that is mixed so that complete intermingling of all ingredients occurs without balling, segregation, and wet or dry portions.

2.3.6.1  Operation and Accuracy

Provide an electronic control system. Provide control system with the capability of changing mixtures instantaneously, producing at least [_____] different mixtures, producing any of the mixtures at a variable rate, and tracking a mixture change to a hopper or a conveyor system. The control panel must display for each ingredient the designed formula values and the instantaneous percentage values and record the instantaneous values at a preset time interval or on demand with a multiple copy printer/recorder.
The recorder must note formula changes and print total quantities of each ingredient and total amounts produced on command. Provide weighing devices (belt scale or other) for continuous weighing of individual ingredients and total ingredients. The plant control must not require manual devices to adjust the material flow. The plant must be capable of total manual control operation for a single product at a limited production for short-time durations in the event of loss of electronic control. Incorporate modular replaceable components to reduce down time in the event of control system malfunction. Maintain an inventory of such replaceable components. Provide a device to monitor the fine aggregate content immediately prior to dispensing into the mixing plant dispensing system. The accuracy of the plant dispensing systems must be within the following limits:

<table>
<thead>
<tr>
<th>MATERIAL</th>
<th>PERCENT OF REQUIRED MASS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pozzolan</td>
<td>0 to +2 percent</td>
</tr>
<tr>
<td>Cement</td>
<td>0 to +2 percent</td>
</tr>
<tr>
<td>Water</td>
<td>± 1 percent</td>
</tr>
<tr>
<td>Aggregate smaller than 37.5 mm 1-1/2 inch size</td>
<td>± 2 percent</td>
</tr>
<tr>
<td>Aggregate larger than 37.5 mm 1-1/2 inch size</td>
<td>± 3 percent</td>
</tr>
<tr>
<td>Admixtures</td>
<td>0 to +6 percent</td>
</tr>
</tbody>
</table>

Note: Calibrate the continuous feeders for each of the ingredients in accordance with the manufacturer's specifications. Maintain devices and tools at the plant location to check the feeder's calibration at the Contracting Officer's request. Provide a technician that is skilled in calibration of the feed devices and the maintenance and repair of the plant control system. The technician must be available within 30 minutes notice during all scheduled plant operations. The technician could be one or more of the Contractor's personnel.

2.3.6.2 Cement, Pozzolan, and Aggregate Feed

Feed cement, pozzolan, and aggregate uniformly, continuously, and simultaneously (at the proper ratios and quantity for the mixture required) into the mixer by belt, auger, vane feeder, or other acceptable method. Keep feed bins or silos for each ingredient sufficiently full and must be of sufficient size to ensure a uniform flow at a constant rate for a specific mixture. The feed bins must have a low-level indicator that both warns the operator and can shut the plant down if insufficient material is available for a uniform and continuous flow.

2.3.6.3 Water and Admixture Dispensers

Provide liquid-dispensing devices capable of metering and dispensing within the specified requirements. Provide liquid valves that are free from leakage in the closed position. Use dispensers with attachments and/or install in such a manner that will permit convenient checking of their accuracy. Ensure plumbing is leak-free and properly valved to prevent backflow and siphoning. Interlock dispenser with the electronic plant control to warn the operator and shut down the plant if insufficient liquid is available. Properly locate separate nozzles for each liquid at the mixer to assure uniform distribution of each liquid to the materials.
entering the mixer.

2.3.6.4 Continuous Mixer(s)

Provide continuous mixer(s) that have proper introduction of ingredients as specified by the manufacturer and do not charge in excess of the manufacturer's recommended capacity. Provide mixer(s) that are capable of combining the materials into a uniform homogeneous mixture and of discharging this mixture without segregation. Operate mixer(s) at the blade speed designated by the manufacturer and mixer(s) must be capable of changing retention time of the ingredients in the mixer. This should be accomplished by manually resetting the mixer(s) blade angles. Predicate mixing time (ingredient retention time in the mixer) upon the uniformity, homogeneity, and consistency of the resultant mixture. Take samples for uniformity testing at 2-minute intervals and test in accordance with COE CRD-C 55 and paragraph MIXER UNIFORMITY REQUIREMENTS below. Maintain mixer(s) in satisfactory operating condition and keep mixer blades free of hardened concrete. Should mixer(s) at any time produce unsatisfactory results, promptly discontinue its use until it is repaired. Provide suitable facilities for obtaining representative samples of concrete for testing. Provide all necessary platforms, shelters, tools, labor, and equipment for obtaining samples.

2.3.6.5 Segregation

Use a means to reduce and minimize segregation and waste which would otherwise result from the continuous stream of concrete being fed into the batch haul devices (concrete buckets, dump trucks, etc.). Provide equipment which retains the concrete between tracks or other means of transport to prevent the need for stopping the mixer. These devices could include, but not be limited to, small-volume conveyor discharge hopper with a large gate that is automatically opened on a timed interval, thereby dumping a series of small batches into larger batch hoppers, trucks, or truck beds.

2.3.6.6 Trial Operation

No less than 7 days prior to commencement of concrete placing, make a test of the plant in the presence of a representative of the Contracting Officer to check operational adequacy. Produce the number of cubic meters yards required in trial runs directed, but do not exceed 40 cubic meters 50 cubic yards and proportion as directed by the Contracting Officer. Waste or use all concrete produced in these tests for purposes other than inclusion in structures covered by this specification. Correct all deficiencies found in plant operation to the satisfaction of the Contracting Officer prior to the start of concrete placing operations. Mixer uniformity tests by the Government will be performed near the end of this trial period. No separate payment will be made to the Contractor for labor or materials required by provisions of this paragraph. Notify the Contracting Officer of the trial operation not less than 7 days prior to the start of the trial operation.

2.3.6.7 Protection

Protect weighing, indicating, recording, and control equipment against exposure to dust, moisture, and vibration so that there is no interference with proper operation of the equipment.
2.3.7 Laboratory Areas

**************************************************************************
NOTE: The specification writer should use this paragraph unless a laboratory building is to be government furnished.
**************************************************************************

Provide a [room] [separate building] adjacent to the plant to house the moisture and grading testing equipment for aggregate and to provide working space for the Government representative. Provide another room for testing fresh concrete and for fabricating and initial curing (approximately 72 hours) of concrete test specimens in accordance with ASTM C31/C31M. The size, arrangement, and location of these rooms will be subject to approval by the Contracting Officer. Provide electricity, air-conditioning, heat, and water as required for use in these laboratory areas.

2.3.8 Mixers

**************************************************************************
NOTE: See the concrete materials DM for information on mixer selection and concrete mixers. Truck mixers are allowed for mixing or transporting RCC or conventional concrete with less than 50 mm 2 inch slump or greater than 38 mm 1-1/2 inch nominal maximum size aggregate (NMSA).
**************************************************************************

Provide stationary mixers or pugmill mixers. [Truck mixers may be used for conventional concrete]. Mixers may be batch or continuous mixing. Combine the materials into a uniform mixture and discharge this mixture without segregation. Do not charge mixers in excess of the capacity recommended by the manufacturer on the nameplate. Excessive overmixing requiring additions of water will not be permitted. Maintain mixers in satisfactory operating condition, and keep mixer drums free of hardened concrete. Replace mixer blades or paddles when worn down more than 10 percent of their depth when compared with the manufacturer's dimension for new blades. Should any mixer at any time produce unsatisfactory results, promptly discontinue its use until it is repaired or replaced.

[2.3.9 Truck Mixers]

Provide truck mixers and the mixing of concrete therein conforming to the requirements of ASTM C94/C94M. A truck mixer may be used for conventional concrete complete mixing (transit-mixed) or to finish the partial mixing done in a stationary mixer (shrink-mixed). Equip each truck with two counters to determine the number of revolutions at mixing speed and the number of revolutions at agitating speed. Do not use truck mixers to mix or agitate concrete with greater than 37.5 mm 1-1/2 inches NMSA or concrete with a slump of 50 mm 2 inches or less. Determine acceptability of truck mixers for uniform mixing by uniformity tests in accordance with ASTM C94/C94M.

[2.3.10 Pugmill Mixers]

Provide a batch or continuous mixing twin-shaft pugmill mixer capable of producing RCC of the same quality and uniformity as would be produced in a conventional plant that meets all the requirements of these specification. All pugmill mixers must meet the requirements of paragraph CONTINUOUS
MIXING PLANT(S) above.

2.3.11 Mixer Uniformity Requirements

All mixers, except for truck mixers, will be tested by the Government in accordance with this paragraph and in accordance with COE CRD-C 55. When regular testing is performed, the conventional concrete must meet the limits of any five of the six applicable uniformity requirements, and the RCC must meet the limits of any three of the four applicable uniformity requirements. When abbreviated testing is performed, the concrete must meet only those requirements listed for abbreviated testing. The initial mixer evaluation test must be a regular test and perform prior to the start of concrete placement. Use concrete proportions the evaluation that contain the largest size aggregate on the project as directed by the Contracting Officer. Regular testing consists of performing all tests on three batches of concrete. The range for regular testing is the average of the ranges of the three batches. Abbreviated testing consists of performing the required tests on a single batch of concrete. The range for abbreviated testing is the range for one batch. If more than one mixer is used and all are identical in terms of make, type, capacity, condition, speed of rotation, etc., the results of tests on one of the mixers apply to the others, subject to the approval of the Contracting Officer. Perform mixer evaluations by the Government. Provide labor and equipment as directed by the Contracting Officer to assist the Government in performing the tests.

Note:
1) = Test for conventional concrete mixed in stationary mixer, 2) = Test for RCC

A regular test will be performed before concrete production begins and when the Contractor requests a reduced mixing time. Perform an abbreviated test every 3 months when concrete is being placed. If a mixer fails the abbreviated test, a regular test will be performed. Cost of testing when the Contractor requests a reduced mixing time will be paid by the Contractor.
2.3.12 Sampling Facilities

2.3.12.1 Sampling Concrete

Provide suitable facilities and labor for obtaining representative samples of concrete in accordance with ASTM C172/C172M for Contractor quality control and Government quality assurance testing.

2.3.12.2 Sampling Aggregates

Provide suitable facilities for readily obtaining representative samples of aggregates for test purposes immediately prior to the material entering the mixer.

2.3.13 Transporting and Conveying Equipment

Provide transporting and conveying equipment conforming to the following requirements.

a. Convey concrete mixtures (RCC, bedding mortar, concrete, and any other concrete that will interface with the RCC) from the plant mixer(s) to placement as rapidly and as continuously as practical by methods which limit segregation, contamination, and surface drying.

b. Convey RCC from the mixing plant to the structure by means of main-line conveyor, end-dump truck, front-end loader, or a combination thereof.

c. Conventional concrete may be transported by ready-mix truck, conveyor, or agitator truck, or properly designed nonagitating truck.

d. Provide indicating and signaling devices for the control and identification of types or classes of concrete as they are mixed and discharged for transfer to the placement site.

e. Identify each type or class of concrete visually by placing a colored tag or other marker as it leaves the mixing plant so that the concrete may be positively identified and placed in the structure in the desired position.

2.3.13.1 Trucks

Use truck mixers or agitators for transporting central-mixed conventional concrete which conform to the applicable requirements of ASTM C94/C94M. Do not use truck mixers to transport concrete with larger than 37.5 mm 1-1/2-inch nominal maximum size aggregate (NMSA) or 50 mm 2 inch slump, or less. Nonagitating trucks may be used for transporting conventional central-mixed concrete over a smooth road when the hauling time is less than 15 minutes and the slump is less than 75 mm 3 inches. Bodies of nonagitating trucks must be smooth, water-tight, metal containers specifically designed to transport concrete, shaped with rounded corners to minimize segregation.

2.3.13.2 Belt Conveyors

Design and operate belt conveyors to assure a uniform flow of concrete from mixer or delivery truck to final place of deposit without segregation of ingredients or loss of mortar and provide with positive means for preventing segregation of the concrete or loss of mortar at transfer points.
and the point of placing. The NMSA required in mixture proportions furnished by the Government will not be changed to accommodate the belt width.

2.3.14 Spreading and Remixing Equipment

Use spreading and remixing equipment conforming to the following requirements:

a. Use dozer to accomplish primary spreading procedure. Graders or other equipment not specified may be used to facilitate the RCC spreading process only when approved.

b. For open, unrestricted areas, use dozer of a minimum size and weight equivalent to a Caterpillar D-6. For restricted placement areas, such as placement of RCC near the dam crest or next to abutments, use dozer of a minimum size and weight equivalent to a Caterpillar D-4.

c. A minimum of one operating dozer for each 150 cubic meters 200 cubic yards of RCC placed each hour. Equip dozers with well maintained grousers. A front-end loader with operator must be available to assist with deposition and spreading of RCC as needed in confined areas.

d. Maintain equipment in good operating condition. The equipment must not leak or drip oil, grease, or other visible contaminants onto the RCC surface.

e. Clean all equipment used for spreading and remixing that leaves the surface of the structure for maintenance or repairs or, for any other reason, of all contaminants by an approved method before returning to the structure surface. Do not operate a dozer or other tracked vehicle on other than fresh uncompacted RCC except to facilitate startup operations for each lift and by approved procedures.

2.3.15 Compaction Equipment

Submit a listing of the equipment proposed for transporting, handling, depositing, spreading, and compacting the concrete for review by the Contracting Officer [(____) days before concrete placement begins.] [not later than 30 days after Notice to Proceed.] Include site drawings or sketches with locations of equipment and placement site. The compaction equipment must conform to the following requirements.

2.3.15.1 Primary Rollers

Use double-drum self-propelled vibratory rollers for primary rolling. Transmit a dynamic impact to the surface through a smooth steel drum by means of revolving weights, eccentric shafts, or other equivalent methods. Provide compactor with a minimum gross mass of 9000 kg 20,000 pounds and produce a minimum dynamic force of 60 000 N/m 350 pounds/linear inch of drum width. Use a variable operating frequency in the approximate range of 1,700 to 3,000 cycles per minute. Use an adjustable amplitude between 0.4 and 1.0 mm 0.015 and 0.04 inches. Provide roller capable of full compaction in both forward and reverse directions. Operate roller at speeds not exceeding 0.7 m/s 2.2 ft/s. Within the range of the operating capability of the equipment, the Contracting Officer may direct or approve variations to the frequency, amplitude, and speed of operation which result in the specified density at the fastest production rate.
2.3.15.2 Small Vibratory Rollers

Use small vibratory rollers to compact the RCC where the larger vibratory rollers specified above cannot maneuver. Compact the RCC to the required density and demonstrate during construction of the test section. Small vibratory rollers cannot compact the RCC to the same density and thickness as the primary rollers; therefore, when small rollers are used, reduce total lift thickness of the RCC layer or lift to no more than 150 mm 6 inches uncompacted thickness to permit adequate compaction. Provide rollers with independent speed and vibration controls and are capable of a wide range of speed adjustments.

2.3.15.3 Tampers (Rammers)

Compact the RCC to the required density and demonstrate during construction of the test section. Tampers cannot compact the RCC to the same density and thickness as the primary rollers; therefore, when tampers are used, reduce thickness of each RCC layer that is to be compacted to no more than 150 mm 6 inches uncompacted thickness to assure adequate compaction.

2.3.15.4 Other Requirements

**************************************************************************

NOTE: See the concrete materials DM or the materials engineer to fill in the blanks.
**************************************************************************

Maintain at least [_____] self-propelled vibratory rollers, at least [_____] small rollers, and at least [_____] tampers meeting these requirements full time at the site and ready for service at all times during production and placement.

2.3.16 Truck-Mounted Vacuum Pickup System

Provide a truck-mounted vacuum pickup system for various cleanup operations from the beginning of foundation cleanup to final placement of job RCC. The unit(s) must be capable of pumping 125 cubic meters 4,500 cubic feet of air per minute through an 200-mm 8-inch diameter opening and capable of pumping water at a minimum rate of 125 L/s 2,000 gpm. Maintain equipment in good operating condition. The equipment must not leak cleanup water and other debris during equipment operation or transit. The equipment must not leak or drip oil, grease, or other visible contamination onto the RCC.

2.3.17 Other Motorized Equipment

All other equipment (backhoe with vibratory plate, backhoe with immersion vibrators, backhoe with mandrel for inserting contraction joint plates, wash trucks, etc.) necessary for the successful completion of RCC production, but not previously discussed within these specifications (or determined to be necessary during the course of the work), must be approved prior to actual use. Such equipment must not result in any damage to the RCC, must be maintained in good operating condition, and must be operated by skilled contractor-provided personnel.

2.3.18 Nuclear Density Gauge

Make tests to determine the density of both the uncompacted and compacted RCC using a two-probe nuclear density gauge supplied by the Contractor. Use nuclear density gauge meeting the applicable requirements of
ASTM C1040/C1040M and capable of taking readings along a horizontal path between the probes at 50-mm 2-inch increments from 50 mm 2 inches from the surface to 600 mm 24 inches below the surface. Make gauge and operator available to the Government until completion of all RCC production at no additional cost. Obtain all permits and certifications for the equipment and the operators.

2.3.19 Calibration

Provide factory calibrated nuclear gauges within 6 months of RCC placement. Construct, at no additional costs to the Government, three conventional concrete test blocks using RCC coarse aggregates and RCC fine aggregate, and with dimensions 300 mm 12 inches larger than the gauge dimensions. Formulate concrete to have densities of approximately 2100, 2300, and 2600 kg/cu m 130, 145, and 160 lb/cu ft using the RCC materials and so far as possible, similar relative proportions. Weigh and measure completed blocks to determine unit weight. Adjust gauge calibration constants for performance on these blocks at least 7 days prior to the evaluation of test strips. Remedy any inconsistencies in gauge performance prior to the start of RCC placement. After the start of RCC placement, field calibrate gauges against cast blocks every 24 hours.

2.3.20 Vibrators

Use internal vibrators of the proper size, frequency, and amplitude for the work being performed as indicated in the chart below to consolidate conventional concrete and the interface between conventional concrete and RCC. Provide vibrators for the conventional concrete/RCC interface consisting of a minimum of four vibrators "gang-mounted" in a line on the boom of a backhoe or similar chassis. Use gang-mounted vibrators that are the large (80 to 150 mm) (3 to 6 inch) models of that listed below:

<table>
<thead>
<tr>
<th>APPLICATION</th>
<th>HEAD DIAMETER (mm) (inch)</th>
<th>FREQUENCY (VPM)</th>
<th>AMPLITUDE (mm) (inch)</th>
</tr>
</thead>
<tbody>
<tr>
<td>RCC interface</td>

<td>9,000 to 13,500</td>
<td>0.50 to 1.00 0.02 to 0.04</td>
</tr>
</tbody>
</table>

Determine the frequency and amplitude in the presence of a Government representative in accordance with COE CRD-C 521.

[2.3.21 Slipforming Equipment

************************************************************************************

NOTE: Consult the materials engineer or the concrete materials DM for whether slipforming is to be allowed or required.

************************************************************************************

Use slipforming equipment capable of slipforming facing elements as specified at a minimum rate of 7.5 mm/s 1.5 ft/min. Provide slip-former with an automated guidance system which guides the slip-former within the specified tolerances. Provide slipformer with the capability of turning
and guiding the form without damage to the RCC and facing element. Provide slipform mold that is at least 1 m 3 feet long to allow the slipform to track easily and to minimize surface tearing caused by friction between the mold and the concrete. Design mold to be mortar-tight and to contain the concrete so that it can be fully consolidated.

PART 3 EXECUTION

3.1 PREPARATION FOR PLACING

**************************************************************************
NOTE: Refer to the appropriate DM and the project coordinator for filling in the correct dates and to choose the optional sentences.
**************************************************************************

3.1.1 Placing Schedule

Start RCC Placement for the main structure no later than [_____] and no earlier than [______]. Complete placement of all RCC by [______]. Before starting RCC production, submit a detailed schedule indicating intended daily and weekly production rates that, when followed, will meet the beginning and ending specified RCC production dates. After initiation of RCC production, update and adjust the Contractor's schedule on a weekly basis for the duration of the RCC placement. If it becomes apparent for any reason that the Contractor is not pursuing a schedule that will meet the specified RCC production dates, take actions necessary to increase the production rate so that production is once again on schedule, within [______] calendar days after written notice. Also, if not back on schedule by the end of the [______] days calendar period, the Government reserves the right at this time to direct the Contractor, at no additional cost to the Government, to increase the amount and size of crews and equipment.

3.1.2 RCC Orientation Session

Prior to or in conjunction with the construction of the RCC test section, supervisors and all other Contractor personnel which are expected to participate in the production of RCC for this job (including laborers, equipment operators, foremen, and QC and inspection staff) must participate in a 2-hour orientation session organized by the Contracting Officer. Provide a facility suitable for slide and videotape presentation. The intent is to orient all individuals on the goals of the RCC placement process, provide clarification of specification requirements if requested, and be provided orientation as to what constitutes good construction practices. Additional orientation sessions will also be made available to, and must be attended by, all new Contractor personnel who are subsequently hired and that will be involved with the production of the RCC.

3.1.3 Aggregate Production Schedule

**************************************************************************
NOTE: See the appropriate DM or the materials engineer to fill in the blanks.
**************************************************************************

Begin aggregate production and initial stockpiling and produce acceptable material by no later than [______] days in advance of the time when placement of the RCC test section is expected to begin. Manufacture and stockpile at least [______] percent of all RCC aggregates for each size.
group necessary for the completed RCC construction prior to start of
placement of RCC for the permanent RCC structures. Submit descriptions and
details for all methods and operations proposed for aggregate and concrete
operations including daily and weekly production rates, [not later than
[_____] days after Notice to Proceed] for review and approval for
conformance with specifications.

3.1.4 RCC Test Section

**********************************************************************
NOTE: See the materials engineer for information
for filling in the blanks.
**********************************************************************

Prior to placement of any RCC, construct a test section. The purpose of
the test section is to demonstrate the suitability of the Contractor's
equipment, methods, and personnel. The test section must be at least [5]
[_____] lifts in height and be at least [60] [_____] m [200] [_____] feet
long and [12] [_____] m [40] [_____] feet wide at the top. The site of the
test section must be approved. After evaluation and assessment of the test
section by the Contracting Officer, dispose of the test section in an
approved manner. Under no circumstances must the test section be
incorporated into or become a part of the permanent RCC structure.
Demonstrate sustained plant production rates, and batching, mixing,
transporting, spreading, and compaction procedures. Also demonstrate the
vertical face construction method along one side, the sloped face
construction method along another side, procedures for foundation and
concrete surface preparation and cleanup, procedures for placement of
bedding concrete, bedding mortar, and other conventional concrete, and the
installation of any contraction joints and waterstops. Do not begin RCC
operations for the main structure until testing and evaluations by the
Government have been completed, and it has been demonstrated to the
satisfaction of the Contracting Officer that all specification requirements
were met. Following completion of test section construction, allow [10]
[_____] calendar days for testing and evaluations. If the Contractor does
not meet requirements as specified, construct an additional test section or
sections at no additional cost to the Government. Provide date of the test
section construction at least 7 days in advance.

3.1.5 Surface Preparation

3.1.5.1 Cleaning

Clean all lift surfaces including any RCC, dental concrete, bedding
cement, bedding mortar, or other conventional concrete placed adjacent to
and at the same time as the RCC prior to placing any additional concrete
thereon. After cleaning, bedding concrete and bedding mortar are to be
used specifically for achieving bond between different types of concrete
and/or foundation and eliminating and preventing segregation or voids along
margins or RCC placements. Do not cover surfaces to receive bedding
cement or bedding mortar with RCC until the prepared surfaces have been
accepted in writing and that acceptance has been recorded on an approved
checkout form. All surfaces upon which RCC or any bedding mortar or
bedding mix is placed must be moist (but contain no visible free water).
Prior to placing any concrete adjacent to and at the same time as the RCC,
ensure all surfaces are clean and free of loose, unkeyed, or deteriorated
rock; all mud and silt accumulations; vegetation; laitance; puddles or
ponds of free surface water; coatings; and any other detrimental
materials. Use high-pressure water jetting, and/or wet sandblasting,
followed by mild high-volume, low-pressure washing, on all hardened concrete surfaces (cold joints) as necessary for the removal of laitance, coatings, stains, or other difficult-to-remove contaminants. High-volume low-pressure water washing and/or water jetting may be used for removal of loose materials. Keep adequate equipment with operators on hand at the site to clean all surfaces in conformance with these specifications without disrupting in any way the RCC production as scheduled.

3.1.5.2 High-Volume Low-Pressure Washing

Washing of loose materials can be accomplished with high-volume low-pressure water washing and/or air water jetting using equipment of similar design to that used in large-scale foundation cleanups. Provide air-water jets with 40-mm 1-1/2-inch nozzles, a water supply of at least 2 L/s 30 gpm, and compressed air at the jet of 550 to 850 kPa 80 to 120 psi. Provide low-pressure water jets with 25-mm 1-inch nozzles available and a capacity of at least 13 L/s 200 gpm for truck-mounted devices.

3.1.5.3 High-Pressure Water Jet

Use a stream of water under a pressure of no less than 10.3 MPa 1,500 psi for RCC and use 27.6 MPa 4,000 psi for conventional concrete to clean all cold joint surfaces, or surfaces with laitance, mortar coatings, stains, or other difficult-to-remove contaminants. Do not undercut coarse-size aggregates. Remove aggregate particles that are undercut. For cleaning large open areas larger than [_____] square meters feet, use a truck-mounted high-pressure water jet system. For cleaning small or confined areas, use a portable high-pressure water jet system.

3.1.5.4 Wet Sandblasting

This method may be used when the RCC has reached sufficient strength to prevent undercutting of coarse aggregate particles. Continue wet sandblasting until all accumulated laitance, coatings, stain, or other difficult-to-remove contaminants are removed. Wet sandblasting may be used in lieu of or in combination with the high-pressure water jet.

3.1.5.5 Waste Disposal

Any waste water employed in cutting, washing, and rinsing of concrete surfaces, and any other surface water must not stain, or affect exposed surfaces of the structure(s) or damage the environment of the project area. The method of disposal is subject to approval.

3.2 PLACING

**************************************************************************
NOTE: Consult the concrete materials DM for the use of optional sentences and filling in the blanks.
**************************************************************************

3.2.1 Procedures

It is the intent of this contract to raise the structure at essentially the same level across the entire horizontal surface area. For a dam, proceed placement from abutment to abutment and from downstream to upstream. Complete each lift in its entirety across the full surface of the mass. As the advancing edge of the lift progresses, keep the exposed leading edges "live" by progressively placing out from the advancing edge in a sloping
and uniform fan-like manner. Deposit RCC (from the conveyor, end-dump truck, or front-end loader) on the uncompacted RCC of the advancing edge in a forward direction from the dump pile. Do not place RCC in consecutive or consistent lanes. Vary dump location to avoid "lane" construction. [See Contract Drawing [_____] showing typical depositing, spreading, and remixing operations.] The interval between batch plant mixing and final RCC compaction must be no greater than 45 minutes for 300 mm 12 inch lifts and 75 minutes for 600 mm 24 inch lifts. Final compaction is defined as: Any RCC lift composed of layers that have been worked twice by dozer grousers, receives four passes with the vibratory roller, and meets the density requirements.

3.2.2 Bedding Mortar

Apply bedding mortar to the existing surface following any required cleanup. Apply bedding mortar no more than 15 minutes ahead of RCC placement, unless otherwise approved. Use bedding mortar between hardened conventional concrete and RCC, between different RCC placements where cold joints occur, and other locations as directed or as shown in the drawings. The bedding mortar must have an average thickness after application of between 6 and 13 mm 1/4 and 1/2 inch and cover 100 percent of the lift area.

3.2.3 Bedding Concrete

Use bedding concrete, a conventional concrete mixture, at the abutment-RCC interface, and except for cast-in-place concrete for the upstream face, between the RCC and any formed sloping or vertical surface and other locations as directed or as shown in the drawings. Place the bedding mixture only after all required surface preparations have been completed.

3.2.4 Lift Thickness

**************************************************************************

NOTE: See the concrete materials DM for the lift thickness.
**************************************************************************

The total lift thickness after final compaction by the vibratory roller must be [300] [_____] mm [12] [_____] inches.

3.2.5 Depositing, Spreading, and Remixing

**************************************************************************

NOTE: See the appropriate Design Memorandum for use of the alternate optional paragraphs below.
**************************************************************************

After the RCC has been deposited, spread the RCC by dozers into gently sloping layers, approximately 150 mm 6 inches thick, that will, after final compaction of the several layers by the vibratory roller, result in the specified lift thickness. During the spreading process, continuously work the RCC surfaces with the dozer blade and grousers in a manner to remix any RCC that may contain pockets of segregated material and to compact the material. Make at least two passes with the grousers to all surfaces of each layer. Operate dozers continuously during the spreading process, even if this action results in more than two passes. Provide a front-end loader with operator to assist with depositing and spreading RCC as needed in confined areas, at the abutments, and at other locations approved or directed. Do not allow the RCC, bedding mixes, or bedding mortar to dry.
Do not operate dozer or other tracked vehicle on other than fresh uncompactd RCC except at the start of each lift placement to facilitate startup operations, and then only by an approved procedure. Do not place RCC or other concrete on a previous lift which has not met specification. Remove unacceptable material.

3.2.6 Compaction/Consolidation

After spreading and working with the dozers, compact the top surface of each lift with a minimum of four, plus as many additional passes with a self-propelled double-drum vibratory roller operating in the vibratory mode as are required to obtain a minimum of 98 percent of the theoretical density. Count a round trip over the same material as two passes (i.e., from point A to point B and return to point A by the same route is two passes). Do not operate rollers in the vibratory mode unless they are moving. Consolidate bedding concrete and any other conventional concrete that interfaces with the RCC with internal vibrators.

3.2.6.1 Theoretical Density (TD) Determination

The TD is defined as the theoretical density (unit weight) of the concrete, kg pounds per cubic meter foot, computed to include an air content of [_____] percent. The TD value to be used during construction will be determined using job mixture proportions and Contractor supplied materials; and, using compaction techniques suitable for RCC, and following the appropriate testing procedures used to determine theoretical unit weight of concrete as described as in ASTM C138/C138M.

3.2.6.2 Required Compaction Density

Compact all RCC to a minimum of 98 percent of the TD value. The anticipated TD, estimated from laboratory test data is approximately [_____] kg pounds per cubic meter foot.

3.2.6.3 Density Determination of Compacted RCC

Measure density using a nuclear density meter in accordance with ASTM C1040/C1040M. Make RCC density value determinations throughout the course of RCC placement to assure that the RCC is compacted to a minimum 98 percent of the TD and detect segregation and/or voids throughout the RCC.

3.2.6.4 Additional Compaction

If more than four passes are required to achieve the required density, make additional passes at no additional cost to the Government.

3.2.6.5 Consolidation of Bedding and Other Conventional Concrete

Do not use vibrators to transport concrete. Insert vibrator vertically at uniform spacing over the entire area of conventional concrete placement area. Make insertions at a distance approximately one and one-half times the radius of action of the vibrator. The vibrator must penetrate rapidly to the bottom of the layer and at least 150 mm 6 inches into any preceding plastic layer if such exists. Hold vibrator stationary until the entrapped air is forced to the surface (up to 6 seconds) and the concrete is
consolidated and then withdrawn slowly. Keep an adequate number of vibrators on hand to meet placing requirements and spare vibrators available to maintain production in the event of breakdown.

3.2.7 Lift Joints

PLACE entire RCC mass with sufficient continuity so that it hardens and acts as one monolithic block without discontinuous joints or potential planes of separation. Keep all lift joints clean, uncontaminated, free from ponded water, and continuously moist until placement of the succeeding RCC or other concrete.

3.2.7.1 Regular Lift-Joint Treatment

Give lift joints that have not hardened or dried and are less than 72 hours old the regular lift-joint treatment. Submit the method and equipment proposed for joint cleanup and waste disposal for review by the Contracting Officer [_____] days before concrete placement begins] [not later than [_____] days after Notice to Proceed] for conformance with specifications. Regular lift-joint treatment and maintenance must include:

a. Maintaining 100 percent of each compacted lift-joint surface continuously moist,

b. If necessary, removing all loose contaminants or deteriorated RCC by low-pressure washing and/or vacuuming, and

c. Application of a 6 to 13 mm 1/4 to 1/2 inch thick bedding mortar over the entire placement surface area immediately before placement of the next lift.

For regular lift-joint treatment, no washing or vacuuming will be necessary provided damage or contamination of the lift surface is prevented.

3.2.7.2 Cold Joints

A cold joint is any vertical or horizontal RCC surface:

a. That does not receive the next RCC lift within 72 hours,

b. In which the RCC has been allowed to dry, or

c. That has been contaminated to the extent that contaminants cannot be removed using low-pressure water.

Prepare cold joints for the next lift by the methods and procedures in paragraph SURFACE PREPARATION above, prior to resumption of RCC placement. Following this initial preparation, keep the cold-joint surface continuously moist until application of the bedding mortar. Whenever a cold joint at any edge or end of any lift occurs, locate it at least 10 m 30 feet from the location of other cold joints that may have previously occurred in the same direction along previous lifts.

3.2.7.3 Vertical Joints

Joints for sloping, near-vertical or vertical RCC surfaces are considered to be vertical joints. A vertical joint most often will occur when an RCC placement is terminated before the entire RCC placement for that lift has been completed. When it does become apparent that placement of RCC will be
terminated prior to completion of a lift, adjust the RCC spreading procedure at the leading zone of the placement to provide a gradual tapered slope to complete that lift. The taper must be no steeper than 25 horizontal on 1 vertical. Where the tapered slope meets the underlying hardened lift surface, take care to prevent or remove any segregated or uncompacted material. Compact tapered surface in accordance with paragraph COMPACTION/CONSOLIDATION above. Prior to resumption of RCC placements, prepare tapered surface in accordance with paragraph SURFACE PREPARATION above.

3.2.8 Downstream Face

**************************************************************************

NOTE: See the concrete materials DM to select one of the two optional systems for the downstream face.
**************************************************************************

[3.2.8.1 Using Sacrificial Concrete]

Construct downstream sloped face of the dam and the exposed slopes of the stilling basin training walls using sacrificial RCC on [[_____] vertical to [_____] horizontal slope] [1 vertical to 0.85 horizontal slope]. Construct slope to the tolerances specified. Overbuild each RCC lift at least 300 mm 12 inches, and subsequently trim to the surface smoothness tolerance. Trim before the RCC is more than 48 hours old. Demonstrate process during the test section. Trim in such a manner to prevent damage to the surface and interior RCC.

[3.2.8.2 Using Conventional Concrete]

Construct downstream face of conventional concrete in accordance with paragraph VERTICAL FACINGS FOR RCC CONSTRUCTION below.

3.3 CURING AND PROTECTION

Submit the curing media and methods to be used for review to the Contracting Officer [[_____] days before concrete placement begins] for conformance with specifications.

3.3.1 Curing

Keep surface of every RCC lift continuously moist, commencing immediately after compaction, by use of water trucks equipped with fog sprayers for 14 days or until the surface is covered with the next lift. The sloping downstream surface of the Dam, [and the [____]] if constructed of uncompacted sacrificial RCC, need not be cured. Curing and protection for all conventional concrete used in the construction of the vertical faces and any horizontal RCC surfaces that will not receive a subsequent concrete covering must be moist cured. Moist cure conventional concrete made with Type II portland cement, or any type of portland cement with pozzolan, and all RCC for 14 days. Moist cure conventional concrete made with Type I portland cement for 7 days. Moist cure conventional concrete by covering with saturated nonstaining burlap or cotton mats. Rinse new burlap or cotton mats to remove soluble substances before using. Maintain concrete that is moist cured continuously, not periodically, wet for the duration of the entire curing period. Use water for curing in compliance with the requirements of paragraph WATER in PART 2. If the water or mats cause staining or discoloration of permanently exposed concrete surfaces, clean the surfaces by a method approved by the Contracting Officer. When wood or
metal forms are left in place during curing, keep the forms continuously wet, except for sealed insulation curing in cold weather. RCC may be cured with saturated cotton or burlap mats in lieu of the approved fog spraying equipment.

3.3.2 Cold-Weather Protection

**************************************************************************
NOTE: See the concrete materials DM or thermal study for the optional numbers.
**************************************************************************

Maintain air and forms in contact with the RCC and any conventional concrete at a temperature above 0 degrees C (32 degrees F) for [14] [_____] days. In addition, at the time insulation or protection is removed, control the air temperature adjacent to the RCC surfaces so that the concrete near the surface will not be subjected to a temperature differential of more than 15 degrees C (25 degrees F) (as determined by observation of ambient air and concrete temperatures). Submit a description of the materials and methods proposed for protection of the concrete, when concrete is to be placed under cold-weather conditions, to the Contracting Officer for review [_____] days in advance of anticipated need date.

3.3.3 Special Cold-Weather Insulation Protection

**************************************************************************
NOTE: See the appropriate DM for use of this paragraph and to fill in the blanks.
**************************************************************************

In addition to the requirements specified above, all RCC and any conventional concrete placed at the same time and in direct contact with the RCC must receive special insulation protection as described for the following time periods:

a. [____].
b. [____].

Provide insulation with an R value no less than [____] square meter degree Celsius per watt hour square foot degree Fahrenheit per BTU.

3.3.4 Hot-Weather Protection

When ambient air temperatures exceeds 30 degrees C (90 degrees F) and as soon as the conventional concrete and RCC is sufficiently hard to withstand washing of surface mortar, apply water by fog spraying in a controlled manner to provide evaporative cooling. Apply water at such a rate that it quickly evaporates and such that the surface remains continuously moist without ponding. In addition, when surface materials begin to dry and while the RCC placement, spreading, and compaction process is still underway and until the concrete has sufficiently hardened to permit the above water spray, apply hand-held fog spraying to the concrete surfaces as directed to prevent drying out of concrete materials and replace moisture lost to evaporation. These hot-weather protection procedures will require additional labor(s) to assure complete coverage of the entire surface areas to prevent unacceptable damage to the RCC and conventional concrete. Submit a description of the materials and methods proposed for protection
of the concrete, when concrete is to be placed under hot-weather conditions, to the Contracting Officer for review [_____] days in advance of anticipated need date.

3.4 VERTICAL FACINGS FOR RCC CONSTRUCTION

**********************************************************
NOTE: See the concrete materials DM to select the appropriate method or methods specified below. It should be noted that the method used for other vertical conventional concrete work may be different from the method used for construction of the upstream face. See paragraphs GALLERY and SPILLWAY CONSTRUCTION, below.
**********************************************************

The vertical faces of the RCC structure are to be constructed using [a form and cast-in-place conventional concrete system] [a slipform facing system] [a precast concrete panel system] as shown and specified. Submit details of the construction methods and equipment for review within [_____] days after Notice to Proceed. Demonstrate vertical facings system on one side of the RCC test section.

[3.4.1 Form and Cast-in-Place Conventional Concrete]

Provide vertical and near-vertical facings as shown in the drawings. The contract drawings are based on designs whereby all vertical and near-vertical faces are constructed of conventional slump concrete at the same time and rate as used in placement of each RCC lift. In construction of vertical facings, place a 0.75 to 1.25 meter 2.5 to 4.0 foot wide zone of conventional concrete against the forms or other hard surface. The design and engineering of the formwork, as well as its construction, is the responsibility of the Contractor. Design formwork for loads, lateral pressure, and allowable stresses in accordance with Chapter 1 of ACI 347R. Use forms of sufficient strength to withstand the pressure resulting from placement and vibration of the concrete and sufficient rigidity to maintain specified tolerances. The required sequence of construction operations after all forms and concrete surface preparations have been approved is: place conventional concrete full height of each RCC lift and full width against the forms; using dozer action, spread each thin RCC layer into and abutting against the conventional concrete while at the same time tracking the interface between the two with dozer grousers; after full-lift thickness of the RCC is in place next to the conventional concrete, consolidate 100 percent of the conventional concrete and the interface; and finally, compact the RCC (to include the interface) using the vibratory roller. Consolidate and "knit" together the interface between the RCC and conventional concrete using the gang heavy-duty, machine-mounted, immersion vibrators. Take extreme care to stage activities to assure all time restrictions are met and to prevent the occurrence of any openwork, honeycombing, or voids at the conventional concrete/RCC interface. Thoroughly consolidate and intermix all conventional concrete and bedding concrete placed along the RCC and the interface using immersion vibrators. Demonstrate satisfactorily the Contractor's construction techniques and equipment used during construction of the test section.

[3.4.2 Slipformed Facing Elements]

Construct a slipformed conventional concrete face on the upstream face of the dam [and [______]]. Provide concrete for the slipformed facing elements
conforming to requirements of this section. The configuration for the facing elements are as shown. The concrete mixture for the facing elements must be proportioned by the Contractor to be formed by a slipform curbing machine and to have sufficient early strength to allow compaction for RCC against its surface within 4 hours.

3.4.2.1 Prequalification of Equipment

Prior to placing any slipformed facing elements for incorporation into the dam, perform a demonstration of the slipform equipment and concrete mixture as a part of the test section. Form one side of the test section using his proposed slipforming equipment, in accordance with paragraph RCC TEST SECTION above. If necessary, adjust the concrete mixture and make any adjustments or modifications to the slipforming equipment and concrete supply procedures and equipment as may be required to produce a satisfactory slipformed facing element. Construct a starting block to enable the first facing element to be formed without modification to the slipform.

3.4.2.2 Slipform Operations

Operate equipment in such a manner as to prevent damage to the RCC surface and facing element. The slipformer must carry a surge hopper of sufficient capacity to enable the slipformer to continue to extrude facing element between concrete deliveries. If the slipformer is stopped, consolidate concrete thoroughly, make a joint, and remove unacceptable concrete from the mold. Use slipformer with an automated guidance system which guides the slipformer within the specified tolerances. Achieve a smooth, mortar-tight joint between successive elements. Keep molds and vibrators available in sufficient quantities to replace worn or damaged ones. Use vibrators that are capable of being adjusted and relocated to achieve complete consolidation.

3.4.2.3 Slipforming - Preparation for Placing

Do not begin placement until after all preparations are complete and the authorized representative of the Contracting Officer has approved in writing completion of all preparations for that placement. Do not place facing element concrete until the surfaces to receive facing element concrete are free of deleterious substances including but not limited to: uncompacted, loose, deteriorated, or improperly cured RCC or facing element concrete, laitance, dirt, ice, curing compounds, and visible free surface water.

3.4.2.4 Slipforming - Placing

All joint surfaces more than 24 hours old, or in any other way damaged or not meeting the specification requirements, must be wet sandblasted, washed with air-water jets, and surface dried prior to placement of adjoining facing elements. Keep molds for the slipform continually full, and concrete vibrated, to prevent voids. Ensure slipformed facing element is uniform, dense, and free of surface blemishes and tears.

3.4.2.5 Slipforming - Finishing

The class of finish and the requirements for finishing of slipformed facing elements must be as specified in this paragraph, paragraph CONSTRUCTION TOLERANCES, and as indicated. The finished surface must be smooth and free from rock pockets and surface voids. Light surface pitting (voids up to 6
mm 1/4 inch diameter) and light slipforming marks are not considered objectionable. Where the surface produced meets specified requirements, no further finishing operations will be required.

][3.4.3 Precast Reinforced Panels

Design the precast panel systems as specified in [Section 03 41 33 PRECAST STRUCTURAL PRETENSIONED CONCRETE] [03 45 00 PRECAST ARCHITECTURAL CONCRETE] [03 45 33 PRECAST [PRESTRESSED] STRUCTURAL CONCRETE] [______]. Provide typical panel systems consisting of interlocked panels measuring 1 m 4 ft by as much as 5 m 16 ft, 4 inches thick (min.), and anchored at four locations. Provide anchor bars, straps, and connections that are oversized or treated to compensate for deterioration due to exposure to moisture. Brace panels adequately with either external strongbacks or by staggering panel placement and connection to adjacent panels. By design, assure the safety and immobility of the panel system. Include upstream face [, downstream face] [, spillway crest] [, spillway training wall] [, and stilling basin training wall panels]. Match panel joints with pier noses, spillway cap, intake structure, and transverse joints.

3.4.3.1 Leveling Pad

No concrete leveling pad for setting panels is required unless the panel design so requires, however, embed the base of the panels at least 300 mm 1 foot into concrete, RCC, or backfill material. Brace, align, and level initial row of panels adequately.

3.4.3.2 Alignment

Install panels so that horizontal joint lines of the upstream and downstream faces and the spillway crest panel joints align and meet the tolerances in paragraph CONSTRUCTION TOLERANCES.

3.5 CONTRACTION JOINTS

**********************************************************************************************************
NOTE: See the appropriate DM to fill in the blanks.
**********************************************************************************************************

Form contraction joints by inserting plates into non-compacted full lift thickness RCC at locations as shown on the drawings. The plates, when installed adjacent to each other (at the same structure stationing within each lift) must form a bond breaker that serves as a contraction joint. Provide plates that are [900] [____] mm [36] [____] inches wide, [300] [____] mm [12] [____] inches deep, up to 6 mm 1/4 inch thick, and made out of [____]. Install plates vertically into the RCC by means of a vibrating plate mounted on a backhoe. Submit the exact details for the design of the contraction joints, as well as installation and methods of maintaining tolerances, alignment, etc., within [____] days after the Notice to Proceed. Control plate alignment by laser or other approved survey technique. Provide waterstops, drains, and contraction joints within any conventional concrete in accordance with Section 03 30 00 CAST-IN-PLACE CONCRETE and as indicated.

3.6 GALLERY

**********************************************************************************************************
NOTE: See the concrete materials DM for use of this optional paragraph and to select the optional
Submit details of the construction methods within [_____] days after the Notice to Proceed. Construct gallery using one of the following schemes or combination thereof, the details which are the Contractor's responsibility:

a. Precast gallery segments,

b. Removable rigid forms against which conventional concrete, or RCC is placed, and

c. A noncementing fill as a temporary filler in the gallery area and removing it to form the gallery after the RCC has gained sufficient strength to be self-supporting.

Regardless of which procedure is used, slope the gallery to drain and include a gutter along the downstream gallery wall as shown in the drawings. Do not allow the gallery floor surface to pond more than 25 mm 1 inch of water. The size and shape of the gallery must be as shown in the drawings.

3.6.1 Precast Gallery Segments

If stay-in-place precast gallery units are used to form the gallery, construct them in accordance with [Section 03 41 33 PRECAST STRUCTURAL PRETENSIONED CONCRETE] [03 45 33 PRECAST [PRESTRESSED] STRUCTURAL CONCRETE] [______]. Submit design for review and comment. Design the sections to carry the full load of the vibratory roller over the first lift of fresh RCC above the ceiling section with a safety factor of 4 and to carry the vibrating load of subsequent compaction without excessive deflection that could damage the previously placed RCC. For each lift, place a ribbon of bedding concrete, approximately 0.09 cubic meter per linear meter 1 cubic foot per linear foot of precast panel, between the RCC and panels. Vibrate RCC bedding concrete interface thoroughly with immersion vibrators to eliminate any voids or segregation within the RCC. A permanent reinforced precast slab may be used to construct the gallery ceiling section in combination with other gallery construction schemes chosen by the contractor.

3.6.2 Temporary Forms

The design of any temporary gallery form system and its adequacy is the responsibility of the Contractor. Provide forms in compliance with the requirements of 03 30 00 CAST-IN-PLACE CONCRETE, except that they need not be mortar-tight, and they must meet the tolerances in paragraph CONSTRUCTION TOLERANCES. Design ceiling form such that it can safely carry the load of the vibratory roller with a safety factor of 4 and is stiff enough to prevent damage to the fresh RCC from elastic deflection and rebound while compaction is being accomplished. Do not remove forms until the RCC has gained sufficient strength to be self supporting (estimated to be 90 days) and not until at least 10 m 40 feet of RCC has been placed above the gallery ceiling.

3.6.3 Noncementing Fill Method

The gallery section may be constructed by placing a noncementitious fill in the cross-sectional area where the gallery is to be located, compacting it at the same time that the adjacent RCC is compacted, and later removing the
fill. Submit details of how this procedure will be followed, what the noncementitious will consist of, how the fill will be removed later, and how the gallery doors will be set for review and comment in accordance with paragraph SUBMITTALS. To form the outline of the gallery, place braced partitions (or forms) along the perimeter of the gallery section between the RCC and non-cementitious fill. Install separate partitions (or forms) for each lift, of such size and configuration, and position on the previous lift's partitions (or forms) to ultimately form the gallery section. Removed braced partitions during the excavation process. Alignment of partitions (or forms) must not result in offsets and irregularities that exceed construction tolerances specified in paragraph CONSTRUCTION TOLERANCES. The noncementitious fill material may be one or more of the standard RCC aggregates or any other approved fill material, without portland cement or pozzolan; however, nominal maximum-size aggregate must not exceed 19.0 mm (3/4 inch). Do not start excavation of the gallery fill until the RCC has gained sufficient strength to be self supporting (a minimum of 30 days) and until at least 10 m 35 feet of RCC has been placed above the gallery section. As soon as the strength and cover requirements have been met, begin removal of the gallery. Dispose excavated fill material in an approved manner.

3.7 SPILLWAY CONSTRUCTION

3.7.1 Spillway Chute and Ogee Section

Construct spillway floor as shown. The drawings are based on a design whereby the spillway is constructed at the same time and rate as used in placement of each RCC lift. Use the same technology and construction procedures as used in the construction of the vertical upstream face. The major difference being, instead of placing conventional concrete for the floor against vertical cantilevered forms, conventional concrete will be placed against sloping cantilevered forms to form the spillway chute. The design and engineering of the formwork, as well as its construction and methods of maintaining tolerances, etc., is the responsibility of the Contractor. Design formwork for loads, lateral pressures, and allowable stresses in accordance with Chapter 1 of ACI 347R. Provide forms of sufficient strength to withstand the pressure resulting from placement and vibration of the concrete and sufficient rigidity to maintain specified tolerances. Take extreme care to prevent the occurrence of any permanent openwork, honeycombing, or voids at the conventional concrete/RCC interface, or next to the forms. Demonstrate construction techniques satisfactorily during placement of the test section. The unformed portion of the spillway will be finished by placing concrete slightly above grade and striking off to grade by accurate screeding. Finish surface as specified in paragraph FLOAT FINISH below.

3.7.2 Training Walls

Provide concrete for training walls as shown in the drawings and as specified in paragraph VERTICAL FACINGS FOR RCC CONSTRUCTION above.

3.7.3 Finishing

3.7.3.1 General

The ambient temperature of spaces adjacent to surfaces being finished must be no less than 10 degrees C 50 degrees F. In hot weather when the rate of evaporation of surface moisture, as determined by use of Figure 2.1.5 of ACI 305R, may reasonably be expected to exceed 1 kg/sq m 0.2 lb/sq ft per
hour, make provisions for windbreaks, shading, fog spraying, or wet covering with a light-colored material in advance of placement, and take such protective measures as quickly as finishing operations will allow. Float finish all unformed surfaces that are not to be covered by additional concrete or backfill, unless a trowel finish is specified, and finish true to the elevation shown. Bring surfaces to receive additional concrete or backfill to the elevation shown in the drawings and leave true and regular. Slope exterior surfaces for drainage unless otherwise shown or as directed. Make joints carefully with a jointing or edging tool. Protect finished surfaces from stains or abrasions.

3.7.3.2 Float Finish

Surfaces must be screeded and darbied or bullfloated to bring the surface to the required finish level with no coarse aggregate visible. Do not add water, cement, or mortar to the surface during the finishing operation. Float concrete, while still green but sufficiently hardened to bear a man's weight without deep imprint, to a true and even plane. Floating may be performed by use of suitable hand floats or power-driven equipment. Use magnesium or aluminum hand floats. Tolerance for a floated finish must be true plane within $8 \text{ mm in 3000 mm } \frac{5}{16} \text{ inch in 10 feet}$ as determined by a 3-m 10-foot straightedge placed anywhere on the slab in any direction.

3.8 CONSTRUCTION TOLERANCES

**************************************************************************
NOTE: Delete any of the following tables that are not applicable. Most projects will require several tables to cover all parts of the structure.
**************************************************************************

The definitions of the terms used in the following tables are as defined in ACI 117. Make level and grade tolerance measurements of slabs as soon as possible after finishing. When forms or shoring are used, make measurements prior to removal. Tolerances are not cumulative. The most restrictive tolerance controls. Tolerances must not extend the structures beyond legal boundaries. Except as specified otherwise, plus tolerance increases the amount or dimension to which it applies or raises a level alignment, and minus tolerance decreases the amount or dimension to which it applied or lowers a level alignment. A tolerance without sign means plus or minus. Where only one signed tolerance is specified, there is no limit in the other direction.

### TOLERANCE FOR FINISHED OR FORMED CONVENTIONAL CONCRETE SURFACES

#### Vertical alignment
- Formed surfaces slope with respect to the specified plane
- Vertical alignment of exposed corner columns and control joint grooves in concrete exposed 9 mm in 3000 mm 3/8 inch in 10 feet
- All other conditions 12 mm in 3000 mm 1/2

Abrupt variation in spillway surface: The offset between concrete surfaces under adjacent pieces of formwork 3 mm 1/8 inch
Gradual variation: Surface finish tolerances as measured by placing a freestanding (unleveled), 1500-mm or 5-ft straightedge for plane surface or curved template for curved surface anywhere on the surface and allowing it to rest upon two high spots within 72 hr after concrete placement. The gap at any point between the straightedge or template and the surface must be within 6 mm/4 inch.

Offsets of adjacent precast gallery segments must not exceed 25 mm/1 inch.

3.8.2 RCC Surfaces

a. Variations from the lines and grades of the gallery walls and ceiling from that shown in the drawings must not exceed plus or minus 75 mm/3 inches except keep tolerances at the gallery entrances within the limits necessary for the bulkheads and doorways to fit and function as designed.

b. Allowable variation from lines and grades of the downstream face of the dam (measured in any direction) must be minus zero (-0) (no under build allowed) and plus 100 mm/4 inches, [except that the elevation and shape of the spillway stilling basin training walls must be such that the training walls match with the downstream face as shown in the drawings or otherwise provided for]. See additional restrictions in paragraph DOWNSTREAM FACE in Part 3.

c. The thickness of compacted lifts of RCC must be within plus or minus 50 mm/2 inches of that specified.

d. The elevation of the surfaces of RCC lifts upon which subsequent RCC or conventional concrete is placed must not vary more than 150 mm/0.5 ft from the design elevation, except that the elevation of the top three lifts of the dam must be within 60 mm/0.2 ft of that shown.

e. The location of anchor bars, waterstops, contraction joints, and drain holes must be within 150 mm/0.5 ft of the designated locations shown.

f. The spacing of individual reinforcing steel bars in RCC must be within 50 mm/2 inches of that shown.

g. Tolerances for exposed surfaces of upstream face concrete [, the face of the spillway chute,] and any other conventional concrete that interfaces with the RCC must be in accordance with paragraph CONVENTIONAL CONCRETE SURFACES above.

3.9 TESTS AND INSPECTIONS

3.9.1 General

Perform the inspection and tests as described below, and based upon the results of these inspections and tests, take the action required and submit reports as required. When, in the opinion of the Contracting Officer, the concreting operation is out of control, cease concrete placement. The laboratory performing the tests must be on-site and conform with ASTM C1077. The individuals who sample and test concrete or the constituents of
concrete as required in this specification will have demonstrated a knowledge and ability to perform the necessary test procedures equivalent to the ACI minimum guidelines for certification of Concrete Field Testing Technicians, Grade I. The individual who performs the inspection will have demonstrated a knowledge and ability equivalent to the ACI minimum guidelines for certification of [Concrete Transportation Construction Inspector (CTCI)] [Concrete Construction Inspector (CCI)], Level II. The Government will inspect the laboratory, equipment, and test procedures prior to start of concreting operations and at least once per year thereafter for conformance with ASTM C1077.

3.9.2 Testing and Inspection Requirements

3.9.2.1 Fine Aggregate

3.9.2.1.1 Grading

At least once during each shift when the concrete plant is operating, make one sieve analysis and fineness modulus determination in accordance with ASTM C136/C136M, ASTM C117, and COE CRD-C 104 for the fine aggregate or for each fine aggregate if it is batched in more than one size or classification. The location at which samples are taken may be selected by the Contractor as the most advantageous for control. However, the Contractor is responsible for delivering fine aggregate to the mixer within specification limits. Record results on a sheet on which are also shown the specification limits applicable to the project.

3.9.2.1.2 Fineness-Modulus Control Chart

Group results for fineness modulus in sets of three consecutive tests, and plot the average and range of each group on a control chart. Draw the upper and lower control limits for average 0.10 units above and below the target fineness modulus, and the upper control limit for range is 0.20.

3.9.2.1.3 Corrective Action for Fine Aggregate Grading

When the amount passing on any sieve is outside the specification limits, resample and retest the fine aggregate immediately. If there is another failure on any sieve, report the fact immediately to the Contracting Officer. Whenever a point on the fineness modulus control chart, either for average or range, is beyond one of the control limits, double the frequency of testing. If two consecutive points are beyond the control limits, consider the process out of control and stop concreting. Notify the Contracting Officer, and take immediate steps to rectify the situation. After two consecutive points have fallen within the control limits, testing at the normal frequency may be resumed.

3.9.2.1.4 Moisture Content Testing

When in the opinion of the Contracting Officer the electric moisture meter is not operating satisfactorily, perform at least four tests for moisture content in accordance with ASTM C566 during each 8-hour period of mixing plant operation. Randomly select times for the tests within the 8-hour period. Make an additional test whenever the slump is out of control or excessive variation in workability is reported by the placing foreman. When an electric moisture meter is operating satisfactorily, make at least two direct measurements of moisture content per week to check the calibration of the meter. Use results of tests for moisture content to adjust the added water in the control of the batch plant.
3.9.2.1.5 Moisture Content Corrective Action

Whenever the moisture content of the fine aggregate changes by 0.5 percent or more from the previous sample, adjust the scale settings for the fine aggregate batcher and water batcher (directly or by means of a moisture compensation device).

3.9.2.2 Coarse Aggregate

3.9.2.2.1 Grading

At least once during each shift in which the concrete plant is operating, perform a sieve analysis in accordance with ASTM C136/C136M for each size of coarse aggregate. The location at which samples are taken may be selected by the Contractor as the most advantageous for production control. A test record of samples of aggregate taken at the same locations must show the results of the current test as well as the average results of the five most recent tests including the current test. The Contractor may adopt limits for control coarser than the specification limits for samples taken other than as delivered to the mixer to allow for degradation during handling. When facilities are available to test samples five times as large as those required in ASTM C136/C136M, no averaging is permitted.

3.9.2.2.2 Corrective Action for Grading

When the amount passing any sieve is outside the specification limits, resample and retest the coarse aggregate immediately. If the second sample fails on any sieve, report that fact to the Contracting Officer. Where two consecutive averages of five tests (or two consecutive tests where large samples are used) are outside specification limits, consider the operation out of control, and report that fact to the Contracting Officer, stop concreting, and take immediate steps to correct the grading.

3.9.2.2.3 Coarse Aggregate Moisture Content

Make a test for moisture content of each size group of coarse aggregate at least once a shift. When two consecutive readings for smallest size coarse aggregate differ by more than 1.0 percent, increase frequency of testing to that specified previously for fine aggregate.

3.9.2.2.4 Coarse Aggregate Moisture Corrective Action

Whenever the moisture content of any size of coarse aggregate changes by 0.5 percent or more from the previous sample, adjust the scale setting for the coarse aggregate batcher and the water batcher to compensate for this.

3.9.2.2.5 Material Finer than the 75 µm No. 200 Sieve

When in the opinion of the Contracting Officer, a problem exists in connection with the cleanliness of the coarse aggregate, make tests in accordance with ASTM C117. Testing frequency must be as directed.

3.9.2.2.6 Corrective Action for material finer than the 75 µm No. 200 Sieve

When material finer than the No. 200 sieve exceeds 1.0 percent of the weight of the coarse aggregate finer than 37.5 mm 1-1/2 inch or 0.5 percent of the weight of the aggregate coarser than 37.5 mm 1-1/2 inch, notify the Contracting Officer, and initiate steps, such as washing or other...
corrective action, immediately.

3.9.2.3 Quality of Aggregates

**************************************************************************

NOTES: Tests should be those listed in paragraph QUALITY in PART 2. Use the petrographic examination to identify deleterious substances in aggregates. List deleterious substances individually with respective limits.

Only a limited number of laboratories are now running ASTM C123/C123M due to the toxic chemicals required. Recommend that ASTM C295/C295M/C295M be specified.

**************************************************************************

3.9.2.3.1 Frequency of Quality Tests

Prior to submitting samples for mixture proportioning studies, perform the tests for aggregate quality in the following list. In addition, after the start of concrete placement, perform tests for aggregate quality during concrete or aggregate production, in accordance with the following frequency schedule. Samples tested after the start of concrete placement must be taken immediately prior to entering the concrete mixer.

#### 3.9.2.3.2 Corrective Action for Aggregate Quality

If the result of a quality test fails to meet the requirements for quality during submittal of samples for mixture-proportioning studies or immediately prior to start of concrete placement, change production procedures or materials and perform additional tests until the material meets the quality requirements prior to proceeding with either mixture-proportioning studies or starting concrete placement. After concrete placement commences, whenever the result of a test for quality fails the requirements, rerun the test immediately. If the second test fails the quality requirement, report the fact to the Contracting Officer and immediate steps taken to rectify the situation.

#### 3.9.2.4 Scales

##### 3.9.2.4.1 Weighing Accuracy

Check the accuracy of the scales by test weights at least once a month for conformance with the applicable requirements of paragraphs BATCH PLANT and CONTINUOUS MIXING PLANT both in PART 2. Also make such tests as directed whenever there are variations in properties of the fresh concrete that could result from batching errors.

##### 3.9.2.4.2 Batching and Recording Accuracy

Check the accuracy of each batching and recording device once a week during a weighing operation by noting and recording the required weight, recorded weight, and the actual weight batched. Confirm that the calibration devices described in paragraph BATCH PLANT in PART 2 for checking the accuracy of dispensed admixtures are operating properly. If a continuous mixing plant is provided, check the accuracy and operation of all feeding and dispensing units before the start of operation each day.

##### 3.9.2.4.3 Scales Corrective Action

When the weighing accuracy or batching accuracy does not comply with specification requirements, do not operate the plant until necessary adjustments or repairs have been made. Correct discrepancies in recording accuracies immediately.
3.9.2.5 Concrete Plant Control

Continuously control the measurement of all constituent materials including cementitious materials, each size of aggregate, water, and admixtures. Adjust aggregate weights and amount of added water as necessary to compensate for free moisture in the aggregates. Prepare a report indicating type and source of cement used, type and source of pozzolan or slag used, amount and source of admixtures used, aggregate source, the required aggregate and water weights per cubic yard, amount of water as free moisture in each size of aggregate, and the as-mixed aggregate and water weights per cubic meter for each class of concrete placed during plant operation.

3.9.2.6 Concrete

3.9.2.6.1 Conventional Concrete Slump Testing

Make at least two slump tests in accordance with ASTM C143/C143M on each conventional concrete mixture, including bedding mortar produced during each 8-hour period or less of concrete production each day. Make additional tests when excessive variation in workability is reported by the placing foreman or Government inspector. Plot the result of each test for each mixture on a control chart on which the upper and lower limits are set as specified in paragraph MIXTURE PROPORTIONS AND STUDIES in PART 1. Plot the range on a control chart on which the upper control limit is 50 mm or 2.0 inches. Take samples for slump at the mixer, however the Contractor is responsible for delivering the concrete to the placement site at the stipulated slump. If the Contractor's materials or transportation methods cause slump loss between the mixer and the placement, take samples at the placement site as often as required by the Contracting Officer.

3.9.2.6.2 Slump Corrective Action

Whenever points on the control chart approach the upper or lower control limits, make an adjustment in the batch weights of water and fine aggregate. The adjustments are to be made so that the total water content does not exceed that amount specified in the mixture proportions provided by the Contracting Officer based on the free water available with the aggregates and that amount of water batched. If the adjustments to the batch weights of water and aggregates do not satisfactorily produce the required slump, the Contracting Officer may adjust the mixture proportions if the fine-aggregate moisture content is found to be stable and within the required limits. When a single slump is outside the control limits, such adjustment is mandatory. As soon as practical after each adjustment, make another test to verify the correctness of the adjustment. Whenever two consecutive individual slump tests, made during a period when there was no adjustment of batch weights, produce a point on the control chart for range above the upper control limits, consider the slump to be out of control, halt concreting operation, and undertake additional testing for required aggregate moisture content, and take action immediately to correct the problem.

3.9.2.6.3 Air Content

Make at least one test for air content of conventional concrete on a randomly selected batch of each concrete mixture produced during each 8-hour period of concrete production. Make additional tests when excessive variation in workability is reported by the placing foreman or Government inspector.
inspector. Make tests in accordance with ASTM C231/C231M. Plot the average of each test for each mixture on control charts on which the average percent and upper and lower limits are set in accordance with paragraph MIXTURE PROPORTIONS AND STUDIES. Plot the range between two consecutive tests for each mixture on a control chart on which the upper control limits is 3.0 percent.

3.9.2.6.4 Air Content Corrective Action

Whenever points on the control chart approach the upper or lower control limits, an adjustment should be made in the amount of air-entraining admixture batched. If a single test result is outside the specification limit, immediate adjustment is mandatory. As soon as practical after each adjustment, make another test to verify the correction of the adjustment. Whenever a point falls above the upper control for range, calibrate the dispenser to ensure that it is operating correctly and with good reproducibility. Whenever two consecutive points either for average or range are outside the control limits, notify the Contracting Officer.

3.9.2.7 Field Density

3.9.2.7.1 Testing and Checking

Determine density for [each 450 square meters 5,000 square feet of completed lift] [at least eight locations per RCC lift] with a calibrated nuclear density gauge in accordance with ASTM C1040/C1040M. Take densities at depths of 100 and 200 mm 4 and 8 inches. If the densities at 100 and 200 mm 4 and 8 inches conflict, acceptance must be at the 200 mm 8 inch depth.

3.9.2.7.2 Action Required

Whenever the nuclear gauge indicates density less than the specified density, make a retest. If the retest indicates unacceptable density, notify the Contracting Officer's Representative, provide additional rolling immediately, and make a determination as to whether the lower density resulted from insufficient passes of the roller or a change in the mix properties. If the mix properties have changed, make adjustments such as increasing or decreasing the moisture content at the batch plant. If the problem persists, the Contracting Officer may adjust the proportions of aggregates, cement, and/or pozzolan. If the lower density is the result of incomplete rolling, notify the operator and the Contracting Officer may require removal of the incompletely compacted material at no cost to the Government.

3.9.2.8 Inspection Before Placing

Inspect foundation or construction joints, forms, and embedded items in sufficient time prior to each concrete placement to certify to the Contracting Officer that they are ready to receive concrete. Report results of each inspection in writing. The inspection of the lift surfaces of the RCC will be a continuing activity and will be accomplished in accordance with paragraph REGULAR LIFT-JOINT TREATMENT above.

3.9.2.9 Placing Inspection

3.9.2.9.1 Inspection

Provide full time supervision of all placing operations to insure that the
correct quality of RCC, conventional concrete, or grout is placed in each location and that all other aspects of the placing operation are performed in accordance with the contract. During placing operations, the quality control staff must measure and record concrete temperatures in accordance with ASTM C1064/C1064M, ambient temperature hourly, record weather conditions, time of placement, yardage placed, and method of placement.

3.9.2.9.2 Corrective Action

Do not permit placing to begin until verification of an adequate number of vibrators, spreaders, and compactors in working order and with competent operators are available. Do not continue placing if any conventional concrete is inadequately consolidated or if any lift of RCC is not fully compacted. Perform additional compaction, if necessary, in accordance with paragraph ADDITIONAL COMPACTION above. If any batch of conventional concrete fails to meet the temperature requirements, take immediate steps to improve temperature controls.

3.9.2.10 Vibrator Tests

3.9.2.10.1 Vibrator Testing and Use

Determine the frequency and amplitude of each vibrator in accordance with COE CRD-C 521 prior to initial use and at least once a month when concrete is being placed. Make additional tests as directed when a vibrator does not appear to be adequately consolidating the concrete. Determine the frequency while the vibrator is operating in concrete with the tachometer being held against the upper end of the vibrator head while almost submerged and just before the vibrator is withdrawn from the concrete. Determine the amplitude with the head vibrating in air. Take two measurements, one near the tip and another near the upper end of the vibrator head, and average these results. Report the make, model, type, and size of the vibrator and frequency and amplitude results in writing. In addition, check the self-propelled vibratory rollers, as specified in PART 2, paragraph PRIMARY ROLLERS, for frequency and amplitude prior to use and once every 3 months when RCC is being placed.

3.9.2.10.2 Vibrator Corrective Action

Remove any vibrator not meeting the requirements of paragraph VIBRATORS immediately from service and repair or replace.

3.9.2.11 Curing Inspection

3.9.2.11.1 Moist Curing Inspections

At least twice each shift, and twice per day on nonwork days inspect all areas subject to moist curing. Note and record the surface moisture condition.

3.9.2.11.2 Moist Curing Corrective Action

When a daily inspection report lists an area of inadequate curing, take immediate corrective action, and extend the required curing period for those areas by one day.

3.9.2.12 Cold-Weather and Hot-Weather Protection

At least once each shift and once per day on nonwork days inspect all areas
subject to cold-weather or hot-weather protection. Note, correct, and report any deficiencies.

3.9.2.13 Cold-Weather and Hot-Weather Protection Corrective Action

When a daily inspection report lists deficiencies, correct the deficiency immediately and extend the period of protection for one day.

3.9.3 Reports

Report all results of tests or inspections conducted informally as they are completed and in writing daily. Prepare a weekly report for the updating of control charts covering the entire period from the start of the construction season through the current week. During periods of cold-weather protection, make reports of pertinent temperatures daily. These requirements do not relieve the Contractor of the obligation to report certain failures immediately as required in preceding paragraphs. Confirm such reports of failures and the action taken in writing in the routine reports. The Contracting Officer has the right to examine all contractor quality control records.

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for concrete cutoff wall structures. This section was originally developed for USACE Civil Works projects.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1 GENERAL

NOTE: The content of this specification is such that guidance given in EM 1110-2-2000, "Standard Practice for Concrete", is applicable.

1.1 UNIT PRICES

NOTE: If Section 01 20 00 PRICE AND PAYMENT PROCEDURES is included in the project specifications, this paragraph title (UNIT PRICES) should be deleted from this section and the remaining appropriately edited subparagraghs below
should be inserted into Section 01 20 00.

With the exception of coring concrete in completed panels, all costs in connection with this section, including all materials, will be included in the payment item(s) specified.

Core recovery percentage for each boring should be a high number such as 90 to 95, since it is expected that a competent concrete material is being cored. The deviation of the core hole should be in relation to the smallest dimension of the panels that will be produced for each jobsite.

1.1.1 Coring Concrete in Completed Panels

1.1.1.1 Payment

Payment will be made for costs associated with Coring Concrete in Completed Panels and backfilling the core holes. This price will constitute full compensation for mobilizing and demobilizing and furnishing all equipment and supplies necessary to perform all operations specified. No payment will be made for coring and backfilling at a location where the coring reveals the presence of "unacceptable concrete", as specified in paragraphs QUALITY ASSURANCE and CONCRETE PLACEMENT. All costs incurred, including the initial core boring and as many additional core borings as may be required to delineate the limits of the unacceptable concrete and the repair of the cutoff wall, are borne by the Contractor and will not result in any additional cost to the Government.

1.1.1.2 Measurement

Coring Concrete in Completed Panels will be measured for payment from the top of the panel to the bottom of the core hole. If overall core recovery for a boring is less than [_____] percent or the boring deviates from the cutoff wall prior to reaching a depth of [_____] meters feet, redrill and backfill the boring at no additional cost to the Government.

1.1.2 Unit of Measure

Unit of measure: per linear meter foot of cored hole.

1.2 REFERENCES

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.
References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

1.3 SUBMITTALS

**************************************************************************
NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.

**************************************************************************
Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-03 Product Data

Concrete Mixture Proportions; G[, [_____]]

Batch Plant

Concrete Mixers
1.4 QUALITY ASSURANCE

"Unacceptable Concrete" is concrete that is honeycombed, segregated, uncemented, or contains voids greater than the diameter of the core boring. When such concrete is encountered in any panel, replace or repair the unacceptable concrete in accordance with paragraph CONCRETE PLACEMENT. Submit a copy of the records and Contractor tests, as well as the records of the corrective action taken where testing has determined that concrete in completed panels is unacceptable, as directed by the Contracting Officer.

1.4.1 Government Testing and Sampling

Provide facilities and labor as may be necessary for procurement of representative test samples. The Government will sample and test aggregates and concrete to determine compliance with the specifications. Samples of aggregates will be obtained at the point of batching in accordance with ASTM D75/D75M. Concrete will be sampled in accordance with ASTM C172/C172M.
1.4.2 Preconstruction Sampling and Testing

1.4.2.1 Aggregates

**************************************************************************
NOTE: The Designer should consult the appropriate DM, identify the sources for aggregates, and attach them to the end of this section. A Format Template for Aggregate Sources is located in the Template Menu of UFGS. Contact the Division Laboratory for information to fill in the blanks below.
**************************************************************************

The aggregate sources listed at the end of this section have been tested and at the time testing was performed were capable of producing materials of a quality required for this project provided suitable processing is performed. The Contractor may furnish materials from a listed source or from a source not listed. Deliver samples from any source of coarse aggregate and any source of fine aggregate selected by the Contractor, consisting of not less than [_____] [70 kg 150 pounds] of each size coarse aggregate and [_____] [35 kg 75 pounds] of fine aggregate taken under the supervision of the Contracting Officer in accordance with COE CRD-C 100 to [_____] within 15 days after notice to proceed. Sampling and shipment of samples are at the Contractor's expense. [_____] days will be required to complete evaluation of the aggregates. Testing will be performed by and at the expense of the Government in accordance with the applicable COE CRD-C or ASTM test methods. The cost of testing one source for each size of aggregate will be borne by the Government. If the Contractor selects more than one source for each aggregate size or selects a substitute source for any size aggregate after the original source was tested, the cost of that additional testing will be borne by the Contractor. Tests to which aggregate may be subjected are listed in paragraph QUALITY in PART 2.

Provide material from the proposed source meeting the quality requirements of this paragraph. The Government's test data and other information on aggregate quality of those sources listed at the end of this section are included in the DM and are available for review in the district office. Testing of aggregates by the Government does not relieve the Contractor of the requirements outlined in paragraph TESTS AND INSPECTIONS in PART 3.

1.4.2.2 Cementitious Materials and Admixtures

**************************************************************************
NOTE: EM 1110-2-2000, "Standard Practice for Concrete", provides guidance in selecting the options for Government or for Contractor testing.
**************************************************************************

At least 60 days in advance of concrete placement, notify the Contracting Officer of the source of materials, along with sampling location, brand name, type, and quantity to be used in the manufacture and/or curing of the concrete.

1.4.3 Construction Testing by the Government

[Sampling and testing will be performed by and at the expense of the Government except as otherwise specified. Do not use material until notice has been given by the Contracting Officer that test results are satisfactory.] [The Government will sample and test chemical admixtures, curing compounds, and cementitious materials].

SECTION 03 37 29 Page 11
1.4.3.1 Chemical Admixtures Requirements

Retest chemical admixtures that have been in storage at the project site for longer than 6 months or that have been subjected to freezing at the expense of the Contractor when directed by the Contracting Officer and reject if test results are not satisfactory. Chemical admixtures will be accepted based on compliance with paragraph CHEMICAL ADМИXTURES of PART 2.

1.4.3.2 Cement and Pozzolan

******************************************************************************
NOTES: Delete this paragraph if materials are to be accepted on the basis of a manufacture's certification of compliance and mill test reports, and the optional sentence in paragraph SUBMITTALS, SD-07 Certificates, will be used. See the appropriate DM or consult the Materials Engineer to select prequalified sources, subparagraphs "a" and "b" below, or sealed bins, subparagraphs "c" and "d" below, or both options, subparagraphs "a" and "b" and "c" and "d". Selection of the sealed bin method, subparagraphs "c" and "d", must be fully justified in the appropriate DM.

In subparagraph "c" below, to fill in the blank for cost of testing excess cement, contact the Structures Laboratory, Concrete Technology Division, WES.
******************************************************************************

If cement or pozzolan is to be obtained from more than one source, state the estimated amount to be obtained from each source and the proposed schedule of shipments in the initial notification.

[1.4.3.2.1 Prequalified Cement Sources]

Deliver and use cement directly from a mill of a producer designated as a qualified source. Samples of cement for check testing will be taken at the project site or concrete-producing plant by a representative of the Contracting Officer for testing at the expense of the Government. A list of prequalified cement sources is available from Director, U.S. Army Corps of Engineers, Waterways Experiment Station, 3909 Halls Ferry Road, Vicksburg, MS 39180-6199, ATTN: CEWES-SC.

][1.4.3.2.2 Prequalified Pozzolan Sources]

Deliver and use pozzolan directly from a producer designated as a qualified source. Samples of pozzolan for check testing will be taken at the project site by the Contracting Officer for testing at the expense of the Government. A list of prequalified pozzolan sources is available from the Director, U.S. Army Corps of Engineers, Waterways Experiment Station, 3909 Halls Ferry Road, Vicksburg, MS 39180-6199, ATTN: CEWES-SC.

][1.4.3.2.3 Nonprequalified Cement Sources]

Cement, if not from a prequalified source, will be sampled at the source and stored in sealed bins pending completion of testing. Sampling, testing, and the shipping inspection from the point of sampling, when the
point is other than at the site of the work, will be made by or under the supervision of the Government and at its expense. Do not use cement until notice has been given by the Contracting Officer that test results are satisfactory. In the event of failure, the cement may be resampled and tested at the request and expense of the Contractor. When the point of sampling is other than at the site of the work, the fill gates of the sampled bin and conveyances used in shipment will be sealed under Government supervision and kept sealed until shipment from the bin has been completed. If tested cement is rehandled at transfer points, the extra cost of inspection is at the Contractor's expense. The cost of testing cement excess to project requirements is also at the expense of the Contractor. The charges for testing cement at the expense of the Contractor will be deducted from the payments due the Contractor at a rate of \[_____/\] dollars per ton of cement represented by the tests.

1.4.3.2.4 Nonprequalified Pozzolan Sources

Pozzolan, if not from a prequalified source, will be sampled at the source and stored in sealed bins pending completion of certain tests. Pozzolan will also be sampled at the site when determined necessary. All sampling and testing will be by and at the expense of the Government. Release for shipment and approval for use will be based on compliance with 7-day lime-pozzolan strength requirements and other physical and chemical and uniformity requirements for which tests can be completed by the time the 7-day lime-pozzolan strength test is completed. Release for shipment and approval for use on the above basis will be contingent on continuing compliance with the other requirements of the specifications. If a bin fails, the contents may be resampled and tested at the Contractor's expense. In this event, the pozzolan may be sampled as it is loaded into cars, trucks, or barges provided they are kept at the source until released for shipment. Unsealing and resealing of bins and sealing of shipping conveyances will be by or under the supervision of the Government. Shipping conveyances will not be accepted at the site of the work unless received with all seals intact. If pozzolan is damaged in shipment, handling, or storage, promptly remove it from the site of the work. Retest pozzolan that has not been used within 6 months after testing at the expense of the Contractor when directed by the Contracting Officer and reject if the test results are not satisfactory. If tested pozzolan is rehandled at transfer points, the extra cost of inspection is at the Contractor's expense. The cost of testing excess pozzolan is at the Contractor's expense at a rate of \[_____/\] cents per ton. The amount will be deducted from payment to the Contractor.

1.4.3.3 Concrete Tests

Provide facilities and labor as necessary for procurement of representative test samples. The Government will sample and test concrete to determine compliance with the specifications. Concrete will be sampled in accordance with ASTM C172/C172M. Slump and air content will be determined in accordance with ASTM C143/C143M and ASTM C231/C231M, respectively. Compression test specimens will be made and laboratory cured in accordance with ASTM C31/C31M, and compression test specimens tested in accordance with ASTM C39/C39M, but results will be used only for determination of the uniformity of the mixture produced.
PART 2   PRODUCTS

2.1  SYSTEM DESCRIPTION

**************************************************************************
NOTE: Well-rounded natural aggregates are preferred due to the increased flowability of concrete containing these aggregates. If crushed aggregates are used, the fine aggregate and cementitious materials contents may have to be increased to achieve satisfactory flowability. If crushed aggregate is used, increase the specified minimum cement content to 335 kg per cubic meter 564 pounds per cubic yard.
**************************************************************************

Submit concrete mixture proportions as determined by the Contractor for review. State concrete mixture quantities of all ingredients per cubic meter yard and nominal maximum coarse aggregate size that will be used in the manufacture of each quality of concrete. Indicate the mass of cement, pozzolan, slag cement when used, and water; the mass of aggregates in a saturated surface-dry condition; and the quantities of admixtures. Include test reports from a laboratory complying with ASTM C1077 which show that proportions thus selected will produce concrete of the qualities indicated. Make no substitution in the source or type of materials used in the work without additional tests to show that the quality of the new materials and concrete are satisfactory. Perform concrete mixture proportioning conforming to the following:

2.1.1  Maximum Water-Cement Ratio

The maximum water-cement ratio by weight of equivalent portland cement must be 0.50, unless otherwise approved in writing.

2.1.2  Cement Content

The cement content of the concrete must be within the range from a minimum of [279 kg] [470 pounds] [_____] to a maximum of 446 kg/cubic meter 752 pounds/cubic yard. When a pozzolan is used, the total absolute volume of cementitious material must be within the same range in absolute volume as previously specified. Of the total absolute volume of cementitious materials, between 20 and 30 percent may be pozzolan that meets the requirements of paragraph POZZOLAN, OTHER THAN SILICA FUME in PART 2. [If slag cement is used, do not exceed 25 percent by absolute volume, and percentage must be as approved before mixture proportioning studies commence.]

2.1.3  Nominal Maximum-Size Coarse Aggregate

The nominal maximum-size coarse aggregate is [19.0 mm 3/4 inch] [25.0 mm 1 inch].

2.1.4  Fine Aggregate

Fine aggregate comprises approximately 40 to 50 percent, by volume, of the total aggregate.
2.1.5 Air Content

Air Content as determined by ASTM C231/C231M to be 6.0 ± 1.5 percent.

2.1.6 Slump

Determined by ASTM C143/C143M between 150 and 225 mm 6 and 9 inches.

2.1.7 Responsibility of Mixture Proportioning

Proportioning of concrete for use in construction of the cutoff wall is the responsibility of the Contractor and to be performed by a laboratory complying with ASTM C1077.

2.1.8 Concrete Proportioning

**************************************************************************
NOTE: There is no requirement for fc'. The results of trial mixture should be basis for QC.
**************************************************************************

Trial batches and testing requirements for concrete are the responsibility of the Contractor. Obtain samples of approved aggregates in accordance with the requirements of ASTM D75/D75M. Use samples of materials other than aggregate that are representative of those proposed for the project and provide manufacturer's test reports indicating compliance with applicable specified requirements. Make trial mixtures having proportions, slumps, and air content suitable for the work based on ACI 211.1. The maximum water-cement ratio required in the paragraph MAXIMUM WATER-CEMENT RATIO above will be converted to a weight ratio of water to cement plus pozzolan or slag cement by mass equivalency as described in ACI 211.1. In the case where GGBFS is used, include the mass of the slag in the equation for the term P, which is used to denote the mass of pozzolan. Proportion trial mixtures for specified slump and air content. Report the temperature of concrete in each trial batch. If a chemical admixture is used, report slump loss versus time in each trial batch. For each trial mixture, make at least three test cylinders for each test age and cure in accordance with ASTM C192/C192M. Test cylinders at 7 and 28 days in accordance with ASTM C39/C39M, or if a pozzolan or slag cement is used, test cylinders at 7, 28, and 90 days. Submit results of these compressive strength tests but use only for quality control purposes. Submit all results of mixture proportioning studies at least 10 days prior to commencing concrete placement.

2.2 MATERIALS

**************************************************************************
NOTE: Delete the requirements for Certificates for air entrainment admixtures, other chemical admixtures, curing compounds, portland cement, and pozzolan if the optional parts of paragraph CEMENTITIOUS MATERIALS below, is used.
**************************************************************************

Submit certificate of compliance with all specification requirements for the following: Air-Entraining Admixture, Accelerators, and other Chemical Admixtures.
2.2.1  Cementitious Materials

**************************************************************************
NOTE: See the appropriate DM to select the proper requirements for the Cementitious Materials Options. Other cementitious materials may be added if specifically recommended and approved in the concrete materials DM.
**************************************************************************

Cementitious Materials are portland cement or portland cement in combination with pozzolan or GGBFS [or [_____] conforming to appropriate specifications listed below. Do not use cementitious materials until notice of acceptance has been given by the Contracting Officer. Cementitious materials will be subject to check testing from samples obtained at the source, at transfer points, or at the project site, as scheduled by the Contracting Officer, and such sampling will be by or under the supervision of the Government at its expense. Promptly remove not meeting specifications from the site of work. Submit the manufacturer's certification of compliance, accompanied by mill test reports that materials meet the requirements of the specification under which they are furnished, for cementitious materials, including Cement and Pozzolan, [and GGBFS]. Certification and mill test reports must be from samples taken from the particular lot furnished.

2.2.1.1  Portland Cement

ASTM C150/C150M, Type I or II, except that the maximum amount of C3A in Type I cement must be 15 percent [including the heat of hydration at 7 days] [including false set requirements] [low alkali when used with aggregates listed at the end of this section which require it]. [In lieu of low-alkali cement, the Contractor may use a combination of portland cement that does not meet the low-alkali requirement with a pozzolan or GGBFS provided the following requirement is met. The expansion of the proposed combination when tested in accordance with ASTM C441/C441M must be equal to or less than the expansion of a low-alkali cement meeting the requirements of ASTM C150/C150M when tested in general conformance with ASTM C441/C441M. Run the expansion tests concurrently at an independent laboratory that is nationally recognized to perform such tests. The Government reserves the right to confirm the test results and to adjust the percentage of pozzolan or slag in the combination to suit other requirements.]

2.2.1.2  Pozzolan, Other than Silica Fume

Provide pozzolan conforming to ASTM C618, Class [C], [F], with the optional requirements for multiple factor, drying shrinkage, and uniformity [and [moderate] [severe] sulfate resistance requirements] of Table 2A. Apply Table 1A requirement for maximum alkalis when used with aggregates listed at the end of this section to require low-alkali cement.

2.2.1.3  Ground Granulated Blast-Furnace (GGBF) Slag

Provide ground granulated blast-furnace slag conforming to ASTM C989/C989M, Grade 100 or Grade 120.

2.2.1.4  Blended Hydraulic Cement

Portland-Limestone cement must conform to ASTM C595/C595M, Type IL.
2.2.2 Aggregates

--------------------------------------------------------------------------------
NOTE: This note may be disregarded for regions where Alkali-Silica Reactivity (ASR) is not a concern. Some aggregate sources may exhibit an ASR potential. ASR is a potentially deleterious reaction between alkalis present in concrete and some siliceous aggregates, reference EM 1110-2-2000 paragraph 2-3b(6) and appendix D. Where ASR is known or suspected to pose a concern for concrete durability, it is recommended that aggregates proposed for use in concrete be evaluated to determine ASR potential and an effective mitigation. EM 1110-2-2000, provides recommendations for evaluating and mitigating ASR in concrete mixtures. Aggregate evaluations may not be practical for projects requiring small quantities of concrete (less than 200 cubic meters 250 cubic yards).

Section 32 13 14.13 CONCRETE PAVING FOR AIRFIELDS AND OTHER HEAVY DUTY PAVEMENTS, paragraph 2.3.1.2 Alkali-Silica Reactivity, provides a specification method for the Contractor to evaluate and mitigate ASR in concrete mixtures. The expansion limits specified in Section 32 13 14.13 are requirements for pavements and exterior slab construction. For structural concrete applications the measured expansion must be less than 0.10 percent. It may not be economical or practical to specify different test limit requirements for use on the same project. In which case the lower limit required by the application should be used.

The designer may use the specification method in Section 32 13 14.13 by incorporating the relevant paragraphs into this specification, or may use the following requirements (retain either the 0.10 or the 0.08 percent expansion limits as appropriate) included in the paragraph below. Delete the following paragraph if not required in the project.

--------------------------------------------------------------------------------
Alkali-Silica Reactivity: Test and evaluate fine and coarse aggregates proposed for use in concrete for alkali-aggregate reactivity in accordance with ASTM C1260. Evaluate the fine and coarse aggregates separately and in combination, which matches the Contractor's proposed mix design proportioning. All results of the separate and combination testing must have a measured expansion less than 0.10 (0.08) percent at 16 days after casting. Should the test data indicate an expansion of 0.10 (0.08) percent or greater, reject the aggregate(s) or perform additional testing using ASTM C1260 and ASTM C1567. Perform additional testing using ASTM C1260 and ASTM C1567 using the low alkali portland cement in combination with ground granulated blast furnace (GGBF) slag, or Class F fly ash. Use GGBF slag in the range of 40 to 50 percent of the total cementitious material by mass. Use Class F fly ash in the range of 25 to 40 percent of the total cementitious material by mass.
2.2.2.1 Listed Sources

******************************************************************************
NOTE: The list of sources and required tests and test limits will be taken from the concrete materials DM.
******************************************************************************

Concrete aggregates may be furnished from any source capable of meeting the quality requirements as stated in paragraph QUALITY below. The sources listed at the end of this section were evaluated during the design phase of the project in [_____] and at that time were capable of meeting the quality requirements when suitably processed. No guarantee is given or implied that any of the listed sources are currently capable of producing aggregates that meet the required quality stated in paragraph QUALITY below. A DM containing the results of the Government's investigation and test results is available for review in the [_____] District Office. Contact [_____] at [_____] to arrange for review of the memorandum. Consider the test results and conclusions valid only for the sample tested and do not take as an indication of the quality of all material from a source nor for the amount of processing required. Provide fine and coarse aggregates conforming to the grading requirements of ASTM C33/C33M. The nominal maximum size is as listed in subparagraph NOMINAL MAXIMUM-SIZE COARSE AGGREGATE of 1.3, 'c'.

2.2.2.2 Concrete Aggregate Sources

******************************************************************************
NOTE: If an aggregate source is provided by the Government, the appropriate paragraphs from Section 03 70 00 should be used.
******************************************************************************

2.2.2.2.1 List of Sources

The concrete aggregates sources may be selected from sources listed at the end of this section.

2.2.2.2.2 Selection of Source

After the award of the contract, designate in writing only one source or combination of sources from which he proposes to furnish aggregates. If the Contractor proposes to furnish aggregates from a source or from sources not listed at the end of this section, then designate only a single source or single combination of sources for aggregates. Regardless of the source, provide selected samples for acceptance testing as required by paragraph GOVERNMENT TESTING AND SAMPLING in PART 1. If a source for coarse or fine aggregates so designated by the Contractor does not meet the quality requirements stated in the paragraph below, the Contractor may not submit for approval other nonlisted sources but furnish the coarse or fine aggregate, as the case may be, from sources listed at the end of this section at no additional cost to the Government.

2.2.2.3 Quality

******************************************************************************
NOTES: The tests selected should be those which are applicable to the concrete to be used in the
******************************************************************************
These tests may include those listed below in addition to others not listed. See EM 1110-2-2000 for schedule of tests.

Depending upon the quality of aggregates available, some tests may not be required. Refer to EM 1110-2-2000 for the purpose of each test.

A list of properties and test values are unique to each project and should be taken from the concrete materials DM. Delete the quality tests not required in the DM.

Use the petrographic examination to identify deleterious substances in aggregates. List deleterious substances individually with respective limits.

In selecting deleterious substances, it should be borne in mind that cutoff walls are to be treated as structures not exposed to weather.

Deliver aggregates to the mixer meeting the following requirements:

</tbody>
</table>
2.2.2.4 Fine Aggregate Grading and Moisture Content

Determine the sieve analysis and fineness modulus of fine aggregate in accordance with ASTM C136/C136M and COE CRD-C 104, respectively. Determine the moisture content with an electric moisture meter in accordance with ASTM C70, ASTM C566, or COE CRD-C 112. When in the Contracting Officer's opinion the electric moisture meter is not operating satisfactorily, determine the moisture content in accordance with either ASTM C70, ASTM C566, or COE CRD-C 112.

2.2.2.5 Coarse Aggregate Grading and Moisture Content

For each size group of coarse aggregate, determine the sieve analysis in accordance with ASTM C136/C136M. Determine the moisture content of each size group of the coarse aggregate in accordance with ASTM C566 or COE CRD-C 112.

2.2.3 Chemical Admixtures

Provide admixtures complying with the following.

2.2.3.1 Air-Entraining Admixture

Provide air-entraining admixture conforming to ASTM C260/C260M and consistently cause the concrete to have an air content in the specified ranges under field conditions.

2.2.3.2 Accelerating Admixture

Provide accelerators meeting the requirements of ASTM C494/C494M, Type C or E, except do not use calcium chloride or admixtures containing calcium chloride.

2.2.3.3 Flowing Concrete Admixtures

Provide other chemical admixtures for use in producing flowing concrete in compliance with ASTM C1017/C1017M, Type I or II. Use these admixtures only if the proposed admixture shows no deleterious effects when used with all other project materials during mixture proportioning studies.

2.2.4 Water

Use water for mixing and curing that is fresh, clean, potable, and free of injurious amounts of oil, acid, salt, or alkali, except that nonpotable water may be used if it meets the requirements of COE CRD-C 400.

2.3 PLANT AND EQUIPMENT

Submit data on all placing equipment and methods for review by the Contracting Officer.
2.3.1 Capacity

NOTE: Experience has shown that to reduce problems associated with placement rates, the minimum capacity should be 77 cubic meters per hour 100 cubic yards per hour.

Furnish batching and mixing equipment with a capacity of at least [_____] cubic meters yards per hour.

2.3.2 Batch Plant

Conform to the requirements of NRMCA CPMB 100 and as specified; however, rating plates attached to batch plant equipment are not required. Submit batch plant data to the Contracting Officer for review for conformance with applicable specifications.

2.3.2.1 Batching Equipment

NOTE: Refer to the appropriate DM to choose the appropriate alternates.

Provide batching controls that are [partially automatic], [semiautomatic], [or] [automatic]. Provide the semiautomatic batching system with interlocks such that the discharge device cannot be actuated until the indicated material is within the applicable tolerance. Equip the batching system with an accurate recorder or recorders that meet the requirements of NRMCA CPMB 100. Provide separate bins or compartments for each size group of aggregate and cement, pozzolan, and GGBFS. Weigh aggregates either in separate weigh batchers with individual scales or cumulatively in one weigh batcher on one scale. Do not weigh aggregate in the same batcher with cement, pozzolan, or GGBFS. If both cement and pozzolan or GGBFS are used, they may be batched cumulatively provided that the portland cement is batched first. If measured by mass, do not batch the mass of the water cumulatively with another ingredient. Provide interlocked water batcher filling and discharging valves so that the discharge valve cannot be opened before the filling valve is fully closed. Provide an accurate mechanical device for measuring and dispensing each admixture. Interlock each dispenser with the batching and discharging operation of the water so that each admixture is separately batched and discharged automatically in a manner to obtain uniform distribution throughout the batch in the specified mixing period. Do not combine admixtures prior to introduction in water. Arrange the plant so as to facilitate the inspection of all operations at all times. Provide suitable facilities for obtaining representative samples of aggregates from each bin or compartment. Clearly mark all filling ports for cementitious materials bins or silos with a permanent sign stating the contents.

2.3.2.2 Scales

Provide equipment for batching by mass conforming to the applicable requirements of NIST HB 44, except that the accuracy must be plus or minus 0.2 percent of scale capacity. Provide standard reference masses and any other auxiliary equipment required for checking the operating performance.
of each scale or other measuring devices. Make tests at the frequency
required in paragraph TESTS AND INSPECTIONS, in PART 3, and in the presence
of a Government inspector.

2.3.2.3 Batching Tolerances

Tolerances on determination of mass:

<table>
<thead>
<tr>
<th>MATERIAL</th>
<th>PERCENT OF REQUIRED MASS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cementitious materials</td>
<td>-0 to +2</td>
</tr>
<tr>
<td>Aggregate</td>
<td>± 2</td>
</tr>
<tr>
<td>Water</td>
<td>± 1</td>
</tr>
<tr>
<td>Chemical admixture</td>
<td>-0 to +6</td>
</tr>
</tbody>
</table>

For volumetric batching equipment, the following tolerances apply to the
required volume of material being batched:

<table>
<thead>
<tr>
<th>Water</th>
<th>Plus or minus 1 percent</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chemical admixtures</td>
<td>Zero to plus 6 percent</td>
</tr>
</tbody>
</table>

2.3.2.4 Moisture Control

Provide plant that is capable of ready adjustment to compensate for the
varying moisture content of the aggregates and to change the masses of the
materials being batched. [Provide an electric moisture meter complying
with the provisions of COE CRD-C 143 for measuring moisture in the fine
aggregate. Arrange the sensing element so that the measurement is made
near the batcher charging gate of the sand bin or in the sand batcher.]

2.3.3 Concrete Mixers

Do not charge the concrete mixers in excess of the capacity recommended by
the manufacturer. Operate the mixers at the drum or mixing blade speed
designated by the manufacturer. Maintain the mixers in satisfactory
operating condition, and keep the mixer drums free of hardened concrete.
Should any mixer at any time produce unsatisfactory results, promptly
discontinue its use until it is repaired. Submit concrete mixer data
including the make, type, and capacity of concrete mixers proposed for
mixing concrete in conformance with specified requirements.

2.3.3.1 Stationary Mixers

Provide tilting, nontilting, horizontal-shaft, vertical-shaft, or pugmill
concrete plant mixers with an acceptable device to lock the discharge
mechanism until the required mixing time has elapsed. Provide mixing time
and uniformity conforming to all the requirements in ASTM C94/C94M
applicable to central-mixed concrete.

2.3.3.2 Truck Mixers

Provide truck mixers, the mixing of concrete, and concrete uniformity
conforming to the requirements of ASTM C94/C94M. A truck mixer may be used
for complete mixing or to finish the partial mixing begun in a stationary
mixer. Equip each truck with two counters from which it will be possible
to determine the number of revolutions at mixing speed and the number of revolutions at agitating speed.

2.3.4 Conveying Equipment

******************************************************************************
NOTE: Experience has shown that to reduce problems associated with placement rates, the minimum conveying capacity should be 75 cubic meters per hour 100 cubic yards per hour.
******************************************************************************

Furnish conveying equipment with a capacity of at least [_____] cubic meters yards per hour. Convey concrete from mixer to trench as rapidly as practicable and within the time interval specified in paragraph PLACING, in PART 3, by methods that will prevent segregation or loss of ingredients. Pass any concrete transferred from one conveying device to another through a hopper that is conical in shape and do not drop vertically more than 1.5 m 5 feet, except where suitable equipment is provided to prevent segregation and where specifically authorized. Submit data on the conveying equipment and methods for transporting, handling, and depositing the concrete.

2.3.4.1 Buckets

Provide an interior hopper slope no less than 58 degrees from the horizontal; provide a clear gate opening with a minimum dimension of at least five times the nominal maximum-size aggregate and an area no less than 0.2 square meters 2 square feet. Maximum dimension of the gate opening greater than twice the minimum dimension is not permitted. Provide bucket gates that are essentially grout tight when closed and may be manually, pneumatically, or hydraulically operated except that manually operated buckets larger than 1.5 cubic meters 2 cubic yards are not acceptable. Provide means for positive regulation of the amount and rate of deposit of concrete in each dumping position.

2.3.4.2 Trucks

Furnish truck mixers operating at agitating speed or truck agitators used for transporting plant-mixed concrete conforming to the requirements of ASTM C94/C94M. Do not use nonagitating equipment for transporting concrete.

2.3.4.3 Chutes

When concrete can be placed directly from a truck mixer or agitator, the chutes attached to this equipment by the manufacturer may be used. Use a discharge deflector when required by the Contracting Officer. Separate chutes and other similar equipment will not be permitted for conveying concrete.

2.3.4.4 Concrete Pumps

Concrete may be conveyed by positive displacement pump when approved. Provide piston or squeeze pressure pumping equipment. Provide pipeline consisting of rigid steel pipe or heavy-duty flexible hose. Furnish pipe with an inside diameter that is at least three times the nominal maximum-size coarse aggregate in the concrete mixture to be pumped, but no less than 100 mm 4 inches. Do not use aluminum pipe. Do not reduce the nominal maximum-size coarse aggregate to accommodate the pumps. The distance to be pumped must not exceed limits recommended by the pump
manufacturer. Supply the concrete to the concrete pump continuously. When pumping is completed, eject concrete remaining in the pipeline without contamination of concrete in place. After each operation, thoroughly clean equipment, and waste flushing water outside of the forms.

PART 3 EXECUTION

3.1 PLACING

Concrete placement will not be permitted when, in the opinion of the Contracting Officer, weather conditions prevent proper placement. Deposit concrete in the tremie hopper with no vertical drop greater than 1.5 m 5 feet except where suitable equipment is provided to prevent segregation and where specifically authorized. Provide sufficient placing capacity so that concrete placement can be kept plastic and free of horizontal cold joints while concrete is being placed. Prior to placement, submit the method and equipment proposed for vertical construction joints cleanup and waste disposal, for review and approval by the Contracting Officer.

3.1.1 Time Interval Between Mixing and Placing

Place concrete within 30 minutes after mixing or agitating ceases. When concrete is truck mixed or when a truck mixer or agitator is used for transporting concrete mixed by a concrete plant mixer, deliver the concrete to the site of the work, and complete discharge within 45 minutes after introduction of the cement to the aggregates.

3.1.2 Placing Temperature

When deposited in the slurry, provide concrete with a temperature of no less than 5 degrees C 40 degrees F. Heating of the mixing water or aggregates is not be permitted until the temperature of the concrete has decreased to 7 degrees C 45 degrees F. Provide materials that are free from ice, snow, and frozen lumps before entering the mixer. Use placing equipment and methods that are subject to [approval] [review]. When heating is necessary to keep the concrete temperature above 5 degrees C 40 degrees F, regulate it so that the concrete temperature does not exceed 15 degrees C 60 degrees F. Do not exceed 32 degrees C 90 degrees F for concrete that is deposited in the slurry. Cooling of the mixing water and/or aggregates may be required to obtain an adequate placing temperature.

3.1.3 Concrete Deposited in Cutoff Trench

**************************************************************************
NOTE: The hopper on top of the tremie pipe must be of a size capable of receiving and passing concrete into the tremie pipe at the capacity rate of the batching, mixing, and conveying equipment.

Depending upon the quality of aggregates available, some tests may not be required. Refer to EM 1110-2-2000 for the purpose of each test.
**************************************************************************

Deposit concrete placed for the cutoff wall in a bentonite slurry-filled trench by a tremie or by a valved tremie. The methods and equipment used are subject to approval. Concrete buckets will not be permitted for placement of concrete in the slurry trench, although they may be used to transport concrete to the tremie hoppers. Provide watertight tremie that
is sufficiently large to permit a free flow of concrete, and no less than 250 mm 10 inches in diameter. A funnel-shaped hopper of at least [_____] cubic meters yards in volume is required at the top of the tremie. Do not construct neither the tremie pipe nor the hopper of aluminum. Make hoisting equipment for raising and lowering the tremie pipe as the concrete is placed and tools for connecting the tremie pipe sections continuously available and on hand. In lieu of use of a tremie, concrete may be placed using a positive displacement pump and pump line provided the entire operation is approved in writing after a demonstration of its use.

3.1.4 Concrete Placement

Suitably secure tremie pipe sections together and use a gasket at each joint to prevent leakage. A retrievable traveling plug (go-devil) or a dry pipe with a plate and gasket wired to the bottom to prevent contact of the concrete and the slurry in the tremie is required to start each placement. Lower the tremie assembly to rest within 150 mm 6 inches of the bottom of the trench prior to beginning placement. During placement of the concrete, avoid any unnecessary movement of the pipe. Keep the bottom of the tremie pipe submerged in fresh concrete at all times to a depth that will produce the flat test surface slope that can practically be achieved. A depth less than 3 m 10 feet or more than 9 m 30 feet except when beginning placement at the bottom of a panel is not acceptable. Supply batches of concrete to the tremie pipe at a uniform rate for a continuous flow. Lift the tremie pipe during placement at a rate that will maintain the bottom of the pipe embedded in fresh concrete to a level that will produce the desired surface slope and rate of flow within the limits specified above. It may be necessary to reduce the amount of embedment as the differential head decreases between the concrete in the tremie pipe and the concrete in the panel. Minimize the repeated raising and lowering of the tremie pipe in the fresh concrete to facilitate placement. Proceed with placement without interruption until the concrete has been brought to the required height. Continuously measure and record the flow and slopes during placement with the use of a sounding line. Do not move the tremie horizontally during a placing operation, except that as the required height is reached, the tremie pipes may be moved to the corners and low areas between the tremie pipes to bring the lift to final elevation. Provide a sufficient number of tremies so that the concrete does not flow horizontally a distance of more than 2.1 m 7 feet from a tremie; i.e., place tremies a maximum of 4.2 m 14 feet on centers. Where more than one tremie pipe is used in the same placement simultaneously, maintain the concrete level at each pipe position nearly level with respect to the other. Take special care to ensure that the bottom of the tremie pipe is not lifted out of the fresh concrete. If this occurs, remove the tremie pipe, insert a dry pipe with a temporary bottom plug, and restart the placement. Also, as soon as practical, drill a NX-size core boring through the center of the cutoff wall to a depth of at least 3 m 10 feet below the depth where the bottom of the tremie pipe was lifted out of the fresh concrete. Repair unacceptable zones of concrete such as honeycombed, segregated, or uncemented zones found within the core boring immediately or remove and replace by an appropriate means. All cost incurred because of this failure, including the initial core boring and as many additional core borings as may be required to delineate the limits of the unacceptable concrete and the repair of the cutoff wall, are borne by the Contractor and will not result in any additional cost to the Government. Submit a plan for repairing or removing and replacing the unacceptable concrete. Placement delays are not permitted for periods of time longer than 30 minutes.
3.1.5 Required Height of Concrete

Place concrete that is free of laitance, scum, slurry, or other contaminants at the top of the wall. Remove all scum, laitance, and contaminated concrete from the top of the concrete as the placement is nearing completion and dispose of in the spoil areas. Finish the top surface to grade by screeding spoil areas.

3.2 CURING AND PROTECTION

Moist cure exposed concrete for 14 days. Immediately after placement, protect concrete from premature drying, extremes in temperatures, rapid temperature change, and mechanical damage. Make all materials and equipment needed for adequate curing and protection available and at the placement site prior to the start of concrete placement. Protect concrete from the damaging effects of rain for 12 hours and from flowing water for 14 days. Fire or excessive heat including welding is not permitted near or in direct contact with concrete or concrete embedments at any time. Submit the curing medium and methods to be used for review and approval.

3.3 TESTS AND INSPECTIONS

Submit statements asserting that the concrete testing technicians and the concrete inspectors meet the specified requirements; also test results and inspection reports daily and weekly as required.

3.3.1 General

Perform the inspection and tests described in the following paragraphs and, based upon the results of these inspections and tests, take the action required and submit reports as required. When, in the opinion of the Contracting Officer, the concreting operation is out of control, cease concrete placement. Perform tests by onsite laboratory and in conformance with ASTM C1077. The individuals who sample and test concrete or the constituents of concrete as required in this specification will have demonstrated a knowledge and ability to perform the necessary test procedures equivalent to the ACI minimum guidelines for certification of Concrete Field Testing Technicians, Grade I. The individuals who perform the inspection of concrete construction will have demonstrated a knowledge and ability equivalent to the ACI minimum guidelines for certification of Concrete Construction Inspector, Level II. The Government will inspect the laboratory, equipment, and test procedures prior to start of concreting operations and at least once per year thereafter for conformance with ASTM C1077.

3.3.2 Testing and Inspection Requirements

3.3.2.1 Fine Aggregate

3.3.2.1.1 Grading

At least once during each shift when the concrete plant is operating, perform one sieve analysis and fineness modulus determination in accordance with ASTM C136/C136M and COE CRD-C 104 for the fine aggregate or for each size range of fine aggregate if it is batched in more than one size or classification. The location at which samples are taken may be selected by the Contractor as the most advantageous for control. However, the Contractor is responsible for delivering fine aggregate to the mixer within specification limits.
3.3.2.1.2 Corrective Action for Fine Aggregate Grading

When the amount passing on any sieve is outside the specification limits, immediately resample and retest the fine aggregate. If there is another failure on any sieve, report the fact immediately to the Contracting Officer.

3.3.2.1.3 Moisture Content Testing

When, in the opinion of the Contracting Officer, the electric moisture meter is not operating satisfactorily, perform at least four tests for moisture content in accordance with ASTM C566 during each 8-hour period of mixing plant operation. Randomly select the times for the tests within the 8-hour period. Make an additional test whenever the slump is out of control or excessive variation in workability is reported by the placing foreman. When the electric moisture meter is operating satisfactorily, make at least two direct measurements of moisture content per week to check the calibration of the meter. Use the results of tests for moisture content to adjust the added water in the control of the batch plant.

3.3.2.1.4 Moisture Content Corrective Action

Whenever the moisture content of the fine aggregate changes by 0.5 percent or more, adjust the scale settings for the fine-aggregate batcher and water batcher (directly or by means of a moisture compensation device) if necessary to maintain the specified slump.

3.3.2.2 Coarse Aggregate

3.3.2.2.1 Grading

At least once during each shift in which the concrete plant is operating, perform a sieve analysis in accordance with ASTM C136/C136M for each size of coarse aggregate. The location at which samples are taken may be selected by the Contractor as the most advantageous for production control. Maintain a test record of samples of aggregate taken at the same locations showing the results of the current test as well as the average results of the five most recent tests including the current test. The Contractor may adopt limits for control which are coarser than the specification limits for samples taken at locations other than as delivered to the mixer to allow for degradation during handling.

3.3.2.2.2 Corrective Action for Grading

When the amount passing any sieve is outside the specification limits, immediately resample and retest the coarse aggregate. If the second sample fails on any sieve, report that fact to the Contracting Officer. Where two consecutive averages of five tests are outside specification limits, consider the operation out of control and report it to the Contracting Officer. Stop concreting and take immediate steps to correct the grading.

3.3.2.2.3 Coarse Aggregate Moisture Content

Make a test for moisture content of each size group of coarse aggregate in accordance with ASTM C566 or COE CRD-C 112 at least once during a shift. When two consecutive readings for smallest-size coarse aggregate differ by more than 1.0 percent, increase frequency of testing to that specified above for fine aggregate, until the difference falls below 1.0 percent.
3.3.2.4 Coarse Aggregate Moisture Corrective Action

Whenever the moisture content of any size of coarse aggregate changes by 0.5 percent or more, adjust the scale setting for the coarse aggregate batcher and the water batcher if necessary to maintain the specified slump.

3.3.2.3 Quality of Aggregates

**************************************************************************

NOTES: Tests should be those listed in paragraph QUALITY. Use the petrographic examination to identify deleterious substances in aggregates. List deleterious substances individually with respective limits.

Depending upon the quality of aggregates available, some tests may not be required. Refer to EM 1110-2-2000 for the purpose of each test.

**************************************************************************

Submit aggregate quality tests results at least 30 days prior to start of concrete placement.

3.3.2.3.1 Frequency of Quality Tests

Thirty days prior to the start of concrete placement perform all tests for aggregate quality listed below. In addition, after the start of concrete placement, perform tests for aggregate quality in accordance with the frequency schedule shown below. Test samples that were taken after the start of concrete placement immediately prior to entering the concrete mixer.

3.3.2.3.2 Corrective Action for Aggregate Quality

If the result of a quality test fails to meet the requirements for quality immediately prior to start of concrete placement, change production procedures or materials and perform additional tests until the material meets the quality requirements prior to proceeding with either mixture proportioning studies or starting concrete placement. After concrete placement commences, whenever the result of a test for quality fails the requirements, rerun the test immediately. If the second test fails the quality requirement, report the fact to the Contracting Officer, and take immediate steps rectify the situation.

3.3.2.4 Deleterious Substances

3.3.2.4.1 Testing

When, in the opinion of the Contracting Officer, a problem exists in connection with deleterious substances in fine or coarse aggregates, make tests in accordance with ASTM C33/C33M at a frequency as directed, but no less than once per week. Report results of tests in writing.

3.3.2.4.2 Corrective Action for Deleterious Substances

When the results for a deleterious substance are out of the specification limit, resample and retest the aggregate for the deleterious substance that failed. If the second sample fails, report that fact to the Contracting Officer. When material finer than 75-µm (No. 200) sieve for coarse aggregate exceeds the specification limit, initiate immediate steps, such as washing or other corrective actions.

3.3.2.5 Scales

3.3.2.5.1 Accuracy

Checked by test weights prior to start of concrete operations and at least once every 3 months for conformance with the applicable requirements of paragraph BATCHING EQUIPMENT. Make such tests as directed whenever there are variations in properties of the fresh concrete that could result from batching errors.
3.3.2.5.2 Batching and Recording Accuracy

Once a week, check the accuracy of each batching and recording device during a weighing operation by noting and recording the required weight, recorded weight, and the actual mass batched. Confirm that the calibration devices described in paragraph BATCH PLANT in PART 2 for checking the accuracy of dispensed admixtures are operating properly.

3.3.2.5.3 Scales Corrective Action

When either the weighing accuracy or batching accuracy does not comply with specification requirements, do not operate the plant until necessary adjustments or repairs have been made. Correct discrepancies in recording accuracies immediately.

3.3.2.6 Batch-Plant Control

Continuously control the measurement of quantities of all constituent materials batched including cementitious materials, each size of aggregate, water, and admixtures. Adjust the aggregate quantities and amount of added water as necessary to compensate for free moisture in the aggregates. Adjust the amount of air-entraining agent to control air content within specified limits. Prepare a report indicating type and source of cement used, type and source of pozzolan or slag used, amount and source of admixtures used, aggregate source, the required aggregate and water amounts per cubic meter yard, amount of water as free moisture in each size of aggregate, and the batch aggregate and water amounts per cubic meter yard for each class of concrete batched during plant operation. Submit the report to the Contracting Officer.

3.3.2.7 Concrete Mixture

3.3.2.7.1 Air Content Testing

Make air content tests when test specimens are fabricated. In addition, make at least two tests for air content on randomly selected batches of each separate concrete mixture produced during each 8-hour period of concrete production. Make additional tests when excessive variation in workability is reported by the placing foreman or Government quality assurance representative. Make tests in accordance with ASTM C231/C231M. Plot test results on control charts which will at all times be readily available to the Government. Keep copies of the current control charts in the field by the Contractor's quality control representatives and results plotted as tests are made. When a single test result reaches either the upper or lower action limit, make a second test immediately. Average the results of the two tests, and use this average as the air content of the batch to plot on the control charts for air content and range and to determine the need for any remedial action. Plot the result of each test, or average as noted in the previous sentence, on a separate chart for each mixture on which an "average line" is set at the midpoint of the specified air content range from subparagraph AIR CONTENT. Set an upper warning limit and a lower warning limit line 1.0 percentage point above and below the average line. Set an upper action limit and a lower action limit line 1.5 percentage points above and below the average line, respectively. Plot the range between each two consecutive tests on a control chart for range where an upper warning limit is set at 2.0 percentage points and an upper action limit is set at 3.0 percentage points. Samples for air content may be taken at the mixer; however, the Contractor is responsible for
delivering the concrete to the placement site at the stipulated air content. If the Contractor's materials or transportation methods cause air content loss between the mixer and the placement, take correlation samples at the placement site as required by the Contracting Officer and the air content at the mixer controlled as directed.

3.3.2.7.2 Air Content Corrective Action

Whenever points on the control chart for percent air reach either warning limit, make an adjustment immediately in the amount of air-entraining admixture batched. As soon as is practical after each adjustment, make another test to verify the result of the adjustment. Whenever a point on the control chart range reaches the warning limit, recalibrate the admixture dispenser to ensure that it is operating accurately and with good reproducibility. Whenever a point on either control chart reaches an action limit line, the air content is considered out of control and halt the concreting operation immediately until the air content is under control. Make additional air content tests when concreting is restarted. All this is at no extra cost to the Government.

3.3.2.7.3 Slump Testing

In addition to slump tests which are made when test specimens are fabricated, make at least four slump tests on randomly selected batches in accordance with ASTM C143/C143M for each separate concrete mixture produced during each 8-hour or less period of concrete production each day. Also, make additional tests when excessive variation in workability is reported by the placing foreman or Government's quality assurance representative. Plot test results on control charts which will at all times be readily available to the Government. Keep copies of the current control charts in the field by the Contractor's quality control representatives and plot results as tests are made. When a single slump test reaches or goes beyond either the upper or lower action limit, make a second test immediately on the same batch of concrete. Average the results of the two tests and use this average as the slump of the batch to plot on the control charts for percent air and for range and to determine the need for any remedial action. Set an upper warning limit at 13 mm 1/2 inch below the maximum allowable slump on separate control charts for percent air used for each type of mixture as specified in subparagraph SLUMP, and set upper and lower action limit lines at the maximum and minimum allowable slumps, respectively, as specified in the same paragraph. Plot the range between each consecutive slump test for each type of mixture on a single control chart for range on which an upper action limit is set at 50 mm 2 inches. Take samples for slump at the mixer; however, the Contractor is responsible for delivering the concrete to the placement site at the stipulated slump. If the Contractor's materials or transportation methods cause slump loss between mixer and the placement, take correlation samples at the placement site as required by the Contracting Officer and control the slump at the mixer as directed.

3.3.2.7.4 Slump Corrective Action

Whenever points on the control chart for slump reach the upper warning limit, make an adjustment immediately in the batch weights of water and fine aggregate. The adjustments are to be made so that the total water content does not exceed that amount allowed by the maximum water-cement ratio specified, based upon aggregates which are in a saturated surface-dry condition. When a single slump reaches the upper or lower action limit, deliver no further concrete to the placing site until proper adjustments.
have been made. Immediately after each adjustment, make another test to verify the correctness of the adjustment. Whenever two consecutive slump tests, made during a period when there was no adjustment of batch weights, produce a point on the control chart for range at or above the upper action limit, halt the concreting operation immediately, and take appropriate steps to bring the slump under control. Also, make additional slump tests as directed. All this is at no additional cost to the Government.

3.3.2.7.5 Compressive Strength

At least once during each shift, fabricate and cure, in accordance with ASTM C192/C192M, four 150 by 300 mm 6 by 12 inch test specimens. Test two specimens at 7 days and two at 28 days. If pozzolan or slag cement is used, fabricate six specimens and test two at 7 days, two at 28 days, and two at 90 days. Perform testing in accordance with ASTM C39/C39M. The results of compressive strength tests will not be used for acceptance. Results will be for record purposes and to evaluate the uniformity of concrete production. Average the results of each set of specimens tested at each age to produce one "test result". Plot these "test results" on control charts for each age. One control chart must consist of each "test result" plotted consecutively. One control chart must consist of the range from the "test result" for any one day to that of the next day. When the range exceeds 6.9 MPa 1,000 psi, notify the Contracting Officer and modify the operation to produce better uniformity.

3.3.2.7.6 Temperature

Measure the temperature of the concrete when compressive strength specimens are fabricated. Measure in accordance with ASTM C1064/C1064M. Report the temperature along with the compressive strength data.

3.3.2.8 Placing

3.3.2.8.1 Preparation for Placing

Inspect each section of wall in sufficient time prior to concrete placement to certify to the Contracting Officer that it is ready to receive concrete. Report the results of each inspection in writing.

3.3.2.8.2 Placing

The placing foreman supervises all placing operations, determines that the correct quality of concrete is placed in each location as directed by the Contracting Officer, and is responsible for measuring and recording concrete temperatures, weather conditions, time of placement, quantity placed, method of placement, depths of tremie pipes and concrete at regular intervals, and loss of concrete. Submit a written report recording these data daily.

3.3.2.8.3 Placing Corrective Action

Do not continue placing if any pile of concrete is inadequately consolidated. If any batch of concrete fails to meet the temperature requirements, take immediate steps to improve temperature controls.
3.3.2.9  Curing

3.3.2.9.1  Moist-Curing Inspections

At least once each shift and once per day on nonwork days, inspect all areas subject to moist curing. Note and record the surface moisture condition.

3.3.2.9.2  Moist-Curing Correction Action

When a daily inspection report lists an area of inadequate curing, take immediate corrective action, and extend the required curing period for such areas by 1 day.

3.3.2.10  Mixer Uniformity

Conform to the following:

3.3.2.10.1  Stationary Mixers

At the start of concrete placing and at least once every 6 months when concrete is being placed, determine uniformity of concrete. Perform tests in accordance with ASTM C94/C94M. Whenever adjustments in mixer or increased mixing times are necessary because of failure of any mixer to comply, retest the mixer after adjustment. Submit in writing the results of the initial mixer uniformity tests at least 5 days prior to the initiation of placing.

3.3.2.10.2  Truck Mixers

At the start of concrete placing and at least once every 6 months when concrete is being placed, determine uniformity of concrete in accordance with ASTM C94/C94M. Select the truck mixers randomly for testing. When satisfactory performance is found in one truck mixer, the performance of mixers of substantially the same design and condition of blades may be regarded as satisfactory. Report result of tests in writing.

3.3.2.10.3  Mixer Uniformity Concrete Action

When a mixer fails to meet mixer uniformity requirements, increase the mixing time or make adjustments to the mixer until compliance is achieved.

3.3.3  Reports

Report all results of tests and inspections as required. Include the updating of control charts covering the entire period from the start of the construction season through the current week in each report. During periods of cold-weather protection, make reports of pertinent temperatures daily. These requirements do not relieve the Contractor of the obligation to report certain failures immediately as required in preceding paragraphs. Confirm such reports of failures and the action taken in writing in the routine reports. The Contracting Officer has the right to examine all Contractor quality control records.

3.3.4  Concrete Coring

**************************************************************************

NOTES: The number of the test panels to be cored should be determined by each district office as

SECTION 03 37 29  Page 33
necessary to give a representation of the work that was done. The core boring of these test panels should be done after the concrete has developed sufficient strength to allow cores of properly placed concrete to be retrieved.

The spacing and timing of the core borings of the concrete cutoff wall should be arranged to retrieve properly placed concrete cores. The concrete should be allowed to develop sufficient strength to allow cores of competent concrete to be retrieved. The spacing of the core holes should be representative of the particular job to give confidence in the work that was performed. The wall construction should not be allowed to get too far ahead of the core boring. This will allow problems discovered by the core boring to be corrected or changed and these changes incorporated in the cutoff wall construction that follows.

**************************************************************************

3.3.4.1 Concrete Coring in Completed Panels

Drill one NX core boring (or one core boring approximately NX) through the concrete in each of the first [_____] test panels. Complete these borings during the installation of the first [_____] linear meters feet of cutoff wall and prior to commencement of the remainder of the wall. Thereafter, drill an NX boring through one panel selected by the Contracting Officer for every [_____] linear meters feet of wall, within [_____] days after completion of each [_____] meter foot section. Additional core borings may be directed by the Contracting Officer. Locate the borings in the center of each panel unless otherwise directed by the Contracting Officer. While coring the completed panels, prepare a log including the elevation of any drill fluid loss, soft zones, drill tool drops, or zones of core loss and provide the log to the Contracting Officer immediately after coring is complete. Do not backfill the core holes until approved by the Contracting Officer. [If the Contracting Officer decides to have falling head permeability tests or other tests conducted due to core results, do not use this as basis for a claim.] Fill core holes deviating through the side of the panel and drill a new core hole at no additional cost to the Government.

3.3.4.2 Method of Drilling

Drill cores by any approved standard and accepted method of rotary rock core wireline drilling using diamond-set coring bits by means of which continuous and complete cores of standard diameter for the specified bit size can be obtained.

3.3.4.3 Equipment and Supplies

Equipment to be furnished by the Contractor for core drilling includes diamond core-drilling machinery of a type or types approved by the Contracting Officer, complete with all accessories for taking continuous cores of a diameter consistent with specified bit size to the depths specified. Provide core drill that is the product of one of the standard core drill manufacturing companies designed primarily for this type of work. Use a ball-bearing, swivel-type, double-tube NX core barrel or manufacturers' equivalent meeting standards established by DCDMA TM. Provide capacity of barrels not exceeding 4.6 m 15 feet of core, and equip
with diamond-set core bits and standard core lifters. Include all casing, drill rods, core barrels, diamond-set coring bits, piping, pumps, water, tools, core boxes, and power required for drilling. Set bits with the proper size stones for drilling the concrete and bed rock.

3.3.4.4 Core Boxes

Use longitudinally partitioned wooden core boxes constructed of dressed lumber or other approved materials in general accordance with arrangement and dimensions shown in the drawing included at the end of this section of the specifications for all cores. Use as many core boxes as may be required in submitting each concrete or rock core or group of cores. Equip core boxes completely with all necessary partitions, covers, hinges, and hasps for holding down the cover. To prevent undue core breakage (while it is being placed in boxes) and to allow for ease of access to core in the specified core boxes, determine the maximum amount of core to be placed in any one box by the Government core drill inspector during the drilling operations. Normally, it is expected that an average of approximately 3.7 m 12 feet of core can be placed in each box. In addition to the spacer blocks shown in the drawing, provide, as required, lengths of 29 by 54 mm 1-1/8 by 2-1/8 inch wood, painted red on one side, cut into 100 mm 4-inch lengths, mark with appropriate depths, and insert in the proper positions in core boring samples to show the location and actual extent of voids and core losses. Mark all core boxes with the appropriate hole number, box number, and depths.

3.3.4.5 Disposition of Core Samples

Upon completion of core drilling and sampling operations for each hole, deliver core boxes containing cores to a storage facility to be designated at the project site. Deliver core boxes containing cores in accordance with schedules prepared by the Contracting Officer. All packing, handling, and transportation of samples are considered as subsidiary obligations of the Contractor.

3.3.4.6 Backfilling Core Holes

Upon completion of core sampling, backfill the holes under gravity pressure with portland cement grout or mortar as directed by the Contracting Officer. Pump the grout into the hole through drill rods or plastic hose set to within 1.5 m 5 feet of the bottom of the hole. The bottom of the core hole is defined as being a point in bedrock 900 mm 3 feet below the bottom of the panel or the point at which the boring deviates from the cutoff wall.

3.3.5 Evaluation and Acceptance

Concrete will be evaluated by examination of cores drilled by the Contractor from completed panels as specified in paragraph CORING CONCRETE IN COMPLETED PANELS in PART 1, and unacceptable concrete is defined in paragraphs QUALITY ASSURANCE and CONCRETE PLACEMENT. Repair or remove concrete determined to be unacceptable and replace as specified in paragraph CONCRETE PLACEMENT above.

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for flat-shaped or channel-shaped roof slabs, max. span 8 feet o.c. placed over purlins or joists spaced not more than 2.5 meter 8 feet on center that receive insulation board and built-up roofing.

Include on the drawings, the following:

Complete design indicating the character of the work to be performed and giving the roof framing, type, and sizes of purlins or joists, thrust angles at walls, bearing angles at ridges for sloping roofs, end bearing plates, dimensions of roof slab units, details of precast cant units, details of cast-in-place concrete cants and other sloping surfaces, details of openings, and sufficient dimensions to convey adequately the quantity and nature of the required roof decking.

Design loads and other design data as may be required for the proper preparation of shop drawings.

Precast concrete slabs for clear spans exceeding 2.5 meter 8 feet are specified in Section 03 41 33 PRECAST STRUCTURAL PRETENSIONED CONCRETE.

A structural steel roof framing system, including steel purlins and framing for openings larger than 1/2 width of roof slabs in any dimension, is specified in Section 05 12 00 STRUCTURAL STEEL.

An open-web steel joist roof framing system is specified in Section 05 21 00 STEEL JOIST FRAMING.

Fire resistance-rated roof and ceiling constructions using precast concrete roof decking are described in Underwriters Laboratories, Inc., "Fire Resistance Ratings (BXUV)" contained in UL FRD and the "Fire
Resistance Ratings" contained in AIA CO-1. Fire
resistance rated construction limits the type and
spacing of the roof framing system; type of roof
slab units and method of fastening the roof slabs to
the supporting frame; ceiling construction; and roof
construction.

Adhere to UFC 1-300-02 Unified Facilities Guide
Specifications (UFGS) Format Standard when editing
this guide specification or preparing new project
specification sections. Edit this guide
specification for project specific requirements by
adding, deleting, or revising text. For bracketed
items, choose applicable item(s) or insert
appropriate information.

Remove information and requirements not required in
respective project, whether or not brackets are
present.

Comments, suggestions and recommended changes for
this guide specification are welcome and should be
submitted as a Criteria Change Request (CCR).

1.2 SUBMITTALS

NOTE: Review Submittal Description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

PART 2   PRODUCTS

2.1   SYSTEM DESCRIPTION

Submit fabrication drawings for precast concrete deck units. On the drawings, provide dimensions, size, and number of openings to be cut.

Provide and submit installation drawings for precast concrete roof slabs and cast-in-place curb units. On the drawings, provide details and layouts indicating structural framing, location and length of concrete slabs corresponding with the sequence and procedure to be followed in placing and fastening roof slabs, and location and type of fasteners. Ensure that drawings also show details of curb units indicating location of cants, crickets, drainage saddles, and other sloping surfaces.

2.1.1  Sub Title

Text

2.2   COMPONENTS

Provide manufacturer's catalog data for all accessories including nails, threaded fasteners, and joint sealing compounds.

2.2.1  Clips and Nails

Use zinc- or cadmium-plated steel strip clips, not less than 0.76 millimeter 0.0299 inch thick. Ensure clips are formed to fit the top flange of steel beam purlins or steel joists having steel angle top chords, and of design recommended by the precast concrete roof slab manufacturer.

Use roofing nails that are 32 millimeter 1 1/4 inches long, galvanized steel, conforming to ASTM C514, Type II, Style 20.

Submit certificates of compliance for clips and nails showing conformance with referenced standards contained in this section.

2.2.2  Threaded Fasteners

Provide fasteners that consist of machine screws, nuts, and washers.

Use slotted, flathead, galvanized, carbon steel machine screws conforming to ASME B18.6.7M ASME B18.6.3, Type I, Style 2s.

Use hexagon, galvanized, carbon steel nuts conforming to ASME B18.2.6 ASME B18.2.2, Type II, Style 10.

Provide round-type, galvanized, carbon steel, general-purpose assembly washers conforming to ASME B18.22M ASME B18.21.1, Type A, Grade I, Class A.

Submit certificates of compliance for threaded fasteners showing conformance with referenced standards contained in this section.
2.3 MATERIALS

**************************************************************************
NOTE: Indicate precast-concrete roof slab dimensions.
**************************************************************************

2.3.1 Precast Concrete Roof Slabs

**************************************************************************
NOTE: Delete the following paragraphs when channel roof slabs are required.
**************************************************************************

Submit design analysis and calculations for precast concrete roof slabs.
Submit certificates of compliance for precast concrete roof slabs showing conformance with referenced standards contained in this section.

**************************************************************************
NOTE: Delete when using channel roof slab.
**************************************************************************

Ensure roof slabs are flat or plank-shaped and conform to ASTM C1705/C1705M, Type I or Type II, with the following modifications:

a. Ensure flat slabs have wire mesh reinforcing in both top and bottom of the slab.
b. Slabs have nailing edges.

**************************************************************************
NOTE: Delete one of the following two paragraphs as applicable to the project. When spacing of the structural framing members is less than 1.5 meter 5-feet, delete the first of the following paragraphs. When spacing of the structural framing members exceeds 1.5 meter 5-feet, delete the second of the following paragraphs.
**************************************************************************

c. Ensure flat slabs have tongue-and-groove edges on sides and square edges on ends, except that edges for exposed roof sides are square.
d. Ensure flat slabs have tongue-and-groove edges on sides and ends, except that edges for exposed roof sides and ends are square.

**************************************************************************
NOTE: Delete the following paragraphs when flat or plank roof slabs are required.
**************************************************************************

Use channel shaped precast concrete roof slabs conforming to ASTM C1705/C1705M, Type I or Type II, with the following modifications:

a. Reinforce channel slabs with steel-wire mesh in the web section and a minimum of one 12.7 millimeter No. 4 steel reinforcing bar in each flange.
b. Ensure slabs have nailing edges.

**************************************************************************

NOTE: The following paragraph applies to both flat and channel roof slabs.
**************************************************************************

c. Ensure that roof slabs, not suitable for nailing, have wood inserts. Pressure treat wood using a water-borne preservative and attain the minimum net retention of the solid preservative for lumber used in protected locations, in accordance with AWPA BOOK. Ensure that inserts are at least 50 by 75 millimeter (nominal), 37.5 by 62.5 millimeter (dressed) 2 by 3 inches (nominal), 1.5 by 2.5 inches (dressed), in section, placed in rows 600 millimeter 24 inches on center, and parallel with the roof slope. Ensure inserts are set flush with surfaces of slabs and rigidly secured in place with anchors designed and spaced to provide the holding strength required for subsequent nailing of roofing.

2.3.2 Precast Curb Units

**************************************************************************

NOTE: Delete paragraph heading and the following paragraphs when precast curb units, such as curbs for vents, skylights, and other units not in the same plane as the roof decking, are not required.
**************************************************************************

Construct curb units of the same material and strength requirements as precast concrete roof slabs. Design precast curb units to fit securely in the anchorage provided by structural framing members.

Submit manufacturer's catalog data for all accessories including nails, threaded fasteners, and joint sealing compounds.

Submit certificates of compliance for precast curb units showing conformance with referenced standards contained in this section.

2.3.3 Cement Grout Joint Sealing Materials

Provide blended hydraulic cement that conforms to ASTM C595/C595M, Type [IS, IP].

Provide portland cement that conforms to ASTM C150/C150M, Type I.

Ensure that aggregate for cement grout is clean, sharp, uniformly graded, natural or manufactured sand conforming to ASTM C33/C33M.

Submit manufacturer's catalog product data for cement grout joint sealing materials.

2.3.4 Bituminous Joint Sealing Materials

Provide bituminous cement that is steep asphalt for use in constructing built-up roof coverings conforming to ASTM D312/D312M, Type IV.

Compose joint-sealing tape of two layers of uncreped kraft paper united by steep asphalt with approximately 13 by 8 millimeter 1/2 by 1/3 inch glass-fiber reinforcement embedded in the asphalt laminate. Tape to meet
requirements of FS UU-B-790, Type I, Grade C, Style 4, with the following modifications:

a. Ensure that width is 150 millimeter 6 inches.

b. Dry tensile strength cannot be less than 6150 newton per meter 35 pounds per inch width, both directions.

Submit manufacturer's catalog product data for bituminous joint sealing materials.

Submit certificates of compliance for bituminous joint sealing materials showing conformance with referenced standards contained in this section.

2.3.5 Packaged Concrete Materials

Ensure that concrete materials are packaged, dry, combined materials for concrete conforming to ASTM C387/C387M, lightweight concrete (using natural sand), and have the following properties:

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compressive strength at 28 days</td>
<td>Not less than 20 Megapascal</td>
</tr>
<tr>
<td>Maximum aggregate size</td>
<td>9.5 millimeters</td>
</tr>
<tr>
<td>Slump</td>
<td>Not more than 75 millimeters</td>
</tr>
<tr>
<td>Total air content by volume</td>
<td>6 to 10 percent</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compressive strength at 28 days</td>
<td>Not less than 3,000 psi</td>
</tr>
<tr>
<td>Maximum aggregate size</td>
<td>3/8 inch</td>
</tr>
<tr>
<td>Slump</td>
<td>Not more than 3 inches</td>
</tr>
<tr>
<td>Total air content by volume</td>
<td>6 to 10 percent</td>
</tr>
</tbody>
</table>

Ensure that materials used as ingredients include: [Blended hydraulic cement conforming to ASTM C595/C595M] [Fly ash conforming to ASTM C618, Class C or F] [Ground granulated blast furnace slag conforming to ASTM C989/C989M, Grade 120.]

2.3.6 Water for Mixing Cement Grout and Concrete

Use potable water for mixing cement grout and concrete.

2.3.7 Concrete Curing Materials

Ensure that the absorption cover for curing concrete is burlap cloth made from jute or kenaf, conforming to AASHTO M 182, Class 3.

Ensure that the moisture-retaining cover for curing concrete is white waterproof paper or white opaque polyethylene sheet conforming to ASTM C171.
PART 3  EXECUTION

Install precast roof slabs and accessories in accordance with the approved drawings and as specified.

3.1  PREPARATION

Ensure that the supporting walls, purlins or joists, and other supporting members are in place before the placing of precast roof slabs is started. Do not place roof slabs during, or while there is a threat of, rain or snow.

3.1.1  Concrete Roof Slab Placement

Place each roof slab on structural framework to bear on at least two structural framing members. Ensure that the end bearing is not less than 50 millimeter 2 inches. For roof slabs having square edges, ensure the ends occur over a structural framing member. Where installation requires cutting roof slabs, ensure the cut ends occur over supports at the wall or at openings. Cut roof slabs as specified.

**************************************************************************
NOTE: Delete following paragraph when the spacing of the structural framing members exceeds 1.5 meter 5 feet, or when flat slabs having tongue-and-groove edge on ends are not required.
**************************************************************************

Ends of roof slabs having tongue-and-groove edges on ends do not need to occur over a structural framing member; stagger such end joints in adjacent rows.

Align roof slabs in each row end to end, with adjacent rows parallel. Alignment does not depend on adjacent walls or structural framing members being accurately square.

3.2  INSTALLATION

Provide installation instructions that indicate the manufacturer's recommended installation methods and sequence.

Submit test reports for precast concrete roof slabs regarding nail driving and nail pulling tests and strength tests in accordance with ASTM C1704/C1704M.

3.2.1  Fastening Roof Slabs

Fasten roof slabs to each structural framework member by means of clips and nails. Where possible, alternate clips in position so that each clip is facing in the opposite direction of the next clip. Secure clips to roof slabs with one nail per clip and fit to the top flange or chord of structural framework member by slots in the clips formed for this purpose.

When the roof slope is greater than a 1 to 4 ratio, fasten roof slabs to supporting members by threaded fasteners in addition to the clips specified. Ensure that the threaded fasteners are not less than 13 millimeter 1/2 inch in diameter. Use countersunk fastener heads. Attach fasteners to the top flange or chord of supporting members by means of offset clips or other approved method. Ensure that the threaded fasteners
are at least one fastener per 3 square meter 30 square feet of roof area.

3.2.2 Cutting and Fitting

NOTE:  Frame openings in precast roof slabs larger than one-half the roof slab width in any dimension with supporting members that are provided as a part of the roof framing system.

Perform roof slab cutting and fitting as required by the approved drawings for passage of other work projecting through or adjacent to the roof decking. Ensure that the cuts are straight and clean through roof slabs and at 90 degrees to severed surfaces without breaking, spalling, or appreciable crumbling at edges.

3.2.3 Sealing Joints

After roof slabs have been placed and fastened, seal the top portion of joints as specified.

Fill joints at ridges and hips and tongue-and-groove joints with cement grout. Provide cement grout that consists of portland cement, sand, and water mixed to manufacturers instructions. Place grout so as to be even with the top surface of roof slabs. Remove excess grout and give grout surface a smooth finish.

Seal other joints with specified bituminous joint sealing materials. Center joint sealing tape over the joint and embedded in hot bituminous cement applied at the rate of 6 to 8 kilogram per 10 square meter 15 to 20 pounds per 100 square feet of joint sealing tape. Provide end laps that are less than 100 millimeter 4 inches. Remove excess bitumen and ensure that the joint sealing tape surface is smooth and free of wrinkles.

3.2.4 Installation Of Precast Curb Units

NOTE: Delete paragraph heading and following paragraph when precast curb units are not required.

Install precast curb units in accordance with approved drawings.

3.2.5 Fill for Sloping Surfaces

Ensure that the fill for curb cants and other sloping surfaces consists of the specified packaged concrete materials mixed with water.

Mix concrete either manually or by mechanical mixer, using the quantity of water indicated on packaged concrete materials. Accurately measure water used in manual mixing. Equip mechanical mixer with a device to measure and control the amount of water used. Keep mixer drums, mixing boxes, tools, and other mixing equipment clean and free from hardened lumps of concrete.

Handle concrete mixture from the point of mixing and transferred to concrete conveying equipment and to locations of final deposit as rapidly as possible by methods that prevent segregation and loss of concrete mix materials. Ensure that the mechanical equipment for conveying concrete
mixtures is of such size and design as to ensure a uniform, continuous flow of concrete mixture at the delivery end. For concrete conveying equipment, maintain the inner surfaces free of hardened concrete, debris, water, snow, ice, or other deleterious materials.

Place and screed concrete mixture in a continuous operation until placing a section is completed. Ensure that the finished surface is free of humps or hollows; sloped to drains; uniform, smooth, even plane; and of granular texture.

Immediately following the concrete finishing operation, ensure that the concrete is kept continuously moist for at least 72 hours by covering the concrete surface with a specified absorptive cover for curing concrete, or kept continuously wet, by covering concrete surface with a specified moisture-retaining cover for curing concrete, or by a combination of both curing methods.

During the concrete curing period, protect concrete from damage caused by rain or running water, by excessively cold or hot temperatures, and from damaging mechanical disturbances.

3.2.6 Cold-Weather Limitations

Do not perform joint sealing, concrete mixing, or placing when the ambient temperature is 5 degrees C 40 degrees F or below.

3.3 ADJUSTING AND CLEANING

Upon completion of roof decking work, sweep roof surfaces clean of debris and other foreign matter and in a condition ready to receive roofing.

3.4 PROTECTION

Protect finished roof decking from damage by weather and construction operations until roofing is installed.

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for fabrication and erection of precast structural concrete framing elements, floor units, and roof units for buildings including, as required by the project, the following:

Precast conventionally reinforced concrete floor and roof units for clear spans up to 10.5 meter 35 feet.

Precast conventionally reinforced concrete columns, joists, beams, and other structural framing elements.

Precast prestressed concrete single- and double-tee slabs, hollow-cored flat slabs, tee- or keystone-joists, columns, and other structural elements.

Precast concrete cellular floor units with cells suitable for use as electrical raceways.

Include in drawings a complete design indicating the character of the work to be performed and giving the following:

Assumed loads, including floor live load, roof live load, wind load, concentrated loads such as partitions, and equipment mounted on or suspended from precast concrete construction, concrete floor topping weight, and other design data as may be required for meeting building codes and the proper preparation of shop drawings.

Layout of the framing system indicating the relative location of the various precast structural concrete sections, floor elevations, column centers and offsets, openings, and sufficient dimensions to adequately convey the quantity and nature of the required precast structural concrete framing system.

Details of all precast structural concrete sections
indicating cross-sections and dimensions.

Location of precast structural concrete sections having an architectural finish on exposed-to-view surfaces when required.

Details of reinforcement indicating reinforcing-bar schedules; location and size of welded-wire fabric; and tenons for prestressed concrete indicating the final stressing force in kips, as required.

Details of connections indicating end bearing minimums and anchorage devices and other items embedded in the precast structural concrete sections.

Location and details of concrete floor topping, when required.

Details of openings including the size of steel framing members as required.

Details of precast concrete filler blocks, as required.

Details of hangers for suspended ceilings, ducts, piping, lighting fixtures, conduit, or other construction, as required.

Precast concrete floor-unit cells that will be used for electrical raceways, when required.

When both fire-resistance-rated construction and non fire-resistance-rated construction are required, the location of fire-resistance-rated construction.

Cast-in-place normal-weight concrete, including concrete floor topping, is specified in Section 03 30 53 MISCELLANEOUS CAST-IN-PLACE CONCRETE.

Precast conventionally reinforced concrete wall panels, solid-section type, are specified in Section 03 45 00 PRECAST ARCHITECTURAL CONCRETE.

Precast-concrete roof slabs placed over purlings or joists spaced not more than 8 feet on center are specified in Section 03 41 16.08 PRECAST CONCRETE SLABS (MAX. SPAN 8 FEET 0.C.).

Sealing joints in exposed-to-view surfaces of precast concrete slabs, such as at ceilings and walls, is specified in Section 07 92 00 JOINT SEALANTS.

Painting exposed-to-view surfaces of precast concrete units such as ceilings and walls, is specified in Section 09 90 00 PAINTS AND COATINGS.

When cells of precast concrete cellular floor units will be used for electrical raceways, the inspection
of cells to be used for electrical raceways, cutting the floor units for inserts, and electrical raceway fittings are specified in Section 26 05 00.00 40 COMMON WORK RESULTS FOR ELECTRICAL.

Fire-resistance-rated construction using precast structural concrete sections is described in Underwriters Laboratories, Inc., "Fire Resistance Ratings (BXUV)" included in UL Fire Resistance Directory and the "Fire-Resistance Ratings" contained in AIA CO-1. Fire-resistance-rated construction limits the types of precast structural concrete sections; the requirements for end restraint; the concrete materials and proportions of concrete mix for floor top fill; the requirements for grouting and sealing joints; and the type of roof insulation and roof covering.

Adhere to **UFC 1-300-02** Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a **Criteria Change Request (CCR)**.

Setting of Concrete Mixtures by Penetration Resistance

ASTM C618  (2023; E 2023) Standard Specification for Coal Fly Ash and Raw or Calcined Natural Pozzolan for Use in Concrete

1.2 SUBMITTALS

**************************************************************************
NOTE: Review Submittal Description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity.

SECTION 03 41 33 Page 12
or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy, and Air Force.

Use the "S" Classification only in SD-11 Closeout Submittals. The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-02 Shop Drawings

1.3 QUALITY CONTROL

1.3.1 Qualifications for Precast-Concrete Manufacturer

Provide precast structural concrete sections manufactured by an organization experienced in the manufacture of precast concrete.

Submit a written description of the manufacturer giving the qualifications of personnel, location of plant, concrete batching facilities, manufacturing equipment and facilities, list of projects similar to specified work[ and [____]].
Produce sections/units under plant-controlled conditions conforming to PCI MNL-116 by a firm certified under the PCI Plant Certification Program and specializing in providing precast/prestressed products and related services.

1.3.2 Qualifications for Installer

Install members by using an organization experienced in the installation of precast structural-concrete sections.

Submit a written description of installers giving the qualifications of personnel, handling and erection equipment, list of projects similar to specified work[ and [_____]].

1.3.3 Qualifications for Welding Work

Submit certificates of Compliance for the following items:

a. Qualifications of personnel
b. A list of projects similar to specified work
c. Performance requirements

[ Section 05 05 23.16 STRUCTURAL WELDING applies to work specified in this section.]

] Ensure all welding procedures are in accordance with AWS D1.1/D1.1M, and welders are qualified by tests in accordance with AWS D1.1/D1.1M.

] Ensure welders make only those types of weldments for which each is specifically qualified.

] Provide installation instructions for the welding sequence and procedure which indicates the manufacturer's recommended sequence and method of installation.

1.3.4 Concrete Sampling and Testing

Submit test reports. Include within each report the following items:

a. Project name and number, date, name of Contractor
b. Name of precast-concrete manufacturer, name of concrete testing service,
c. Type of concrete
d. Structural-member identification letter and number
e. Design compressive strength at 28 calendar days
f. Concrete-mix proportions and materials
g. Compressive breaking strength and type of break
h. A record of gage pressures or dynamometer readings,
i. Compression strength of concrete at time of detensioning, and type of
Submit design mix reports for approval at least 15 calendar days prior to start of work.

1.3.4.1 Tests for Concrete Materials

*NOTE: Delete the following materials and tests that are not required.*

Sample and test concrete materials proposed for use in the work as follows:

<table>
<thead>
<tr>
<th>MATERIAL</th>

</table>

NOTE: Delete the following paragraph when normal-weight concrete is not required.

From the results of the tests for normal-weight concrete, plot a curve showing the relationships between water/cement ratios and compressive strengths. When producing a design-minimum laboratory Compressive Strength at 28 calendar days, do not exceed the maximum water/cement ratio specified for normal-weight concrete properties shown by the curve.

NOTE: Delete the following paragraph when lightweight structural concrete is not required.

From the results of the tests for lightweight structural concrete, plot a curve showing the relationships between cement contents and compressive strengths. When producing a design-minimum laboratory compressive strength at 28 calendar days, do not provide less than the minimum cement content specified for lightweight structural properties shown by the curve.

1.3.4.3 Quality Control Testing During Fabrication

NOTE: Delete the following types of concrete not required by the project.

Sample and test concrete for quality control during fabrication as follows:

<table>

</table>

Submit test results on the same day that tests are made.

PART 2 PRODUCTS

2.1 SYSTEM DESCRIPTION

Submit fabrication drawings. Show type and location of all reinforcement, size and spacing of welds within Fabrication Drawings.

Submit installation drawings indicating type and location of all anchorage devices, size and spacing of all welded connections, grouting and joint sealant details, and dimensions and locations of all openings in structural concrete sections.

2.1.1 Quality Of Concrete

2.1.1.1 Normal-Weight Concrete Properties

****************************** Delete paragraph heading and the following **********
paragraphs when normal-weight concrete will not be required.

<table>
<thead>
<tr>
<th>PROPERTY</th>
<th>VALUE</th>

</tbody>
</table>
2.1.2 Performance Requirements

2.1.2.1 Design Methods

Design in accordance with ACI/MCP-3, ACI 318, ACI 318M and PCI MNL-120.

2.1.2.2 Allowable Design Loads and Deflections

******************************************************************************
NOTE: Allowable design loads indicated and include dead loads, live loads, stationary loads, concentrated moving loads, deflection of roof slab sections, etc.

Recommended design loads are found in ASCE 7-10.
******************************************************************************

Allowable design loads and deflections as indicated.

2.1.2.3 UL Fire-Resistance Listing and Label

******************************************************************************
NOTE: Delete paragraph heading and the following paragraph when UL-listed fire-resistant precast structural concrete sections are not required. The UL lists several manufacturers of prestressed precast-concrete, hollow-core flat slabs, and single-tee and double-tee slabs. Indicate location and fire-resistance classification of fire-resistant-rated structural sections.
******************************************************************************

Indicate sections requiring a fire-resistance classification as listed in UL Fire Resistance part, PRECAST CONCRETE UNITS (CFTV), and bear the UL
label and marking.

2.1.2.4 Electrical Raceway UL Listing and Label

**************************************************************************
NOTE: Delete paragraph heading and the following paragraph when hollow-core floor-slab precast structural sections will not be used for electrical raceways, either under this contract or in the future. Indicate location of electrical raceway structural sections.
**************************************************************************

List the hollow-core floor slabs indicated as electrical raceways in UL Electrical Construction part, RACEWAYS (RGKT) CELLULAR CONCRETE FLOOR (RGYR), and bear the UL label and marking.

2.2 FABRICATION

2.2.1 Fabrication Tolerances

**************************************************************************
NOTE: Delete the following fabrication tolerances that are not required by the project.
**************************************************************************

Fabricate sections within the following tolerances:

<table>
<thead>
<tr>
<th>Overall dimensions</th>
<th>Plus or minus 3 millimeter per 3048 millimeter but not greater than 19.1 millimeter overall</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cross-sectional dimensions of up to 150 to 460 millimeter</td>
<td>Plus or minus 3 millimeter</td>
</tr>
<tr>
<td>Over 460 to 915 millimeter</td>
<td>Plus or minus 4.8 millimeter</td>
</tr>
<tr>
<td>Over 915 millimeter</td>
<td>Plus or minus 6.4 millimeter</td>
</tr>
<tr>
<td>Deviation from straight line parallel to centerline of section up to 12.2 meters in length</td>
<td>Not over 9.5 millimeter</td>
</tr>
<tr>
<td>12.2 to 18.3 meter in length</td>
<td>Not over 12.7 millimeter</td>
</tr>
<tr>
<td>Over 18.3 meter in length</td>
<td>Not over 19.1 millimeter</td>
</tr>
<tr>
<td>Deviation from camber indicated on</td>
<td>Plus or minus 3 millimeter per 3</td>
</tr>
<tr>
<td>Ends out of square, up to 305</td>
<td>0.80 millimeter per 25.4 millimeter</td>
</tr>
<tr>

2.2.2  Forms

**************************************************************************
NOTE: Indicate structural-section dimensions, cross-sections, and other details as required by the project.
**************************************************************************
Use forms and form-facing materials that are nonreactive with concrete such as wood, metal, plastic, or other approved materials and are within the limits of the specified fabrication tolerances. Conform to the shapes, lines, and dimensions indicated.

2.2.3  Reinforcement

**************************************************************************
NOTE: Indicate reinforcement types, sizes, and arrangement as required for structural strength after the structural sections have been installed.
**************************************************************************
Provide types, sizes, and arrangement as indicated on the approved drawings. Detail reinforcement in accordance with ACI/MCP-3 and ACI 318.

Place and secure steel bars, welded-wire fabric, and other reinforcement by means of metal bar supports and spacers.

**************************************************************************
NOTE: Delete the following paragraph when prestressed structural-concrete sections are not required by the project.
**************************************************************************
Place tendons and anchorages in accordance with ACI/MCP-3 and ACI 318. Provide anchorages that are permanently protected with concrete; free of loose rust, grease, oil, paint, and other foreign matter. Ensure bearing surface is between anchorages and concrete; perpendicular to and concentric with the tendons and the line of action prestressing force.

**************************************************************************
NOTE: Revise or delete the following paragraph when not applicable to the project. Indicate concrete cover for reinforcement.
**************************************************************************
Provide concrete cover for reinforcement in accordance with ACI/MCP-3 and ACI 318.

2.2.4  Built-In Anchorage Devices

**************************************************************************
NOTE: Indicate anchorage devices that are to be embedded in the precast structural concrete
**************************************************************************
sections. Anchorage devices include weld plates, bearing plates and steel shapes.

Position, anchor, and locate anchorage devices where they do not affect the position of the main reinforcement or placing concrete. Set bearing plates level, aligned properly, and anchor in the exact location indicated.

2.2.5 Lifting Devices

Provide lifting devices designed in accordance with ASME BTH-1, and of materials sufficiently ductile to ensure visible deformation before fracture.

2.2.6 Blockouts

---

NOTE: Blockouts are openings in slabs that would require the cutting of primary reinforcement if such openings were to be cut in the field. Ensure openings are cast in the unit during fabrication and indicated. The maximum size of field-cut openings may be from 150 to 300 millimeter (6 to 12 inches) depending on the type of unit used such as the inside diameter of the voids in hollow cored flat slabs and the spacing of reinforcement.

---

Provide blockouts as indicated on drawings.

2.2.7 Pretensioning

---

NOTE: Delete paragraph heading and the following paragraph when prestressed structural-concrete sections are not required by the project.

---

Pretensioning of tendons may be accomplished either by the single-strand or multiple-strand tensioning method. Determine the prestressing force by measuring the tendon elongation, either by checking the jack pressure on a recently calibrated gage or by use of a recently calibrated dynamometer. Correct any discrepancy that exceeds 5 percent. Base elongation requirements on the load-elongation curves for the type of tendon used. The total loss of prestress due to unreplaced broken tendons is not to exceed 2 percent of the total prestress.

2.2.8 Concrete Mixing and Conveying

Measure concrete materials, concrete batching plant, concrete mixers, and concrete mixing in accordance with ASTM C94/C94M.

Handle concrete to prevent segregation and loss of concrete mix materials.

2.2.9 Preparations for Placing Concrete

Keep form interiors and reinforcement free of accumulations of hardened concrete, form-parting compound, standing water, ice, snow, or other deleterious substances. Secure in position, inspect and approve
reinforcement and other embedded items.

2.2.10 Weather Limitations

Do not place concrete when temperature of the atmosphere is below 5 degrees C or 40 degrees F nor during rain, sleet, and snow unless adequate protection is provided. Provide protection during inclement weather; prevent the entry of rain, sleet, or snow into the forms or into the fresh concrete.

2.2.11 Concrete Placing

Deposit concrete so that no concrete is placed on concrete that has hardened sufficiently to cause formation of seams or planes of weakness. Consolidate concrete in a manner that will prevent segregation and will produce concrete free of honeycomb or rock pockets and with the required surface finish.

2.2.12 Identification Markings

Clearly mark each structural section in a permanent manner to indicate its location and orientation in the building and the pickup points.

Ensure each structural section has the date of casting plainly indented in the unexposed face of the concrete.

2.2.13 Finishing Unformed Surfaces

Trowel finish unformed surfaces unless otherwise specified. Provide smooth surface free of trowel marks, uniform in texture and appearance, and be plane to a tolerance not exceeding 3.2 millimeter in 3048 millimeter 1/8-inch in 10-feet when tested with a 3000 millimeter 10-foot straightedge.

Provide top surfaces of sections that are to receive concrete topping after installation with a transversely scarified scratch finish and remove laitance.

2.2.14 Curing

Cure concrete by keeping the concrete damp for not less than 7 calendar days if made of Type I portland cement and for not less than 3 calendar days if made of Type III portland cement. For each decrease of 3 degrees below 21 degrees C or 5 degrees below 70 degrees F in the average curing temperature, increase the curing period by 4 calendar days for concrete made of Type I portland cement and by 2 calendar days for concrete made of Type III portland cement.

Curing by low-pressure steam, steam vapor, radiant heat and moisture, or other acceptable process may be employed provided that the compressive strength of the concrete is equal to that obtained by moist curing and the 28-day compressive strength of the concrete meets the requirements specified, as determined by test cylinders of the same concrete cured by the same curing process.

Do not remove sections from their casting beds until the curing period is completed or concrete has attained at least 75 percent of its design compressive strength.
2.2.15 Protection of Concrete After Placing

Meet protection requirements of ACI/MCP-2 for hot or cold weather, as applicable.

2.2.16 Detensioning

NOTE: Delete paragraph heading and the following paragraphs when prestressed structural-concrete sections are not required by the project.

Do not detension tendons until the concrete compressive strength, as indicated by test cylinders, is as follows:

<table>
<thead>
<tr>
<th>TYPE OF REINFORCEMENT</th>
<th>COMPRRESSIVE STRENGTH OF CONCRETE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Concentrically stressed sections</td>
<td>Not less than 20 Megapascal</td>
</tr>
<tr>
<td>Eccentrically stressed sections</td>
<td>Not less than 24.1 Megapascal</td>
</tr>
<tr>
<td>Beams or other sections in which camber must be minimized</td>
<td>Not less than 27.6 Megapascal</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>TYPE OF REINFORCEMENT</th>
<th>COMPRRESSIVE STRENGTH OF CONCRETE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Concentrically stressed sections</td>
<td>Not less than 3,000 psi</td>
</tr>
<tr>
<td>Eccentrically stressed sections</td>
<td>Not less than 3,500 psi</td>
</tr>
<tr>
<td>Beams or other sections in which camber must be minimized</td>
<td>Not less than 4,000 psi</td>
</tr>
</tbody>
</table>

Remove test cylinders to be used to establish the compressive strength of the concrete from the casting bed at least 1 hour prior to the start of the detensioning operation. Allow test cylinders from heat-cured casting beds to cool for approximately 1/2 hour prior to capping, and allow caps of sulfur compound to cure for 1/2 hour prior to the compressive-strength test.

If concrete has been heat cured, ensure the detensioning operation is done following the curing period while the concrete is still warm and moist to avoid cracking or undesirable stresses in the concrete.

Ensure prior to detensioning operations, forms, ties, inserts, holddowns, or other devices that would restrict the longitudinal movement of the sections along the casting bed are removed or loosened to provide free movement of the structural section. Alternately, perform detensioning so that longitudinal movement is precluded.

In detensioning operations, ensure prestressing forces are kept nearly symmetrical about the vertical axis of the section and applied in a manner that will minimize sudden or shock loading. Limit maximum eccentricity about the vertical axis to one strand. Detensioning of pretensioned tendons may be accomplished either by gradual release of the tensioning jacks or by heat-cutting the tendons in accordance with an approved pattern and sequence to prevent severe unbalancing of the loading.
2.2.17 Finishing Formed Surfaces

Upon removal of forms, repair and patch defective areas. Limit defective areas to holes left by tie rods and other temporary inserts and to honeycomb or rock pockets not deep enough to expose the reinforcement and not located in bearing areas. Cut out defective areas to sound concrete and clean. Ensure patches on lower side of sections, near the center or in areas of variable tensile strength, are bonded by a two-component epoxy-polysulfide or epoxy-polyamine bonding adhesive. Other areas will be dampened with water and patched with portland cement grout. Where the concrete surface will be exposed to view, match the patches, when dry, to the surrounding concrete.

Formed surfaces of sections that will be concealed by other construction can have the standard smooth finish having the texture imparted by the forms. Repair and patch defective areas as specified and remove fins and other projections.

******************************************************************************

NOTE: Delete the following paragraph and specify the required finish when an architectural finish is required. For an exposed-aggregate finish refer to Section 03 45 00 PRECAST ARCHITECTURAL CONCRETE. Indicate the location of precast structural concrete sections having an architectural finish.

******************************************************************************

Provide grout finish on formed surfaces of sections that are to be exposed-to-view after installation. Ensure final color of the grout, when dry, is the same for all concrete surfaces. Spread over dampened concrete surface with clean burlap pads, carpet, or sponge rubber floats to fill pits, air bubbles, and surface holes. Remove excess grout by scraping and then rubbing the surface with clean burlap or carpet to remove visible grout film. In hot dry weather, kept grout damp by means of fog-spraying during the setting period.

2.3 MATERIALS

2.3.1 Concrete Materials

2.3.1.1 Normal-Weight Aggregates

******************************************************************************

NOTE: Delete paragraph heading and the following paragraphs when precast structural-concrete sections will be fabricated of lightweight structural concrete. Fabricate precast concrete elements exposed to the weather of normal-weight concrete. When an architectural finish, such as exposed aggregate, is required for exposed-to-view surfaces, refer to Section 03 45 00 PRECAST ARCHITECTURAL CONCRETE for concrete aggregate specifications.

******************************************************************************

Provide fine and coarse aggregates conforming to ASTM C33/C33M and the following:

a. Where a structural member is exposed to the weather, and for all concrete aggregates where surface appearance of the concrete is
important, meet the requirements of ASTM C33/C33M for fine aggregate subject to abrasion, for coarse aggregate subject to severe exposure.

b. Maximum size of coarse aggregate is as specified.

2.3.1.2 Lightweight Aggregates

**************************************************************************
** NOTE: Delete paragraph heading and the following paragraph when all precast structural-concrete sections will be fabricated of normal-weight concrete. Fire-resistance-rated structural sections may be fabricated of lightweight structural concrete, especially when the fire-resistance rating exceeds 2 hours. **
**************************************************************************

Conform to ASTM C330.

2.3.1.3 Portland Cement

**************************************************************************
** NOTE: If high early strength concrete is required, add Type III. **
**************************************************************************

[ Portland cement conforms to ASTM C150/C150M, Type [____]. ]

[ Blended hydraulic cement conforms to ASTM C595/C595M, Type [____]. ]

Use one brand and type of cement for formed concrete having exposed-to-view finished surfaces.

2.3.1.4 Fly Ash

Use fly ash as an admixture, conforming to ASTM C618, Class [C or F], with 4 percent maximum loss on ignition and between 15 to 35 percent maximum cement replacement by weight.

**************************************************************************
** NOTE: Ground granulated blast furnace slag is one of the materials listed in the EPA’s Comprehensive Procurement Guidelines (CPG) at https://www.epa.gov/smm/comprehensive-procurement-guidelines-construction-product. **
**************************************************************************

If the Architect/Engineer determines that use of certain materials meeting the CPG content standards and guidelines would result in inadequate competition, do not meet quality/performance specifications, are available at an unreasonable price or are not available within a reasonable timeframe, the Architect/Engineer may submit written justification and supporting documentation for not procuring designated items containing recovered material.

**************************************************************************
2.3.1.5 Ground Granulated Blast Furnace (GGBF) Slag

GGBF slag [is required] [used] as an admixture [and] conforming to ASTM C989/C989M, Grade [120] with between 25 to 50 percent maximum cement replacement by weight.

2.3.1.6 Air-Entraining Admixture

Use an admixture free of sodium chloride and nitrates, conforming to ASTM C260/C260M.

2.3.1.7 Water

Use potable water.

2.3.2 Reinforcement Materials

**************************************************************************
NOTE: Delete the following reinforcement materials that are not required. Concrete reinforcement materials are required for both conventionally reinforced and prestressed precast structural-concrete sections.
**************************************************************************

2.3.2.1 Reinforcement Bars

Provide deformed bars conforming to ASTM A615/A615M, Grade 60, except that 9.5 millimeter 0.375 inches diameter bars may be Grade 40.

**************************************************************************
NOTE: Delete the following paragraph when galvanized reinforcing bars for concrete reinforcement is not required. Galvanizing is recommended when the concrete cover over reinforcing bars is less than 38 millimeter 1-1/2 inches for structural sections exposed to the weather.
**************************************************************************

Galvanize bars for structural sections exposed to the weather in accordance with ASTM A767/A767M.

2.3.2.2 Cold-Drawn Steel Wire

Provide wire conforming to ASTM A1064/A1064M.

2.3.2.3 Welded-Wire Fabric

Provide uncoated wire fabric conforming to ASTM A1064/A1064M. Provide galvanized wire fabric in structural sections exposed to the weather.

2.3.2.4 Supports for Concrete Reinforcement

Include bolsters, chairs, spacers, and other devices necessary for proper spacing, supporting, and fastening reinforcement bars and wire in place.

Provide wire supports conforming to ACI/MCP-4, ASTM E648, ACI SP-66 and CRSI 10MSP.
Ensure legs of supports in contact with formwork for sections that will be exposed to weather are hot-dip galvanized after fabrication, plastic coated, or corrosion-resistant steel bar supports.

2.3.3 Prestressing Materials

**************************************************************************
NOTE: Delete paragraph heading and the following paragraphs when prestressed structural-concrete sections are not required.
**************************************************************************

2.3.3.1 Strand Tendons

**************************************************************************
NOTE: Strand tendons for prestressed concrete are primarily intended for use in pretensioned, bonded, prestressed concrete construction. Use galvanized tendons in project locations with Environmental Severity Classifications (ESC) of C4 or C5. See UFC 1-200-01 for determination of ESC for project locations.
**************************************************************************

Provide [uncoated][galvanized], 7-strand, stress-relieved, steel wire conforming to ASTM A416/A416M.

2.3.3.2 Wire Tendons

**************************************************************************
NOTE: Delete paragraph heading and the following paragraph when wire tendons for prestressed concrete will not be required. Prestressing steel wire is commonly used in prestressed linear concrete construction in which the steel wire ends are anchored by cold-end deformation (that is, button anchorage) or in which the steel wire ends are anchored by wedges.
**************************************************************************

Provide tendons conforming to ASTM A421/A421M, Type BA or Type WA, as required to suit the steel-wire anchorage method used.

2.3.3.3 Steel-Bar Tendons

**************************************************************************
NOTE: Delete paragraph heading and the following paragraphs when steel-bar tendons for prestressed concrete will not be required. Steel bars are principally used in post tensioning.
**************************************************************************

Provide uncoated round steel bars conforming to ASTM A322.

Tensile properties of the bars after processing, when tested in accordance with ASTM A370, as follows:

**************************************************************************
NOTE: Select one of the following values of tensile
property and value as applicable to the project.

<table>
<thead>
<tr>
<th>TENSILE PROPERTY</th>
<th>VALUE NO. 1</th>
<th>VALUE NO. 2</th>
</tr>
</thead>
<tbody>

</tbody>
</table>

2.3.3.4 Tendon Anchorages for Pretensioning

Provide tendon anchorages capable of anchoring reinforcement without slippage after seating.

Proof test by the manufacturer, steel cases for prestressing steel strand to at least 90 percent of the ultimate tensile strength of the strand.

2.3.3.5 Tendon Anchorages for Post Tensioning

NOTE: Delete paragraph heading and the following paragraphs when tendon anchorages for post tensioning will not be required. Normally, pretensioning only is required for prestressed precast structural concrete sections for building construction. Post tensioning may be required for field connections.

Provide anchorages capable of developing 100 percent of the guaranteed ultimate tensile strength of the reinforcement for prestressed concrete without excessive deformation. Provide anchorage plates of sufficient size to keep bearing pressures within the stress allowed by ACI/MCP-3 and ACI 318 for the specified concrete strength at stressing.

Submit test data confirming the adequacy of anchorages.
2.3.4 Connection Materials

2.3.4.1 Steel Plates, Shapes, and Bars

Ensure plates conform to ASTM A283/A283M, Grade C, or to ASTM A36/A36M.

Ensure structural-steel shapes conform to ASTM A36/A36M.

Ensure bar shapes, flats, and rounds conform to ASTM A675/A675M, Grade 65, or ASTM A36/A36M.

Where connectors are recessed, allow a minimum 64 millimeters 2-1/2 inches of concrete cover for epoxy resin filler. Do not use welded or bolted metal connectors where exposed to the weather, unless such components are of stainless steel, galvanized steel or fusion-bonded epoxy coated steel.

2.3.4.2 Steel Anchor Bolts

**************************************************************************
NOTE: Delete paragraph heading and the following paragraph when anchor bolts will not be required.
Anchor bolts are normally required for precast concrete column base connections.
**************************************************************************

Provide anchor bolts made of steel, with steel hexagon nuts and steel washers.

2.3.4.3 Electrodes for Welding

**************************************************************************
NOTE: Delete paragraph heading and the following paragraphs when welded connections are not required.
**************************************************************************

Provide electrodes for manual shielded metal-arc welding connections consisting of structural quality carbon-steel members conforming to the AWS Code and be covered mild-steel electrodes conforming to AWS A5.1/A5.1M, E60 series.

Provide electrodes for welding steel bars for concrete reinforcement conforming to AWS D1.4/D1.4M.

2.3.4.4 Flexible Bearing Pads

**************************************************************************
NOTE: Delete one of the following paragraphs as applicable to the project. Delete paragraph heading and the following paragraphs when flexible bearing pads are not required. Hardboard bearing pads are recommended for gravity connections having a bearing load not exceeding 1725 kilopascal 250 pounds per square inch (psi). Elastomeric nonlaminated bearing pads are recommended for gravity connections having a bearing load not exceeding 5500 kilopascal 800 psi. Where the bearing load exceeds 5500 kilopascal 800 psi or where there are small rotations, ensure laminated type bearing pads designed and constructed to meet the requirements for loading and movement is
Considered. Indicate the location and size of flexible bearing pads.

Provide tempered hardboard pads not less than 3 millimeter 1/8-inch in thickness, smooth-two-sides, conforming to AHA A135.4.

Provide pads molded or cut from elastomeric material. Provide pad dimensions as indicated and within the following tolerances: thickness, plus or minus 1.5 millimeter 1/16-inch; width, minus 3 to plus 6.5 millimeter 1/8-to plus 1/4-inch; length, plus or minus 3 millimeter 1/8-inch. Material: vulcanized, chloroprene elastomeric compound conforming to the following tests:

<table>
<thead>
<tr>
<th>PROPERTY</th>

2.3.5 Grouting Materials

**NOTE:** Delete the following paragraphs that are not applicable to the project. When fire-resistance rated precast structural-concrete sections are required, the applicable fire agency’s requirements for grouting materials are consulted.

**NOTE:** Ground granulated blast furnace slag is one of the materials listed in the EPA’s Comprehensive Procurement Guidelines (CPG) https://www.epa.gov/smm/comprehensive-procurement-guidelines-construction-prod If the Architect/Engineer determines that use of certain materials meeting the CPG content standards
and guidelines would result in inadequate competition, do not meet quality/ performance specifications, are available at an unreasonable price or are not available within a reasonable time frame, the Architect/Engineer may submit written justification and supporting documentation for not procuring designated items containing recovered material.

Provide Portland cement conforming to ASTM C150/C150M, Type I.

Provide Blended hydraulic cement conforming to ASTM C595/C595M, Type [______].

Provide Aggregate for cement grout conforming to ASTM C404, Size No. 2.

For shrinkage-resistant grouting compound, use premixed and packaged ferrous aggregate conforming to ASTM C1107/C1107M, for expansive grouts.

Use potable water.

Provide two-component, mineral-filled, epoxy-polysulfide epoxy-resin grout conforming to ASTM C881/C881M, [Type I][Type II][______].

Provide two-component, epoxy-polyamide cured type epoxy-resin adhesive conforming to AASHTO M 200.

2.3.6 Bituminous Joint Sealing Materials

NOTE: Delete paragraph heading and the following paragraphs when single- or double-tee roof slab structural sections are not required.

Use asphalt bituminous cement conforming to ASTM D312/D312M, Type IV.

Provide joint sealing tape 15.24 cm 6-inches wide, multilayered, asphalt treated, glass-fiber reinforced, conforming to [ASTM D2103] [ASTM D4397] [FS UU-B-790, Type I, Grade C, Style 4,] with the following modification:

Dry tensile strength not be less than 6130 newton per meter 35 pounds per inchwidth, both directions.

PART 3 EXECUTION

3.1 PREPARATION

3.1.1 Anchorage Items Embedded In Other Construction

NOTE: Delete the paragraph heading and the following paragraph when precast structural-concrete sections will not be connected to cast-in-place concrete construction or masonry construction. Such anchorage items include anchor bolts, steel dowels, and steel bearing plates.
Deliver items to the work site before the start of other construction. Provide setting drawings, templates, instructions, and directions for the installation of anchorage items.

******************************************************************************
NOTE: Ensure where architectural finishes such as exposed-aggregate finish are specified for exposed-to-view surfaces, such surfaces are cleaned as specified in Section 03 45 00 PRECAST ARCHITECTURAL CONCRETE.
******************************************************************************

Protect exposed-to-view surfaces against staining and other damage until completion of the work.

3.2 INSTALLATION

Install precast sections in accordance with the drawings and as specified.

3.2.1 Welded Connections

******************************************************************************
NOTE: Welded connections are the most commonly used type of connection. Other types of connections that may be employed are gravity, structural-steel bolted, post-tensioned, cast-in-place reinforced-concrete, and doweled connections. Ensure connection details are indicated.
******************************************************************************

Ensure welding reinforcing steel, metal inserts, and connections in precast-concrete structural-member construction are in accordance with AWS D1.4/D1.4M.

Ensure welding structural steel connections are in accordance with AWS D1.1/D1.1M.

3.2.2 Installation of Flexible Bearing Pads

******************************************************************************
NOTE: Delete paragraph heading and the following paragraphs when flexible bearing pads are not required. Ensure bearing pads are indicated.
******************************************************************************

Install pads into cast-in-place concrete where indicated; set in correct position, and have a uniform bearing. Keep in the correct position while placing sections.

3.2.3 Strength of Structural Precast Sections at Installation

******************************************************************************
NOTE: Delete one of the following paragraphs as applicable to the project. Select the first paragraph except when the project schedule indicates installation of 28-day structural sections.
******************************************************************************
Do not install precast sections until concrete has attained the specified minimum laboratory strength at 28 calendar days.

Do not install precast sections before 28 calendar days from the date of casting has elapsed unless approval has been obtained to make one compressive-strength test, ASTM C39/C39M, and one flexural strength test using simple beam with third point loading, ASTM C78/C78M, on field cured concrete test specimens, ASTM C31/C31M, for each individual structural section to determine the strength of the concrete.

3.2.4 Installation Tolerances

Install precast sections within the following tolerances:

<table>
<thead>
<tr>
<th>Description</th>
<th>Tolerance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deviation in location from indicated</td>
<td>Plus or minus 6.4 millimeter</td>
</tr>
<tr>
<td>Deviation from plumb for columns in any story or 6.1 meter maximum</td>
<td>Not over 6.4 millimeter</td>
</tr>
<tr>
<td>In 12.2 meter or more</td>
<td>Not over 12.7 millimeter</td>
</tr>
<tr>
<td>Deviation from elevations indicated for girders, beams, joists, and slabs in any bay or 6.1 meter maximum</td>
<td>Not over 6.4 millimeter</td>
</tr>
<tr>
<td>In 12.2 meter or more</td>
<td>Not over 12.7 millimeter</td>
</tr>
<tr>
<td>Difference between adjacent structural sections in erected position</td>
<td>Plus or minus 1.6 millimeter per 3000 millimeter but not greater than 6.4 millimeter overall</td>
</tr>
<tr>
<td>Deviation in location from indicated</td>
<td>Plus or minus 1/4-inch</td>
</tr>
<tr>
<td>Deviation from plumb for columns in any story or 20-feet maximum</td>
<td>Not over 1/4-inch</td>
</tr>
<tr>
<td>In 40-feet or more</td>
<td>Not over 1/2-inch</td>
</tr>
<tr>
<td>Deviation from elevations indicated for girders, beams, joists, and slabs in any bay or 20-feet maximum</td>
<td>Not over 1/4-inch</td>
</tr>
<tr>
<td>In 40-feet or more</td>
<td>Not over 1/2-inch</td>
</tr>
<tr>
<td>Difference between adjacent structural sections in erected position</td>
<td>Plus or minus 1/16-inch per 10-feet but not greater than 1/4-inch overall</td>
</tr>
</tbody>
</table>

3.2.5 Placing Framing Structural Sections

**************************************************************************
NOTE: Delete paragraph heading and the following paragraphs when framing structural sections such as columns, beams, girders, and joists will not be required.
**************************************************************************

Place supporting sections, including anchorage items attached to or embedded in other construction before placing of precast sections is
Installation of precast concrete columns with attached steel bearing plates is as follows:

a. Ensure concrete and steel plate bearing surfaces are cleaned of laitance, dirt, oil, grease, and other foreign materials. Roughen concrete surface.

b. Space between the top of the concrete bearing surface and the bottom of the steel plate is approximately 1/24 of the width of the bearing plate, but not less than 12.7 millimeter (1/2-inch) for bearing plate that is less than 300 millimeter (12-inches) wide. Support and align bearing plate on steel wedges or shims.

c. After precast concrete columns have been positioned and braced and anchor bolts tightened, grout the space between the top of the bearing surface and the bottom of the steel bearing plate.

Do not remove wedges or shims but, when protruding, cut off flush with the edge of the steel bearing plate prior to grouting.

Install sections plumb, level, and in alignment within the limits of the installation tolerances specified.

3.2.6 Placing Slab Structural Sections

Ensure supporting sections, including bearing pads or plates, are in place before placing of precast sections is started. Slab structural sections are placed on supporting construction with ends bearing on the structural framing sections or bearing walls as indicated. End bearings cannot be less than 75 millimeter (3-inches). Accurately align slabs end to end with sides and ends butted together. Provide grouting void at sides and ends of the slabs as indicated.

NOTE: Delete the following paragraph when electrical-raceway hollow-cored flat-slab structural sections will not be required.
Place electrical raceway hollow-cored flat-slab structural sections in straight alignment for the entire length of run of the hollow cores and with close alignment between hollow cores at the ends of abutting slab structural sections.

3.2.7 Grouting Connections and Joints

NOTE: Delete paragraph heading and the following paragraphs when precast structural-concrete framing sections or floor-slab structural sections or both will not be required. When fire-resistance-rated precast structural-concrete sections are required, consult the applicable fire agency's requirements for grouting joints.

After precast sections have been placed and connected, grout open spaces at connections and joints.

NOTE: Delete the following paragraph when shrink-resistant grout only is required.

Ensure cement grout is 1 part cement, 2-1/2 parts of specified aggregate for cement grout, and not more than 17 liter 4-1/2 gallons of water per 42.6 kilogram 94-pound sack of cement.

NOTE: Delete the following paragraph when cement grout only is required.

Mix shrink-resistant grout compound with potable water to provide a flowable mixture without segregation or bleeding.

Provide forms or other approved methods to retain the grout in place. Pack spaces with grout until the voids are completely filled. At slab structural section interfaces, finish the grout flush with top surface of the slab and remove excess. Keep grout damp for not less than 24 hours.

NOTE: Delete the following paragraphs when cement grout only is required or when epoxy-resin grout or adhesive instead of shrink-resistant grout is not required.

Epoxy-resin grout or adhesive may be used in lieu of shrink-resistant grout. Ensure installation of epoxy-resin grout or adhesive is in accordance with the manufacturer's printed instructions.

NOTE: Delete the following paragraph when electrical raceway hollow-cored flat-slab structural sections are not required.
Ensure open spaces at abutting ends of electrical raceway hollow-cored flat-slab structural sections are sealed with pressure-sensitive tape. Keep free from grout and other foreign materials hollow cores use for electrical raceways.

3.2.8 Sealing Joints in Roof Slabs

NOTE: Delete paragraph heading and the following paragraphs when roof slab structural sections will not be required. Ensure where fire-resistance-rated roof slab structural sections are required, the applicable fire agency’s requirements for sealing joints is consulted.

After precast-concrete roof slab sections have been placed and connected, seal open spaces at connections and the top portion of joints.

Fill keyways and joints at ridges, hips, and connections with cement grout. Finish grout level with the top surfaces of slabs, remove excess grout, and apply a smooth finish.

Seal other joints with bituminous joint-sealing material. Center joint-sealing tape over the joint and fill joint with hot bituminous cement. Lap ends not less than 100 millimeter 4-inches. Remove excess bitumen and provide a smooth tape surface.

3.2.9 Field Cut Openings in Slab Structural Sections

NOTE: The maximum size of field-cut openings is governed by the spacing of reinforcement and the inside diameter of the voids in hollow-cored flat slabs.

Cut and fit sections as required for other work projecting through, or adjacent to, the members. Ensure cuts are straight and at 90 degrees to the surfaces without breaking or spalling the edges. Do not cut reinforcing bars, strands, or wires. Do not allow cut size to exceed inside diameter of voids in hollow core flat slabs.

NOTE: Use the following paragraph when hollow-cored flat-slab structural sections are not required. Ensure openings larger than the width of a slab structural section are framed with supporting members.

Ensure openings in hollow-core flat-slab sections having any dimension more than the inside diameter of the hollow cores and not exceeding the width of the slab structural section are reinforced by means of hung steel angle saddle headers. Ensure headers are shop prime-coat painted and as indicated on the approved drawings.
3.2.10  Touchup Painting

**************************************************************************
NOTE: Delete paragraph heading and the following paragraph when precast structural-concrete sections will not be supported by steel structural members.
**************************************************************************

Ensure after sections have been installed, scarred surfaces on steel supporting members and weld plates are wire brushed, cleaned, and touchup painted.

3.2.11  Cleaning

Upon completion of installation, swept clean and leave ready slab surfaces to receive concrete floor topping, roofing, or other covering.

3.3  FIELD QUALITY CONTROL

3.3.1  Evaluation of Compressive Strength Tests

Concrete quality control tests will be evaluated as specified.

**************************************************************************
NOTE: Delete the following paragraph when normal-weight concrete will not be required.
**************************************************************************

Do not use normal-weight concrete delivered to the point of placement having a slump or total air content outside the values specified.

**************************************************************************
NOTE: Delete the following paragraph when lightweight structural concrete will not be required.
**************************************************************************

Do not use lightweight structural concrete delivered to the point of placement having a unit weight of fresh concrete that varies more than 2 percent from the design mix wet unit weight or having a slump or total air content outside the values specified.

Compressive-strength tests will be considered satisfactory if the average of any group of 5 consecutive compressive-strength tests that may be selected is in each instance equal to or greater than the 28-day design compressive strength or if not more than one compressive-strength test in 10 has a value less than 90 percent of the 28-day design compressive-strength.

If the compressive-strength tests fail to meet the minimum requirements specified, the fabricated concrete sections represented by such tests will be considered deficient in strength and subject to the provisions specified in the supplemental testing paragraph below.

3.3.2  Dimensional Tolerances

Members having any dimension outside the limits for fabrication tolerances specified will be rejected.
3.3.3 Surface-Finish Requirements

Sections will be rejected for any of the following surface-finish deficiencies:

**************************************************************************
NOTE: Delete the first of the following paragraphs when architectural finishes such as exposed-aggregate finish, are not required for exposed-to-view surfaces.
**************************************************************************

a. Exposed-to-view surfaces having architectural finishes that do not match the color, aggregate size and distribution, and texture of the approved sample for the exposed-to-view finish

b. Exposed-to-view formed surfaces that contain cracks, spalls, air bubbles, honeycomb, rock pockets, or stains or other discoloration that cannot be removed by cleaning

c. Concealed formed surfaces that contain cracks in excess of 0.25 millimeter 0.01 inch wide; cracks or any other surface deficiency that penetrates to the reinforcement regardless of the width of crack or size of other deficiency; honeycomb and rock pockets located in bearing surfaces; and spalls except minor breakage at corners

d. Unformed surfaces that contain cracks and other surface deficiencies as specified for concealed formed surfaces

3.3.4 Strength of Structural Members

Strength of precast structural-concrete sections will be considered deficient if they fail to comply with the requirements that control the strength of the structural members, including the following conditions:

a. Failure to meet compressive strength tests

b. Reinforcement and pretensioning and detensioning of tendons of prestressed concrete not conforming to the requirements specified

c. Concrete curing and protection of structural sections against extremes in temperature during curing not conforming to the requirements specified

d. Structural sections damaged during handling and erection

3.3.5 Supplemental Testing of Deficient Structural Sections for Strength

When there is evidence through concrete cylinder testing that the strength of precast structural-concrete sections do not meet specification requirements, make supplemental compressive strength determinations through the use of cores drilled into the hardened concrete in accordance with ASTM C42/C42M and as follows:

a. Take at least three representative cores from the precast structural concrete sections that are considered potentially deficient. Do not cut reinforcing bars, strands, or wires.

b. Test cores saturated-surface-dry if the concrete they represent will be
wet at all times during the use of the completed structure.

c. Test cores air-dry if the concrete they represent will be dry at all times during the use of the completed structure.

d. Strength of cores will be considered satisfactory if their average is equal to or greater than the 28-day design compressive strength of 150 by 300 millimeter 6-by 12-inch cylinders.

Fill core holes solidly with patching mortar and finished to match the adjacent concrete surfaces.

If the results of the core tests are unsatisfactory or if core tests are impractical to obtain, make static load tests of a structural section and evaluated in accordance with ACI/MCP-3 and ACI 318, except that the superimposed test load is as specified for the proof-test method of strength design.

Ensure sections that are found inadequate by the core tests or by the results of static load tests are replaced with sections that meet the specified requirements.

3.3.6 Inspection of Welding

**************************************************************************
NOTE: Delete paragraph heading and the following paragraphs when inspection of welding will not be required.
**************************************************************************

Perform inspection of welding in accordance with[ AWS D1.1/D1.1M, Section 6][ AWS D1.4/D1.4M, Section 7], and as follows:

**************************************************************************
NOTE: Delete the following paragraphs that are not applicable to the project. Ensure the location of welds requiring inspection and the type of inspection are indicated. The liquid-penetration inspection of welds is the most economical and commonly used method.
**************************************************************************

Ensure liquid-penetration inspection of welds conforms to ASTM E165/E165M.

Conduct Magnetic-particle inspection of welds in conformance with ASTM E709.

3.3.6.1 Weld Acceptance

**************************************************************************
NOTE: Drawings or the text of the contract specifications must specify the weld requirements: tensile strength, elongation, shear strength, size, length, type, and location. Complete penetration welds subject to primary tensile stress or cyclic loading must be identified in the contract drawings for purpose of selecting the correct NDT acceptance criteria.
**************************************************************************
Conform dimensional tolerances for welded construction, details of welds, and quality of welds with the applicable requirements of AWS D1.4/D1.4M and the contract drawings. Perform nondestructive testing by visual inspection [and ultrasonic,] [magnetic particle,] [or] [dye penetrate] methods. The minimum extent of nondestructive testing is a random [_____] percent of welds or joints, as indicated on the drawings. Submit all records of nondestructive testing.

Nondestructive Testing

The welding is subject to inspection and tests in the mill, shop, and field. Inspection and tests in the mill or shop does not relieve the Contractor of the responsibility to furnish weldments of satisfactory quality. When materials or workmanship do not conform to the specification requirements, the Government reserves the right to reject material or workmanship or both at any time before final acceptance of the structure containing the weldment. Any indication of a defect is regarded as a defect, unless re-evaluation by nondestructive methods or by surface conditioning shows that no unacceptable defect is present.

3.3.7 Structural Sections-in-Place

Sections-in-place will be rejected for any one of the following deficiencies:

a. Sections not conforming to the requirements for installation tolerances specified

b. Sections that are damaged during construction operations

c. Sections having exposed-to-view surface finishes that develop surface finish deficiencies specified

NOTE: This guide specification covers the requirements for precast, non-prestressed concrete products used for below grade construction (Sewage Systems, Subdrainage Systems, Storm Drainage Systems, Utility and Communications Structures, etc.).

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1  GENERAL

1.1  REFERENCES

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically
place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

1.2 SUBMITTALS

**************************************************************************

NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy.
and Air Force projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.

**************************************************************************

All submittals are the responsibility of the precast concrete producer. Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

- **SD-01 Preconstruction Submittals**
  - Quality Control Procedures

Recycled content for steel; S

1.3 QUALITY ASSURANCE

Demonstrate adherence to the standards set forth in NPCA QC Manual or ACPA QPC. Meet requirements written in the subparagraphs below.

1.3.1 NPCA and ACPA Plant Certification

**************************************************************************
NOTE: The use of this paragraph may limit competition. Verify the availability of NPCA and ACPA certified precasters in the bidding area.
**************************************************************************

The precast concrete producer must be certified by the National Precast Concrete Association's or the American Concrete Pipe Association's Plant Certification Program prior to and during production of the products for this project.

1.3.2 Qualifications, Quality Control and Inspection

1.3.2.1 Qualifications

Select a precast concrete producer that has been in the business of producing precast concrete units similar to those specified for a minimum of 3 years. The precast concrete producer must maintain a permanent quality control department or retain an independent testing agency on a continuing basis.

1.3.2.2 Quality Control Procedures

Submit quality control procedures established by the precast manufacturer in accordance with NPCA QC Manual and ACPA QPC. Show that the following QC tests are performed as required and in accordance with the ASTM standards indicated.

1.3.2.2.1 Slump

Perform a slump test for each 115 cubic m 150 cu yd of concrete produced, or once a day, whichever comes first. Perform slump tests in accordance with ASTM C143/C143M.

1.3.2.2.2 Temperature

Measure the temperature of fresh concrete when slump or air content tests are made and when compressive test specimens are made in accordance with ASTM C1064/C1064M.
1.3.2.2.3 Compressive Strength

Make at least four compressive strength specimens for each 115 cubic m 150 cubic yards of concrete of each mix in accordance with the following Standards: ASTM C31/C31M, ASTM C192/C192M, ASTM C39/C39M.

1.3.2.2.4 Air Content

Perform tests for air content on air-entrained, wet-cast concrete for each 115 cubic m 150 cu yd of concrete, but not less often than once each day when air-entrained concrete is used. Determine the air content in accordance with either ASTM C231/C231M or ASTM C173/C173M for normal weight aggregates and ASTM C173/C173M for lightweight aggregates.

1.3.2.2.5 Unit Weight

Perform tests for unit weight a minimum of once per week to verify the yield of batch mixes. Perform unit weight tests for each 75 cubic m 100 cu yd of lightweight concrete in accordance with ASTM C138/C138M.

1.3.2.3 Inspection

The Contracting Officer may place an inspector in the plant when the units covered by this specification are being manufactured. The burden of payment for plant inspection will be clearly detailed in the specification. The precast concrete producer must give notice 14 days prior to the time the units will be available for plant inspection. Neither the exercise nor waiver of inspection at the plant will affect the Government's right to enforce contractual provisions after units are transported or erected.

1.3.2.4 Test Reports

Submit the following:

1.3.2.4.1 Material Certifications or Laboratory Test Reports

Include mill tests and all other test data, for portland cement, blended cement, pozzolans, ground granulated blast furnace slag, silica fume, aggregate, admixtures, and curing compound proposed for use on this project.

1.3.2.4.2 Mix Test

Submit reports showing that the mix has been successfully tested to produce concrete with the properties specified and will be suitable for the job conditions. Such tests may include compressive strength, flexural strength, plastic or hardened air content, freeze thaw durability, abrasion and absorption. Clearly detail in the specifications special tests for precast concrete or cast-in items.

1.3.2.4.3 Self-Consolidating Concrete

Submit sufficient documentation, when the use of self-consolidating concrete (SCC) is proposed, showing a minimum of 30-days production track records demonstrating that SCC is appropriate for casting of the product.

1.3.2.4.4 In-Plant QA/QC Inspection Reports

Submit inspection reports upon the request of the Contracting Officer.
1.4 DELIVERY, STORAGE, AND HANDLING

1.4.1 Delivery

Deliver precast units to the site in accordance with the delivery schedule to avoid excessive build-up of units in storage at the site. Upon delivery to the jobsite, all precast concrete units will be inspected by the Contracting Officer for quality and final acceptance.

1.4.2 Storage

Store units off the ground or in a manner that minimizes potential damage.

1.4.3 Handling

Handle, transport, and store products in a manner to minimize damage. Lifting devices or holes must be consistent with industry standards. Perform lifting with methods or devices intended for this purpose as indicated on shop drawings.

PART 2 PRODUCTS

2.1 SYSTEM DESCRIPTION

Furnish precast concrete units designed and fabricated by an experienced and acceptable precast concrete manufacturer who has been, for at least three years, regularly and continuously engaged in the manufacture of precast concrete work similar to that indicated on the drawings. Coordinate precast work with the work of other trades. Below grade structures must comply with ASTM C858.

2.1.1 Standard Precast Units

Design standard precast concrete units to withstand indicated design load conditions in accordance with applicable industry design standards ACI 318M ACI 318, ASTM C857[1, ACPA 01-102, Chapter 7-Design for Sulfide Control]. Design must also consider stresses induced during handling, shipping and installation as to avoid product cracking or other handling damage. Indicate design loads for precast concrete units on the shop drawings. Submit drawings for standard precast concrete units furnished by the precast concrete producer for approval by the Contracting Officer. These drawings must demonstrate that the applicable industry design standards have been met. Include installation and construction information on shop drawings. Include details of steel reinforcement size and placement as well as supporting design calculations, if appropriate. Produce precast concrete units in accordance with the approved drawings. Submit cut sheets, for standard precast concrete units, showing conformance to project drawings and requirements, and to applicable industry design standards listed in this specification.

2.1.2 Custom-Made Precast Units

Submit design calculations for custom-made precast units, prepared and sealed by a registered professional engineer, for approval prior to fabrication. Include in the calculations the analysis of units for lifting stresses and the sizing of lifting devices. Submit drawings furnished by the precast concrete producer for approval by the Contracting Officer. Show on these drawings complete design, installation, and construction
information in such detail as to enable the Contracting Officer to 
determine the adequacy of the proposed units for the intended purpose. 
Include details of steel reinforcement size and placement as well as 
supporting design calculations, if appropriate. Produce precast concrete 
units in accordance with the approved drawings.

2.1.3 Proprietary Precast Units

Products manufactured under franchise arrangements must conform to all the 
requirements specified by the franchiser. Items not included in the 
franchise specification, but included in this specification, must conform 
to the requirements in this specification. Submit standard plans or 
informative literature, for proprietary precast concrete units. Make 
available supporting calculations and design details upon request. Provide 
sufficient information as to demonstrate that such products will perform 
the intended task.

2.1.4 Joints and Sealants

Provide joints and sealants between adjacent units of the type and 
configuration indicated on shop drawings meeting specified design and 
performance requirements.

2.1.5 Concrete Mix Design

2.1.5.1 Concrete Mix Proportions

Base selection of proportions for concrete on the methodology presented in 
ACI 211.1 for normal weight concrete and ACI 211.2 for lightweight 
concrete. Develop the concrete proportions using the same type and brand 
of cement, the same type and brand of pozzolan, the same type and gradation 
of aggregates, and the same type and brand of admixture that will be used 
in the manufacture of precast concrete units for the project. Do not use 
calcium chloride in precast concrete containing reinforcing steel or other 
embedded metal items. At a minimum of thirty days prior to precast 
concrete unit manufacturing, the precast concrete producer will submit a 
mix design and proportions for each strength and type of concrete that will 
be used. Furnish a complete list of materials, including quantity, type, 
brand and applicable data sheets for all mix design constituents as well as 
applicable reference specifications. The use of self-consolidating 
concrete is permitted, provided that mix design proportions and 
constituents meet the requirements of this specification.

2.1.5.2 Concrete Strength

Provide precast concrete units with a 28-day compressive strength (f'c) of 
[_____] MPa psi.

2.1.5.3 Water-to-Cement Ratio

Where exposed to freezing and thawing, furnish concrete containing 
entrained air and with a water-cementitious ratio of 0.45 or less. Where 
not exposed to freezing, but required to have a low permeability, furnish 
cementitious ratio of 0.48 or less. Where exposed to deicer salts, brackish water, or seawater, furnish concrete with a 
water-cementitious ratio of 0.40 or less, for corrosion protection.
2.1.5.4 Air Content

The air content of concrete that will be exposed to freezing conditions must be within the limits given below.

<table>
<thead>
<tr>
<th>NOMINAL MAXIMUM AGGREGATE SIZE</th>
<th>EXPOSURE CLASS F1</th>
<th>EXPOSURE CLASSES F2 and F3</th>
</tr>
</thead>
<tbody>
<tr>
<td>10 mm 3/8 inch</td>
<td>6.0</td>
<td>7.5</td>
</tr>
<tr>
<td>13 mm 1/2 inch</td>
<td>5.5</td>
<td>7.0</td>
</tr>
<tr>
<td>19 mm 3/4 inch</td>
<td>5.0</td>
<td>6.0</td>
</tr>
<tr>
<td>25 mm 1.0 inch</td>
<td>4.5</td>
<td>6.0</td>
</tr>
<tr>
<td>38 mm 1.5 inch</td>
<td>4.5</td>
<td>5.5</td>
</tr>
</tbody>
</table>

Note: For specified compressive strengths greater than 34.5 MPa 5000 psi, air content may be reduced 1 percent.

2.1.5.5 Corrosion Control for Sanitary Sewer Systems

Follow design recommendations outlined in Chapter 7 of ACPA 01-102 or the ACPA 01-110 when hydrogen sulfide is indicated as a potential problem.

2.2 MATERIALS

Except as otherwise specified in the following paragraphs, conform material to Section 03 30 00 CAST-IN-PLACE CONCRETE.

2.2.1 Material Sustainability Criteria

For products in this section, where applicable and to extent allowed by performance criteria, provide and document the following in accordance with Section 01 33 29 SUSTAINABILITY REQUIREMENTS AND REPORTING:

a. Recycled content for fly ash and pozzolan
b. Recycled content for Ground Iron Blast-Furnace Slag
c. Recycled content for Silica Fume
d. Recycled content for Synthetic Fiber Reinforcement
e. Recycled content for steel, 75 percent minimum

2.2.2 Pigments

Non-fading and lime-resistant

2.2.3 Reinforcement

2.2.3.1 Reinforcing Bars

******************************************************************************
NOTE: Specify ASTM A706/A706M reinforcing where welding or bending of reinforcement bars is
important. In addition, ASTM A775/A775M epoxy coated reinforcing may be specified where extra reinforcement corrosion protection is required.

**************************************************************************

2.2.3.2 Reinforcing Wire

a. Plain Wire: ASTM A1064/A1064M
b. Deformed Wire: ASTM A1064/A1064M

2.2.3.3 Welded Wire Reinforcement

a. Plain Wire: ASTM A1064/A1064M
b. Deformed Wire: ASTM A1064/A1064M

2.2.3.4 Epoxy Coated Reinforcement

a. Reinforcing Bars: ASTM A775/A775M
b. Wires and Welded Wire: ASTM A884/A884M

2.2.3.5 Galvanized Reinforcement

Provide galvanized reinforcement conforming to ASTM A767/A767M.

2.2.4 Synthetic Fiber Reinforcement

Provide fiber reinforced concrete in accordance with ASTM C1116/C1116M Type III, synthetic fiber reinforced concrete, and as follows. Synthetic reinforcing fibers must be [100 percent virgin] monofilament polypropylene fibers[, with a minimum of [5][10][_____] percent post-consumer recycled content, or a minimum of [20][40][_____] percent post-industrial recycled content]. Provide fibers that have a specific gravity of 0.9, a minimum tensile strength of 480 MPa 70 ksi, graded per manufacturer, and specifically manufactured to an optimum gradation for use as concrete secondary reinforcement. [Toughness indices must meet requirements for performance level I.]

2.2.5 Inserts and Embedded Metal

All items embedded in concrete must be of the type required for the intended task, and meet the following standards.

a. Structural Steel Plates, Angles, etc.: ASTM A36/A36M
b. Hot-dipped Galvanized: ASTM A153/A153M
c. Proprietary Items: In accordance with manufacturers published literature

2.2.6 Accessories

Submit proper installation instructions and relevant product data for items including, but not limited to, sealants, gaskets, connectors, steps, cable
racks and other items installed before or after delivery.

d. Elastomeric Joint Sealants: ASTM C920

2.2.7 Pipe Entry Connectors

Pipe entry connectors must conform to ASTM C923M ASTM C923 or ASTM C1478M ASTM C1478.

2.2.8 Grout

**************************************************************************
NOTE: Delete air-entraining requirements when the project is located in a nonfreezing climate.
**************************************************************************

Nonshrink Grout must conform to ASTM C1107/C1107M. Cementitious grout must be a mixture of portland cement, sand, and water. Proportion one part cement to approximately 2.5 parts sand, with the amount of water based on placement method. [Provide air entrainment for grout exposed to the weather.]

PART 3 EXECUTION

3.1 FABRICATION AND PLACEMENT

Perform fabrication in accordance with NPCA QC Manual or ACPA QPC unless specified otherwise.

3.1.1 Forms

Use forms, for manufacturing precast concrete products, of the type and design consistent with industry standards and practices. They should be capable of consistently providing uniform products and dimensions. Construct forms so that the forces and vibrations to which the forms will be subjected can cause no product damage. Clean forms of concrete build-up after each use. Apply form release agents according to the manufacturers recommendations and do not allow to build up on the form casting surfaces.

3.1.2 Reinforcement

Follow applicable ASTM Standard or ACI 318MACI 318 for placement and splicing. Fabricate cages of reinforcement either by tying the bars, wires or welded wire reinforcement into rigid assemblies or by welding, where permissible, in accordance with AWS D1.4/D1.4M. Position reinforcing as specified by the design and so that the concrete cover conforms to requirements. The tolerance on concrete cover must be one-third of that specified but not more than 13 mm 1/2 inch. Provide concrete cover not less than 13 mm 1/2 inch. Take positive means to assure that the reinforcement does not move significantly during the casting operations.
3.1.3 Embedded Items

Position embedded items at locations specified in the design documents. Perform welding in accordance with AWS D1.1/D1.1M when necessary. Hold rigidly in place inserts, plates, weldments, lifting devices and other items to be imbedded in precast concrete products so that they do not move significantly during casting operations. Submit product data sheets and proper installation instruction for anchors, lifting inserts and other devices. Clearly indicate the products dimensions and safe working load.

3.1.4 Synthetic Fiber Reinforced Concrete

**************************************************************************

**NOTE:** Synthetic fiber reinforcement may be used in concrete as an aid in preventing plastic or shrinkage cracking in placements susceptible to this condition. Fiber reinforcement will not be used as a substitute for wire mesh and where service temperature may exceed 150 degrees C 300 degrees F. Concentrations above 0.1 percent by volume are not cost-effective.

**************************************************************************

Add fiber reinforcement to the concrete mix at the batch plant in accordance with the applicable sections of ASTM C1116/C1116M and the recommendations of the manufacturer. Use a minimum of 0.9 kg of fibers per cubic meter 1.5 pounds of fibers per cubic yard of concrete.

3.2 CONCRETE

3.2.1 Concrete Mixing

Mixing operations must produce batch-to-batch uniformity of strength, consistency, and appearance.

3.2.2 Concrete Placing

Deposit concrete into forms as near to its final location as practical. Keep the free fall of the concrete to a minimum. Consolidate concrete in such a manner that segregation of the concrete is minimized and honeycombed areas are kept to a minimum. Use vibrators to consolidate concrete with frequencies and amplitudes sufficient to produce well consolidated concrete.

3.2.2.1 Cold Weather Concreting

Perform cold weather concreting in accordance with ACI 306.1.

a. Provide adequate equipment for heating concrete materials and protecting concrete during freezing or near-freezing weather.

b. All concrete materials, reinforcement, forms, fillers, and ground with which concrete is to come in contact must be free from frost.

c. Do not use frozen materials or materials containing ice.

d. In cold weather the temperature of concrete at the time of placing must not be below 8 degrees C 45 degrees F. Discard concrete that freezes before its compressive strength reaches 3.45 MPa 500 psi.
3.2.2  Hot Weather Concreting

Follow recommendations for hot weather concreting in ACI 305R. During hot weather, give proper attention to constituents, production methods, handling, placing, protection, and curing to prevent excessive concrete temperatures or water evaporation that could impair required strength or serviceability of the member or structure. The temperature of concrete at the time of placing must not exceed 32 degrees C 90 degrees F.

3.2.3  Concrete Curing

**************************************************************************

NOTE: Due to the immediacy of form removal, dry-cast products have a tendency to undergo undesirable accelerated drying. Consequently, early curing periods are most critical to ensure protection from extreme temperatures and dryness. Dry-cast products must be protected from drafts to prevent cracking.

**************************************************************************

Commence curing immediately following the initial set and completion of surface finishing.

3.2.3.1  Curing by Moisture Retention

Prevent moisture evaporation from exposed surfaces until adequate strength for stripping is reached by one of the following methods:

a. Cover with polyethylene sheets a minimum of 0.15 mm 6 mils thick in accordance with ASTM C171.

b. Cover with burlap or other absorptive material and keep continually moist.

c. Use a membrane-curing compound, conforming to ASTM C309 and applied at a rate not less than 19 square m/4L 200 square ft/gallon, or in accordance with manufacturers' recommendations.

3.2.3.2  Curing with Heat and Moisture

**************************************************************************

NOTE: Cure surfaces that will be exposed to weather during service, a minimum of 3 days. Forms should be considered effective in preventing evaporation from the contact surfaces. If air temperature is below 10 degrees C 50°F the curing period must be extended.

**************************************************************************

Do not subject concrete to steam or hot air until after the concrete has attained its initial set. Apply steam, if used, within a suitable enclosure, which permits free circulation of the steam in accordance with CSA A23.4. If hot air is used for curing, take precautions to prevent moisture loss from the concrete. The temperature of the concrete must not be permitted to exceed 65 degrees C 150 degrees F. These requirements do not apply to products cured with steam under pressure in an autoclave.
3.2.4 Surface Finish

Finish unformed surfaces of wet-cast precast concrete products as specified. If no finishing procedure is specified, finish such surfaces using a strike-off to level the concrete with the top of the form.

3.2.4.1 Formed Non-Architectural Surfaces

Cast surfaces against approved forms following industry practices in cleaning forms, designing concrete mixes, placing and curing concrete. Normal color variations, form joint marks, small surface holes caused by air bubbles, and minor chips and spalls will be accepted but no major imperfections, honeycombs or other major defects will be permitted.

3.2.4.2 Unformed Surfaces

Finish unformed surfaces with a vibrating screed, or by hand with a float. Normal color variations, minor indentations, minor chips and spalls will be accepted. Major imperfections, honeycombs, or other major defects are not permitted.

3.2.4.3 Special Finishes

Troweled, broom or other finishes must be according to the requirements of project documents and performed in accordance with industry standards or supplier specifications. Submit finishes for approval when required by the project documents. The sample finishes must be approved prior to the start of production.

3.2.5 Stripping Products from Forms

Do not remove products from the forms until the concrete reaches the compressive strength for stripping required by the design. If no such requirement exists, products may be removed from the forms after the final set of concrete provided that stripping damage is minimal.

3.2.6 Patching and Repair

No repair is required to formed surfaces that are relatively free of air voids and honeycombed areas, unless the surfaces are required by the design to be finished.

3.2.6.1 Repairing Minor Defects

Defects that will not impair the functional use or expected life of a precast concrete product may be repaired by any method that does not impair the product.

3.2.6.2 Repairing Honeycombed Areas

When honeycombed areas are to be repaired, remove all loose material and cut back the areas into essentially horizontal or vertical planes to a depth at which coarse aggregate particles break under chipping rather than being dislodged. Use proprietary repair materials in accordance with the manufacturer's instructions. If a proprietary repair material is not used, saturate the area with water. Immediately prior to repair, the area should be damp, but free of excess water. Apply a cement-sand grout or an approved bonding agent to the chipped surfaces, followed immediately by consolidating an appropriate repair material into the cavity.
3.2.6.3 Repairing Major Defects

Evaluate, by qualified personnel, defects in precast concrete products which impair the functional use or the expected life of products to determine if repairs are feasible and, if so, to establish the repair procedure.

3.2.7 Shipping Products

Do not ship products until they are at least five days old, unless it can be shown that the concrete strength has reached at least 75 percent of the specified 28-day strength, or that damage will not result, impairing the performance of the product.

3.3 INSTALLATION

3.3.1 Site Access

It is the Contractor's responsibility to provide adequate access to the site to facilitate hauling, storage and proper handling of the precast concrete products.

3.3.2 General Requirements

a. Install precast concrete products to the lines and grades shown in the contract documents or otherwise specified.

b. Lift products by suitable lifting devices at points provided by the precast concrete producer.

c. Install products in accordance with the precast concrete producer's instructions. In the absence of such instructions, install underground utility structures in accordance with ASTM C891. Install pipe and manhole sections in accordance with the procedures outlined by the American Concrete Pipe Association.

d. Field modifications to the product will relieve the precast producer of liability even if such modifications result in the failure of the product.

3.3.3 Water Tightness

Where water tightness is a necessary performance characteristic of the precast concrete product's end use, watertight joints, connectors and inserts should be used to ensure the integrity of the entire system.

3.4 FIELD QUALITY CONTROL

*****************************************************************************

NOTE: Manholes should be tested prior to backfilling to verify the integrity of the installed product. Testing prior to backfilling facilitates quick and easy repair when required. When vacuum testing a backfilled manhole, appropriate adjustments must be made to the testing procedure to account for site conditions such as high water tables as to avoid over loading boots and connectors. Prior to vacuum testing, make
calculations to ensure that connectors and boots are not loaded past the design limit as indicated in ASTM C923.

3.4.1 Site Tests

When water tightness testing is required for an underground product, use one of the following methods:

3.4.2 Vacuum Testing

Prior to backfill vacuum test system according to ASTM C1244M ASTM C1244.

3.4.3 Water Testing

Perform water testing according to the contract documents and precast concrete producer's recommendations.

NOTE: This guide specification covers the requirements for fabrication and erection of reinforced precast autoclave aerated concrete (PAAC) panels, used as structural floor units, and roof units and wall units for buildings.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1 GENERAL

NOTE: Precast autoclave aerated concrete (PAAC) floor, roof, and wall units for clear spans up to 5.94 meters 19 feet 6 inches

Drawings must include a complete design indicating the character of the work to be performed and giving the following:

Assumed loads, including floor live load, roof live load, wind load, concentrated loads such as partitions, and equipment mounted on or suspended from precast concrete construction, concrete floor
topping weight, and other design data as may be required for the proper preparation of shop drawings.

Layout of the framing system indicating the relative location of the structural PAAC sections, floor elevations, column centers and offsets, openings, and sufficient dimensions to adequately convey the quantity and nature of the required structural PAAC framing system and/or elements.

Details of all structural PAAC Sections indicating cross-sections and dimensions.

Location of structural PAAC Sections having an architectural finish on exposed-to-view surfaces when required.

Details of reinforcement indicating smooth welded wire reinforcing schedule for PAAC panels as required.

Details of connections indicating end bearing minimums and anchorage devices in the structural PAAC sections.

Location and details of concrete floor topping, when required.

Details of openings including the size of steel framing members as required.

Details of precast concrete filler blocks, as required.

Details of hangers for suspended ceilings, ducts, piping, lighting fixtures, conduit, or other construction, as required.

When both fire-resistance-rated construction and nonrated construction are required, the location of fire-resistance-rated construction.

Cast-in-place normal-weight concrete, including concrete floor topping, is specified in Section 03 30 53 MISCELLANEOUS CAST-IN-PLACE CONCRETE.

Precast conventionally reinforced concrete wall panels, solid-section type, are specified in Section 03 45 00 PRECAST ARCHITECTURAL CONCRETE.

Precast-concrete roof slabs placed over purlins or joists spaced not more than 2.4 m 8 feet on center are specified in Section 03 41 16.08 PRECAST CONCRETE SLABS (MAX. SPAN 8 FEET 0.C).

Sealing joints in exposed-to-view surfaces of PAAC slabs, such as at ceilings and walls, is specified in Section 07 92 00 JOINT SEALANTS.

Painting exposed-to-view surfaces of PAAC units such
as ceilings, is specified in Section 09 90 00 PAINTS AND COATINGS.

Fire-resistance-rated construction using PAAC sections is described in Underwriters Laboratories, Inc., "Fire Resistance Ratings (BXUV)" included in UL Fire Resistance Directory and the "Fire-Resistance Ratings" contained in AIA CO-1. Fire-resistance-rated construction limits the types of structural PAAC sections; the requirements for end restraint; the PAAC materials and proportions of concrete mix for floor top fill; the requirements for grouting and sealing joints; and the type of roof insulation and roof covering.

Prior to installation of reinforced PAAC panels, schedule and hold a pre-installation conference to review scope of the work. Attendees will include a representative from each subcontractor involved with reinforced PAAC panels and adjacent construction material installation. Notify Contracting Officer at least seven days prior to the meeting.
1.2.2 Sequencing and Scheduling of PAAC element Installation

1.2.2.1 Panel Loading

Loading AAC wall panels is prohibited prior to the following:

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Uniform floor or roof</td>
<td>12 hours, minimum</td>
</tr>
<tr>
<td>loads</td>
<td></td>
</tr>
<tr>
<td>Concentrated loads</td>
<td>Three days, minimum</td>
</tr>
</tbody>
</table>

1.2.2.2 Construction Activities Coordination

a. Work required under this Section includes chase and routing coordination with construction activities specified in other Specification Sections.

b. As panel installation is completed, coordinate with work required in other Specification Sections for chases or routing areas required in AAC panels for electrical, plumbing, and other items.

c. Request relevant construction activities to mark actual routing or chase locations; include required depth.

d. Filling in chases and routed areas specified in other Specification Sections.

1.3 SUBMITTALS

**************************************************************************
NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification.
and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.

**************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-02 Shop Drawings

Fabrication Drawings; G[, [_____]]

Welding Sequence and Procedure
Epoxy-Resin Grout
1.4 PERFORMANCE REQUIREMENTS

1.4.1 Design Methods

For PAAC elements, design in accordance with ACI 523.4R. Also design PAAC wall elements in accordance with ACI 530/530.1, Chapter 11 entitled "Strength Design of Autoclaved Aerated Concrete Masonry". Determine Weld-Point Shear Strength in the reinforcement of PAAC panels in accordance with ASTM C1694, Section 8, and conform to the requirements in ASTM C1694, Table 2.

1.4.2 Allowable Design Loads and Deflections

**************************************************************************
NOTE: Allowable design loads must be indicated and include dead loads, live loads, stationary loads, concentrated moving loads, deflection of roof slab sections, etc.
Recommended design loads are specified in article ix of the National Building Code, recommended by the American Insurance Association AIA CO-1 and ANSI A58.1.
**************************************************************************

Allowable design loads and deflections are as indicated.

1.4.3 UL Fire-Resistance Listing and Label

**************************************************************************
NOTE: Delete paragraph heading and the following paragraph when UL-listed fire-resistant structural PAAC sections are not required. The UL lists several manufacturers of PAAC panels. Location and fire-resistance classification of fire-resistant-rated structural sections must be indicated.
**************************************************************************

Sections indicated requiring a fire-resistance classification must be listed in UL Fire Resistance, part entitled, "Precast Concrete Units (CFTV)," and bear the UL label and marking.

1.5 DRAWINGS

Show type and location of all reinforcement, size and spacing of welds within Fabrication Drawings. Indicate loads used for the design of reinforced AAC panels.

Indicate type and location of all anchorage devices, size and spacing of all welded connections, grouting and joint sealant details, and dimensions and locations of all openings in structural concrete sections within Installation Drawings. Indicate dimensions of panels, arrangement of joints, reinforcement, and erection details. Include location of openings fabricated in panels. Identify reinforced AAC panels with mark used on shop drawings. Locate identifying marks on surfaces not visible in installed configuration. Indicate AAC Strength Class – AC4, AC4.4 or AC6.
1.6 QUALITY CONTROL

1.6.1 Qualifications for **PAAC Manufacturer**

Provide structural PAAC sections manufactured by an organization experienced in the manufacture of reinforced PAAC sections. Submit a written description of the manufacturer giving the qualifications of personnel, location of plant, concrete batching facilities, manufacturing equipment and facilities, list of projects similar to specified work, and that the PAAC material and panels are manufactured in accordance with ASTM C1693, and ASTM C1694. (these ASTM specs supersede ASTM C1452).

1.6.2 Qualifications For **Installer**

Install members by an organization experienced in the installation of precast PAAC members, if applicable. Submit a written description of installers giving the qualifications of personnel, handling and erection equipment, list of projects similar to specified work, and other information as may be required.

1.6.3 Qualifications For **Welding Work**

[Section 05 05 23.16 STRUCTURAL WELDING applies to work specified in this section.][Perform welding procedures in accordance with AWS D1.1/D1.1M.]
[Provide welders that are qualified by tests in accordance with AWS D1.1/D1.1M.][Welders are to make only those types of weldments for which each is specifically qualified.]

Provide installation instructions for the **Welding Sequence and Procedure** which indicates the manufacturer's recommended sequence and method of installation.

1.6.4 **Concrete Sampling and Testing**

1.6.4.1 Tests for Concrete Materials

**************************************************************************
NOTE: Manufacturers of precast Autoclaved Aerated Concrete (PAAC) typically have proprietary mixes/recipes to produce AAC material for meeting the various ASTM-designated strength classifications, and therefore have various inspection and testing requirements unique to their raw materials and proprietary recipe specifications. The following are a list of sample raw material testing requirements for PAAC. (Note: some requirements may be satisfied by a "certificate of analysis" from the raw material supplier based on testing performed prior to shipment of material to PAAC manufacturer).
**************************************************************************

Sample and test concrete materials proposed for use in the work as follows:
<table>

[1.6.5 PAAC Framing Mock-up]

Build a mock-up demonstrating the following features:

- a. Mortar joints.
- b. Control joint complete with joint sealant.
- c. Workmanship.
- d. Reinforcement in joints.
- e. Flashing.
- f. Exterior finishes.
- g. Interior finishes.

Prepare mock-up at least 14 days prior to beginning PAAC unit work. Should mock-up be disapproved, prepare additional mock-ups until approved. Maintain mock-up throughout work as a standard of PAAC unit work. Do not destroy mock-up until directed.

]1.7 DELIVERY, STORAGE, AND HANDLING PAAC ELEMENTS

1.7.1 Packing and Shipping of PAAC Elements:

Transport and handle reinforced AAC panels with equipment designed to protect panels from strain, warping, cracking, chipping, or staining. Placing reinforced AAC panels in direct contact with earth is prohibited.

1.7.2 Storage and Protection of PAAC Elements:

Store to protect from strain, warping, cracking, chipping, or staining. Store in same position as transported. Store on firm, level, smooth surface. Place so identification marks are easily discernible.
PART 2   PRODUCTS

2.1  CONCRETE MATERIALS

2.1.1  Aggregates

Size aggregates in accordance with the AAC manufacturer specification, using ASTM C33/C33M for reference.

2.1.2  Portland Cement

Provide portland cement conforming to ASTM C150/C150M, as set forth in Table 1 for Type I/II cement. Use one brand and type of cement for formed concrete having exposed-to-view finished surfaces.

2.1.3  Ground Granulated Blast Furnace (GGBF) Slag

GGBF slag [is required as an admixture and] [used as an admixture] must conform to ASTM C989/C989M to the extent identified by the AAC manufacturer, in addition to conforming to other specifications required by the AAC manufacturer's proprietary mix design.

2.1.4  Air Entraining Admixture

Provide admixture that is free of sodium chloride and nitrates and conforms to ASTM C260/C260M.

2.1.5  Water

Use potable water.

2.2  REINFORCEMENT MATERIALS

2.2.1  Reinforcement Bars

Provide deformed bars conforming to ASTM A615/A615M, Grade 60, except that...
9.5 millimeter diameter Number 3 bars may be Grade 40.

2.2.2 Cold-Drawn Steel Wire

Provide wire reinforcement conforming to ASTM A1064/A1064M and the requirements in ASTM C1694, Table 1. Weld-Point Shear Strength in the reinforcement must conform to the requirements in ASTM C1694, Table 2. Apply a corrosion protective coating of appropriate material for reinforcement for PAAC elements. Determine the effectiveness of the corrosion protection for the steel reinforcement as noted in ASTM C1694.

2.3 CONNECTION MATERIALS

2.3.1 Steel Plates

Provide plates conforming to ASTM A283/A283M, Grade C[, or to ASTM A36/A36M].

2.3.2 Steel Shapes

Provide structural-steel shapes conforming to ASTM A36/A36M.

2.3.3 Steel Bars

Provide bar shapes, flats, and rounds conforming to ASTM A675/A675M, Grade 65[, or ASTM A36/A36M].

2.4 GROUTING MATERIALS

**************************************************************************
NOTE: Delete the following paragraphs that are not applicable to the project. When fire-resistance rated structural PAAC sections are required, the applicable fire agency's requirements for grouting materials must be consulted.
**************************************************************************
**************************************************************************
NOTE: Ground granulated blast furnace slag is one of the materials listed in the EPA's Comprehensive Procurement Guidelines (CPG)(http://www.epa.gov/cpg/). If the Architect/Engineer determines that use of certain materials meeting the CPG content standards and guidelines would result in inadequate competition, do not meet quality/ performance specifications, are available at an unreasonable price or are not available within a reasonable time frame, the Architect/Engineer may submit written justification and supporting documentation for not procuring designated items containing recovered material.
**************************************************************************

[2.4.1 Cement Grout

[Portland cement must conform to ASTM C150/C150M, Type I.][Blended hydraulic cement must conform to ASTM C595/C595M, Type [______].] Aggregate for cement grout must conform to ASTM C404, Size No. 2.

SECTION 03 44 00  Page 18
][2.4.2 Shrink-Resistant Grout

Provide premixed and packaged ferrous aggregate shrinkage-resistant grouting compound conforming to ASTM C1107/C1107M, for expansive grouts.

][2.4.3 Epoxy-Resin Grout

[Provide two-component, mineral-filled, epoxy-polysulfide epoxy-resin grout conforming to FS MMM-A-001993, Type I.][Provide two-component, epoxy-polyamide cured type epoxy-resin adhesive conforming to AASHTO M 200.]

][2.5 BITUMINOUS JOINT SEALING MATERIALS

**************************************************************************

NOTE: Delete this paragraph when single- or double-tee roof slab structural sections are not required.
**************************************************************************

Use asphalt bituminous cement conforming to ASTM D312/D312M, Type IV. Use 150 millimeter 6 inches wide joint sealing tape; multilayered, asphalt treated, glass-fiber reinforced, conforming to [ASTM D2103] [ASTM D4397] [FS UU-B-790, Type I, Grade C, Style 4,]. However, a dry tensile strength less than 6130 Newton per meter 35 pounds per inch width, both directions, is not acceptable.

2.6 FABRICATION

2.6.1 Fabrication Tolerances

Fabricate sections within the following tolerances as stated in ASTM C1694

<table>
<thead>
<tr>
<th>Description</th>
<th>Tolerance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Length</td>
<td>Plus or minus 5 mm 0.2 inch</td>
</tr>
<tr>
<td>Width</td>
<td>Plus or minus 3 mm 1/8 inch</td>
</tr>
<tr>
<td>Thickness</td>
<td>Plus or minus 3 mm 1/8 inch</td>
</tr>
<tr>
<td>Tongue/Groove Alignment</td>
<td>Plus or minus 3 mm 1/8 inch</td>
</tr>
</tbody>
</table>

2.6.2 Forms

**************************************************************************

NOTE: Structural-section dimensions, cross-sections, and other details as required by the project must be indicated.
**************************************************************************

Use forms and form-facing materials that are nonreactive with concrete. Conform to the shapes, lines, and dimensions indicated and adhere to the specified fabrication tolerances.

2.6.3 Reinforcement

**************************************************************************

NOTE: Reinforcement types, sizes, and arrangement as required for structural strength after the
structural sections have been installed must be indicated.

Revise the following paragraphs when not applicable to the project. Concrete cover for reinforcement must be indicated.

**************************************************************************

Provide types, sizes, and arrangement as indicated. Submit details of reinforcement in accordance with ACI/MCP-3 and ACI 318, unless otherwise specified.

Use metal bar supports and spacers when placing and securing steel bars, welded-wire fabric, and other reinforcement. Provide concrete cover for reinforcement in accordance with ACI/MCP-3 and ACI 318.

2.6.4 Lifting Devices

Provide lifting devices designed for 100-percent impact, and of materials sufficiently ductile to ensure visible deformation before fracture.

2.6.5 Concrete Mixing and Conveying

Measure concrete materials, concrete batching plant, concrete mixers, and concrete mixing in accordance with ASTM C94/C94M. Handle concrete to prevent segregation and loss of concrete mix materials.

2.6.6 Preparations for Placing Concrete

Keep form interiors and reinforcement free of accumulations of hardened concrete, form-parting compound, standing water, ice, snow, or other deleterious substances. Secure in position, inspect and approve reinforcement and other embedded items.

2.6.7 Weather Limitations

Do not place concrete when temperature of the atmosphere is below 5 degrees C 40 degrees F nor during rain, sleet, and snow unless adequate protection is provided. Protection during inclement weather must prevent the entry of rain, sleet, or snow into the forms or into the fresh concrete.

2.6.8 Concrete Placing

Depost concrete so that no concrete is placed on concrete that has hardened sufficiently to cause formation of seams or planes of weakness. Consolidate concrete in a manner that will prevent segregation and will produce concrete free of honeycomb or rock pockets and with the required surface finish.

2.6.9 Identification Markings

Clearly mark each structural section in a permanent manner to indicate its location and orientation in the building.

For reinforced PAAC elements, clearly mark each structural section in a permanent manner to indicate its location and orientation in the building. Locate identifying marks, consistent with those shown on the Shop Drawings and the Panel Schedule on surfaces of PAAC elements not visible in their installed configuration. Indent marks for identification and quality
tracking on a surface of every reinforced PAAC element not visible in their installed configuration. These marks will be coded to determine, at a minimum, the following identification and quality control tracking information for the panel: 1. Panel identification. 2. Compressive strength and density classification. 3. Production date. 4. Position of the panel in the mold.

2.6.10 Finishing Unformed Surfaces

Trowel finish unformed surfaces unless otherwise specified. Provide smooth surface free of trowel marks, uniform in texture and appearance, and be plane to a tolerance not exceeding 3.2 millimeter in 3048 millimeter 1/8 inch in 10 feet when tested with a 3000 millimeter 10-foot straightedge. Provide top surfaces of sections that are to receive concrete topping after installation with a transversely scarified scratch finish and remove laitance.

2.6.11 Protection of Concrete After Placing

Protect in accordance with ACI/MCP-2, particularly with regards to hot or cold weather conditions.

2.6.12 Finishing Formed Surfaces

Upon removal of forms, repair and patch defective areas. Limit defective areas to holes left by tie rods and other temporary inserts and to honeycomb or rock pockets not deep enough to expose the reinforcement and not located in bearing areas. Cut out defective areas to solid concrete and cleaned. Where the concrete surface will be exposed to view, the patches, when dry, must match the surrounding concrete.

2.6.12.1 Concealed Formed Surfaces

Formed surfaces of sections that will be concealed by other construction can have the standard smooth finish having the texture imparted by the forms. Repair and patch defective areas as specified and all fins and other projections removed.

2.6.12.2 PAAC Element Patching

Make patches on lower side of sections, near the center or in areas of variable tensile strength, or at bearing areas, with AAC panel repair mortar specified by the AAC manufacturer. Other areas can be patched with the same material, or with AAC "block patch" or Portland cement grout.

2.6.12.3 Finishing Exposed-To-View

**************************************************************************
NOTE: Delete the following paragraph and specify the required finish when an architectural finish is required. For an exposed-aggregate finish refer to Section 03 45 00 PRECAST ARCHITECTURAL CONCRETE.
The location of precast structural concrete sections having an architectural finish must be indicated.
**************************************************************************

Provide grout finish on formed surfaces of sections that are to be exposed-to-view after installation. Final color of the grout, when dry,
must be the same for all concrete surfaces. Spread over dampened concrete surface with clean burlap pads, carpet, or sponge rubber floats to fill pits, air bubbles, and surface holes. Remove excess grout by scraping and then rubbing the surface with clean burlap or carpet to remove visible grout film. In hot dry weather, kept grout damp by means of fog-spraying during the setting period.

2.7 QUALITY OF CONCRETE

2.7.1 Quality Control Testing During Fabrication

Sample and test concrete for quality control during fabrication as follows. Submit test results on the same day that tests are made.

<table>
<thead>
<tr>
<th>REQUIREMENT</th>
<th>TEST METHOD</th>
<th>NUMBER OF TESTS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Proprietary mix to meet specified AAC strength class requirements for AAC compressive strength and AAC dry bulk density as defined by ASTM C1693</td>
<td>ASTM C1693</td>
<td>See paragraph CONCRETE SAMPLING AND TESTING</td>
</tr>
<tr>
<td>PAAC manufacturer's Quality Control Manual</td>
<td></td>
<td>See paragraph CONCRETE SAMPLING AND TESTING</td>
</tr>
<tr>
<td>PAAC manufacturer's certification of quarterly inspection of Quality Control process by a qualified third-party agency such as UL</td>
<td>on-site inspection by qualified third-party agency</td>
<td>quarterly, i.e. at least once every 90 days</td>
</tr>
</tbody>
</table>

2.7.2 Autoclaved Aerated Concrete Properties

<table>
<thead>
<tr>
<th>PROPERTY</th>
<th>VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compressive strength</td>
<td>as specified for the Strength Classification in accordance with ASTM C1693</td>
</tr>
<tr>
<td>Dry bulk density</td>
<td>within range shown for the specified Strength Classification in accordance with ASTM C1693</td>

<tr>
<td>Drying shrinkage</td>
<td>within range shown for the specified Strength Classification/Dry Bulk Density in accordance with ASTM C1693</td>
</tr>
</tbody>
</table>

PART 3 EXECUTION

3.1 ANCHORAGE ITEMS EMBEDDED IN OTHER CONSTRUCTION

**************************************************************************************************
NOTE: Delete the paragraph heading and the following paragraph when structural PAAC sections will not be connected to cast-in-place concrete construction or masonry construction. Such anchorage items include anchor bolts, steel dowels,
and steel bearing plates, steel studs, and steel straps.

Deliver items to the site before the start of other construction. Provide setting drawings, templates, instructions, and directions for the installation of anchorage items.

3.2 STRENGTH OF STRUCTURAL SECTIONS AT INSTALLATION

Do not install sections until PAAC concrete has attained the specified minimum laboratory strength at 1 to 7 calendar days.

3.3 INSTALLATION TOLERANCES

Install PAAC sections within the following tolerances:

<table>
<thead>
<tr>
<th>Deviation from plumb</th>
<th>Not over 10 mm in 4.8 m 1/4 inch in 10 feet, but not greater than 10 mm in 6.4 m 3/8 inch in 20 feet</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deviation from level</td>
<td>Not over 5 mm in 4.8 m 1/4 inch in 20 feet, but not greater than 10 mm in 9.6 m 1/2 inch in 40 feet</td>
</tr>
<tr>
<td>Deviation from linear building line from location indicated</td>
<td>Not over 6 mm 1/4 inch at base of wall</td>
</tr>
</tbody>
</table>

3.4 PLACING FRAMING STRUCTURAL SECTIONS

**NOTE:** Delete paragraph heading and the following paragraphs when framing structural sections such as columns, beams, girders, and joists will not be required.

Place supporting sections, including anchorage items attached to or embedded in other construction before placing sections is started.

3.4.1 Placing PAAC Framing Sections

a. For mortared joints specified between PAAC elements, only use "thin-bed mortar" for AAC masonry manufactured in accordance with ASTM C1660.

b. For mortared joints used as leveling material for PAAC elements, use large grain mortar as specified by the PAAC manufacturer or mortar specified by the Engineer-of-Record.

c. Secure reinforced PAAC panels in place as indicated on approved shop drawings. Provide temporary bracing as required to resist construction loads, including wind, especially for wall panels.

d. Provide supplemental steel framing at openings in PAAC wall and/or floor and/or roof systems.

3.4.2 Cold Weather Precautions When Utilizing Thin Bed Mortar Joints

Do not install panels when temperature of AAC panel is below -6 degrees C 20 degrees F. Remove visible ice on AAC panel prior to installation. Heat
mortar sand or mixing water to produce mortar temperatures between 4 degrees C and 50 degrees C 40 degrees F and 120 degrees F at time of mixing. Maintain mortar temperature above freezing until placed.

3.4.2.1 Ambient Temperature Requirements

a. Between -4 degrees C and -7 degrees C 25 degrees F and 20 degrees F: Use heat sources on both sides of AAC panels under construction. Install wind breaks when wind velocity is in excess of 24 km/hr 15 mph.

b. Below - 7 degrees C 20 degrees F: Provide enclosure for AAC panels under construction. Use heat sources to maintain temperatures above 0 degrees C 32 degrees F within enclosures.

3.4.2.2 Daily Mean Temperature Requirements for Cold Weather

a. Between 4 degrees C and 0 degrees C 40 degrees F and 32 degrees F: Protect completed AAC panels from rain or snow by covering with weather resistive membrane for a minimum of 24 hours after construction.

b. Between 0 degrees C and - 4 degrees C 32 degrees F and 25 degrees F: Completely cover completed AAC panels with weather resistive membrane for a minimum of 24 hours after construction.

c. Between -4 degrees C and -7 degrees C 25 degrees F and 20 degrees F: Completely cover completed AAC panels with insulating blankets or equal protection for a minimum of 24 hours after construction.

d. Below -7 degrees C 20 degrees F: Maintain AAC panel construction environment above 0 degrees C 32 degrees F for 24 hours after completion by an enclosure(s) with supplementary heat, electric heating blankets, infrared heat lamps, or other acceptable methods outlined to Contracting Officer's Representative.

3.4.3 Hot Weather Precautions When Utilizing Thin Bed Mortar Joints

When erected in ambient air temperature of 37 degrees C 100 degrees F or ambient air temperature of 32 degrees C 90 degrees F with wind velocity in excess of 13 km/hr 8 mph, implement the following:

a. Spreading mortar beds more than 1200 mm 4 feet ahead of AAC panels is prohibited.

b. Installing AAC panel more than two minutes after spreading mortar is prohibited.

3.5 PLACING STRUCTURAL PAAC FLOOR OR ROOF SLAB SECTIONS

**************************************************************************
NOTE: Delete the paragraph heading and the following paragraphs when slab structural sections, such as PAAC floor or roof panels will not be required. PAAC floor or roof panels may be placed over structural-steel framing members, precast structural-concrete framing sections, cast-in-place structural-concrete framing sections, or bearing walls, or a combination thereof.
**************************************************************************
Place supporting sections, including bearing pads or plates before placing sections.

a. Place slab structural sections on supporting construction with ends bearing on the structural framing sections or bearing walls as indicated. End bearings less than 75 millimeter 3 inches are not acceptable.

b. Accurately align slabs end to end with sides and ends spaced as shown on shop drawings.

c. Provide grouting void at sides and ends of the slabs.

d. Secure reinforced PAAC panels in place as indicated on approved shop drawings. Provide temporary bracing as required to resist construction loads, including wind.

e. Provide supplemental steel framing at openings in PAAC wall and/or floor and/or roof systems.

3.6 GROUTING CONNECTIONS AND JOINTS

**************************************************************************

NOTE: Delete paragraph heading and the following paragraphs when precast structural-concrete framing sections or floor-slab structural sections or both will not be required. When fire-resistance-rated precast structural-concrete sections are required, consult the applicable fire agency’s requirements for grouting joints.

**************************************************************************

After sections have been placed and connected, grout open spaces at connections and joints. Reinforce and grout cells at joints between PAAC wall panels, as specified and shown in structural drawings and shop drawings. Fill joints between reinforced PAAC floor or roof panels using reinforcing bars and grout, as specified in structural drawings and shop drawings.

3.6.1 Cement Grout

Provide cement grout consisting of 1 part cement, 2-1/2 parts of specified aggregate, and not more than 17 L 4-1/2 gallons of water per 42.6 kg 94-pound sack of cement.

3.6.2 Shrink-Resistant Grout

Mix shrink-resistant grout compound with water to provide a flowable mixture without segregation or bleeding. Provide forms or other approved methods to retain the grout in place. Pack spaces with grout until the voids are completely filled. Flush grout at slab structural sections with top surface of the slab and remove excess. Keep grout damp for not less than 24 hours.

3.6.3 Epoxy-Resin Grout

Epoxy-resin grout or adhesive may be used in lieu of shrink-resistant grout. Install epoxy-resin grout or adhesive in accordance with the manufacturer's printed instructions.

3.7 SEALING JOINTS IN ROOF SLABS

**************************************************************************
NOTE: Delete paragraph heading and the following paragraphs when roof slab structural-sections will not be required. Where fire-resistance-rated roof slab structural sections are required, the applicable fire agency's requirements for sealing joints must be consulted.
**************************************************************************

After PAAC roof slab sections have been placed and connected, seal open spaces at connections and the top portion of joints.

a. Fill keyways and joints at ridges, hips, and connections with cement grout. Level with the top surfaces of slabs, remove excess grout, and apply a smooth finish.

b. Fill keyways and joints between reinforced PAAC floor or roof panels using reinforcing bars and grout, as specified in structural drawings and shop drawings.

c. Seal other joints with bituminous joint-sealing material. Center joint-sealing tape over the joint and embedded in hot bituminous cement. Lap Ends not less than 100 mm (4 inches). Remove excess bitumen and provide a smooth tape surface.

3.8 OPENINGS IN SLAB STRUCTURAL SECTIONS

**************************************************************************
NOTE: In PAAC flat slabs, the maximum size of field-cut openings is governed by approval of the PAAC panel Manufacturer, based on spacing and reinforcing in the panel. Maximum size and relative location of such openings must be communicated to the PAAC panel manufacturer prior to initiation of the shop drawings. Regardless of reinforcing, the maximum size of an opening or notch within a single PAAC panel, in the direction of panel width, is typically limited to 25 percent of the panel width.
**************************************************************************

Cut and fit sections as required for other work projecting through, or adjacent to, the members. Cut straight and at 90 degrees to the surfaces without breaking or spalling the edges.

**************************************************************************
NOTE: Openings larger than 300 mm (12 inches) in the panel width direction must be framed with supporting members.
**************************************************************************

a. Reinforce openings in sections having a dimension more than 300 mm (12 inches) in the panel width direction by means of hung steel angle saddle headers or additional framing. Headers must be shop prime-coat painted.

b. Provide headers at penetrations in floor and roof systems as detailed
by the AAC Panel Manufacturer.

3.9 TOUCHUP PAINTING

**************************************************************************
NOTE: Delete this paragraph when precast structural members will not be supported by steel structural members.
**************************************************************************

Wire brush, clean, and touchup paint scarred surfaces on steel supporting members and weld plates after sections have been installed.

3.10 PROTECTION AND CLEANING

**************************************************************************
NOTE: Where architectural finishes such as exposed-aggregate finish are specified for exposed-to-view surfaces, such surfaces must be cleaned as specified in Section 03 45 00 PRECAST ARCHITECTURAL CONCRETE.
**************************************************************************

a. Patch spalls and chips in reinforced AAC panels in accordance with AAC panel manufacturer’s recommendations.

b. Upon completion of installation, sweep clean and leave ready slab surfaces to receive concrete floor topping, roofing, or other covering.

c. Protect exposed-to-view surfaces against staining and other damage until completion of the work.

3.11 INSPECTION AND ACCEPTANCE PROVISIONS

3.11.1 Dimensional Tolerances

Members having any dimension outside the limits for fabrication tolerances specified will be rejected.

3.11.2 Surface-Finish Requirements

Sections will be rejected for any of the following surface-finish deficiencies:

**************************************************************************
NOTE: Delete the first of the following paragraphs when architectural finishes such as exposed-aggregate finish, are not required for exposed-to-view surfaces.
**************************************************************************

a. Exposed-to-view surfaces having architectural finishes that do not match the color, aggregate size and distribution, and texture of the approved sample for the exposed-to-view finish

b. Exposed-to-view formed surfaces that contain cracks, spalls, air bubbles, honeycomb, rock pockets, or stains or other discoloration that cannot be removed by cleaning
c. Concealed formed surfaces that contain cracks in excess of 0.25 millimeter 0.01 inch wide; cracks or any other surface deficiency that penetrates to the reinforcement regardless of the width of crack or size of other deficiency; honeycomb and rock pockets located in bearing surfaces; and spalls except minor breakage at corners.

d. Unformed surfaces that contain cracks and other surface deficiencies as specified for concealed formed surfaces.

3.11.3 Strength of Structural Members

Strength of structural PAAC sections will be considered potentially deficient if they fail to comply with the requirements that control the strength of the structural members, including the following conditions:

a. Failure to meet compressive strength tests

b. Reinforcement of PAAC section not conforming to the requirements specified

c. Concrete curing and protection of structural sections against extremes in temperature during curing not conforming to the requirements specified

d. Structural sections damaged during handling and erection

e. Reinforcement and Weld-Point Shear Strength of Precast Autoclaved Aerated Concrete (PAAC) panels not conforming to the requirements specified

3.11.4 Testing Structural Sections for Strength

When there is evidence that the strength of precast structural-concrete sections does not meet specification requirements, cores drilled in hardened concrete for compressive strength determination must be made in accordance with ASTM C42/C42M and as follows:

a. Take at least three representative cores from the precast structural concrete sections that are considered potentially deficient.

   (1) Test cores saturated-surface-dry if the concrete they represent will be wet at all times during the use of the completed structure.

   (2) Test cores air-dry if the concrete they represent will be dry at all times during the use of the completed structure.

b. Strength of cores will be considered satisfactory if their average is equal to or greater than the Minimum Compressive Strength (f' AAC) specified for the AAC Strength Class material intended for the PAAC sections, per the Shop Drawings and Panel Schedule.

c. Fill core holes solidly with patching mortar and finished to match the adjacent concrete surfaces.

d. If the results of the core tests are unsatisfactory or if core tests are impractical to obtain, perform static load tests of a structural section. The test will be evaluated in accordance with ACI/MCP-3 and ACI 318, except that the superimposed test load must be as specified for the proof-test method of strength design.
Replace sections that are found inadequate by the core tests or by the results of static load tests with sections that meet the specified requirements.

3.11.5 Inspection of Welding

Perform inspection of welding in accordance with AWS D1.1/D1.1M, Section entitled, "Inspection," and as follows:

**************************************************************************
NOTE: Delete the following paragraphs that are not applicable to the project. The location of welds requiring inspection and the type of inspection must be indicated. The liquid-penetration inspection of welds is the most economical and commonly used method.
**************************************************************************

a. Liquid-penetration inspection of welds must conform to ASTM E165/E165M.

b. Magnetic-particle inspection of welds must conform to ASTM E709.

3.11.6 Structural Sections-in-Place

Sections-in-place will be rejected for any one of the following deficiencies:

a. Sections not conforming to the requirements for installation tolerances specified

b. Sections that are damaged during construction operations

c. Sections having exposed-to-view surface finishes that develop surface finish deficiencies specified

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for architectural precast concrete products, that through their finish, shape, color, or texture contribute to a structure's architectural expression. These products may be custom designed or feature standard shapes. They may be manufactured with conventional mild-steel reinforcement, or they may be pretensioned or posttensioned. These products typically have more stringent requirements for dimensional tolerances, finish variations, and color consistency. Architectural precast concrete products includes wall panels, mullions, bollards, urns, railings, sills, copings, benches, planters, pavers, and other types of miscellaneous shapes.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

NOTE: The panels specified are intended for attachment of the building framing system at each floor elevation and at the roof elevation. The panels may be provided with built-in anchorage.
devices for the attachment of thermal insulation blankets to the interior face of the wall panels and for the attachment of metal flashing after the wall panels have been installed.

**************************************************************************

Note: Drawings should include a complete design indicating the character of the work to be performed and the following:

1. Location and details of wall panels and precast units, showing all dimensions, and size and type of reinforcement.

2. Details of joints between wall panel and precast units, showing sealant or gasket shape, dimensions, and location.

3. Details showing both the location and type of anchorage devices of the precast units to the building framing system and the connection of other materials (reglets, insulation nailers, etc.) to the precast units. Indicate gravity loads, live loads, dynamic loads, and stresses inherent in the structure for the manufacturer to provide embedded precast units anchorage.

4. Locations where flashing reglets are required.

5. Locations of inserts (wedge type, slotted type, etc.) cast into the precast concrete units.

6. Location of each type of surface finish, with details of transitions between different types of surface finishes.

7. Indicate integral color(s) of precast units.

**************************************************************************

1.2 SUBMITTALS

**************************************************************************

NOTE: Review Submittal Description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.

**************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

1.3 MODIFICATION OF REFERENCES

In the referenced ACI and PCI publications, consider the advisory provisions to be mandatory. Interpret reference to the "Building Official," the "Structural Engineer," and the "Architect/Engineer" to mean the Contracting Officer.

1.4 GENERAL REQUIREMENTS

Precast concrete units must be designed and fabricated by an experienced and certified precast concrete manufacturer. The manufacturer needs to have been regularly and continuously engaged in the manufacture of precast concrete work similar to that indicated on the drawings for at least 3 years. The Contractor must submit a statement detailing the Manufacturer's Qualifications. Coordinate precast work with the work of other trades.

1.5 DESIGN

1.5.1 Standards and Loads

**************************************************************************
NOTE: Design loads will be shown on the drawings. Criteria for design loads are contained in ASCE 7-16 and UFC 3-301-07. The differential temperature of 89 degrees C 160 degrees F is based on extreme values of 40 degrees C 40 degrees F below zero to 49 degrees C 120 degrees F above zero; it should be used for computing volume changes due to temperature variations. Other values, greater or smaller, should be used instead whenever justified by climatic conditions at the jobsite. For in-house design delete all references to design by others.
**************************************************************************

Precast unit design must conform to ASCE 7-16, ACI 318M ACI 318 and PCI MNL-122. Indicate design loads for precast concrete on the drawings. A differential temperature of [89] [_____] degrees C [192] [_____] degrees F, between interior and exterior faces of the units, must be considered in the design. Stresses due to restrained volume change caused by shrinkage and temperature differential, handling, transportation and erection must be accounted for in the design.
1.5.2 Connections

Connection of units to other members, or to other units must be of the type and configuration indicated. The design and sizing of connections for all design loads will be completed by the Contractor.

1.5.3 Concrete Proportion

Base the selection of proportions for concrete on the methodology presented in ACI 211.1 for normal weight concrete and ACI 211.2 for lightweight concrete. Develop the concrete proportion using the same type and brand of cement, the same type and gradation of aggregates, and the same type and brand of admixture that will be used in the manufacture of precast concrete units for the project. Do not use calcium chloride in precast concrete and admixtures containing chloride ions, nitrates, or other substances that are corrosive will not be used in prestressed concrete.

1.5.4 Design Calculations

Calculations for design of members, connections and embedments not shown must be made by a registered professional engineer experienced in the design of precast architectural concrete. Calculation will include the analysis of member for lifting stresses and the sizing of the lifting inserts. Submit calculations for review and approval prior to fabrication, signed and sealed by the registered design professional who prepared the design.

1.5.5 Thermal Calculations

Submit thermal calculations prepared and sealed by a registered professional engineer for review complying with ASHRAE 90.1 - SI ASHRAE 90.1 - IF, for the steady state thermal resistance for the precast concrete wall panels. Thermal calculations must demonstrate the thermal conductivity of all components, the spacing of all connectors, the percent area of the wall that is solid concrete, and the thermal resistance of all components.

1.6 DELIVERY, STORAGE, AND HANDLING

Deliver packaged materials, except for wall panels, to the project site in the original, unbroken packages or containers, each bearing a label clearly identifying manufacturer's name, brand name, weight or volume, and other pertinent information. Store packaged materials, and materials in containers, in a weathertight and dry place until ready for use.

Store products in manufacturer's unopened packaging in dry storage area, with ambient temperature between minus 1 degree C and 41 degrees C 30 degrees F and 120 degrees F, until installation.

1.7 STORAGE AND INSPECTION AT MANUFACTURER'S PLANT

Protect precast units temporarily stored at the manufacturer's plant from damage in accordance with PCI MNL-117 and PCI MNL-122. Immediately prior to shipment to the jobsite, all precast concrete units must be inspected for quality to insure all precast units conform to the requirements specified. Inspection for quality will include, but will not be limited to, the following elements: color, texture, dimensional tolerances, chipping, cracking, staining, warping and honeycombing. Replace or repair all defective precast concrete units as approved.
1.8  PLANT INSPECTION

[At the option of the Contracting Officer, precast units may be inspected.]  
[Precast units must be inspected by the QC representative prior to being  
transported to the job site.] The Contractor is to give notice 14 days  
prior to the time the units will be available for plant inspection. Neither  
the exercise nor waiver of inspection at the plant will affect the  
Government's right to enforce contractual provisions after units are  
transported or erected.

1.8.1  Fabricator Quality Certifications

Plants must be certified by the PCI Plant Certification Program for Group  
A, Category A1, or Architectural Precast Association (APA) certification or  
National Precast Concrete Association (NPCA). When plants are not  
currently enrolled in one of the three certification programs listed above  
then they must provide a product quality control system in accordance with  
PCI MNL-117 and perform concrete and aggregate quality control testing  
using an approved, independent commercial testing laboratory.

1.9  ERECTOR CERTIFICATION

Erector with erecting organization and all erecting crews certified and  
designated by PCI's Certificate of Compliance to erect Category [A  
(Architectural Systems) for non-load][S2 (Complex Structural Systems) for  
load]-bearing members.

[1.10  ERECTOR QUALIFICATIONS

**************************************************************************
NOTE: Use the following paragraph when a PCI  
Certified erector is not available in the project  
location.
**************************************************************************

A precast erector that is not certified by PCI who retains a PCI-Certified  
Field Auditor, at the erector's expense, to conduct a field audit of a  
project in the same category as this project prior to start of precast  
concrete erection and must submit the Erector's Post Audit Declaration to  
be considered qualified.

]1.11  CONCRETE SAMPLING AND TESTING

1.11.1  Test for Concrete Materials

Sample and test concrete materials proposed for use in the work in  
accordance with PCI MNL-117.

Submit reports for each material sampled and tested prior to the start of  
work. Reports must contain the project name and number, date, name of  
Contractor, name of precast unit manufacturer, name of concrete testing  
service, source of concrete aggregates, generic name of aggregate, and  
values specified.

1.11.2  Quality Control Testing During Fabrication

Sample and test concrete for quality control during fabrication as follows:
### REQUIREMENT | TEST METHOD | NUMBER OF TESTS
---|---|---
Sampling fresh concrete | ASTM C172/C172M except modified for slump per ASTM C94/C94M | As required for each test

**Slump test**

Slump test | ASTM C143/C143M | One for each concrete load at point of discharge and one for each set of compressive strength tests

**Air Content** by pressure method

Air Content by pressure method | ASTM C231/C231M | One for each set of compressive strength tests

Compressive test specimens

Compressive test specimens | ASTM C31/C31M | One set of six specimens for each Compressive Strength test, one set per day or for every 15 cubic meters 20 cubic yards of concrete placed, whichever is greater.

Compression test specimens may be either standard 150 by 300 millimeter 6 by 12 inch cylinders or 100 millimeter 4-inch cubes. Cubes may be molded individually or cut from slabs. Preparation and testing of cube specimens must be as nearly consistent with the test methods specified as possible, with the exception that the concrete will be placed in a single layer.

Curing of compression test specimens must be the same as the curing method used for the precast concrete wall panels until panels are stripped of forms and then standard moist cure will continue.

### REQUIREMENT | TEST METHOD | NUMBER OF TESTS
---|---|---
Concrete temperature | Each time a set of compression test specimens is made |
Compressive strength tests | ASTM C39/C39M | One set of facing strength tests mix and one set of backing mix for every ten panels or fraction thereof cast in any one day; two specimens in each set tested at 7 calendar days; three specimens in each set tested at 28 calendar days, and one specimen in each set retained in reserve for testing if required.

Evaluate compression test results at 28 days in accordance with ACI 214R using a coefficient of variation of 20 percent. Evaluate the strength of concrete by averaging the test results (two specimens) of standard cylinders tested at 28 days. Not more than 20 percent of the individual tests can have an average compressive strength less than the specified ultimate compressive strength. Submit test reports on the same day that tests are made.

Reports for Compressive Strength tests need to contain the project name and number, date of concrete placement, name of Contractor, name of precast concrete wall panel manufacturer, name of concrete testing service, panel identification letter and number, use of concrete mixture (facing or backing), design compressive strength at 28 calendar days, concrete-mix proportions and materials, and compressive breaking strength and type of break.

If 100 millimeter 4-inch cubes are used for compressive strength specimens, average strength of the cubes at any test age must be multiplied by the factor of 0.8 to arrive at an estimate of the corresponding 150 by 300 millimeter 6 by 12 inch cylinder strength. Report both of these values.

1.12 QUALITY ASSURANCE

1.12.1 Precast Drawings

Submit precast drawings with the following information:

a. Precast dimensions, cross-section, and edge details; location, size, and type of reinforcement, including reinforcement necessary for safe handling and erection of precast units and other embedded items. Comply with ACI SP-66.

b. Layout, dimensions, and identification of each precast unit, corresponding to installation sequence.

c. Setting drawings, instructions, and directions for installation of concrete inserts.

d. Location and details of anchorage devices and lifting devices embedded in panels, and connection details to building framing system.

[ e. Location of embedded brick work including joint locations, joint widths, brick coursing, brick coursing alignment across panel joints and reveal and false-joint locations and dimensions.
1.12.2 Concrete Wall Panel Surface Finish Sample

Submit a concrete wall panel sample 300 mm by 300 mm 12 inches by 12 inches by approximately 40 mm 1 1/2 inches in thickness, to illustrate quality, color, and texture of both exposed-to-view surface finish and finish of panel surfaces that will be concealed by other construction. [Obtain approval prior to submission of sample panels.]

After approval of the surface, Contractor must provide one full size sample Wall Panel. Approved sample may be used in construction when properly identified.

1.12.3 Required Records

ASTM C94/C94M. Submit mandatory batch ticket information for each load of ready-mixed concrete.

1.12.4 Mock-Up

Provide mock-up to establish that proposed materials and construction techniques provide acceptable visual effect. Materials used for mock-up should be those proposed for actual construction. Include all anchors, connections, flashing and joint fillers. Apply specified products to determine acceptability of appearance and optimum coverage rate required for application.

Provide mock-up sections of building and structures which typify the most difficult areas to build.

a. Finish areas designated by Contracting Officer.

b. Apply water repellent in accordance with manufacturer's instructions.

c. After materials have cured, water test surface to determine that sufficient water repellent has been applied.

d. Do not proceed with remaining work until workmanship, color, and detail are approved by Contracting Officer.

e. Modify mock-up area as required to produce acceptable work.

Job Mock Up Panel: Minimum 1.2 meters by 1.2 meters 4 feet by 4 feet

a. Incorporate edge, reveal[, and brick coursing detail] as shown on drawings.

b. Utilize full range of brick sizes, variance of brick size, general color of brick and variance in color and texture of brick.

][c. Show clean, pressure washed brick and concrete surface.

][d. Utilize full range of color of concrete mortar joints.

] e. Maintain Mock Up for comparison with finished work.

After approval by Contracting Officer, transport mock-up to job-site and erect where directed by [Contracting Officer][____].
1.12.5 Pre-Installation Meeting

Hold a meeting at the job site with representative of the manufacturer[ and the applicator prior to application of water repellents] and all other trades that may be effected by work of this section. Notify the Contracting Officer at least 3 days in advance of the time of the meeting.

1.13 TOLERANCES

Dimensions of the finished panel, at the time of erection in the structure, must conform to the tolerances for precast, non-prestressed elements in PCI MNL-117, unless otherwise specified by the Architect.

PART 2 PRODUCTS

2.1 CONCRETE

2.1.1 Contractor-Furnished Mix Design

**************************************************************************
NOTE: If gap-graded or one size architectural aggregates are used in a high coarse aggregate mix, delete the air percentage requirements and use the second bracketed sentence.
**************************************************************************

ACI 211.1 and ACI 301M ACI 301. The Contractor must submit the mix design report giving the maximum nominal coarse aggregate size, the proportions of all ingredients and the type and amount of any admixtures that will be used in the manufacture of each strength and type of concrete, a minimum of sixty days prior to commencing operations. Provide mix proportion data using at least three different water-cementitious material ratios for each type of mixture, which produce a range of strength encompassing those required for each type of concrete required. Plot a curve for each concrete mixture, showing the relationships between water-cementitious material ratios and compressive strengths. Maximum permissible water-cementitious material ratio must be that value not exceeding the maximum water-cementitious material ratio specified, indicated by the curve to produce a design minimum laboratory compressive strength at 28 calendar days not less than that specified. The mix design report is to contain the project name and number, date, name of Contractor, name of precast concrete wall panel manufacturer, name of concrete testing service, use of concrete mixture (facing or backing), source of concrete aggregates for each mixture. Submit certified copies of laboratory test reports, including mill tests and all other test data, for portland cement, blended cement, pozzolan, ground granulated blast furnace slag, silica fume, and aggregates. The statement must be accompanied by test results from an approved testing laboratory, certifying that the proportions selected will produce concrete of the properties required. Make no substitutions without additional tests to verify that the concrete properties are satisfactory. Concrete must have a 28-day compressive strength of 28 MPa [4000] [_____] psi.[ Air content of plastic concrete must be between 4 and 6 percent air by volume.][ Provide a dosage of air entraining agent which will produce 19 plus or minus 3 percent air in a 1 to 4 by weight standard sand mortar in accordance ASTM C185.]

If, the compressive strength falls below that specified, adjust the mix proportions and water content and make necessary changes in the temperature, moisture, and curing procedures to secure the specified
strength. Notify the Contracting Officer of all changes.

2.1.2 Exposed-to-View Facing Mixture

Provide aggregates for exposed-to-view facing mixture; white, gray, or buff portland cement or a blend of two or more portland cements; [air-entraining admixture;] and water. Provide exact proportions of facing mixture to produce concrete having the specified properties and capable of obtaining the approved surface color and finish.

2.1.3 Backing Mixture

Provide the approved mix design.

2.2 MATERIALS

2.2.1 Material Sustainability Criteria

For products in this section, where applicable and to extent allowed by performance criteria, provide and document the following in accordance with Section 01 33 29 SUSTAINABILITY REQUIREMENTS AND REPORTING:

a. Recycled content for fly ash and pozzolan
b. Recycled content for Ground Iron Blast-Furnace Slag
c. Recycled content for Silica Fume

2.2.2 Fine Aggregates

**************************************************************************
NOTE: Choose appropriate gradation based upon use of concrete. Where concrete is for back-up and separate facing aggregate is used, a gradation or maximum aggregate size may be specified.
**************************************************************************

ASTM C33/C33M. The optional method of reducing the No. 50 and No. 100 sieve aggregates does not apply. The restriction to use only fine aggregates that do not contain any materials that are deleteriously reactive with alkalis in cement does apply.

2.2.3 Coarse Aggregate

**************************************************************************
NOTE: Choose appropriate gradation based upon use of concrete. Where concrete is for back-up and separate facing aggregate is used, a gradation or maximum aggregate size may be specified. Class 5S is for exposed architectural concrete.
**************************************************************************

ASTM C33/C33M, Size No. [57] [67], Class 5S. The restriction to use only coarse aggregates that do not contain any materials that are deleteriously reactive with alkalis in cement does apply. Aggregate must not contain slag or crushed concrete.
2.2.4 Exposed Aggregate

NOTE: Choose appropriate gradation based upon use of concrete. Where concrete is for back-up and separate facing aggregate is used, a gradation or maximum aggregate size may be specified.

In addition to the above, facing mixture aggregate, and aggregate for homogeneous panels with exposed aggregate finish, will be [gravel] [crushed gravel] [crushed stone] of size and color to produce exposed surfaces to match the color and texture of the sample on file with the Contracting Officer.

NOTE: Aggregates for exposed-to-view facing mixture may be natural mineral particles, natural building stone particles, or combinations thereof, or synthetic materials such as glass or plastic; natural aggregates may be crushed or gravel. Delete the following paragraph when crushed natural aggregate is not required by the project. Specify the mineral or rock generic name, color, particle shape, size range of particles, and other information relative to the appearance of the exposed-to-view finish surface as applicable to the project.

Crush coarse aggregate by a means that will produce material of cubical shape with a minimum of elongated, thin, or partially fractured particles. Material or crushing methods that produce particles classified by petrographic examination as being weak, highly fractured or somewhat friable, or both, in excess of 16 percent of the particles in any whole sample will be rejected. Material for coarse aggregate must be free of substances that change color on oxidation. Obtain material used for the work from the same basic source and stratum. Quarry material to produce a uniformly colored aggregate that does not change color upon weathering. During quarrying operations, the uniformity of rock face color must be verified by periodically comparing the rock face color to the approved coarse aggregate sample.

NOTE: Revise the following paragraph when fine white-quartz aggregate is not required by the project.

Fine aggregate will be white quartz natural sand or stone screenings, or manufactured sand produced from white quartz. Aggregate must be free of substances that change color on oxidation. Color must conform to the approved sample.

2.2.5 Cementitious Materials

NOTE: Acceptable types of cement are as follows:
### ASTM C150/C150M
Portland

<table>
<thead>
<tr>
<th>Type</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type I</td>
<td>Type IP, IS, IL, or IT</td>
</tr>
<tr>
<td></td>
<td>For general use in construction.</td>
</tr>
<tr>

<tr>
<td></td>
<td>resistance is required.</td>
</tr>
</tbody>
</table>

For concrete subjected to salt water, near salt water or exposed to alkali/sulfate soils refer to specification Section 03 31 30 MARINE CONCRETE for additional criteria.

**************************************************************************
NOTE: For NAVFAC LANT: Typically allow Type II, IP(MS), or IS(MS). May use Type I if Type II not locally available and no sulfate problems expected (i.e. not near seawater or sulfate soils). Type III is for high early strength. Type V, IP (HS), IS (HS), IL (HS), and IT (HS) are for high sulfate resistance.
**************************************************************************

NOTE: Coal fly ash, slag, cenospheres, and silica fumes are EPA designated products to be ingredients in concrete and cement. See Section 01 33 29 SUSTAINABILITY REQUIREMENTS AND REPORTING and include additive options unless designer determines that justification for non-use exists.
For exposed concrete, use one manufacturer and one source for each type of cement, ground slag, fly ash, and pozzolan.

2.2.5.1 Fly Ash

NOTE: Fly ash, pozzolan, and slag cement may produce uneven discoloration of the concrete during the early stages of construction, depending upon the type of curing provided. Fly ash or pozzolan meeting the specified test results, which are more stringent than ASTM C618, should provide acceptable end results. It is suggested that fly ash be used as a replacement for 35 percent of the cement. Class C fly ash is not permitted.

Add with cement. Fly ash content must be a minimum of [15] [20] [30] [35] [40] [_____] percent by weight of cementitious material, provided the fly ash does not reduce the amount of cement in the concrete mix below the minimum requirements of local building codes. Where the use of fly ash cannot meet the minimum level, provide the maximum amount of fly ash permittable that meets the code requirements for cement content. Report the chemical analysis of the fly ash in accordance with ASTM C311/C311M. Evaluate and classify fly ash in accordance with ASTM D5759.

2.2.5.2 Raw or Calcined Natural Pozzolan

Natural pozzolan must be raw or calcined and conform to ASTM C618, Class N, including the optional requirement for uniformity.

2.2.5.3 Ultra Fine Fly Ash and Ultra Fine Pozzolan

Ultra Fine Fly Ash (UFFA) and Ultra Fine Pozzolan (UFP) must conform to ASTM C618, Class F or N, and the following additional requirements:

a. The strength activity index at 28 days of age must be at least 95 percent of the control specimens.

b. The average particle size must not exceed 6 microns.

c. The sum of SiO2 + Al2O3 + Fe2O3 must be greater than 77 percent.

2.2.5.4 Ground Granulated Blast-Furnace Slag

ASTM C989/C989M, Grade [100] [120]. Slag content must be a minimum of [25][50][70] percent by weight of cementitious material.

2.2.5.5 Silica Fume

NOTE: Silica fume must only be used for OCONUS projects where Class F fly ash and GGBF slag are not available, and when approved by the Contracting Officer. Guidance for use of silica fume should be
sought from the agency's Subject Matter Expert in Concrete Materials.

**************************************************************************
NOTE: The initial cost of the concrete must increase, and supervision at the batch plant, finishing, and curing is necessary. A HRWR must be used with silica fume, the slump can be increased 50 mm to 125 mm 2 to 5 inches without reducing strength. Finishing may be more difficult. Proper curing is essential because there is a tendency for plastic shrinkage cracking.

**************************************************************************
Silica fume must conform to ASTM C1240, including the optional limits on reactivity with cement alkalis. Silica fume may be furnished as a dry, densified material or as slurry. Proper mixing is essential to accomplish proper distribution of the silica fume and avoid agglomerated silica fume which can react with the alkali in the cement resulting in premature and extensive concrete damage. Supervision at the batch plant, finishing, and curing is essential. Provide at the Contractor's expense the services of a manufacturer's technical representative, experienced in mixing, proportioning, placement procedures, and curing of concrete containing silica fume. This representative must be present on the project prior to and during at least the first 4 days of concrete production and placement using silica fume. A High Range Water Reducer (HRWR) must be used with silica fume.

2.2.5.6 Portland Cement

**************************************************************************
NOTE: If high early strength concrete is required, specify Type III after consulting the agency's Subject Matter Expert in Concrete Materials.

When concrete is exposed to sea water use specification Section 03 31 30 MARINE CONCRETE.

When high-volume fly ash mixtures, mixtures where fly ash replacement of portland cement is greater than 50 percent by weight, are specified they may be blended with Type II or Type III cement for higher early strength. Consult the agency's Subject Matter Expert in Concrete Materials prior to using Type III cement.

**************************************************************************
Provide cement that conforms to ASTM C150/C150M, Type [I][II][III], [including false set requirements] with tri-calcium aluminates (C3A) content less than 10 percent and a maximum cement-alkali content of 0.80 percent Na2Oe (sodium oxide) equivalent. Use one brand and type of cement for formed concrete having exposed-to-view finished surfaces.

[For portland cement manufactured in a kiln fueled by hazardous waste, maintain a record of source for each batch.][ Supplier must certify that no hazardous waste is used in the fuel mix or raw materials.][ Supplier must certify that the hazardous waste is neutralized by the manufacturing process and that no additional pollutants are discharged.]
2.2.5.7 Blended Cements

a. Blended cements must conform to ASTM C595/C595M Type [IP,] [IS,] [IL,] [IT,] [IP (MS),] [IS (MS),] [IL (MS),] [IT (MS),] [IP (MH),] [IS (MH),] [IL (MH),] [IT (MH),] [IP (HS),] [IS (HS),] [IL (HS),] [IT (HS),] [IP (HE),] [IS (HE),] [IL (HE),] [IT (HE),] or ASTM C1157/C1157M Type [GU,] [MS,] [MH,] [HE,].

b. Slag cement added to the Type IS blend must meet ASTM C989/C989M.

c. The pozzolan added to the Type IP blend must be ASTM C618 [Class F,] [Class C,] or [Class N] and must be interground with the cement clinker. The manufacturer must state in writing that the amount of pozzolan in the finished cement will not vary more than plus or minus 5 mass percent of the finished cement from lot-to-lot or within a lot. The percentage and type of pozzolan used in the blend must not change from that submitted for the aggregate evaluation and mixture proportioning.

2.2.6 Admixtures

ASTM C260/C260M for air-entraining admixtures. Other admixtures: ASTM C494/C494M. [Certify that admixtures are free of chlorides.]
[Coloring Admixture: ASTM C979/C979M, synthetic or natural mineral oxide or colored water reducing admixtures, temperature stable, and non-fading. [Certify that coloring admixtures are free of chlorides.]]

2.2.7 Water

Water must comply with the requirements of ASTM C1602/C1602M. Minimize the amount of water in the mix. Improve workability by adjusting the grading rather than by adding water. Water must be [potable] [from rainwater collection] [from graywater] [from recycled water]; free from injurious amounts of oils, acids, alkalis, salts, organic materials, or other substances deleterious to concrete. Submit test report showing water complies with ASTM C1602/C1602M.

2.2.8 Reinforcement

**************************************************************************
NOTE: Specify ASTM A775/A775M for epoxy-coated reinforcing bars or ASTM A767/A767M and ASTM A780/A780M for zinc-coated (galvanized) bars. Define where coated bars are to be used, if not for entire project. Include ASTM publications in paragraph REFERENCES:

A 767: Zinc-Coated (Galvanized) Steel Bars for Concrete Reinforcement

A 775: Epoxy-Coated Reinforcing Bars

A 780: Repair of Damaged Hot-Dip Galvanized Coatings
**************************************************************************

All exposed steel must be phosphate treated, primed, and coated to prevent rust.
2.2.8.1 Reinforcing Bars

ACI 301MACI 301 unless otherwise specified. ASTM A615/A615M, Grade [400] [60], [ASTM A706/A706M, Grade [400] [60], or ASTM A996/A996M, Grade [300] [40], or ASTM A996/A996M, Grade [400] [60].]

2.2.8.2 Welded Wire Reinforcement

ASTM A1064/A1064M.

2.2.8.3 Supports for Concrete Reinforcement

Include bolsters, chairs, spacers, and other devices necessary for proper spacing, supporting, and fastening in place in accordance with PCI MNL-117.

2.2.9 Prestressing Strands

**************************************************************************

NOTE: This paragraph will be retained only when prestressed units are permitted or required.
**************************************************************************

Prestressing strands need to conform to ASTM A416/A416M Grade 1860 Grade 270.

2.2.10 Tie Wire

Tie wire must be soft monel or 18-8 stainless steel.

2.2.11 Plates, Angles, Anchors and Embedment

ASTM A36/A36M, ferrous metal plate connectors for attachment to the structural framing using manufacturer standard construction procedures. Headed studs will use 400 MPa 60,000 psi steel with construction conforming to AWS D1.1/D1.1M, Type B. Deformed bar anchors must conform to ASTM A1064/A1064M. Coat steel items, other than stainless, with a rust-inhibiting paint or provide hot-dip galvanized after fabrication in accordance with ASTM A153/A153M.

Furnish and install anchors, inserts, lifting devices, and other accessories which are to be embedded in the precast units in accordance with the approved detail drawings. Embedded items must be accurately positioned in their designed location, and have sufficient anchorage and embedment to satisfy design requirements.

2.2.12 Form Release Agent

Release agent must be manufacturer's standard non-staining type.

2.2.13 Grout

Packaged, nonmetallic, noncorrosive, nonstaining grout containing selected silica sands, portland cement, shrinkage-compensating agents, plasticizing and water-reducing agents, complying with ASTM C1107/C1107M and of consistency suitable for application within a 30-minute working time. Water-soluble chloride ion content less than 0.06 percent by weight of cement when tested according to ASTM C1218/C1218M.
2.3 CAST-IN EMBEDDED ITEMS AND CONNECTORS

2.3.1 Inserts

2.3.1.1 Threaded-Type Concrete Inserts

ASTM A47/A47M, Grade 22010 Grade 32510 or 35018, or may be medium strength cast steel conforming to ASTM A27/A27M, Grade 415-205 Grade U-60-30.
Provide[ galvanized] ferrous casting having enlarged base with two nailing lugs minimum length less than the thickness of panel less 20 mm 3/4 inch, and internally threaded to receive 20 mm 3/4 inch diameter machine bolt. Ferrous castings must be ferritic malleable iron.[ Provide inserts hot-dip galvanized after fabrication in accordance with ASTM A153/A153M.]

2.3.1.2 Wedge-Type Concrete Inserts

Provide galvanized, box-type ferrous castings with integral anchor loop at back of box to accept 20 mm 3/4 inch diameter bolts having special wedge-shaped head. Provide ferrous castings [ASTM A47/A47M, Grade 22010, Grade 32510 or 35018, ferritic malleable iron][ or ][ASTM A27/A27M, Grade 415-205, Grade U-60-30, medium-strength cast steel].[ Provide inserts hot-dip galvanized after fabrication in accordance with ASTM A153/A153M.]

2.3.1.3 Slotted-Type Concrete Inserts

Provide pressed steel plate, welded construction, box type with slot to receive 20 mm 3/4 inch diameter square head bolt, and provide lateral adjustment of bolt. Length of insert body, less anchorage lugs, must be 110 mm 4 1/2 inches minimum. Provide insert with knockout cover. Steel plate must be 3 mm 1/8 inch minimum thickness, ASTM A283/A283M, Grade C.[ Provide inserts hot-dip galvanized after fabrication in accordance with ASTM A153/A153M.]

2.3.1.4 Wood Nailer Inserts

**************************************************************************
NOTE: Location and size of wood nailer inserts must be indicated.

NOTE: AWPA use category UC3A is for wood that is exposed to all weather cycles but not exposed to prolonged wetting. AWPA use category UC3B is for wood that is exposed to all weather cycles including prolonged wetting.
**************************************************************************

Inserts will be kiln-dried "standard" grade Douglas fir or "No. 2" grade southern pine, surfaced 4 sides, and sized as indicated. Treat with waterborne pressure-preservative in accordance with AWPA U1, use category [UC3A][UC3B]. All wood needs to be air or kiln dried after treatment. Verify specific treatments by the report of an approved independent inspection agency. The AWPA U1 Quality Mark ["UC3A"] ["UC3B"] on each piece will be accepted, in lieu of inspection reports, as evidence of compliance with applicable AWPA treatment standards.

2.3.1.5 Flashing Reglets

**************************************************************************
NOTE: Location of flashing reglets embedded in
**************************************************************************
Precast-concrete panels must be indicated.

Reglets must be sheet metal open-type with continuous groove not less than 30 millimeter deep by 5 millimeter wide 1-1/8 inches deep by 3/16-inch wide at opening and sloped upward, designed to anchor snap-lock counter flashing.

NOTE: Delete the following paragraphs if not applicable to the project.

When visible staining from the flashing reglets can occur, corrosion-resisting chromium-nickel steel only must be specified.

When the precast units will be subjected to a sea coast atmosphere, galvanized carbon steel flashing reglets must not be specified.

Metal must be minimum 0.28 millimeter 0.011-inch thick conforming to ASTM A666, Type 302 or 304, No. 1 finish, soft temper.

Metal must be copper strip weighing a minimum of 4.8 kilogram per square meter 16 ounces per square foot, and conforming to ASTM B370, cold-rolled temper.

Metal is to be 0.55 millimeter 26-gage galvanized steel sheet conforming to ASTM A653/A653M, Z275 G90.

2.3.2 Connection Devices

2.3.2.1 Clip Angles

ASTM A36/A36M steel, galvanized after fabrication in accordance with ASTM A153/A153M.

2.3.2.2 Ferrous Casting Clamps

ASTM A47/A47M, Grade 22010, Grade 32510 or Grade 35018 malleable iron or cast steel, or ASTM A27/A27M, Grade 415-205 Grade 60-30, cast steel casting, hot-dip galvanized in accordance with ASTM A153/A153M.

2.3.2.3 Threaded Fasteners

Provide galvanized machine bolts, washers and, when required, nuts.

b. Washers: ASME B18.21.1, medium or heavy lock-spring washers.

2.4 PRECAST ELEMENT FABRICATION

2.4.1 Formwork and Fabrication Tolerances

Provide forms and form-facing materials of wood, metal, plastic, or other approved material to produce concrete having the specified finish. Construct forms mortar-tight and of sufficient strength to withstand all pressures due to concrete placing operations and temperature changes. Brace and stiffen against deformation. Provide form liners where required to produce indicated finish. Provide dimensional tolerances per PCI MNL-117.

2.4.2 Reinforcement

ACI 301MACI 301. Place reinforcing bars and welded wire reinforcement. Secure in position with tie wires, bar supports, and spacers.

2.4.3 Preparation for Placing Concrete

Remove hardened concrete, excess form parting compound, standing water, ice, snow, or other deleterious substances from form interiors and reinforcement before concrete placement. Secure reinforcement and embedded items.

2.4.4 Concrete Mixing and Conveying

2.4.4.1 Batch Plant, Mixer, Mixing, and Measuring of Materials

ASTM C94/C94M.

2.4.4.2 Conveying

Prevent segregation and loss of materials.

2.4.5 Concrete Placing

ACI 304R. Deposit concrete in the forms continuously or in layers of such thickness that no concrete will be placed on concrete which has hardened sufficiently to cause formation of seams or planes of weakness within the precast concrete units. Place concrete at a constant temperature of between 10 and 32 degrees C 50 and 90 degrees F throughout fabrication of each unit. Make temperature of forms or molds the same as or close to the concrete temperature. For hot or cold weather, use methods recommended by ACI 305R and ACI 306.1. Vibrate and consolidate concrete to prevent segregation and to produce a high-density concrete free of honeycomb and rock pockets. When specified, the exposed-to-view facing mixture is required to be a minimum thickness of 20 mm 3/4 inches. Place backing mixture before facing mixture attains initial set.

2.4.6 Identification Markings

Permanently mark each precast unit to indicate pick-up points, location, orientation in the building, and date of casting. Identification markings need to correlate with approved detail drawings. Do not locate in exposed-to-view finished surfaces.
2.4.7 Finishing

2.4.7.1 Unformed Concealed Surfaces (Standard Smooth Finish)

Provide a trowel finish. Level surface with a straightedge, and strike off. After surface water has disappeared, float and trowel surface. Provide smooth finished surface, free of trowel marks, and uniform in texture and appearance.

2.4.7.2 Smooth, Exposed-to-View Surfaces

Provide a standard smooth finish to all exposed-to-view surfaces of panels, unless otherwise indicated. Provide a concrete surface having the texture imparted by a steel form or other approved smooth surfaces form-facing material.

2.4.7.3 Exposed Aggregate Finish

Provide for exposed-to-view surfaces of panels, including chamfers, edges, recesses, and projections, unless otherwise indicated. Provide standard smooth finish with outer skin of mortar removed, before concrete has hardened, and exposing coarse aggregate. A chemical retarder may be used on exposed face to facilitate removal of mortar. Match finish of the approved surface finish sample. Expose aggregates as soon after concrete placing as practicable [by wire brushing, sand blasting, or bush hammering] [by washing the concrete surface with a diluted solution of muriatic acid to thoroughly clean exposed aggregate. Rinse concrete surface with fresh, clean water to remove traces of acid].

2.4.7.4 Other Surfaces

Surfaces of precast units not exposed to view or not otherwise indicated to be finished are to be finished in accordance with ACI 301M ACI 301 for a Surface Finish of 1.0.

2.4.8 Curing

Provide moist or steam curing or curing compound. Do not remove precast units from forms; prevent moisture loss and maintain 10 degrees C 50 degrees F minimum for at least 24 hours after finishing. Maintain precast units in a surface damp condition at 10 degrees C 50 degrees F minimum until concrete has attained 75 percent minimum of the design compressive strength. [Do not use steam curing with wood forms or in connection with chemically retarded exposed aggregate surfaces].

2.4.9 Repair of Surface Defects

Cut out defective areas to solid concrete, with edges of cuts perpendicular to the surface of the concrete, and clean thoroughly. Dampen area to be patched and brush-coat with nonshrink grout or bonding agent. Patch the surface in accordance with procedures previously submitted by the Contractor and approved by the Contracting Officer. Where exposed to view, the patches, when dry, needs to be indistinguishable from the surrounding surfaces.

2.4.9.1 Smooth, Concealed Surfaces

Acceptable defective area will be limited to holes left by rods and other temporary inserts, and to honeycomb or rock pockets of 6 mm 1/4 inch.
diameter maximum. Remove fins and other projections on the surfaces.

2.4.9.2 Exposed-to-View Surfaces

The combined area of acceptable defective areas must not exceed 0.2 percent of the exposed-to-view surface area and will be limited to holes of 6 mm 1/4 inch diameter maximum.

2.4.10 Stripping

Do not remove precast concrete units from forms until units develop sufficient strength to safely strip the formwork and to remove the precast concrete units from the forms to prevent damage to the units from overstress or chipping.

2.4.11 Built-In Anchorage Devices

**************************************************************************
NOTE: Anchorage devices to be embedded in the panels must be indicated. Anchorage devices include threaded concrete inserts for bolted connections; wood nailers to receive thermal insulation that will be applied to the panel; and flashing reglets to receive sheetmetal counter flashing.
**************************************************************************

Accurately position and securely anchor all anchorage devices. Openings in anchorage devices must be filled temporarily to prevent entry of concrete.

2.4.12 Lifting Devices

Lifting devices must be provided, and designed for a safety factor of 4, which includes 100 percent impact. Do not use brittle material.

2.4.13 Finishing for Formed Surfaces

Upon removal of forms, repair and patch defective areas. Where the finished surface will be exposed to view, the combined area of defective areas must not exceed 0.2 percent of the surface and will be limited to honeycomb or rock pockets not deep enough to expose the reinforcement. Where the finished surface will be concealed by other construction, defective areas are limited to holes left by the rods and other temporary inserts and honeycomb or rock pockets not deep enough to expose the reinforcement. Defective areas must be cut out to solid concrete, cleaned, and patched with grout. Where concrete surface will be exposed to view, the patches, when dry, must be indistinguishable from the surrounding surfaces.

**************************************************************************
NOTE: Delete the following paragraph, and specify the required finish or finishes when an exposed-aggregate finish is not required for exposed-to-view panel surfaces. Other finishes include textured form finishes, sculptured inserts, rubbed finishes, and combinations thereof; such finishes may require the specified exposed-to-view facing mixture.
**************************************************************************

It is recommended that a sample of the required
Exposed-to-view finish be on display where it may be seen by bidders during the bidding period.

Exposed-aggregate finish must match the finish of the approved sample. Aggregates in exposed-to-view surfaces will be exposed as soon after concrete placing as practical by power sanders, wire brushes, or other acceptable methods. Give surfaces one or more washings with a dilute solution of muriatic acid, then washed with fresh, clean water to remove all traces of the acid.

Create an abrasive-blast finish using an abrasive grit, equipment, application techniques, and cleaning procedures to expose aggregate and surrounding matrix surfaces.

Create an acid-etched finish using acid and hot-water solution, equipment, application techniques, and cleaning procedures to expose aggregate and surrounding matrix surfaces. Protect hardware, connections, and insulation from acid attach.

Create a honed finish using a continuous mechanical abrasion with fine grit, followed by filling and rubbing procedures.

Create a polished finish using a continuous mechanical abrasion with fine grit, followed by filling and rubbing procedures.

2.5 JOINT MATERIALS

NOTE: Cross sections of gaskets with dimensions must be indicated.

Gasket must be elastomeric material, premolded to cross section indicated.

Material must be a vulcanized closed-cell expanded chloroprene conforming to ASTM D1056, Grade No. 2A2, with the following additional properties:

a. Brittleness temperature will be minus 5 degrees C 40 degrees F when tested in accordance with ASTM D746.

b. Flammability resistance needs to be self-extinguishing when tested in accordance with ASTM D635.

c. Resistance to ozone must be "no cracks" after exposure of a sample, at 20 percent elongation, to an ozone concentration of 100 parts per million of air by volume in air for 100 hours at 40 degrees C 104 degrees F when tested in accordance with ASTM D1149.

2.6 MISCELLANEOUS ARCHITECTURAL PRECAST CONCRETE SYSTEMS

2.6.1 Thin Brick Veneer

Not less than 13 mm 1/2 inch or more than 25 mm 1 inch thick, and as follows:

a. Dimensional Tolerances: Plus 0 mm 0 inch or minus 1.6 mm 1/16 inch for any dimension 203 mm 8 inches or less and plus 0 mm 0 inch or minus 2.4 mm 3/32 inch for any dimension more than 203 mm 8 inches.
b. Out-of-Square Tolerance: Plus or minus 1.6 mm 1/16 inch.
c. Warpage Tolerance: Plus 0 mm 0 inch or minus 1.6 mm 1/16 inch.
d. Variation of Shape from Specified Angle: Plus or minus one degree.
e. Modulus of Rupture: Not less than 1.7 MPa 250 psi when tested according to ASTM C67/C67M.
f. Tensile Bond Strength: Not less than 1.0 MPa 150 psi when tested before and after freeze-thaw test according to ASTM E488/E488M as modified: Adhere a steel plate with a welded rod on a single thin-brick face with epoxy for each test.
g. 24-Hour Cold-Water Absorption: Not more than 6 percent when tested according to ASTM C67/C67M.
h. Freeze-Thaw Resistance: No detectable disintegration or separation after 300 freezing-and-thawing cycles when tested according to ASTM C666/C666M, Method B.
i. Chemical Resistance: Tested according to ASTM C650 and rated "not affected."
j. Efflorescence: Tested according to ASTM C67/C67M and rated "not effloresced."
k. Surface Coating: Thin brick with colors or textures applied as coatings must withstand 50 cycles of freezing and thawing; ASTM C67/C67M with no observable difference in applied finish when viewed from 3 m 10 feet.
l. Back Surface Texture: Scored, combed, wire roughened, ribbed, keybacked, or dovetailed.
m. Face Size: [57 mm 2-1/4 inches high by 194 mm 7-5/8 inches long][57 mm 2-1/4 inches high by 295 mm 11-5/8 inches long][92 mm 3-5/8 inches high by 194 mm 7-5/8 inches long][92 mm 3-5/8 inches high by 295 mm 11-5/8 inches long][______].

Submit the following for thin brick veneer:

a. Brick Color chips representing color and size of each brick type to be used.
b. Form Liner Samples representing all brick inlay form liners which will be used.
c. Bond breaker sample on brick chip representing bond breaker which will be used.
d. Printed product data and installation instructions for brick inlay form liner system, and brick.

**************************************************************************
NOTE: Use the following paragraph when filling thin-brick joints with mortar before placing precast concrete.
**************************************************************************
2.6.1.1 Sand-Cement Mortar

Portland cement, ASTM C150/C150M, Type I, and clean, natural sand, ASTM C144. Mix at ratio of 1 part cement to 4 parts sand, by volume, with minimum water required for placement.

2.6.1.2 Pointing Grout

**************************************************************************
NOTE: Use the following paragraph when filling thin-brick joints with pointing grout after precast concrete panel production.
**************************************************************************

Packaged, polymer-modified, sanded grout complying with ANSI A118.7.

2.6.1.3 Thin Brick Facing

a. Place form liner templates accurately to provide grid for thin-brick facings. Provide solid backing and supports to maintain stability of liners while placing thin bricks and during concrete placement.

b. Securely place thin-brick units face down into form liner pockets and place concrete backing mixture.

**************************************************************************
NOTE: Delete the following two paragraphs if joint cavities are filled with concrete instead of using mortar or pointing grout.
**************************************************************************

c. Completely fill joint cavities between thin-brick units with sand-cement mortar, and place precast concrete backing mixture while sand-cement mortar is still fluid enough to ensure bond.

d. Mix and install pointing grout according to ANSI A108/A118/A136.1. Completely fill joint cavities between thin-brick units with pointing grout, and compress into place without spreading grout onto faces of thin-brick units. Remove excess grout immediately to prevent staining of thin brick.

2.7 BEARING PADS

Submit product data for all bearing pads being used.

2.7.1 Elastomeric

AASHTO M 251, for plain neoprene bearings.

2.7.2 Hardboard (Interior Only)

AHA A135.4, class as specified by the precast manufacturer.

2.7.3 Random-Oriented, Fiber-Reinforced Elastomeric Pads

Preformed, randomly oriented synthetic fibers set in elastomer. Surface hardness of 70 to 90 Shore A durometer according to ASTM D2240. Capable of supporting a compressive stress of 20.7 Mpa 3000 psi with no cracking,
splitting or delaminating in the internal portion of the pad.

2.7.4  Cotton-Duck-Fabric-Reinforced Elastomeric Pads

Preformed, horizontally layered cotton-duck fabric bonded to an elastomer. Surface hardness of 80 to 100 Shore A durometer according to ASTM D2240. Conforming to Division II, Section 18.10.2 of AASHTO LRFD Bridge Design Specifications or Military Specification MIL-C-882E.

2.7.5  Frictionless Pads

Polytetrafluoroethylene (PTFE), glass-fiber reinforced, bonded to stainless or mild-steel plates, or random-oriented, fiber-reinforced elastomeric pads, of type required for in-service stress.

2.7.6  High-Density Plastic

Multimonomer, nonleaching, plastic strip capable of supporting loads with no visible overall expansion.

2.8  INSULATED PANEL ACCESSORIES

2.8.1  Molded-Polystyrene (EPS) Board Insulation

ASTM C578, [Type XI, 12 kg/cu. m 0.70 lb/cu. ft][Type I, 15 kg/cu. m 0.90 lb/cu. ft][Type VIII, 18 kg/cu. m 1.15 lb/cu. ft][Type II, 22 kg/cu. m 1.35 lb/cu. ft][Type IX, 29 kg/cu. m 1.80 lb/cu. ft].

2.8.2  Extruded-Polystyrene (XPS) Board Insulation

ASTM C578, [Type X, 21 kg/cu. m 1.30 lb/cu. ft][Type IV, 25 kg/cu. m 1.55 lb/cu. ft][Type VI, 29 kg/cu. m 1.80 lb/cu. ft][Type VII, 35 kg/cu. m 2.20 lb/cu. ft][Type V, 48 kg/cu. m 3.00 lb/cu. ft].

2.8.3  Polyisocyanurate Board Insulation

ASTM C591, [Type I, 29 kg/cu. m 1.8 lb/cu. ft][Type II, 40 kg/cu. m 2.5 lb/cu. ft][Type III, 48 kg/cu. m 3.0 lb/cu. ft].

PART 3  EXECUTION

3.1  PREPARATION

Deliver anchorage devices to the site in time to be installed before the start of concrete placing or during steel erection. Contractor must provide setting drawings, instructions, and directions for the installation of anchorage devices.

3.2  EXAMINATION

Do not begin installation until supporting structures have been properly prepared.

Verify that all parts of the supporting structure are complete and ready to receive the precast units and that site conditions are conducive to proper installation.

If support structure is the responsibility of another installer, notify Contracting Officer of unsatisfactory preparation before proceeding.
3.3 INSTALLATION

Install precast concrete units and accessories in accordance with approved detail drawings and descriptive data, and as specified below.

3.3.1 Building Framing System

Provide supporting members, including anchorage items attached to or embedded in building structural elements, prior to placement of precast units.

3.3.2 Concrete Strength at Time of Precast Unit Installation

********************************************************************************
NOTE: Delete one of the following paragraphs as applicable to the project. First paragraph will be selected except when the project schedule indicates installation of 28-day units.
********************************************************************************

Do not install precast units until concrete has attained the minimum laboratory compressive strength at 28 calendar days specified.

Do not install precast units before 28 calendar days from the date of casting unless approval has been obtained to make one compressive strength test, ASTM C39/C39M, and one flexural strength test using simple beam with third-point loading, ASTM C78/C78M, on field cured concrete test specimens, ASTM C31/C31M, for each individual precast unit to determine the strength of the concrete.

3.3.3 Erection

Erect precast units in accordance with the detail drawings and without damage to other units or to adjacent members. Set units true to alignment and level, with joints properly spaced and aligned both vertically and horizontally. Erection tolerances must be in accordance with the requirements of PCI MNL-117 and PCI MNL-122. As units are being erected, shims and wedges will be placed as required to maintain correct alignment. After final attachment, grout precast units as shown. After erection, clean and touch-up welds and abraded surfaces of steel with a zinc-rich paint. Welds must be made by a certified welder in accordance with the manufacturer's erection drawings. Finish pickup points, boxouts, inserts, and similar items to match adjacent areas after erection. Erection of precast units must be supervised and performed by workmen skilled in this type of work. Welding and the qualifications of welders must be in accordance with AWS D1.1/D1.1M.

3.3.4 Erection Tolerances

Erect architectural precast concrete units level, plumb, square and in alignment without exceeding the noncumulative erection tolerances of PCI MNL-117, Appendix I.

3.3.5 Joints

Joint widths between precast units will be as specified unless otherwise indicated.
3.3.5.1 Joint Sealing

Joint sealing will be as specified in Section 07 92 00 JOINT SEALANTS.

3.3.6 Protection

Protect exposed-to-view facing from staining and other damage from subsequent operations. Do not allow laitance to penetrate, stain, or harden on exposed surfaces.

3.4 DEFECTIVE WORK

Repair precast concrete units damaged during erection as soon after occurrence as possible or replaced, as directed, using approved procedures. All repairs to precast concrete units must match the adjacent surfaces in color and texture, as approved. Unless otherwise approved, repair procedures will conform to PCI MNL-117.

3.5 JOINTS AND GASKETS

Joints between precast units must be the width indicated and within limits of installation tolerances.

Install gaskets in joints as indicated, continuous throughout the joint length, and compressed at least 25 percent by volume.

3.6 INSPECTION AND ACCEPTANCE PROVISIONS

3.6.1 Dimensional Tolerances

Precast units having dimensions outside the limits for fabrication tolerances will be rejected.

3.6.2 Surface Finish Requirements

Precast units will be rejected for the following surface finish deficiencies:

a. Exposed-to-view surfaces that do not match the color, aggregate size and distribution, and texture of the approved sample

b. Exposed-to-view surfaces that contain defects that affect the appearance of the finish, such as cracks, spalls, honeycomb, rock pockets, or stains and discoloration of aggregate or matrix that cannot be removed by cleaning

c. Concealed surfaces that contain cracks in excess of 0.2 millimeter 0.01 inch wide, cracks that penetrate to the reinforcement regardless of width, honeycomb, rock pockets, and spalls except minor breakage at corners and edges

3.6.3 Strength of Precast Units

Strength of precast concrete units will be considered potentially deficient if the units fail to comply with the requirements that control the strength of the units, including the following conditions:

a. Failure to meet compressive strength tests
b. Reinforcement not conforming to the requirements specified

c. Concrete curing and protection of precast units against extremes of temperature during curing not conforming to the requirements specified

d. Precast units damaged during handling and erection

3.6.4 Testing Precast Units for Strength

When there is evidence that the strength of precast concrete units does not meet specification requirements, cores drilled from hardened concrete for compressive strength determination must be made in accordance with ASTM C42/C42M and as follows:

a. Take at least three representative cores from the precast-concrete units that are considered potentially deficient.

b. Test cores with the saturated surface dry.

c. Strength of cores will be considered satisfactory if their average is equal to or greater than 90 percent of the 28-day design compressive strength of 150 by 300 millimeter 6 by 12 inch cylinders.

Submit test reports on the same day that tests are made. Reports must contain the project name and number, date, name of contractor, name of precast concrete wall units manufacturer, name of concrete-testing service, identification letter and number of units represented by core tests, nominal maximum size of aggregate, design compressive strength of concrete at 28 calendar days, compressive breaking strength and type of break, length of core test specimen before capping, compressive strength after correcting for length diameter ratio, direction of application of the load on the core test specimen with respect to the horizontal plane of the concrete as placed, and the moisture condition of the core test specimen at time of testing.

If the results of the core tests are unsatisfactory or if core tests are impractical to obtain, a static load tests of a precast unit will be evaluated in accordance with ACI 318M ACI 318.

Replace precast units used for core tests or static load tests with units that meet the requirements of this section.

3.7 SAMPLING AND TESTING

3.7.1 Rejection

Precast units in place may be rejected for any one of the following product defects or installation deficiencies remaining after repairs and cleaning have been accomplished. "Visible" means visible to a person with normal eyesight when viewed from a distance of 6 m 20 feet in broad daylight.

a. Nonconformance to specified tolerances.

b. Air voids (bugholes or blowholes) larger than 10 mm 3/8 inch diameter.

c. Visible casting lines.

d. Visible from joints.
e. Visible irregularities.
f. Visible stains on precast unit surfaces.
g. Visible differences between precast unit and approved sample.
h. Visible non-uniformity of textures or color.
i. Visible areas of backup concrete bleeding through the facing concrete.
j. Visible foreign material embedded in the face.
k. Visible repairs.
l. Visible reinforcement shadow lines.
m. Visible cracks.
n. Precast units that are damaged during construction operations.

3.7.2 Field Quality Control

Perform field inspection of precast unit connections. Notify the Contracting Officer in writing of defective welds, bolts, nuts and washers within 7 working days of the date of inspection. All defective connections or welds are to be removed and re-welded or repaired as required by the Contracting Officer.

3.7.2.1 Welded Connection Visual Inspection

AWS D1.1/D1.1M, furnish the services of AWS-certified welding inspector for erection inspections. Welding inspector must visually inspect all welds and identify all defective welds.

3.8 CLEANING

Clean exposed-to-view surfaces of precast units thoroughly with detergent and water; use a brush to remove foreign matter. Remove stains that remain after washing in accordance with recommendations of the precast manufacturer. Surfaces must be clean and uniform in color. Include precast concrete wall panel manufacturer's written recommendations for installation and cleaning.

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for precast non-prestressed and precast prestressed concrete used for structural purposes (floor units, roof units, joists, beams, planks, columns, single- and double-tee slabs, hollow-cored flat slabs, tee- or keystone-joists, and other structural framing elements, etc.) and for minor architectural purposes (copings, window sills, etc.) in building and waterfront facilities construction.

Adhere to [UFC 1-300-02](#) Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

NOTE: This guide specification does not cover precast concrete wall panels (Section 03 45 00 PRECAST ARCHITECTURAL CONCRETE), major precast non-prestressed architectural concrete, post tensioned concrete, or precast concrete which is site manufactured and must not be used for bridge or roadway construction. Precast concrete sound fences should be considered in lieu of block walls for use where sound barriers are used for noise abatement.
NOTE: The following information must be shown on the project drawings:

1. Live and dead loads, and whether the topping is included in the dead load.

2. Details of fitting, bearing, and connections.

3. Location of expansion and control joints.

4. Layout of the framing system indicating the relative location of the various precast structural concrete sections, floor elevations, column centers and offsets, openings, and sufficient dimensions to adequately convey the quantity and nature of the required precast structural concrete framing system.

5. Details of all precast structural concrete sections indicating cross-sections and dimensions.

6. Location of precast structural concrete sections having an architectural finish on exposed-to-view surfaces when required.

7. Details of openings including the size of steel framing members as required.

8. Style and area of steel welded wire reinforcement in areas where required. Kind and size of reinforcing bars and spacing.

10. Detail of placement of sealant or fillers in joints.

11. Fire rating.

12. Lightweight concrete unit weight.

13. Special requirements for concrete cover over reinforcing.

14. Areas where toppings are required, indicate areas where the full thickness of the topping is not present.

15. Camber.

16. Tendon types, physical properties, and allowable design stresses.
PART 1   GENERAL

1.2 MODIFICATION TO REFERENCE

In the ACI publications, reference to the "Building Official," the "Structural Engineer" and the "Architect/Engineer" must be interpreted to mean the Contracting Officer.

1.3 SUBMITTALS

**************************************************************************
NOTE: Review Submittal Description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

SECTION 03 45 33 Page 10
Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

1.4 QUALITY ASSURANCE

1.4.1 Qualifications

1.4.1.1 Manufacturer Qualifications

******************************************************************************
NOTE: Use first bracketed paragraph unless no PCI certified plant are available. Then select the second paragraph.

******************************************************************************

[ PCI MNL-116. Plants must be certified by the PCI Plant Certification Program for Category [C1] [C2] [C3] [C4] work. At the Contracting Officer's option, PCI Plant quality control program records must be available for review.
]

Erector with erecting organization and all erecting crews certified and designated by PCI's Certificate of Compliance to erect Category[ S1 (Simple Structural Systems)][ S2 (Complex Structural Systems)].

1.4.1.2 Erector Certification

******************************************************************************
NOTE: Use Category S1 for horizontal decking members such as hollow core slabs. Use Category S2 for total precast concrete systems, vertical and horizontal load bearing members, and single- or multistory loadbearing members, including those with architectural finishes.
******************************************************************************

[PCI MNL-116. Where panels are manufactured by specialists in plants not currently enrolled in the PCI "Quality Control Program," provide a product quality control system in accordance with PCI MNL-116 and perform concrete and aggregate quality control testing using an approved, independent commercial testing laboratory. Submit test results to the Contracting Officer.
]

1.4.1.3 Erector Qualifications
NOTE: Use the following paragraph when a PCI Certified erector is not available in the project location.

A precast erector that is not certified by PCI must retain a PCI-Certified Field Auditor, at the erector's expense, to conduct a field audit of a project in the same category as this project prior to start of precast concrete erection and must submit the Erector's Post Audit Declaration to be considered qualified.

1.4.1.4 Welding Qualifications

Provide AWS D1.1/D1.1M qualified welders who are currently certified at contract award date and have maintained their certificates over the past year.

1.4.2 Regulatory Requirements

NOTE: Modify to add any local codes and regulations.

Provide precast [prestressed] members in conformance with ACI 318M ACI 318 and PCI MNL-120.

1.4.3 Concrete Mix Design

NOTE: Normal precast design is based on concrete having a compressive strength of 35 MPa 5000 psi at 28 days. Some precast manufacturers like to speed up production by using Type III (high early strength) concrete. For marine exposure, (moderate and severe sulfate exposure) include last bracketed sentence, which limits the water-cement ratio to a maximum of 0.40.

NOTE: Delete air entraining requirements when the project is located in a nonfreezing climate.

ACI 318MACI 318. The minimum compressive strength of concrete at [28] [_____] days must be 35 MPa 5000 psi [____], unless otherwise indicated. Add air-entraining admixtures at the mixer to produce between 4 and 6 percent air by volume. For marine exposure, ensure a dense concrete free of shrinkage cracks, with a minimum degree of permeability. The maximum water cement ratio must be 0.40.

Sixty days minimum prior to concrete placement, submit a mix design for each strength and type of concrete. Submit a complete list of materials including type; brand; source and amount of cement, complementary cementitious materials, [polypropylene fibers], and admixtures; and applicable reference specifications. Submit mill test and all other test for cement, complementary cementitious materials, aggregates, and admixtures. Provide documentation of maximum nominal aggregate size, gradation analysis, percentage retained and passing sieve, and a graph of...
percentage retained verses sieve size. Provide mix proportion data using at least three different water-cementitious material ratios for each type of mixture, which produce a range of strength encompassing those required for each type of concrete required. If source material changes, resubmit mix proportion data using revised source material. Provide only materials that have been proven by trial mix studies to meet the requirements of this specification, unless otherwise approved in writing by the Contracting Officer. Indicate clearly in the submittal where each mix design is used when more than one mix design is submitted. Resubmit data on concrete components if the qualities or source of components changes. For previously approved concrete mix designs used within the past twelve months, the previous mix design may be re-submitted without further trial batch testing if accompanied by material test data conducted within the last six months. Obtain mix design approval from the contracting officer prior to concrete placement.

1.4.4 Certificates: Record Requirement

ASTM C94/C94M. Submit mandatory batch ticket information for each load of ready-mixed concrete.

1.5 DELIVERY, STORAGE, AND HANDLING

1.5.1 Transportation

1.5.1.1 Transporting Members

Transport members in a manner to avoid excessive stresses that could cause cracking or other damage.

1.5.1.2 Lateral Deflection or Vibration

Any noticeable indication of lateral deflection or vibration during transportation must be corrected by rigid bracing between members or by means of lateral trussing.

1.5.2 Storage

1.5.2.1 Storage Areas

Storage areas for precast [prestressed] members must be stabilized, and suitable foundations must be provided, so differential settlement or twisting of members will not occur.

1.5.2.2 Stacked Members

Stack members with adequate dunnage and bracing to control cracking, distortion, warping or other physical damage. Stack members such that lifting devices will be accessible and undamaged.

1.5.3 Handling of Members

The location of pickup points for handling of the members and details of the pickup devices must be shown in shop drawings. Members must be handled only by means of approved devices at designated locations. Members must be maintained in an upright position at all times and picked up and supported as shown in approved shop drawings.
PART 2   PRODUCTS

2.1   SYSTEM DESCRIPTION

The work includes the provision of precast[ non-prestressed concrete herein referred to as precast members] and[ precast, prestressed concrete herein referred to as prestressed members] except that precast concrete wall panels must be provided as specified in Section 03 45 00 PRECAST ARCHITECTURAL CONCRETE. [Precast][ and ][Prestressed] members must be the product of a manufacturer specializing in the production of precast [prestressed] concrete members.

**************************************************************************
NOTE: When concrete toppings are indicated, they are normally allowed to be used in establishing the design strength of the precast [prestressed] member. However, areas where the topping is not the full thickness, and areas without topping located inside of larger areas with topping need to be indicated so that the topping is not used in the untopped areas to establish the design strength of the precast [prestressed] members.
**************************************************************************

2.1.1   Design Requirements

Design precast [prestressed] members in accordance with ACI 318M ACI 318 and the PCI MNL-120. Design precast [prestressed] members (including connections) for the design load conditions and spans indicated, and handling and erection stresses, and for additional loads imposed by openings and supports of the work of other trades. Design precast[ prestressed] members for handling without cracking in accordance with the PCI MNL-120. [Concrete toppings must [not] be used in establishing the design strength of the precast[ prestressed] members.]

**************************************************************************
NOTE: Evaluate the loading requirements for the member design including all dead and live loads, and other specified loads for member, where applicable. Show design loads on the drawings. The designer of the precast [prestressed] members should also consider the effects of initial handling and erection stress in the final design of the elements.
**************************************************************************

2.1.1.1   Loads

Loadings for members and connections must include all dead load, live load, applicable lateral loads such as wind and earthquake, applicable construction loads such as handling, erection loads, and other applicable loads.

2.1.1.2   Drawing and Design Calculation Information

**************************************************************************
NOTE: Modify requirements based on the scope of the project.
**************************************************************************
Submit drawings and design calculations indicating complete information for the fabrication, handling, and erection of the precast[ prestressed] member. Include a cover page with the design calculations, signed and sealed by the registered design professional who prepared the design. Drawings must not be reproductions of contract drawings. Design calculations[, drawings of precast members][, and ]drawings of precast prestressed concrete members] (including connections) must be made by a registered professional engineer experienced in the design of precast [prestressed ]concrete members, and submitted for approval prior to fabrication. The drawings must indicate, as a minimum, the following information:

a. Plans, elevations and other drawing views showing the following:

   (1) Member piece marks locating and defining products furnished by the manufacturer.

   (2) Headers for openings.

   (3) Location and size of openings [that cut prestressing strands or require the location of prestressing strands to miss field cut openings].

   (4) Relationships to adjacent material.

   (5) Joints and openings between members and between members and other construction.

   (6) Location of field installed anchors.

   (7) Erection sequences and handling requirements

[  (8) Areas receiving toppings and magnitude of topping thickness. Identify areas where topping is an integral part of the structural capacity of the precast members.

  ]  (9) Lifting and erection inserts

b. Elevations, sections and other details for each member showing the following:

   (1) Connections between members and connections between members and other construction.

   (2) Connections for work of other trades and cast-in items and their relation to other trades.

   (3) Dimensioned size and shape for each member with quantities, position and other details of reinforcing steel, anchors, inserts and other embedded items.

   (4) Lifting, erection and other handling devices and inserts.

   (5) Surface finishes of each member.

   (6) Estimated cambers

[  c. Magnitude, schedule and sequence of tensioning and detensioning prestressing strands.

SECTION 03 45 33 Page 16
2.1.2 Performance Requirements

**************************************************************************
NOTE: Edit when precast [prestressed] members are to be fire rated. On most large jobs, not all members will have the same fire rating, so fire ratings for each specific member should be indicated for clarity.
**************************************************************************

Precast[ prestressed] members [where indicated] must have a fire rating [of [_____] -hours] [as indicated] in accordance with UL Fire Resistance, or as designed in accordance with PCI MNL-124.

2.2 MATERIALS

2.2.1 Material Sustainability Criteria

For products in this section, where applicable and to extent allowed by performance criteria, provide and document the following in accordance with Section 01 33 29 SUSTAINABILITY REQUIREMENTS AND REPORTING:

a. Recycled content for fly ash and pozzolan
b. Recycled content for Ground Iron Blast-Furnace Slag
c. Recycled content for Silica Fume

2.2.2 Cementitious Materials

**************************************************************************
NOTE: Acceptable types of cement are as follows:
**************************************************************************

<table>
<thead>
<tr>
<th>ASTM C150/C150M Portland</th>
<th>ASTM C595/C595M Blended</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type I</td>
<td>Type IP, IS, IL, or IT</td>
<td>For general use in contraction</td>
</tr>
<tr>
<td>ASTM C150/C150M Portland</td>
<td>ASTM C595/C595M Blended</td>
<td>Use</td>
</tr>
<tr>
<td>--------------------------</td>
<td>--------------------------</td>
<td>-----</td>
</tr>
<tr>
<td>Type II</td>
<td>Type IP, IS, IL, or IT (MS) or (MH)</td>
<td>For general use in construction where concrete is exposed to moderate sulfate action or where moderate heat of hydration is required. ASTM C595/C595M (blended hydraulic cements): add the suffix MS or MH where either moderate sulfate resistance or moderate heat of hydration, respectively, is required.</td>
</tr>
<tr>
<td>Type III</td>
<td>Type IP, IS, IL, or IT (HE)</td>
<td>For use when high early strength is required. ASTM C595/C595M (blended hydraulic cements): add the suffix HE where high early strength is required. Confer with the agency’s Subject Matter Expert in Concrete Materials before specifying High early strength cement.</td>
</tr>
<tr>
<td>Type V</td>
<td>Type IP, IS, IL, or IT (HS)</td>
<td>For use when high sulfate resistance is required. ASTM C595/C595M (blended hydraulic cements): add the suffix HS where high sulfate resistance is required.</td>
</tr>
</tbody>
</table>

For concrete subjected to salt water, near salt water or exposed to alkali/sulfate soils refer to specification Section 03 31 30 MARINE CONCRETE for additional criteria.

**************************************************************************
NOTE: For NAVFAC LANT: Typically allow Type II, IP (MS), or IS (MS). May use Type I if Type II not locally available and no sulfate problems expected (i.e., not near seawater or sulfate soils). Type III is for high early strength. Type V, IP (HS), IS (HS), IL (HS), and IT (HS) are for high sulfate resistance.
**************************************************************************

NOTE: Coal fly ash, slag, cenospheres, and silica fumes are EPA designated products to be ingredients
in concrete and cement. See Section 01 33 29
SUSTAINABILITY REQUIREMENTS AND REPORTING and
include additive options unless designer determines
that justification for non-use exists.

**************************************************************************
For exposed concrete, use one manufacturer and one source for each type of
cement, ground slag, fly ash, and pozzolan.

2.2.2.1 Fly Ash

**************************************************************************
NOTE: Fly ash, pozzolan, and slag cement may
produce uneven discoloration of the concrete during
the early stages of construction, depending upon the
type of curing provided. Fly ash or pozzolan
meeting the specified test results, which are more
stringent than ASTM C618, should provide acceptable
end results. It is suggested that fly ash be used
as a replacement for 35 percent of the cement.
Class C fly ash is not permitted.

**************************************************************************
ASTM C618, Class F, except that the maximum allowable loss on ignition must
not exceed [3][6] percent.

Add with cement. Fly ash content must be a minimum of
[15][20][30][35][40][_____] percent by weight of cementitious material,
provided the fly ash does not reduce the amount of cement in the concrete
mix below the minimum requirements of local building codes. Where the use
of fly ash cannot meet the minimum level, provide the maximum amount of fly
ash permissible that meets the code requirements for cement content.
Report the chemical analysis of the fly ash in accordance with
ASTM C311/C311M. Evaluate and classify fly ash in accordance with
ASTM D5759.

2.2.2.2 Raw or Calcined Natural Pozzolan

Natural pozzolan must be raw or calcined and conform to ASTM C618, Class N,
including the optional requirement for uniformity.

2.2.2.3 Ultra Fine Fly Ash and Ultra Fine Pozzolan

Ultra Fine Fly Ash (UFFA) and Ultra Fine Pozzolan (UFP) must conform to
ASTM C618, Class F or N, and the following additional requirements:

a. The strength activity index at 28 days of age must be at least 95
   percent of the control specimens.

b. The average particle size must not exceed 6 microns.

c. The sum of SiO2 + Al2O3 + Fe2O3 must be greater than 77 percent.

2.2.2.4 Ground Granulated Blast-Furnace Slag

ASTM C989/C989M, Grade [100][120]. Slag content must be a minimum of
[25][50][70] percent by weight of cementitious material.
2.2.2.5 Silica Fume

NOTE: Silica Fume must only be used for OCONUS projects where Class F fly ash and GGBF slag are not available, and when approved by the Contracting Officer. Guidance for use of silica fume should be sought from the agency's Subject Matter Expert in Concrete Materials.

NOTE: The initial cost of the concrete must increase, and supervision at the batch plant, finishing, and curing is necessary. A HRWR must be used with silica fume, the slump can be increased 50 to 125 mm 2 to 5 inches without reducing strength. Finishing may be more difficult. Proper curing is essential because there is a tendency for plastic shrinkage cracking.

Silica fume must conform to ASTM C1240, including the optional limits on reactivity with cement alkalis. Silica fume may be furnished as a dry, densified material or as slurry. Proper mixing is essential to accomplish proper distribution of the silica fume and avoid agglomerated silica fume which can react with the alkali in the cement resulting in premature and extensive concrete damage. Supervision at the batch plant, finishing, and curing is essential. Provide at the Contractor's expense the services of a manufacturer's technical representative, experienced in mixing, proportioning, placement procedures, and curing of concrete containing silica fume. This representative must be present on the project prior to and during at least the first 4 days of concrete production and placement using silica fume. A High Range Water Reducer (HRWR) must be used with silica fume.

2.2.2.6 Portland Cement

NOTE: If high early strength concrete is required, specify Type III after consulting the agency's Subject Matter Expert in Concrete Materials.

When concrete is exposed to sea water use specification Section 03 31 30 MARINE CONCRETE.

When high-volume fly ash mixtures, mixtures where fly ash replacement of portland cement is greater than 50 percent by weight, are specified they may be blended with Type II or Type III cement for higher early strength. Consult the agency's Subject Matter Expert in Concrete Materials prior to using Type III cement.

Provide cement that conforms to ASTM C150/C150M, Type [I][II][III], [including false set requirements] with tri-calcium aluminates (C3A) content less than 10 percent and a maximum cement-alkali content of 0.80 percent Na2Oe (sodium oxide) equivalent. Use one brand and type of cement.
for formed concrete having exposed-to-view finished surfaces.

[For portland cement manufactured in a kiln fueled by hazardous waste, maintain a record of source for each batch.][ Supplier must certify that no hazardous waste is used in the fuel mix or raw materials.][ Supplier must certify that the hazardous waste is neutralized by the manufacturing process and that no additional pollutants are discharged.]

2.2.2.7 Blended Cements

a. Blended cements must conform to ASTM C595/C595M Type [IP,] [IS,] [IL,] [IT,] [IP (MS),] [IS (MS),] [IL (MS),] [IT (MS),] [IP (MH),] [IS (MH),] [IL (MH),] [IT (MH),] [IP (LS),] [IS (LS),] [IL (LS),] [IT (LS),] [IP (HS),] [IS (HS),] [IL (HS),] [IT (HS),] [IP (HE),] [IS (HE),] [IL (HE),] [IT(HE),] or ASTM C1157/C1157M Type [GU][MS] [MH] [HE].

b. Slag cement added to the Type IS blend must meet ASTM C989/C989M.

c. The pozzolan added to the Type IP blend must be ASTM C618 [Class F,] [Class C,] or [Class N] and must be interground with the cement clinker. The manufacturer must state in writing that the amount of pozzolan in the finished cement will not vary more than plus or minus 5 mass percent of the finished cement from lot-to-lot or within a lot. The percentage and type of pozzolan used in the blend must not change from that submitted for the aggregate evaluation and mixture proportioning.

2.2.3 Water

Water must comply with the requirements of ASTM C1602/C1602M. Minimize the amount of water in the mix. Improve workability by adjusting the grading rather than by adding water. Water must be [potable][from rainwater collection][from graywater][from recycled water]; free from injurious amounts of oils, acids, alkalis, salts, organic materials, or other substances deleterious to concrete. Submit test report showing water complies with ASTM C1602/C1602M.

2.2.4 Aggregates

ASTM C33/C33M, except as modified herein. Furnish aggregates for exposed concrete surfaces from one source. Provide aggregates that do not contain any substance which may be deleteriously reactive with the alkalies in the cement. Submit test report showing compliance with ASTM C33/C33M.

Fine and coarse aggregates must show expansions less than 0.08 percent at 28 days after casting when testing in accordance with ASTM C1260. Should the test data indicate an expansion of 0.08 percent or greater, reject the aggregate(s) or perform additional testing using ASTM C1567 using the Contractor's proposed mix design. In this case, include the mix design low alkali portland cement and one of the following supplementary cementitious materials:

a. GGBF slag at a minimum of 40 percent of total cementitious

b. Fly ash or natural pozzolan at a minimum of total cementitious of

   (1) 30 percent if (SiO2 plus Al2O3 plus Fe2O3) is 65 percent or more,
   (2) 25 percent if (SiO2 plus Al2O3 plus Fe2O3) is 70 percent or more,
(3) 20 percent if \((\text{SiO}_2 \text{ plus } \text{Al}_2\text{O}_3 \text{ plus } \text{Fe}_2\text{O}_3)\) is 80 percent or more,
(4) 15 percent if \((\text{SiO}_2 \text{ plus } \text{Al}_2\text{O}_3 \text{ plus } \text{Fe}_2\text{O}_3)\) is 90 percent or more.

[ c. Silica fume at a minimum of 7 percent of total cementitious.

] If a combination of these materials is chosen, the minimum amount must be a linear combination of the minimum amounts above. Include these materials in sufficient proportion to show less than 0.08 percent expansion at 28 days after casting when tested in accordance with ASTM C1567.

Aggregates must not possess properties or constituents that are known to have specific unfavorable effects in concrete when tested in accordance with ASTM C295/C295M.

[2.2.4.1] Aggregates for Lightweight Concrete

ASTM C330/C330M.

[2.2.5] Grout

2.2.5.1 Nonshrink Grout

ASTM C1107/C1107M.

2.2.5.2 Cementitious Grout

**************************************************************************
NOTE: Delete air entraining requirements when the project is located in a nonfreezing climate.
**************************************************************************

Must be a mixture of portland cement, sand, and water. Proportion one part cement to approximately 2.5 parts sand, with the amount of water based on placement method. [ Provide air entrainment for grout exposed to the weather.]

2.2.6 Admixtures

[2.2.6.1] Air-Entraining

**************************************************************************
NOTE: Delete air entraining requirements when the project is located in a nonfreezing climate.
**************************************************************************

ASTM C260/C260M.

[2.2.6.2] Accelerating

ASTM C494/C494M, Type C or E.

2.2.6.3 Water Reducing

ASTM C494/C494M, Type A, E, or F.
2.2.7 Reinforcement

2.2.7.1 Reinforcing Bars

**************************************************************************

NOTE: Specify ASTM A706/A706M reinforcing where welding or bending of reinforcement bars is important. In addition in locations where reinforcing maybe subject to corrosive environmental conditions such as bridge decking use either epoxy coated reinforcement, epoxy coated prefabricated steel reinforcing bars or zinc-coated (galvanized) bars, ASTM A775/A775M epoxy coated reinforcing, ASTM A934/A934M epoxy coated prefabricated steel reinforcing bars or ASTM A767/A767M respectively may be specified where extra reinforcement protection is required.

**************************************************************************

ASTM A615/A615M, Grade [280] [420] [40] [60]; [ASTM A706/A706M, Grade 420 60]; or ASTM A996/A996M, Grade [350][420] [50] [60].

[ Epoxy-coated steel bars must comply with the requirements of { ASTM A775/A775M}[ASTM A934/A934M], including written certifications for coating material and coated bars, sample of coating material, and 700 g 0.5 pounds of patching material. Submit written certification with the delivery of the bars.

][Zinc-coated (galvanized) bars must comply with the requirements of ASTM A767/A767M, Class II coating, galvanized after fabrication.

]2.2.7.2 Wire

ASTM A1064/A1064M.

2.2.7.3 Welded Wire Reinforcement

ASTM A1064/A1064M.

2.2.7.4 Supports for Concrete Reinforcement

Include bolsters, chairs, spacers, and other devices necessary for proper spacing, supporting, and fastening reinforcement bars and wire in place.

Ensure legs of supports in contact with formwork for sections that will be exposed to weather are hot-dip galvanized after fabrication, plastic coated, or corrosion-resistant steel bar supports.

2.2.8 Prestressing Strands

[ Uncoated, 7-wire strand stress- relieved, ASTM A416/A416M, Grade 1725 250 1860 270, strand diameter as shown.

][Single wire stress- relieved, ASTM A421/A421M for low relaxation wire.

][High-strength steel bars must conform to ASTM A722/A722M, Type I or II, meeting all supplementary requirements.
2.2.9 Metal Accessories

Provide ASTM A123/A123M or ASTM A153/A153M galvanized.

2.2.9.1 Inserts

ASTM A47/A47M, Grade 22010 32510, or ASTM A27/A27M Grade 415-205 60-30. Submit product data.

2.2.9.2 Structural Steel

ASTM A36/A36M.

2.2.9.3 Bolts

ASTM A307; ASTM A325M ASTM A325.

2.2.9.4 Nuts

ASTM A563M ASTM A563.

2.2.9.5 Washers

2.2.10 Bearing Pads

Submit product data for all bearing pads being used.

2.2.10.1 Elastomeric

AASHTO M 251, for plain neoprene bearings.

2.2.10.2 Hardboard (Interior Only)

AHA A135.4, class as specified by the precast manufacturer.

2.2.10.3 Random-Oriented, Fiber-Reinforced Elastomeric Pads

Preformed, randomly oriented synthetic fibers set in elastomer. Surface hardness of 70 to 90 Shore A durometer according to ASTM D2240. Capable of supporting a compressive stress of 20.7 Mpa 3000 psi with no cracking, splitting or delaminating in the internal portion of the pad.

2.2.10.4 Cotton-Duck-Fabric-Reinforced Elastomeric Pads

Preformed, horizontally layered cotton-duck fabric bonded to an elastomer. Surface hardness of 80 to 100 Shore A durometer according to ASTM D2240. Conforming to Division II, Section 18.10.2 of AASHTO LRFDCONS Bridge Design Specifications or Military Specification MIL-C-882.

2.2.10.5 Frictionless Pads

Polytetrafluoroethylene (PTFE), glass-fiber reinforced, bonded to stainless or mild-steel plates, or random-oriented, fiber-reinforced elastomeric pads, of type required for in-service stress.
2.2.10.6 High-Density Plastic

Multimonomer, nonleaching, plastic strip capable of supporting loads with no visible overall expansion.

2.3 PRODUCTION QUALITY CONTROL PROCEDURES

**************************************************************************
NOTE: Refer to PCI for tolerance information.
Modify to add critical tolerance if different than PCI.
**************************************************************************

PCI MNL-116 unless specified otherwise. Submit quality control procedures established in accordance with PCI MNL-116 by the precast manufacturer.

2.3.1 Forms

Brace forms to prevent deformation. Forms must produce a smooth, dense surface. Use forms and form-facing materials that are nonreactive with concrete such as wood, metal, plastic, or other approved materials. Conform to the shapes, lines, and dimensions indicated and are within the limits of the specified fabrication tolerances. Chamfer exposed edges of columns and beams 200 mm 3/4 inch, unless otherwise indicated. Provide threaded or snap-off type form ties.

2.3.2 Tolerances

Fabricate structural precast concrete members of shapes, lines and dimensions indicated, so each finished member complies with PCI MNL-135 product tolerances as well as position tolerances for cast-in items.

2.3.3 Reinforcement Placement

ACI 318MACI 318 and PCI MNL-116 for placement and splicing. Place and secure steel bars, welded-wire reinforcement, and other reinforcement by means of metal bar supports and spacers. Reinforcement may be preassembled before placement in forms. Provide exposed connecting bars, or other approved connection methods, between precast [prestressed ]and cast-in-place construction. Remove any excess mortar that adheres to the exposed connections.[ Provide curvature or drape of the prestressing strands using approved hold-down devices.]

2.3.4 Inserts

When the ends of the prestressed member will be exposed, recess the prestressing stands using inserts. After detensioning, remove inserts and fill the recess with nonshrink grout.

2.3.5 Built-In Anchorage Devices

**************************************************************************
NOTE: Indicate anchorage devices that are to be embedded in the precast structural concrete sections. Anchorage devices include weld plates, bearing plates and steel shapes.
**************************************************************************

Position, anchor, and locate anchorage devices where they do not affect the
position of the main reinforcement or placing concrete. Bearing plates; set level, aligned properly, and anchored in the exact location indicated.

2.3.6 Lifting Devices

Provide lifting devices designed for 100-percent impact, and of materials sufficiently ductile to ensure visible deformation before fracture.

2.3.7 Blockouts

**************************************************************************

NOTE: Blockouts or openings in slabs that would require the cutting of primary reinforcement if such openings were to be cut in the field ensure openings are cast in the unit during fabrication and indicated. The maximum size of field-cut openings may be from 150 to 300 millimeter 6 to 12 inches depending on the type of unit used such as the inside diameter of the voids in hollow core flat slabs and the spacing of reinforcement.

**************************************************************************

Provide blockouts as indicated.

2.3.8 Identification Markings

Clearly mark each structural section in a permanent manner to indicate its location and orientation in the building and the pickup points.

Ensure each structural section has the date of casting plainly indented in the unexposed face of the concrete.

2.3.9 Concrete

2.3.9.1 Concrete Mixing

ASTM C94/C94M. Mixing operations must produce batch-to-batch uniformity of strength, consistency, and appearance.

2.3.9.2 Concrete Placing

PCI MNL-116.

2.3.9.3 Concrete Curing

PCI MNL-116.

2.3.10 Prestressing

**************************************************************************

NOTE: For normal prestressing use a release strength of 23 MPa 3500 psi, unless the design requires a higher release strength. Some release strengths are indicated in the PCI Design Handbook for selected prestressed members based on different load conditions, strand patterns, and span lengths.

**************************************************************************

PCI MNL-116. Do not transfer prestressing forces during detensioning until
the concrete has reached a minimum compressive strength of \( [24 \text{ MPa}] \) \([3500 \text{ psi}] \) \([_____]\), unless a higher strength is required by the Contractor furnished design.

2.3.11 Surface Finish

Repairs located in a bearing area must be approved by the Contracting Officer prior to repairs. Defects must be repaired or rejected as specified in paragraph ACCEPTANCE/REJECTION OF DEFECTS.

**************************************************************************

NOTE: Sample panels should only be required when a finish Grade A or better is specified.
**************************************************************************

[ Submit two 300 by 300 by 50 mm 12 by 12 by 2 inch thick sample panels representative of the color and finish for each type of precast member requiring a finish Grade \[A]\[_____]\] surface finish.

2.3.11.1 Unformed Surfaces

Provide a [floated] [steel troweled] finish.

2.3.11.2 Formed Surfaces

**************************************************************************

NOTE: PCI MNL-116 different grades of formed surface finishes:

Commercial Grade: Concrete produced in forms that produce a rough finish. Fins are removed and large surface blemishes filled. Sharp edges that will be visible in the finished structure are ground down.

Standard Grade: Same finish as commercial grade, except the forms do not produce a texture on the concrete. Surface can be painted, but will have surface voids.

Finish Grade B: Same as standard grade, except all surface blemishes should be filled or finished to provide a smooth surface or uniform appearance if painted.

Finish Grade A: Same as Finish Grade B, except that the components of the completed structure, where exposed, must be reasonably color matched. This finish is difficult to obtain.

**************************************************************************

PCI MNL-116, Appendix C, for grades of surface finishes.

a. Unexposed Surfaces: Provide a [commercial] [standard] grade surface finish.

b. Exposed Surfaces: Provide a [standard grade] [finish Grade B] [_____] surface finish.[ The combined area of acceptable defective areas must not exceed 0.2 percent of the exposed to view surface area, and the patches must be indistinguishable from the surrounding surfaces when
In addition to a Grade B surface finish, members must have a smooth rubbed finish.

2.3.11.3 Architectural Finish

Provide a [finish Grade A] [_____] surface finish to those members indicated.

2.3.12 Acceptance/Rejection of Defects

2.3.12.1 Minor Defects

All honeycombed areas, chipped corners, air pockets over 6 mm 1/4 inch in diameter, and other minor defects involve less than 900 mm$^2$ 36 square inches of concrete must be repaired. Form offsets of fins over 3 mm 1/8 inch must be ground smooth. All unsound concrete must be removed from defective areas prior to repairing. All surfaces permanently exposed to view must be repaired by a blend of portland cement and white cement properly proportioned so that the final color when cured will be the same as adjacent concrete. Precast [prestressed] members containing hairline cracks which are visible and are less than 0.25 mm 0.01 inches in width, may be accepted, except that cracks larger than 0.1 mm 0.005 inches in width for surfaces exposed to the weather must be repaired.

2.3.12.2 Major Defects

Major defects are those which involve more than 900 mm$^2$ 36 square inches of concrete or expose stressing tendons or reinforcing steel. If one or more major defects appear in a member, it will be rejected. Cracks of a width of more than 0.25 mm 0.01 inch will be cause for rejection of the member.

2.4 TESTS, INSPECTIONS, AND VERIFICATIONS

**************************************************************************

NOTE: If marine environment or exposed to severe environmental conditions, recommend including chloride ion penetration requirements.

**************************************************************************

2.4.1 Chloride Ion Concentration Test

Sampling and determination of water soluble chloride ion content in accordance with ASTM C1218/C1218M. Maximum water soluble chloride ion concentrations in hardened concrete at ages from 28 to 42 days contributed from the ingredients including water, aggregates, cementitious materials, and admixtures must not exceed 0.06 percent by weight of cement.

2.4.2 Chloride Ion Penetration Test

To ensure the durability of concrete in marine environment, concrete must be proportioned to have the chloride ion penetration test in accordance with ASTM C1202, and be below 1500 coulombs for concrete specimens tested at 28 days. Alternatively, a ponding test in accordance with AASHTO T 259 may be performed to validate chloride ion penetration in accordance with ASTM C1202.

2.4.3 Factory Inspection

**************************************************************************
NOTE: Check with the designer and Resident in Charge of Construction and edit appropriately.

At the option of the Contracting Officer, [precast[ prestressed] units may be inspected by the Contracting Officer] [precast[ prestressed] units must be inspected by the QC Representative] prior to being transported to the job site. The Contractor must give notice 14 days prior to the time the units will be available for plant inspection. Neither the exercise nor waiver of inspection at the plant will affect the Government's right to enforce contractual provisions after units are transported or erected.

PART 3 EXECUTION

3.1 EXAMINATION

Prior to erection, and again after installation, precast[ prestressed] members must be checked for damage, such as cracking, spalling, and honeycombing. As directed by the Contracting Officer, precast[ prestressed] members that do not meet the surface finish requirements specified in paragraph SURFACE FINISH must be repaired, or removed and replaced with new precast [prestressed ]members.

3.2 ERECTION

Precast [prestresed ]members must be erected after the concrete has attained the specified compressive strength, unless otherwise approved by the precast[ prestressing] manufacturer. [In addition, prestressed members must not be rigidly fixed in position until the prestressed member has "aged" [90] [_____] days after detensioning.] Erect in accordance with the approved shop drawings. PCI MNL-135 for tolerances. Provide a 1:500 tolerance, if no tolerance is specified. Brace precast [prestressed ]members, unless design calculations submitted with the shop drawings indicate bracing is not required. Follow the manufacturer's recommendations for maximum construction loads. Place precast[ prestressed] members level, plumb, square, and true within tolerances. Align member ends.

3.3 BEARING SURFACES

Must be flat, free of irregularities, and properly sized. Size bearing surfaces to provide for the indicated clearances between the precast[ prestressed] member and adjacent precast[ prestressed] members or adjoining field placed surfaces. Correct bearing surface irregularities with nonshrink grout. Provide bearing pads where indicated or required. Do not use hardboard bearing pads in exterior locations. Place precast[ prestressed] members at right angles to the bearing surface, unless indicated otherwise, and draw-up tight without forcing or distortion, with sides plumb.

3.4 ANCHORAGE

Provide anchorage for fastening work in place. Conceal fasteners where practicable. Make threaded connections up tight and nick threads to prevent loosening.

3.5 WELDING

AWS D1.1/D1.1M, AWS D1.4/D1.4M for welding connections and reinforcing
splices. [Do not weld prestressing strands. ]Protect the concrete and other reinforcing from heat during welding. Weld continuously along the entire area of contact.[ Grind smooth visible welds in the finished installation.] Welding of epoxy-coated reinforcing is not allowed.

3.6 OPENINGS

Holes or cuts requiring [reinforcing ][ prestressing steel ]to be cut, which are not indicated on the approved shop drawing, must only be made with the approval of the Contracting Officer and the precast manufacturer. Drill holes less than 300 mm 12 inches in diameter with a diamond tipped core drill. Ensure cuts are straight and at 90 degrees to the surfaces without breaking or spalling the edges.

3.7 GALVANIZING REPAIR

Repair damage to galvanized coatings using ASTM A780/A780M zinc rich paint for galvanized surfaces damaged by handling, transporting, cutting, welding, bolting, or acid washing. Do not heat surfaces to which repair paint has been applied.

3.8 GROUTING

Clean and fill [indicated] keyways between precast[ prestressed] members, and other indicated areas, solidly with nonshrink grout or cementitious grout. Provide reinforcing where indicated. Remove excess grout before hardening.

3.9 SEALANTS

Provide as indicated and as specified in Section 07 92 00 JOINT SEALANTS.

3.10 PROTECTION AND CLEANING

**************************************************************************
** NOTE:  Ensure where architectural finishes such as exposed-aggregate finish are specified for exposed-to-view surfaces, such surfaces are cleaned as specified in Section 03 45 00 PRECAST ARCHITECTURAL CONCRETE. **
**************************************************************************

Protect exposed-to-view surfaces against staining and other damage until completion of the work.

Upon completion of installation, swept clean and leave ready slab surfaces to receive concrete floor topping, roofing, or other covering.

[3.11 CONCRETE TOPPING

Provide as indicated and as specified in Section 03 30 00 CAST-IN-PLACE CONCRETE.

][3.12 CONSTRUCTION RECORDS

Complete construction records must be kept of the manufacturing, handling, and erection of the precast-prestressed concrete members and submitted. Records must be kept for, but not limited to, the following items:

SECTION 03 45 33 Page 30
a. Specifications of material used in the manufacture of the members.

b. Time-temperature history of the concrete members from casting to the transfer of the prestress force.

c. Records of the tendon stressing operation including initial prestress force, measured elongation, how it was measured, and how the tendons were stressed and destressed.

d. Records of inspection of the members before and after the prestress force is transferred to the members.

e. Records of the inspection of the members each time they are moved.

f. Records of any defects in the member and any corrective measures taken.

PART 3   EXECUTION

3.1 PREPARATION
3.2 INSTALLATION
   3.2.1 Reinforcement And Embedded Items
NOTE: This guide specification covers the requirements for tilt-up concrete wall panels precast on a previously prepared casting bed, usually the floor slab, and erection with a crane by tilting to a near vertical position, lifting free of the floor, and placing in final location.

This section includes various materials such as release agents, lifting and bracing inserts, cast-in accessories, special finishes, and installation as related to tilt-up construction. This section also includes form liners, placing concrete, tolerances, and erection and cleanup of panels.

This section does not include concrete materials common to all concrete work such as cements, aggregates, and lime.

Ensure drawings illustrate a complete design, indicating sizes of panels, reinforcing, locations of lifting inserts, connections details, and relative location of various structural members to which panels are connected, with sufficient dimensions to convey adequately the quantity and nature of the required work. Verify that drawings indicate whether the interior or exterior surface is cast face up.

Ensure bolted and welded joints and connections are indicated when these connections are required to resist applied loads.

Ensure architectural concrete wall panels are indicated.

Formwork, reinforcing steel, and concrete are specified in Section 03 30 53 MISCELLANEOUS CAST-IN-PLACE CONCRETE.
Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1 GENERAL

Section 05 05 23.16 STRUCTURAL WELDING, Section 03 30 53 MISCELLANEOUS CAST-IN-PLACE CONCRETE, and Section 07 92 00 JOINT SEALANTS, along with ACI 551.1R and ACI CP-50 apply to work specified in this section.

1.1 REFERENCES

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

AMERICAN CONCRETE INSTITUTE (ACI)

ACI 302.1R (2015) Guide for Concrete Floor and Slab Construction
ACI 551.1R (2014) Tilt-up Concrete Construction Guide
1.2 ADMINISTRATIVE REQUIREMENTS

1.2.1 Pre-Installation Meetings

No later than [30] [_____] days after Contract Award, the Contracting Officer will schedule a pre-installation meeting. Bring to attention of the Contracting Officer any discrepancies found in the architectural and structural drawings. Submit the following:

a. Submit Fabrication Drawings signed and sealed by a registered professional engineer. Include dimensions of panels and size and location of openings for concrete formwork on the fabrication drawings. Show connection details, reinforcing details, and lifting devices on the installation drawings, used for the following items:

   (1) Panels
   (2) Reinforcement and Embedded Items

b. Submit certificates for the following items showing conformance with referenced standards contained in this section:

   (1) Facing Aggregate
   (2) Concrete Aggregates
   (3) Chemical Admixtures
   (4) Release Agent
   (5) Pick-Up Inserts
   (6) Bracing Inserts
   (7) Reglets

1.3 SUBMITTALS

**************************************************************************
NOTE: Review Submittal Description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other
submital items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy, and Air Force.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.

**************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-02 Shop Drawings
    Fabrication Drawings
    Panels
    Reinforcement and Embedded Items
SD-04 Samples
    Concrete Panel Sample; G[, [____]]
    Exposed Aggregate; G[, [____]]
SD-07 Certificates
    Facing Aggregate
    Concrete Aggregates
    Chemical Admixtures
    Release Agent
1.4 QUALITY CONTROL

1.4.1 Erector Qualifications

Provide an experienced supervisor for panel construction and erection having at least [2] [_____] years of successful experience in tilt-up construction, similar to the size and amount required for this project. Personnel working pursuant to this section, may at the Contracting Officer's option, be required to demonstrate technical competence by performing sample work [and/or by displaying their state qualifications/certificates], at no additional cost to the Government.

1.4.2 Tolerances

Apply the following tolerances to this work:

**************************************************************************
NOTE: Tolerances may need to be changed depending on location of work.
**************************************************************************

a. Dimensional tolerances: Plus or minus 3.2 millimeter 1/8 inch in length and height, 4.8 millimeter 3/16 inch across diagonals

b. Bowing or warpage tolerance: Plus or minus 12.7 millimeter in 3050 millimeter 1/2[_____] inch in 10 feet

c. Thickness tolerance: Plus 12.7, minus 3.2 millimeter 1/2, minus 1/8 inch

[1.4.2.1 Samples

Cast a 1200 by 1200 millimeter 4 by 4 foot Concrete Panel sample on a casting slab to demonstrate releasing ability of release agent and architectural effects. Also provide three, 300 by 300 millimeter 12 by 12 inches test panels of Exposed Aggregate.

]PART 2 PRODUCTS

2.1 SYSTEM DESCRIPTION

2.1.1 Water Absorption

**************************************************************************
NOTE: Maximum absorption is 2 percent but not less than the percentage obtained by testing the facing aggregates in the sample panel.
**************************************************************************

Ensure water absorption of facing aggregates is not less than the percentage obtained by testing the facing aggregates in the approved sample panel.
2.2  EQUIPMENT

2.2.1  Form Liners

**************************************************************************
NOTE: Delete the paragraph heading and the following sentence when form liners are not required. If required, select type of liner from list below.
**************************************************************************
Provide [rubber matting][wood board][plywood panel][nailed-on inserts][fiberglass][plastic sheets][pattern as shown on drawings] form liners.

2.3  MATERIALS

2.3.1  Chemical Admixtures

**************************************************************************
NOTE: Specify admixtures when they are not included under cast-in-place concrete.
**************************************************************************
[ Provide admixture conforming to ASTM C494/C494M, Type B for retarder. ]
[ Provide admixture conforming to ASTM C494/C494M, Type C for accelerator. ]

2.3.2  Release Agent

**************************************************************************
NOTE: Ensure additional finishes are specified.
Ensure resin type agents are used for panels to receive additional finishes.
**************************************************************************
[ Use resin type release agent, containing no materials that could affect bond of subsequent finishes or natural appearance of exposed concrete surfaces. ]
[ Use paraffin type release agent. ]

2.3.3  Facing Aggregate

**************************************************************************
NOTE: Delete paragraph heading and the following sentence when facing aggregates are not required. Select applicable option(s).
**************************************************************************
Provide [gravel][limestone][quartz][marble][granite][glass][ceramic] aggregate. Match color and gradation appearance of facing aggregates of panels to the accepted sample panel.

2.3.4  Concrete Aggregates

Provide concrete aggregates conforming to Section 03 30 53 MISCELLANEOUS CAST-IN-PLACE CONCRETE for concrete aggregates, except that coarse aggregate ranges from 31.5 to 9.5 millimeter 1-1/4 to 3/8 inch in size.
2.4 CAST-IN ACCESSORIES

2.4.1 Pick-Up Inserts
[ Provide [double] [single] type inserts. ]
][Provide [corrosion-resistant steel] [hot-dip galvanized] inserts.

2.4.2 Bracing Inserts
Provide [corrosion-resistant steel] [hot-dip galvanized] inserts with a height corresponding to the thickness of the panel.

2.4.3 Reglets
**************************************************************************
NOTE: Select either metal or polyvinylchloride reglets. If metal reglets are required, specify either corrosion-resistance steel or hot-dip galvanized. Minimum thickness for metal reglets is 0.38 millimeter 0.015 inch.
**************************************************************************
[ Provide [corrosion-resistant] [hot-dip galvanized-] steel, 0.48 millimeter 28-gage, metal reglets with styrofoam rigid filler.
][Provide extruded polyvinylchloride reglets with styrofoam rigid filler.

2.4.4 Sleeves
**************************************************************************
NOTE: Delete paragraph heading and the following two sentences if sleeves are specified under another section or if they are not required.
**************************************************************************
[ Provide pipe sleeves, size as indicated.
][Provide sheetmetal sleeves, size as indicated.

2.4.5 Lifting Devices
Provide hot-dipped galvanized [angle] [swivel] type lifting devices.

PART 3 EXECUTION

3.1 PREPARATION

Clean forms and the casting slab of extraneous materials. Locate the casting area for the panel in an area were floor joints are preferably avoided or at least minimize the impact to the panel being casted. Spackle and/or caulk floor joints and temporarily patch floor openings that occur in the casting area.
**************************************************************************
NOTE: Specify and/or verify at the time of submittal review that the releasing agent is compatible with the final finish, such as sealants,
Treat casting slab with a release agent before placing reinforcing and embedded items. Use care not to scuff the release agent when placing reinforcing and embedded items.

Re-treat scuffed areas with the release agent, using care not to coat reinforcing and embedded items. Repair holes and spalling within the slab surface from previous cast and allow to cure before applying a new coat of releasing agent.

NOTE: Include concrete requirements for tilt-up panels within Section 03 30 00 CAST-IN-PLACE CONCRETE and Section 03 30 53 MISCELLANEOUS CAST-IN-PLACE CONCRETE. These may include joint locations, Slab thickness, Levelness, embed locations, etc.

Field verify and correct any errors in the footings and foundations such as levelness, embed locations, etc. prior to lifting. Refer to Section 03 33 00 CAST-IN-PLACE ARCHITECTURAL CONCRETE for additional requirements.

3.2 INSTALLATION

3.2.1 Reinforcement And Embedded Items

Accurately locate reinforcing and items to be embedded in the panels in accordance with approved drawings and place into forms.

NOTE: Delete the following paragraph when the supporting members are not poured-in-place columns.

 Extend horizontal reinforcing rods at sides of panels a minimum of 300 millimeter 12 inches into column forms.

3.2.2 Casting

NOTE: When structurally possible the panel thickness should be equal to nominal thickness of wood members to improve installation and cost efficacy.

Cast panels individually on a temporary casting slab or on the concrete floor slab of the building. Refer to Section 03 30 53 MISCELLANEOUS CAST-IN-PLACE CONCRETE and comply with ACI 302.1R. Vibrate concrete to produce the maximum density without voids throughout the entire panel thickness. Do not displace reinforcement or inserts, or cause scoring of forms, liners, or the casting slab.

Install [_____] millimeter inch cant strip along edges of formwork.

Install strong backs at locations were panel legs are less then [_____]
millimeter inches in width.

Furnish plastic or plastic tipped steel chairs for placement of reinforcing.

3.2.3 Finishes

Finish exposed face surfaces of panels to match the approved sample panel.

******************************************************************************
NOTE: Select finish required for inside surface of panels.

Unexposed panel backs usually have a smooth float finish or a broom finish. When the inside surfaces are exposed, the panels can receive a smooth steel-trowel finish or light broom finish.
******************************************************************************

Provide exposed panels with a [smooth trowel] [light broom] [exposed aggregate] [[brick][stone] pattern] finish.

Provide architectural accents and reveals per construction drawings.

Provide unexposed panel backs with a [smooth float] [broom] finish.

Cracks, voids, protrusions, spalls, or nonuniform color or texture are not acceptable. Patch and repair minor defects from casting to match adjacent final finish.

3.2.4 Curing

After casting, form-cure panels until sufficient strength has developed to permit handling the units without damage.

******************************************************************************
NOTE: The number of days for moisture curing may be changed to meet project requirements.
******************************************************************************

After removal of forms, moist-cure panels for a minimum of 6 calendar days.

3.3 FIELD QUALITY CONTROL

******************************************************************************
NOTE: Specify higher-strength concrete if required.
******************************************************************************

Do not start erection of panels until representative concrete test cylinders have a minimum compressive strength as specified on the drawings.

Locate pickup points in concrete panels so that concrete tensile stresses during erection do not exceed 10 percent of the cylinder compressive strength at time of erection.

3.4 ERECTION

Level the setting bed for wall panels using high-strength mortar so that the panel in place will have a level tolerance within 1 to 500.
Erect panels using spreader bars, chokers with equalizer sheaves, adjustable bracing, and other erecting accessories as required to place panels in location. Ensure bracing equipment meets applicable codes.

Tilt panels from the casting platform to slope within 1 horizontal to 6 vertical ratio.

Plumb initial setting of panels within 75 millimeter 3 inches of true.

Plumb final setting of panels with adjustable braces to vertical tolerance of 1 to 500, leaving braces in place until panels are secured in their final location as indicated.

**************************************************************************

NOTE: Panels may be connected to steel columns, precast concrete columns, or cast-in-place concrete columns. Ensure details of connecting panels to supporting structures are indicated. Delete paragraphs which are not applicable.

**************************************************************************

Bolt panels to the supporting structure with high-strength bolts as specified in Section 05 12 00 STRUCTURAL STEEL.

Weld panels to the supporting structure.

**************************************************************************

NOTE: Include all the following paragraphs for welded panels.

**************************************************************************

Ensure welding meets the requirements of AWS D1.1/D1.1M.

Before welding, clean surfaces of loose scale, slag, rust, grease, and other foreign substances that could affect the strength of the welds.

Weld connections with weld materials that correspond to the steel being welded.

Use and maintain shielded metal arc welding.

Provide inspection gages for checking the size, length, and quality of welds.

Correct or replace welds having cracks, surface porosity, slag accumulation, insufficient throat, or concavity.

Remove weld splatter from steel surfaces to be painted.

Brace panels with adjustable turnbuckle pipe braces or timber braces.

**************************************************************************

NOTE: Select either plastic or portland mortar. Portland mortar (dry-packing) is recommended for tighter joints.

**************************************************************************

Pack joints between wall panels and foundation and wall panels and columns with [portland cement] [plastic] mortar.
3.5 PATCHING

Dry pack holes in panels left after lifting rigging has been removed with nonshrink mortar to match adjacent surfaces.

**************************************************************************

NOTE: Select one of the following paragraphs.

Specify sack-rubbed cleaning when surface air pockets and minor rust stains occur.

Specify acid-cleaning solution when stains are caused by rust from reinforcing and impurities in curing water.

**************************************************************************

[ Wet stained surfaces, coat surfaces with a thick mortar mixture, and rub the area with burlap pads to remove the excess mortar and fill surface voids.  

][Remove surface stains with diluted muriatic acid, scrubbing with stiff brushes and flushing with clean water.

NOTE: This guide specification covers the requirements for cementitious wood fiber decks.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1   GENERAL

1.1 REFERENCES

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.
References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

AMERICAN WELDING SOCIETY (AWS)

AWS D1.1/D1.1M (2020; Errata 1 2021) Structural Welding Code - Steel

APA - THE ENGINEERED WOOD ASSOCIATION (APA)

APA PS 2 (2010; R 2014) Performance Standard for Wood-Based Structural Use Panels

ASTM INTERNATIONAL (ASTM)

ASTM C423 (2023) Sound Absorption and Sound Absorption Coefficients by the Reverberation Room Method

ASTM E1349 (2006; R 2013) Standard Test Method for Reflectance Factor and Color by Spectrophotometry Using Bidirectional (45°:0° or 0°:45°) Geometry

1.2 SUBMITTALS

NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the
Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.

**************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-02 Shop Drawings
Roof Decking Installation; G[, [_____]]

1.3 DELIVERY, STORAGE, AND, HANDLING

Store roof decking units off the ground and protect from weather, marring, damage, or overload. Provide adequate ventilation to prevent condensation. Provide temporary plank walkways or platforms for distributing the weight of materials that are required to be placed upon or transported over the roof decking.

PART 2 PRODUCTS

2.1 SYSTEM REQUIREMENTS

**************************************************************************

NOTE: Because there is a limited number of manufacturers of these units, there are no national standards governing the design or manufacture of these units. Designer should consult manufacturers' literature for additional information.

**************************************************************************

Roof decking units must be factory-produced items of a firm specializing in cementitious wood fiber decking. Design of the roof decking must be for the load conditions and spans indicated and any additional load imposed by openings; work of other trades; and all loading and restraining conditions from fabrication, handling, and erection. Deflection must not exceed L/240 of span. Submit detail drawings showing roof decking installation, including framing at all openings for support of roof units. The detail drawings must be accompanied by setting details, design calculations showing that the roof decking installation meets material and design
requirements, a descriptive list of materials, and the manufacturer's current printed installation instructions.

2.2 DECK UNITS

**************************************************************************
NOTE: Type of units specified will be limited by design requirements. Thickness and other dimensions, if essential to the design, will be indicated. Cement-fiber deck units are available with foam insulation attached. If roof is to be insulated, the use of these units should be investigated.
**************************************************************************

Fabrication of roof deck units must be under plant controlled conditions. Provide openings for mechanical and utility systems and for architectural purposes as indicated. Special shapes must be fabricated as indicated or required. Surfaces to receive subsequent application must be suitable for the purpose intended and free of any coatings that would interfere with adhesion or bond. Surfaces showing as exposed ceilings must have a light reflection of 60 percent in accordance with ASTM E1349.

2.2.1 Structural Cementitious Wood Fiber Roof Decking

Structural cementitious wood fiber roof decking must be shaped under pressure to required dimensions from a mixture of wood fibers and cementitious materials in proportions to produce deck units meeting the loading conditions specified. Exterior surfaces must be suitable for applying roof. Metal edge members, if furnished with units, must be galvanized. Flame spread must not exceed 25 and smoke developed rating must not exceed 50 when tested in accordance with ASTM E84. [Roof decking must achieve a noise reduction coefficient (NRC) of [NRC 0.55][NRC 0.60][NRC 0.65][NRC 0.70][NRC 0.75][NRC 0.80] in accordance with ASTM C423.]

2.2.1.1 Monolithic Cementitious Wood Fiber Plank Units

Manufacturer's standard, tongue-and-groove-edged, cementitious wood fiber units with a plank thickness of [51 mm 2 inches][ 63 mm 2-1/2 inches][ 76 mm 3 inches]. Planks to have the manufacturer's standard [natural][or][prime-painted] finish. [Provide channel reinforced planks with factory-installed, cold formed, 1.5 mm 0.060 inch thick, galvanized steel channel set in grooved edge.][ Provide planks with edges kerfed, back rabbeted, and beveled for a concealed tee system.]

2.2.1.2 Composite Cementitious Wood Fiber Plank Units

2.2.1.2.1 Insulated Composite Plank

Manufacturer's standard factory laminated composite deck units consisting of a standard tongue-and-groove-edged, cementitious wood fiber plank base with a thickness of [38 mm 1-1/2 inches][ 51 mm 2 inches][ 63 mm 2-1/2 inches][ 76 mm 3 inches], ASTM C578, [Type IV extruded-polystyrene insulation][Type I expanded-polystyrene insulation] with a thickness of [38 mm 1-1/2 inch][ 51 mm 2 inches][ 76 mm 3 inches][ 102 mm 4 inches][ 127 mm 5 inches][ 152 mm 6 inches][ 177 mm 7 inches][ 202 mm 8 inches], and a top layer of APA-rated oriented-strand-board sheathing, Exposure 1 complying with APA PS 2, 11 mm 7/16 inch thick.
2.2.1.2.2 Composite Nailable Surface Plank

Manufacturer's standard factory laminated composite deck units consisting of a standard tongue-and-groove-edged, cementitious wood fiber plank base with a thickness of 63 mm (2-1/2 inches), 76 mm (3 inches), 89 mm (3-1/2 inches), 102 mm (4 inches), insulation, and a top layer of APA-rated oriented-strand-board sheathing, Exposure 1 complying with APA PS 2, 11 mm (7/16 inch) thick.

2.2.1.3 Composite Wood Fiber Tile Units

2.2.1.3.1 Monolithic Tile

Manufacturer's standard, rabbet-edged, cementitious wood fiber units with a thickness of 38 mm (1-1/2 inches), 51 mm (2 inches), 63 mm (2-1/2 inches), 76 mm (3 inches), 102 mm (4 inches), 127 mm (5 inches), and a nominal width of 610 mm (24 inches), 813 mm (32 inches), 1219 mm (48 inches), and length indicated. Tiles to have the manufacturer's standard [natural] [or] [prime-painted] finish.

2.2.1.3.2 Insulated Composite Tile

Manufacturer's standard factory laminated composite deck units consisting of a rabbet edged, cementitious wood fiber tile base with a thickness of 38 mm (1-1/2 inches), 51 mm (2 inches), 63 mm (2-1/2 inches), 76 mm (3 inches), ASTM C578, Type IV extruded-polystyrene insulation with a thickness of 38 mm (1-1/2 inch), 51 mm (2 inches), 63 mm (2-1/2 inches), 76 mm (3 inches), 102 mm (4 inches), 127 mm (5 inches), 152 mm (6 inches), 177 mm (7 inches), 202 mm (8 inches), and a top layer of APA-rated oriented-strand-board sheathing, Exposure 1 complying with APA PS 2, 11 mm (7/16 inch) thick. Tiles must have a nominal width of 610 mm (24 inches), 813 mm (32 inches), 1219 mm (48 inches), and length indicated. Tiles to have the manufacturer's standard [natural] [or] [prime-painted] finish.

2.3 STRUCTURAL STEEL SUBPURLINS

Steel for structural subpurlin members, if required, must conform to [the manufacturer's standard] [_____]. Subpurlins must span over at least three supports.

2.4 ANCHORAGE

Fasteners must be of steel, zinc-coated or equivalent protective metallic coatings.

2.5 JOINT MATERIAL

Joint material must be a gypsum concrete grout that is factory-packaged and of a formulation recommended by the cementitious wood fiber unit manufacturer with a minimum compressive strength of 3.45 MPa (500 psi).

PART 3 EXECUTION

3.1 INSTALLATION

Installation must be in accordance with the submitted and approved detail drawings. Installation of equipment required by other trades must be accomplished as the work progresses if required by the design. Field-cut openings for utilities penetrations must be accomplished in accordance with
the manufacturer's recommendations. Roof deck must be straight and true, and when laid in place must present a flat, level surface suitable for application of roofing. All roof decking units must bear on at least two structural framing members with a 25 mm 1 inch minimum bearing. Any cantilever plank must not exceed the design span. Installation must require a minimum of cutting. Cutting, where required, must be at a true angle to the top of the unit. All units must be made to fit around openings and projections, valleys, walls, and curbs, so that cut ends occur on supports and in a manner that will not damage the units. Mechanically fasten the roof decking to the support structure. No attachment for carrying loads must be made directly to the roof decking or subpurlins.

3.1.1 Subpurlins

Align subpurlins to the required spacing and bear evenly on structural framing members. End bearings must be a minimum of 25 mm 1 inch. Subpurlin ends must have at least 3 mm 1/8 inch clearance to allow for expansion. Weld subpurlins to each structural framing member at every point of crossing, over supporting member with a 19 mm 3/4 inch long fillet weld on alternate sides of the flange except at ends, where both sides must be welded. Conform to AWS D1.1/D1.1M for welding subpurlins.

3.1.2 Joint Treatment

Job-mixed materials must be screeded to true, even surfaces and protected until sufficiently hardened to withstand traffic and freezing temperatures. Fill joints at hips and ridges with the specified joint material finished in true planes with tops of units and with surfaces to receive roofing.

3.2 CLEANING AND PROTECTION

The complete decking must be kept clean and free of damaged or defaced units, and left ready to receive roofing. The installed roof decking units must be protected from damage by weather and construction operations by a temporary cover until application of roofing.

NOTE: This guide specification covers the requirements for insulating concrete roof deck systems with embedded insulation board only.

Adhere to **UFC 1-300-02** Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a [Criteria Change Request (CCR)](https://example.com).

**NOTE:** The following information should be included on the project drawings:

1. High points and valleys on roof plan
2. Specific slope requirements
3. Roof drain details
4. Reinforcement locations and details.
5. Location of roof projections.
6. Moisture venting details and locations for insulating concrete over cast-in-place or precast structural concrete substrates.
7. Location of corrugated steel form decking sections with slots for moisture venting.

8. Insulation board thickness.

9. Vented flashing details and a mechanical fastening base sheet for built-up roof.

10. Seismic design details. Include diaphragm shear values, steel form deck design, and welding patterns if Section 05 30 00 STEEL DECKS is not in contract.

**************************************************************************
**************************************************************************
NOTE: Insulating concrete could be applied over structural or precast concrete, or corrugated steel form decking. Provide design details to meet minimum roof slope of 1/24.
**************************************************************************
**************************************************************************

PART 1   GENERAL

1.1 REFERENCES

**************************************************************************
**************************************************************************
NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.
**************************************************************************
**************************************************************************

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

AMERICAN SOCIETY OF HEATING, REFRIGERATING AND AIR-CONDITIONING ENGINEERS (ASHRAE)

1.2 QUALIFICATIONS OF APPLICATOR

Perform work by or under the supervision of personnel specializing in insulating concrete application and having not less than 2 years experience.

1.3 SUBMITTALS

**************************************************************************
NOTE: Review Submittal Description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G". Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office.
following the "G" typically are not used for Navy and Air Force projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.

**************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-03 Product Data

Performance Requirements

Submit, indicating compressive strength, oven dry density, and coefficient of heat transmission.

SD-06 Test Reports

Performance Requirements

Submit certified test reports on laboratory testing of insulating concrete samples taken at time of placement.

SD-07 Certificates

Fabricator's Compatibility Certificates

SD-08 Manufacturer's Instructions

Application

1.4 DELIVERY AND STORAGE

Deliver all materials to the building site in original unopened, undamaged packages or containers, or approved bulk handling equipment, with manufacturer's brand name and contents clearly identified. Protect materials against dampness. Store materials under cover and off the ground, in well-ventilated areas, not exposed to extreme changes of temperature and humidity. Prevent deterioration or intrusion of foreign substances. Keep materials dry until ready for use. Protect metal components from rusting.

1.5 ENVIRONMENTAL CONDITIONS

1.5.1 Normal Conditions

When ambient air temperatures of 3 degrees C 40 degrees F or above are
predicted for the initial 24 to 72 hours after placement of insulating concrete, the use of hot water and other cold weather protection measures are not required.

1.5.2 Cold Weather Conditions

When ambient air temperature at time of placing insulating concrete is between 3 and 0 degrees C 40 and 32 degrees F, use hot water in temperature range of 32 and 39 degrees C 90 to 120 degrees F at the point of placement. When ambient air temperatures of 0 degrees C 32 degrees F or below are predicted for the initial 24 to 72 hours after placement of insulating concrete, provide additional protection measures as recommended by the aggregate manufacturer.

1.6 SAFETY AND HEALTH REQUIREMENTS

Comply with manufacturer's protective measures in the safe installation of the insulation board.

1.7 QUALITY ASSURANCE

1.7.1 Fabricator's Compatibility Certificates

Submit a written statement from the insulating concrete fabricator certifying that materials for this project are chemically and physically compatible.

PART 2 PRODUCTS

2.1 PORTLAND CEMENT

******************************************************************************  
NOTE: Uses of Types I, II, and III portland cement are as follows:

Type I - For use when the special properties specified for other types are not required

Type II - For general use, more especially when moderate resistance or moderate heat of hydration is desired

Type III - For use when high early strength is desired.
******************************************************************************

ASTM C150/C150M, Type [I] [II] [III].

2.2 AGGREGATE

******************************************************************************  
NOTE: Lightweight perlite and vermiculite aggregate or cellular concrete, without embedded insulation, should be specified in Section 03 30 00 CAST-IN-PLACE CONCRETE. Insulation board applied over lightweight perlite and vermiculite aggregate or cellular concrete should be specified Section 07 22 00, ROOF AND DECK INSULATION.
******************************************************************************
ASTM C332, Group I.

2.3 AIR-ENTRAINMENT

******************************************************************************
NOTE: Air-entraining agent is not required with cellular concrete.
******************************************************************************

The air-entrainment agent shall be prepackaged or added at the mixer. Provide amount and type of air-entrainment in accordance with the aggregate manufacturer's recommendations. Do not use calcium chloride.

2.4 FOAMING AGENTS

ASTM C796/C796M.

2.5 WATER

Water shall be clean and free from injurious amounts of acids, alkali, organic matter, or other deleterious substances.

2.6 EXPANSION JOINT FILLER MATERIAL

ASTM C612, Class 1, semi-rigid, modified for maximum density of 96 kg per cubic meter 6.0 pounds per cubic foot.

2.7 WELDED WIRE FABRIC

******************************************************************************
NOTE: Insulating concrete requires reinforcement where slope substrate exceeds 1/3, and for achieving specific fire rated systems for metal deck systems, not over structural concrete.
******************************************************************************

Galvanized steel welded wire fabric shall conform to ASTM A1064/A1064M.

2.8 INSULATION BOARD

******************************************************************************
NOTE: Design and specify insulating concrete with embedded insulation board to obtain contract U value requirements. Insulation board applied over insulating concrete is specified in Section 07 22 00 ROOF AND DECK INSULATION.
******************************************************************************

Polystyrene insulation board conforming to ASTM C578 RCPS Type [I], [II], [IV], or [V], 600 by 1200 mm 24 by 48 inches, and of thickness [indicated] [necessary to provide a "C" value not greater than [_____]]. Boards shall be factory fabricated and slotted or perforated for keying the insulation board into the insulating concrete.
PART 3   EXECUTION

3.1   PERFORMANCE REQUIREMENTS

Provide insulating concrete design mix to shall meet the following performance requirements. Test as specified.

3.1.1   Minimum Compressive Strength

[9] [_____] MPa [125] [_____] pounds per square inch in 28 days as tested with ASTM C495/C495M.

3.1.2   Minimum Oven Dry Density

**************************************************************************
NOTE: Oven dry density should not be less than 350
kg per cubic meter 22 pcf.
**************************************************************************

[350] [_____] kg per cubic meter [22] [_____] pounds per cubic foot as determined by ASTM C495/C495M.

3.1.3   Coefficient of Heat Transmission

**************************************************************************
NOTE: Meet contract U value requirements. Specify insulation board applied over insulating concrete in Section 07 22 00 ROOF AND DECK INSULATION.
**************************************************************************

U value of [0.28] [_____] watt/square foot/degrees C [0.05] [_____] Btu/hr/square foot/degrees F, as determined in accordance with ASHRAE FUN SI ASHRAE FUN IP. The U value shall incorporate the total roof deck and roofing system design and represent the average U value for the total roof area.

3.2   SURFACE PREPARATION

Clean surfaces to receive insulating concrete of dirt, debris, and other foreign materials that would affect bonding. Deck shall be free of standing water, snow, and ice.

3.3   STEEL ROOF DECKING

**************************************************************************
NOTE: Select the applicable paragraph(s) from the following:

NOTE: Insert the appropriate Section number and title in the blank below using format per UFC 1-300-02.
**************************************************************************

As specified in Section [05 30 00 STEEL DECKS].
[[CAST-IN-PLACE] [PRECAST] STRUCTURAL CONCRETE DECK
As specified in [_____].]
3.4 REINFORCING MESH OR WELDED WIRE FABRIC

NOTE: Insulating concrete requires reinforcement where slope on substrate exceeds 1 to 3, and for achieving specific fire rated systems for metal deck systems, not over structural concrete. Reinforcement size and spacing should be indicated on drawings.

Install reinforcing mesh or welded wire fabric with a minimum end lap of 150 mm 6 inches and no side lap. Cut mesh or fabric to fit at all [walls,] [curbs,] [roof drains,] and [openings]. [Mesh not required over structural concrete decks.]

3.5 APPLICATION OF INSULATING CONCRETE AND INSULATION BOARD

NOTE: Use Section 07 51 13 BUILT-UP ASPHALTROOFING or Section 07 53 23 ETHYLENE-PROPYLENE-DIENE-MONOMER ROOFING, as guidance in developing details and specifications for venting, roof expansion joints, and application of roofing materials. In addition to providing expansion joints in the structure, provide expansion joints in roofing membrane at all expansion joints in the insulating concrete roof deck except those located at the perimeter of the roof deck and where the roof deck abuts vertical surfaces.

NOTE: Edit application procedures for concrete requirements. When the roof deck is designed for resistance to seismic or other lateral forces, the aggregate manufacturer should be consulted for specific criteria. Expansion joints other than those located at expansion joints in the structure shall not be provided when the roof deck is designed as a diaphragm to resist horizontal forces.

Apply insulating concrete, insulation board and related materials in accordance with respective specifications and manufacturer's instructions, except as modified herein.

3.5.1 Mixing

Mix insulating concrete materials mechanically to produce a uniform distribution.

3.5.2 Conveying

Convey insulating concrete from the mixer to place of final deposit by methods that prevent segregation or loss of materials. Convey the concrete without material separation or loss of air content.
3.5.3 Expansion Joints

**************************************************************************
NOTE: Provide specifications for expansion joints in this or other sections. Normally expansion joints are specified in Section 03 30 00 CAST-IN-PLACE CONCRETE. When one of these sections is included in the project specification, coordinate the requirements for expansion joints and construction joints with this section.
**************************************************************************

**************************************************************************
NOTE: Locations and dimensions of expansion joints: Expansion joints in the lightweight insulating concrete should be 32 mm 1 1/2 inch wide or 25 mm one inch wide as required. Expansion joints greater than 32 mm 1 1/2 inch wide should be located at expansion joints in the structure. Expansion joints not less than one inch wide should be located at the perimeter of the roof deck, where the roof deck abuts vertical surfaces and at the following locations:

1. On cast-in-place structural concrete substrates, expansion joints in the light weight insulating concrete should be located at expansion joints in the building.

2. On precast concrete and steel form decking substrates, expansion joints in the light weight insulating concrete should be placed as they correspond with the structure and where the direction of the metal deck changes.

**************************************************************************
Provide expansion joints through the depth of the light-weight insulating concrete at the perimeters of the roof deck, where the roof deck abuts vertical surfaces and where indicated. [Perimeter expansion joints are not required with cellular concrete.]

3.5.4 Slurry Coat and Insulation Board

**************************************************************************
NOTE: Insulation board applied over insulating concrete should be installed in accordance with Section 07 22 00 ROOF AND DECK INSULATION.
**************************************************************************

Bond the insulation board to the structural deck with a slurry coat of the same insulating concrete mix ratio as used for fill over the insulation board. Screed the slurry of concrete to an even surface, to a minimum of 3 mm 1/8 inch over the top of the structural deck. [Fill corrugations of steel decking with insulating concrete and screed even with the slurry coat.]

3.5.5 Insulating Concrete Fill

Place the insulating concrete on the insulation board and screed to an even
surface in a continuous operation until placement of a section is completed. Provide slopes as indicated for high points, valleys and positive drainage [to roof drains] and to eliminate ponding. At no place shall the minimum and maximum thickness of the insulating concrete be less than 50 mm or greater than 200 mm 2 inches or greater than 8 inches respectively over the top of insulation board.

3.5.5.1 Compacting

Rodding, tamping, or vibrating are not permitted.

3.5.5.2 Curing

**************************************************************************
NOTE: The insulating concrete should be covered with subsequent roofing materials soon after being allowed to cure for a minimum of 10 days.
**************************************************************************

Minimize traffic on the surface during the curing period. Under normal conditions, roofing may begin in 3 days. When the insulating concrete is placed during extremely dry conditions, sprinkle additional water on the concrete for hydration of the cement and to minimize shrinkage cracking. After a freezing or heavy rainfall or minor scaling of less than 6 mm 1/4 inch depth, broom the surface immediately prior to installation of roofing.

3.5.5.3 Patching

Remove portions of the insulating concrete deck with excessive scaling of more than 6 mm 1/4 inch depth to sound concrete. Patch the surface with portland cement concrete slurry.

3.6 FIELD TESTS

During progress of work, insulating concrete specimens shall be taken for laboratory testing as specified herein.

3.6.1 Test Specimens

**************************************************************************
NOTE: A minimum of one test should be required for each 40 to 60 cubic meters 50 to 75 cubic yards of insulating concrete.
**************************************************************************

Take test cylinder specimens for compressive strength in the presence of the Contracting Officer. Notify the Contracting Officer one day prior to the date of taking specimens. A minimum of [four] [_____] test specimens shall be made for each day's concreting, with at least one test required for each [57] [_____] cubic meters [75] [_____] cubic yards of insulating concrete. Label specimens to indicate the location at which they were taken. Store specimens in an undisturbed place which will not be exposed to rain and extreme changes of temperature and humidity until ready for testing.

NOTE: This guide specification covers the requirements for low density cast-in-place concrete roof decking.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1 GENERAL

1.1 REFERENCES

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature
to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

**************************************************************************

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

AMERICAN IRON AND STEEL INSTITUTE (AISI)

AISI SG03-3 (2002; Suppl 2001-2004; R 2008)
Cold-Formed Steel Design Manual Set

AMERICAN SOCIETY OF HEATING, REFRIGERATING AND AIR-CONDITIONING ENGINEERS (ASHRAE)

AMERICAN WELDING SOCIETY (AWS)

ASTM INTERNATIONAL (ASTM)

ASTM A653/A653M (2023) Standard Specification for Steel Sheet, Zinc-Coated (Galvanized) or Zinc-Iron Alloy-Coated (Galvannealed) by the Hot-Dip Process

ASTM A1064/A1064M (2022) Standard Specification for Carbon-Steel Wire and Welded Wire Reinforcement, Plain and Deformed, for Concrete

ASTM C332 (2023) Standard Specification for Lightweight Aggregates for Insulating Concrete

NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-02 Shop Drawings

Low Density Roof Systems; G[, [_____]]
2.1 SYSTEM REQUIREMENTS

Provide the services of a firm experienced in the installation of cast-in-place low density roof systems. Supervise the mixing, transporting, placing, finishing, and testing of the low density concrete. Submit drawings indicating shop and erection details for form systems proposed to be used. Show on the drawings cuts, vent holes, cut-outs for other trades, connections, and welds. Indicate welds in accordance with AWS A2.4.

2.1.1 Concrete

**************************************************************************
NOTE: Oven-dry unit weight of low density concrete should not exceed 800 kg/cubic meter 50 pcf; nor should the compressive strength exceed 3100 kPa 450 psi. Insulation value decreases with high unit weights. Unit weight of 400 kg/cubic meter 25 pcf with a minimum compressive strength of 862 kPa 125 psi will normally be specified. Manufacture of this type of concrete is specialized and manufacturer's data should be relied on to establish mixture proportions. See ACI 523.1R for additional information.
**************************************************************************

Establish the strength qualities of the low density concrete proposed for use from manufacturer's submitted data prior to the beginning of construction operations. Perform the preparation of the design mix and subsequent testing through an approved testing laboratory capable of performing such services or, if approved, by the manufacturer of the low density concrete. Prepare trial design batches with the same materials proposed for use in the work. Make and test Test Cylinders in accordance with ASTM C495/C495M for perlite and vermiculite concrete and ASTM C796/C796M for cellular concrete. Proportion low density concrete for a minimum oven-dry unit weight of [400] kg/cubic meter [25] pcf and the minimum average compressive strengths at 28 days of [862] kPa [125] psi. Submit certified copies of the design mix report for low density concrete indicating mixture proportions, average compressive strength in MPa psi, and wet unit weight at point of placement for the type proposed for the project. Make allowances for any unit weight changes resulting from handling and placing methods.

2.1.2 Required U-Value

The actual average installed thickness of concrete, forms, and insulation, if used, must be sufficient to provide a coefficient of heat transmission, or U-value, based on winter conditions, through the affected construction, not in excess of [_____] W per square meter, per degree K Btu per hour, per square foot, per degree F temperature difference, when determined in accordance with recognized methods set forth in the ASHRAE FUN SI ASHRAE FUN IP. Determine the U-value from inside air to outside air.
2.1.3 Steel Forms

Design steel forms in conformance to AISI S03-3. Design units for attachment to the structural supports by welding or by a special system of clips as recommended by the manufacturer. Deflection of the steel forms under the design live load indicated exceeding 1/240 of the clear span is unacceptable.

2.2 MATERIALS

2.2.1 Admixtures

Provide air-entraining admixtures conforming to ASTM C260/C260M. Do not use admixtures containing chloride ions.

2.2.2 Aggregate

Provide light weight aggregate free of asbestos and conforming to ASTM C332, Group I.

2.2.3 Foaming Agent

Provide foaming agents, for making cellular concrete, conforming to ASTM C869/C869M.

2.2.4 Cementitious Material

Provide portland cement conforming to ASTM C150/C150M, Type I, III; or ASTM C595/C595M, Type IS.

2.2.5 Wire Reinforcement

Provide reinforcement consisting of either wire mesh or welded wire fabric. Mesh must be 50 mm 2 inch hexagonal, woven from 19 gauge 19 gauge steel wire and reinforced with 16 gauge 16 gauge longitudinal steel wire spaced on 75 mm 3 inch maximum centers. Wires forming common sides of mesh spaces that are adjacent to longitudinal wires must be woven around longitudinal wires. Wire must be galvanized conforming to ASTM A1064/A1064M. Welded wire fabric must conform to ASTM A1064/A1064M, galvanized, 12 gauge 12 gauge longitudinal wires spaced on 100 mm 4 inch maximum centers with 14 gauge 14 gauge transverse wires spaced on 200 mm 8 inch maximum centers.

2.2.6 Steel Forms

Provide forms that are galvanized corrugated steel conforming to ASTM A653/A653M, Grade A or E, with coating Class G 90. Provide forms with side lap venting clips, formed in side lap vents, or vent slots in the corrugation. Vent area must be at least 700 square mm per square m 0.10 square inch per square foot of roof deck area.

2.2.7 Rigid Insulation

Provide insulation conforming to ASTM C578, Type as recommended by the manufacturer.

2.2.8 Expansion Joint Materials

Provide expansion joint material that is compressible up to at least 50 percent under 172 kPa 25 psi of pressure, weather resistant, and compatible
with the roofing system used.

2.3 MIXING PROCEDURE

Mechanically mix concrete ingredients to produce low density concrete of uniform consistency and a wet unit weight at point of placement required to obtain the compressive strength specified. Mix and transport concrete in accordance with the low density concrete material manufacturer's recommendation.

PART 3 EXECUTION

3.1 FORMWORK

Attach forms to structural members by plug welding or special clips furnished by the manufacturer. Weld or use clips in conformance with recommendations of the manufacturer. Place sheets with edge-corrugation lips pointing upward and do not lap less than one full corrugation. Locate end laps over permanent supports. Make end laps a minimum of 50 mm 2 inches. Vent as recommended by the manufacturer. Prior to placing low density concrete, remove welding flux, spatter and slag from areas of coating that have been damaged by welding or other operations. Clean loose rust and other foreign matter by wire brushing, and coat with zinc-rich paint.

3.2 WIRE REINFORCEMENT

Unroll and place wire reinforcement so that the long dimension is perpendicular with the corrugation in the steel forms. Locate reinforcement approximately in the center of the lower one-third of the slab in which it is placed, and provide a 19 mm 3/4 inch minimum cover for reinforcement.

3.3 LOW DENSITY CONCRETE CONVEYING AND PLACEMENT

Convey low density concrete from the mixer to place of deposit by methods that will prevent segregation and loss of material. Use equipment for conveying concrete of such size and design to ensure uniform, continuous placement of concrete. Deposit and screed low density concrete in a continuous operation until the placing of a panel or section is completed. Do not use rodding, tamping, vibrating, or steel troweling. Use temporary runways during placement. The actual thickness of the roof system must be that required to obtain the U-value specified; however, the minimum thickness of the top-most layer of low-density concrete must not be less than 50 mm 2 inches. If used to obtain the required U-value, encapsulate rigid insulation in low density concrete as recommended by the manufacturer.

3.4 EXPANSION JOINTS

**************************************************************************
NOTE: Expansion joints will be as required by normal building design and construction. Perlite systems require expansion joints at all intersections with vertical surfaces except where designed as diaphragms in seismic design. Use 40 mm 1-1/2 inch joints when roof exceeds 30 m 100 feet in length.
**************************************************************************

Locate expansion joints as indicated. In addition, where perlite aggregate
is used, install [25] [40] mm [1] [1-1/2] inch expansion joints at junctions of roof and vertical surfaces. Extend joints the full depth of the roof system.

3.5 COLD WEATHER PLACEMENT

Provide reinforcement, forms, fillers, and other materials that will come in contact with the low density mixture that are free of frost, snow, or ice. Do not place low density concrete at temperatures below 4 degrees C 40 degrees F or when temperatures are predicted to fall below 4 degrees C 40 degrees F during placement, unless precautions recommended by the manufacturer are employed and such placement is approved.

3.6 CURING

Cure low density concrete in accordance with the manufacturer's recommendation. Commence curing operations at initial set of the concrete. After curing, allow surfaces to dry to permit subsequent application of roofing system, as determined by installation firm.

3.7 FIELD-CONTROL TESTS

Provide field-control tests performed by an approved commercial testing laboratory and consisting of wet-density at time of placement and compressive strength tests. If the specimens tested fail to meet the compressive-strength requirements, remove and replace the portion of roof decking represented by the specimens.

3.7.1 Wet-Density Tests

Make wet-density tests as required, but no less than twice during each day's pour. Take samples for wet-density tests at the point of placement. A variation in excess of 5 percent under the laboratory-established design of wet density, after discharge at point of placement, requires a modification of mix proportions or changes in mixing procedure, or both.

3.7.2 Compressive Strength Tests

Prepare and test cylinders in accordance with ASTM C495/C495M, or ASTM C796/C796M as applicable, except obtain samples at the point of placement. Take samples at least once a day and for each 60 cubic meters 75 cubic yards of low density concrete placed. Properly identify the area of roof decking represented by the sample. One sample will be sufficient to make at least four cylinders.

3.8 CLEANING AND PROTECTION

Upon completion of the roof deck, sweep the roof surfaces clean of debris leaving it ready to receive the roofing. Protect the finished deck from damage by weather and construction operations prior to installation of roofing.

NOTE: This guide specification covers the requirements for insulating concrete roof deck systems with embedded insulation board only.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

NOTE: The following information should be included on the project drawings:

1. High points and valleys on roof plan
2. Specific slope requirements
3. Roof drain details
4. Reinforcement locations and details.
5. Location of roof projections.
6. Moisture venting details and locations for insulating concrete over cast-in-place or precast structural concrete substrates.
7. Location of corrugated steel form decking sections with slots for moisture venting.

8. Insulation board thickness.

9. Vented flashing details and a mechanical fastening base sheet for built-up roof.

10. Seismic design details. Include diaphragm shear values, steel form deck design, and welding patterns if Section 05 30 00 STEEL DECKS is not in contract.

**************************************************************************

NOTE: Insulating concrete could be applied over structural or precast concrete, or corrugated steel form decking. Provide design details to meet minimum roof slope of 1/24.

**************************************************************************

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

**************************************************************************

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

AMERICAN SOCIETY OF HEATING, REFRIGERATING AND AIR-CONDITIONING ENGINEERS (ASHRAE)

1.2 QUALIFICATIONS OF APPLICATOR

Perform work by or under the supervision of personnel specializing in insulating concrete application and having not less than 2 years experience.

1.3 SUBMITTALS

**************************************************************************
NOTE: Review Submittal Description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G". Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes
following the "G" typically are not used for Navy and Air Force projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.

**************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-03 Product Data

Performance Requirements

Submit, indicating compressive strength, oven dry density, and coefficient of heat transmission.

SD-06 Test Reports

Performance Requirements

Submit certified test reports on laboratory testing of insulating concrete samples taken at time of placement.

SD-07 Certificates

Fabricator's Compatibility Certificates

SD-08 Manufacturer's Instructions

Application

1.4 DELIVERY AND STORAGE

Deliver all materials to the building site in original unopened, undamaged packages or containers, or approved bulk handling equipment, with manufacturer's brand name and contents clearly identified. Protect materials against dampness. Store materials under cover and off the ground, in well-ventilated areas, not exposed to extreme changes of temperature and humidity. Prevent deterioration or intrusion of foreign substances. Keep materials dry until ready for use. Protect metal components from rusting.

1.5 ENVIRONMENTAL CONDITIONS

1.5.1 Normal Conditions

When ambient air temperatures of 3 degrees C 40 degrees F or above are
predicted for the initial 24 to 72 hours after placement of insulating concrete, the use of hot water and other cold weather protection measures are not required.

1.5.2 Cold Weather Conditions

When ambient air temperature at time of placing insulating concrete is between 3 and 0 degrees C 40 and 32 degrees F, use hot water in temperature range of 32 and 39 degrees C 90 to 120 degrees F at the point of placement. When ambient air temperatures of 0 degrees C 32 degrees F or below are predicted for the initial 24 to 72 hours after placement of insulating concrete, provide additional protection measures as recommended by the aggregate manufacturer.

1.6 SAFETY AND HEALTH REQUIREMENTS

Comply with manufacturer's protective measures in the safe installation of the insulation board.

1.7 QUALITY ASSURANCE

1.7.1 Fabricator's Compatibility Certificates

Submit a written statement from the insulating concrete fabricator certifying that materials for this project are chemically and physically compatible.

PART 2 PRODUCTS

2.1 PORTLAND CEMENT

**************************************************************************
NOTE: Uses of Types I, II, and III portland cement are as follows:

Type I - For use when the special properties specified for other types are not required

Type II - For general use, more especially when moderate resistance or moderate heat of hydration is desired

Type III - For use when high early strength is desired.
**************************************************************************

ASTM C150/C150M, Type [I] [II] [III].

2.2 AGGREGATE

**************************************************************************
NOTE: Lightweight perlite and vermiculite aggregate or cellular concrete, without embedded insulation, should be specified in Section 03 30 00 CAST-IN-PLACE CONCRETE. Insulation board applied over lightweight perlite and vermiculite aggregate or cellular concrete should be specified Section 07 22 00 ROOF AND DECK INSULATION.
**************************************************************************
ASTM C332, Group I.

2.3 AIR-ENTRAINMENT

**************************************************************************
NOTE: Air-entraining agent is not required with cellular concrete.
**************************************************************************

Prepackage or add the air-entrainment agent at the mixer. Provide amount and type of air-entrainment in accordance with the aggregate manufacturer's recommendations. Do not use calcium chloride.

2.4 FOAMING AGENTS

ASTM C796/C796M.

2.5 WATER

Water shall be clean and free from injurious amounts of acids, alkali, organic matter, or other deleterious substances.

2.6 EXPANSION JOINT FILLER MATERIAL

ASTM C612, Class 1, semi-rigid, modified for maximum density of 96 kg per cubic meter 6.0 pounds per cubic foot.

2.7 WELDED WIRE FABRIC

**************************************************************************
NOTE: Insulating concrete requires reinforcement where slope substrate exceeds 1/3, and for achieving specific fire rated systems for metal deck systems, not over structural concrete.
**************************************************************************

Galvanized steel welded wire fabric shall conform to ASTM A1064/A1064M.

2.8 INSULATION BOARD

**************************************************************************
NOTE: Design and specify insulating concrete with embedded insulation board to obtain contract U value requirements. Insulation board applied over insulating concrete is specified in Section 07 22 00 ROOF AND DECK INSULATION.
**************************************************************************

Polystyrene insulation board conforming to ASTM C578 RCPS Type [I], [II], [III], [IV], or [V], 600 by 1200 mm 24 by 48 inches, and of thickness [indicated] [necessary to provide a "C" value not greater than [_____]]. Boards shall be factory fabricated and slotted or perforated for keying the insulation board into the insulating concrete.
PART 3   EXECUTION

3.1 PERFORMANCE REQUIREMENTS

Provide insulating concrete design mix to shall meet the following performance requirements. Test as specified.

3.1.1 Minimum Compressive Strength

[9] [_____] MPa [125] [_____] pounds per square inch in 28 days as tested with ASTM C495/C495M.

3.1.2 Minimum Oven Dry Density

**************************************************************************
NOTE: Oven dry density should not be less than 350
kg per cubic meter 22 pcf.
**************************************************************************

[350] [_____] kg per cubic meter [22] [_____] pounds per cubic foot as determined by ASTM C495/C495M.

3.1.3 Coefficient of Heat Transmission

**************************************************************************
NOTE: Meet contract U value requirements. Specify insulation board applied over insulating concrete in Section 07 22 00 ROOF AND DECK INSULATION.
**************************************************************************

U value of [0.28] [_____] watt/sq. ft/degree C [0.05] [_____] Btu/hr/sq. ft/degree F, as determined in accordance with ASHRAE FUN SI ASHRAE FUN IP. The U value shall incorporate the total roof deck and roofing system design and represent the average U value for the total roof area.

3.2 SURFACE PREPARATION

Clean surfaces to receive insulating concrete of dirt, debris, and other foreign materials that would affect bonding. Deck shall be free of standing water, snow, and ice.

3.3 STEEL ROOF DECKING

**************************************************************************
NOTE: Select the applicable paragraph(s) from the following:
**************************************************************************

NOTE: Insert the appropriate Section number and title in the blank below using format per UFC 1-300-02, "Unified Facilities Guide Specifications (UFGS) Format Standard".

As specified in Section [05 30 00 STEEL DECKS].

[[CAST-IN-PLACE] [PRECAST] STRUCTURAL CONCRETE DECK

As specified in [______].]
3.4  REINFORCING MESH OR WELDED WIRE FABRIC

**************************************************************************
NOTE:  Insulating concrete requires reinforcement where slope on substrate exceeds 1 to 3, and for achieving specific fire rated systems for metal deck systems, not over structural concrete. Reinforcement size and spacing should be indicated on drawings.
**************************************************************************

Install reinforcing mesh or welded wire fabric with a minimum end lap of 150 mm 6 inches and no side lap. Cut mesh or fabric to fit at all [walls,] [curbs,] [roof drains,] and [openings]. [Mesh not required over structural concrete decks.]

3.5  APPLICATION OF INSULATING CONCRETE AND INSULATION BOARD

**************************************************************************
NOTE: Use Section 07 51 13 BUILT-UP ASPHALT ROOFING or Section 07 53 23 ETHYLENE PROPYLENE-DIENE-MONOMER ROOFING as guidance in developing details and specifications for venting, roof expansion joints, and application of roofing materials. In addition to providing expansion joints in the structure, provide expansion joints in roofing membrane at all expansion joints in the insulating concrete roof deck except those located at the perimeter of the roof deck and where the roof deck abuts vertical surfaces.
**************************************************************************

**************************************************************************
NOTE: Edit application procedures for concrete requirements. When the roof deck is designed for resistance to seismic or other lateral forces, the aggregate manufacturer should be consulted for specific criteria. Expansion joints other than those located at expansion joints in the structure shall not be provided when the roof deck is designed as a diaphragm to resist horizontal forces.
**************************************************************************

Apply insulating concrete, insulation board and related materials in accordance with respective specifications and manufacturer's instructions, except as modified herein.

3.5.1  Mixing

Mix insulating concrete materials mechanically to produce a uniform distribution.

3.5.2  Conveying

Convey insulating concrete from the mixer to place of final deposit by methods that prevent segregation or loss of materials. Convey the concrete without material separation or loss of air content.
3.5.3 Expansion Joints

NOTE: Provide specifications for expansion joints in this or other sections. Normally expansion joints are specified in Section 03 30 00 CAST-IN-PLACE CONCRETE. When one of these sections is included in the project specification, coordinate the requirements for expansion joints and construction joints with this section.

NOTE: Locations and dimensions of expansion joints:
Expansion joints in the lightweight insulating concrete should be 32 mm 1-1/2 inch wide or 25 mm 1 inch wide as required. Expansion joints greater than 32 mm 1-1/2 inch wide should be located at expansion joints in the structure. Expansion joints not less than one inch wide should be located at the perimeter of the roof deck, where the roof deck abuts vertical surfaces and at the following locations:

1. On cast-in-place structural concrete substrates, expansion joints in the light weight insulating concrete should be located at expansion joints in the building.

2. On precast concrete and steel form decking substrates, expansion joints in the light weight insulating concrete should be placed as they correspond with the structure and where the direction of the metal deck changes.

Provide expansion joints through the depth of the light-weight insulating concrete at the perimeters of the roof deck, where the roof deck abuts vertical surfaces and where indicated. [Perimeter expansion joints are not required with cellular concrete.]

3.5.4 Slurry Coat and Insulation Board

NOTE: Insulation board applied over insulating concrete should be installed in accordance with Section 07 22 00 ROOF AND DECK INSULATION.

Bond the insulation board to the structural deck with a slurry coat of the same insulating concrete mix ratio as used for fill over the insulation board. Screed the slurry of concrete to an even surface, to a minimum of 3 mm 1/8 inch over the top of the structural deck. [Fill corrugations of steel decking with insulating concrete and screed even with the slurry coat.]

3.5.5 Insulating Concrete Fill

Place the insulating concrete on the insulation board and screed to an even
surface in a continuous operation until placement of a section is completed. Provide slopes as indicated for high points, valleys and positive drainage [to roof drains] and to eliminate ponding. At no place shall the minimum and maximum thickness of the insulating concrete be less than 50 mm or greater than 200 mm 2 inches or greater than 8 inches respectively over the top of insulation board.

3.5.5.1 Compacting

Rodding, tamping, or vibrating are not permitted.

3.5.5.2 Curing

**************************************************************************
NOTE: The insulating concrete should be covered with subsequent roofing materials soon after being allowed to cure for a minimum of 10 days.
**************************************************************************

Minimize traffic on the surface during the curing period. Under normal conditions, roofing may begin in 3 days. When the insulating concrete is placed during extremely dry conditions, sprinkle additional water on the concrete for hydration of the cement and to minimize shrinkage cracking. After a freezing or heavy rainfall or minor scaling of less than 6 mm 1/4 inch depth, broom the surface immediately prior to installation of roofing.

3.5.5.3 Patching

Remove portions of the insulating concrete deck with excessive scaling of more than 6 mm 1/4 inch depth to sound concrete. Patch the surface with portland cement concrete slurry.

3.6 FIELD TESTS

During progress of work, take insulating concrete specimens for laboratory testing as specified herein.

3.6.1 Test Specimens

**************************************************************************
NOTE: A minimum of one test should be required for each 40 to 60 cubic meters 50 to 75 cubic yards of insulating concrete.
**************************************************************************

Take test cylinder specimens for compressive strength in the presence of the Contracting Officer. Notify the Contracting Officer one day prior to the date of taking specimens. Make a minimum of [four] [_____] test specimens for each day's concreting, with at least one test required for each [57] [_____] cubic meters [75] [_____] cubic yards of insulating concrete. Label specimens to indicate the location at which they were taken. Store specimens in an undisturbed place which will not be exposed to rain and extreme changes of temperature and humidity until ready for testing.

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for light reflective, non-oxidizing, metallic (not silica or quartz) dry shake surface hardener for concrete floor finish. This is intended to be an interior application utilized in warehouses, maintenance facilities and hangars in which a light colored, dense, hard, low-dusting concrete surface is desired. This system should not be used in locations subjected to acids.

Other concrete floor hardeners with silica or quartz additives are located within products of Section 03 33 00 CAST-IN-PLACE CONCRETE. This nonferrous metallic aggregate is greatly more robust for abrasion resistance when compared to silica or quartz additives.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).
PART 1   GENERAL

1.1 REFERENCES

**************************************************************************
NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

**************************************************************************

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

AMERICAN CONCRETE INSTITUTE (ACI)

ACI 308.1 (2011) Specification for Curing Concrete
ACI 308R (2016) Guide to External Curing of Concrete

ASTM INTERNATIONAL (ASTM)

1.2 PRE-INSTALLATION MEETING

Upon approval of preconstruction submittals and before placing concrete, conduct a meeting to review the quality control requirements specifically
for the application of the floor hardener. This meeting may be conducted in coordination with the Preparatory Meeting required for Section 03 30 00 CAST-IN-PLACE CONCRETE. Attendees must include the Quality Control Manager and other Contractor personnel directly responsible for the application of the floor hardener material, Contracting Officer's Representative, the Designer of Record and a representative of the floor hardener system manufacturer. Include discussion points specific to the floor hardener system in the notes to document Preparatory Meeting. Notify the Contracting Officer at least 10 days in advance of the scheduled meeting date.

1.3 SUBMITTALS

**************************************************************************
NOTE: Review Submittal Description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G". Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.
**************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-01 Preconstruction Submittals

Application Plan; G[, [_____]]
SD-03 Product Data

Non-oxidizing Metallic Aggregate surface hardener; G[, [______]]

SD-04 Samples

Initial Application

Material Sample

SD-11 Closeout Submittals

Video Recording

1.3.1 Application Plan

Submit a written plan describing in detail all phases of floor hardener system application. Address work sequencing, floor hardener system application, cure time projections, curing activities, protection of surfaces during the curing period, as well as how each step will be controlled, tested, and evaluated. For each process, provide procedures that include appropriate work instructions, material and equipment to be used, controls, and process verification procedures. Address safety measures, work scheduling around weather, and record keeping. Plan must adhere to the manufacturer's instructions and Contract requirements outlined herein. Assign one supervisor to the job who is to remain at the site throughout all phases of work and who is to act as the Contractor's primary point of contact. Identify this person in the submitted plan.

1.3.2 Initial Application

Finish a minimum of 9.3 square meters 100 square feet of the [hangar] floor slab in a location approved by the Contracting Officer. The initial application must be witnessed by the manufacturer's representative and may become part of the permanent structure with written approval by the manufacturer's representative and Contracting Officer. Color, texture and installation procedures must be approved by the manufacturer's technical representative and Contracting Officer before proceeding with additional application. Upon approval, the initial application will be used as the standard for workmanship for future work.

1.3.3 Material Sample

Submit samples of materials, color, and finish type to the Contracting Officer for approval.

1.4 DELIVERY AND STORAGE

Deliver product in sealed moisture-resistant packages. Protect packages from damage. Store in an enclosed area. Replace damaged packages with new packages. Provide manufacturer's information regarding date of manufacture, shelf life and date of purchase no later than the date delivered on site. Products must be identifiable by lot numbers.

1.5 WARRANTY

Provide a manufacturer's standard warranty stating that the material is free of defects and that when applied in accordance with the manufacturer's
instructions, the product will perform as specified herein. The manufacturer's standard warranty must not contain any disclaimers, limiting their responsibility to the purchase price of the material. The manufacturer must state in the warranty that they will contribute to replacing defective materials, as determined by accepted test methods.

PART 2 PRODUCTS

**************************************************************************
NOTE: Coordinate with Section 03 30 00, CAST-IN-PLACE CONCRETE to ensure requirements of ACI 117, ACI 212.3R, ACI 301, ACI 302.1R, ACI 304R, ACI 318 and ACI 318M are included.
**************************************************************************

2.1 CONCRETE

Provide concrete materials as specified in Section 03 30 00 CAST-IN-PLACE CONCRETE, in addition to items required by this section and the following:

The concrete mix, including admixtures and plasticizers, must be in strict compliance with the aggregate surface hardener manufacturer's recommendations and must be approved in conjunction by both the Contracting Officer and the manufacturer's technical representative prior to the placement of concrete.

2.2 NON-FERROUS, NON-OXIDIZING METALLIC AGGREGATE, DRY-SHAKE SURFACE HARDENER

Provide a surface hardener system consisting of specially processed, non-ferrous, malleable, non-oxidizing, metallic aggregates, specially graded cementitious binder, plasticizer, and water-reducing admixtures, formulated and processed under the stringent quality control of the manufacturer. Provide hardener that is proportioned and sealed in standard moisture-resistant bags. The manufacturer must guarantee the aggregate to be free of rust, corrosive materials, oil, petroleum, or other water-based materials, when delivered. The manufacturer must replace any material found to contain any such materials, or any other material which is deemed unsatisfactory. The manufacturer must provide a technical representative, qualified in designing and adjusting concrete mixes, to assist in the application of the aggregate surface hardener system.

Provide floor hardener system with minimum compressive strength at 28 days of 75.6 MPA 11,000 psi in accordance with ASTM C109/C109M. System must also achieve minimum relative abrasion resistance at 28 days (abrasion at 60 minutes) of 0.8 mm 0.03 inches in accordance with ASTM C779/C779M.

2.3 SURFACE EVAPORATION RETARDANT

Provide a mono molecular surface evaporation retardant film, as recommended by ACI 305R and ACI 308R, for use under drying conditions, due to high concrete or ambient temperatures, low humidity, or high winds. This includes work in heated interiors during cold weather, to aid in the maintaining of concrete moisture during the early placement stages of plastic concrete. Provide a retarder certified by the manufacturer to be compatible with the surface hardener and provide in accordance with the manufacturer's recommendations.
2.4 CURING AND SEALING

Curing and sealing materials and procedures must be as recommended by the manufacturer of the aggregate surface hardener system and must comply with ASTM C309 or ASTM C1315.

PART 3 EXECUTION

3.1 CONCRETE PLACEMENT

For concrete placement, refer to Section 03 30 00 CAST-IN-PLACE CONCRETE in addition to items required by this section and the following:

a. Maximum slump must be 89 mm 3.5 inches, when peak ambient temperatures are anticipated to be in excess of 18.33 degrees Celsius 65 degrees Fahrenheit, and must be no greater than 96.2 mm 4 inches, when such temperatures are below 29.4 degrees Celsius 85 degrees Fahrenheit. Water reducing admixtures compatible with the surface hardener's written product information and instructions can be used to aid in workability without affecting dry shake hardener.

b. Maximum total air content must not exceed 3 percent.

c. As previously noted, water-reducing additives can be used. Provider must certify that the water reducer will not contribute to or cause increased air content.

d. Do not use calcium chloride or set accelerating admixtures, containing calcium chloride.

Place base slab between screed points to minimize handling. Move concrete into place with square-tipped shovels; do not use rakes. Vibrators, when used, must be inserted and withdrawn vertically. Strike concrete to the specified level. Further level and consolidate concrete with wood bull float or wood darby. Complete floating before free moisture rises to the surface (bleeding). Begin floating adjacent to columns, forms, and walls.

3.1.1 Application of Surface Hardener

Apply first shake to floated concrete adjacent to forms, entry ways, columns and walls, where moisture will be lost first. Apply two-thirds of the specified total shake immediately following the floating of total area. Apply material at a minimum rate of 9.76 kg/square meter 2 pounds per square foot of slab. Bleed water must not be present during or following the application of this shake. Distribute Evenly. Apply by means of calibrated mechanical spreader except small areas not accessible to mechanical spreader may be hand applied. Wood bull floats can be used as soon as the shake has absorbed moisture (indicated by the darkening of the surface). Float just sufficiently to bring moisture from base slab through the shake. Use finishing machines with float blades to "open" the surface, prior to the application of the remaining one-third of the total specified shake, and also use to incorporate this second shake. Provide further surface compaction by a second mechanical floating, if time and setting characteristics of the concrete will allow, without removing the cement surface paste from the metallic aggregate system. AT NO TIME MUST WATER BE ADDED TO THE SURFACE. As surface further stiffens, indicated by loss of sheen, hand or mechanically trowel with blades relatively flat. Run trowel blades as slowly as possible, to achieve the desired finish. Excessive trowel blade speed will "burn" or darken the floor surface.
resulting in a possible loss of the desired even surface color. Remove all marks and pinholes in the raised trowel operation. DO NOT OVER FINISH. Do not burnish trowel. Type or texture of surface must conform to job mock-up.

3.1.2 Field Quality Control

Provide a manufacturer's representative at the job site a minimum of three times during the application of the floor hardener for the purposes of monitoring the quality of the application process and floor hardener materials to ensure proper application. Site visits must occur during the initial (sample) application, at mid-point of the overall application and the final application. After each site visit, submit a report signed by the manufacturer's representative within 3 working days. The report must document that all work was completed satisfactorily in accordance with the manufacturer's instructions.

3.1.3 Video Recording

**************************************************************************
NOTE: Include this paragraph to require digital video recording of the application when the project is at a remote location or when a Government representative will not be present during construction.
**************************************************************************

As directed by the Contracting Officer, provide a digital video recording of the actual application of the floor surface hardener material and finishing process. Video must clearly show the material being applied with an even distribution and the concrete being finished. Provide a separate video recording for each day the floor surface hardener is applied and finished. Submit the videos to the Contracting Officer electronically as directed.

3.1.4 Curing and Protection (Water Based Wax Emulsion)

Refer to ACI 308.1. Cure floors, finished with the non-rusting, metallic-aggregate surface hardener, as recommended by the manufacturer of the surface hardener. When high efficiency membrane curing compound is recommended, apply the membrane curing compound immediately after the floor surface has hardened sufficiently, so surface will not be marred by the application. Apply compound uniformly over the entire surface, to meet the required moisture retention of ASTM C1315, at a maximum rate of 6.136 square meters per liter 250 square feet per gallon. When dry, protect the coating from droppings of plaster, paint, dirt, and other debris, by a covering of scuff-proof building paper. Make provisions for maintaining the concrete temperature at 10 degrees Celsius 50 degrees Fahrenheit, or above during the curing period. Floor must remain covered and be kept free of traffic and loads for at least 10 days after completion. At the direction of the Contracting Officer, remove the curing compound between 2 and 4 weeks after placement.

3.2 CURTAIL SURFACE ACTIVITY

After installation of the product, the slab and hardener must cure for 28 days in which construction equipment, hoists, overhead access equipment, and material storage must remain off the slab. Follow specific instructions given by the manufacturer's representative at the pre-installation conference.
3.3 Cleaning and Surface Preparation

After the aggregate surface hardener system has cured for 28 days, clean and buff the floor surfaces in accordance with the manufacturer's recommendations. Perform the cleaning and surface preparation to remove projections that permit soil and foreign bodies to embed into the floor and to permit easier cleaning of a less porous, more densified concrete surface.

Expansion; G[, [____]]

Compressive Strength; G[, [____]]

Grout Placement and Inspection Reports; G[, [____]]

Expansive Grout; G[, [____]]

Portland Cement; G[, [____]]

SD-07 Certificates

Portland Cement; G[, [____]]

Expansive Admixtures; G[, [____]]

Expansive Grout; G[, [____]]

Aggregates; G[, [____]]
1.3 QUALITY CONTROL

1.3.1 Grout Placement Plan and Inspection Reports

Provide examples of grout placement and inspection reports in accordance with ACI 214R, ACI 211.5R, ACI 311.4R and ACI MCP SET. Show details of proposed methods of application, with written instructions from the manufacturer for the use of expansive admixture at least [45] [_____] calendar days before the start of expansive concrete operations.

Include a copy of records of inspections and tests, as well as the records of corrective action taken. Include descriptions of preparation of cavities for placement of grout; and proper mixing, placement, and curing of grout with methods of preventing discoloration.

PART 2 PRODUCTS

2.1 MATERIALS

2.1.1 Portland Cement

Provide portland cement grout conforming to ASTM C150/C150M for Cement, Type I.

2.1.2 Aggregates

Submit samples conforming to ASTM C33/C33M for aggregates and the gradation as directed.

2.1.3 Water

Provide potable water.

2.1.4 Expansive Admixtures

**************************************************************************
NOTE: Select one of next two paragraphs, depending on type of expansive admixture required.
Select the first paragraph for Type A expansive grout, described below.
**************************************************************************

[ Use admixture consisting of an oxidizable metallic aggregate.
][Use admixture consisting of a metallic aluminum powder.
] Submit samples to the Contracting Officer before commencement of work for review and acceptance.

2.1.5 Expansive Grout

**************************************************************************
NOTE: Select one of the following two paragraphs, depending on the type of grout required. Last paragraph is applicable to either selection. Types are described as follows:
**************************************************************************
Type A grout derives its expansive properties from oxidation of metallic aggregate. Oxidation and consequent expansion may be expected to continue either until the aggregate has been completely oxidized or until the grout, in plane, has been sealed off from further contact with oxygen.

Type B grout derives its expansive properties from the liberation of gas into the mixture during and after mixing. Chemical reaction causes evolution of hydrogen gas. Expansion may be expected to continue either until the gas-liberating mechanism has been exhausted or until the mixture has solidified to such an extent that the tendency for evolving gas to expand is effectively resisted by the stiffness of the grout.

**************************************************************************
[ Provide Type A grout containing an oxidizable metallic aggregate and an oxidation-promoting ingredient in accordance with manufacturer's instructions.
]
[ Provide Type B grout containing a metallic aluminum powder with alkali hydroxides in solution. Do not exceed 0.3 percent by weight or as recommended by the grout manufacturer.
]

PART 3 EXECUTION

3.1 PREPARATION

**************************************************************************

NOTE: Verify that the section cited below is included in specification.
**************************************************************************

Prepare cavities for grouting by cleaning away foreign matter, laitance, dirt, grease, or oil in accordance with manufacturer's instructions. Clean all contact surfaces of concrete and masonry no less than 24 hours before grout application.

3.1.1 Mixing

Mix grout ingredients for both cementitious grout and epoxy grout in accordance with the manufacturer's instructions and recommendations.

Mix grout materials with properly sized and powered mechanical mixers.

Mix grout as close to the work area as possible.

3.2 APPLICATION

3.2.1 Placing Grout

Place grout in accordance with the manufacturer's installation instructions and recommendations. Do not use grout that has begun to set or if more than one hour has elapsed after initial mixing.

Fill blind cavities by pressure injection under controlled venting. Provide continuous injection with vent open until waste grout is expelled.
through the vent with the same consistency. Then block the vent for pressurization to 413 kilopascal 60 psi. Use lower pressures when damage to construction may result.

3.3 FIELD QUALITY CONTROL

Provide testing and submit test reports in accordance with ASTM C1107/C1107M for the expansive grout to meet the following performance requirements:

- **Expansion**: 28 calendar days - Percent maximum: 0.3
  - Percent minimum: 0.0

  **Compressive Strength**: 34 [_____] Megapascal 5,000 [_____] psi

3.4 PROTECTION

Protect freshly placed grout from premature drying and excessive cold or hot temperatures. Comply with manufacturer's instructions for cold-weather and hot-weather protection during curing.

  2.3.4.11 Washing Plant
  2.3.4.12 Trial Operation
  2.3.4.13 Protection
2.3.5 Laboratory Areas
2.3.6 Plant Layout Drawings
2.3.7 Mixers
  2.3.7.1 Stationary Mixer Uniformity Requirements
  2.3.7.2 Truck Mixers
2.3.8 Sampling Facilities
2.3.9 Coarse Aggregate
2.3.10 Transporting Equipment
  2.3.10.1 Buckets
  2.3.10.2 Trucks
  2.3.10.3 Chutes
  2.3.10.4 Belt Conveyors
  2.3.10.5 Pump Placement

PART 3 EXECUTION

3.1 PREPARATION FOR PLACING
  3.1.1 Vibrators
  3.1.2 Embedded Items
  3.1.3 Concrete on Earth Foundations
  3.1.4 Concrete on Rock Foundations
  3.1.5 Construction Joint Treatment
    3.1.5.1 Joint Preparation
    3.1.5.2 Air-Water Cutting
3.1.5.3 High-Pressure Water Jet
3.1.5.4 Wet Sandblasting
3.1.5.5 Waste Water Disposal

3.2 TRANSPORTING AND PLACING

3.2.1 Transporting
  3.2.1.1 Transporting by Bucket
  3.2.1.2 Transporting by Pump
  3.2.1.3 Transporting by Belt Conveyor

3.2.2 Placing
  3.2.2.1 Time Interval Between Mixing and Placing
  3.2.2.2 Hot-Weather Placing
  3.2.2.3 Cold Weather Placing
  3.2.2.4 Special Temperature-Controlled Concrete
  3.2.2.5 Concrete Lifts
  3.2.2.6 Consolidation
  3.2.2.7 Placing Concrete in Unformed Curved Sections
  3.2.2.8 Placing Concrete Underwater

3.3 FINISHING

3.3.1 Unformed Surfaces
  3.3.1.1 Float Finish
  3.3.1.2 Trowel Finish
  3.3.1.3 Broom Finish
  3.3.1.4 Abrasive Aggregate Finish
  3.3.1.5 High Velocity Finishes

3.3.2 Formed Surface Repair
  3.3.2.1 Classes A, A-HV, & B Finishes
  3.3.2.2 Class C Finish
  3.3.2.3 Class D Finish
  3.3.2.4 Material and Procedure for Repairs

3.3.3 Grout-Cleaned Finish

3.4 CURING AND PROTECTION

3.4.1 Curing Time
3.4.2 Moist Curing
3.4.3 Membrane Curing
  3.4.3.1 Pigmented Curing Compound
  3.4.3.2 Nonpigmented Curing Compound
  3.4.3.3 Application
3.4.4 Sheet Curing
3.4.5 Sealed Insulation Curing
3.4.6 Protection
3.4.7 Cold Weather-Protection

3.5 BASE PLATES AND BEARING PLATES

3.5.1 Setting of Plates
3.5.2 Nonshrink Grout
  3.5.2.1 Mixing and Placing
  3.5.2.2 Treatment of Exposed Surfaces
  3.5.2.3 Curing

3.6 BLOCK-OUT CONCRETE

3.6.1 Composition and Proportions
3.6.2 Placing Block-out Concrete

3.7 TESTS AND INSPECTIONS

3.7.1 General
3.7.2 Testing and Inspection Requirements
  3.7.2.1 Fine Aggregate
    3.7.2.1.1 Grading
    3.7.2.1.2 Fineness Modulus Control Chart
    3.7.2.1.3 Corrective Action for Fine Aggregate Grading
    3.7.2.1.4 Moisture Content Testing
    3.7.2.1.5 Moisture Content Corrective Action
3.7.2.2 Coarse Aggregate
  3.7.2.2.1 Grading
  3.7.2.2.2 Corrective Action for Grading
  3.7.2.2.3 Coarse Aggregate Moisture Content
  3.7.2.2.4 Coarse Aggregate Moisture Corrective Action
  3.7.2.2.5 Particle Shape Testing
  3.7.2.2.6 Particle Shape Corrective Action
  3.7.2.2.7 Material Finer than the 75-µm No. 200 Sieve
  3.7.2.2.8 Corrective Action for Material Finer than the 75-µm No. 200 Sieve

3.7.2.3 Quality of Aggregates
  3.7.2.3.1 Frequency of Quality Tests
  3.7.2.3.2 Corrective Action for Aggregate Quality

3.7.2.4 Scales
  3.7.2.4.1 Weighing Accuracy
  3.7.2.4.2 Batching and Recording Accuracy
  3.7.2.4.3 Scales Corrective Action

3.7.2.5 Batch-Plant Control

3.7.2.6 Concrete
  3.7.2.6.1 Air Content
  3.7.2.6.2 Air Content Corrective Action
  3.7.2.6.3 Slump Testing
  3.7.2.6.4 Slump Corrective Action
  3.7.2.6.5 Compression Test Cylinders

3.7.2.7 Inspection Before Placing

3.7.2.8 Concrete Placement
  3.7.2.8.1 Placing Inspection
  3.7.2.8.2 Placing Corrective Action

3.7.2.9 Vibrators
  3.7.2.9.1 Vibrator Testing and Use
  3.7.2.9.2 Vibrator Corrective Action

3.7.2.10 Curing
  3.7.2.10.1 Moist Curing Inspections
  3.7.2.10.2 Moist Curing Corrective Action
  3.7.2.10.3 Membrane Curing Inspection
  3.7.2.10.4 Membrane Curing Corrective Action
  3.7.2.10.5 Sheet Curing Inspection
  3.7.2.10.6 Sheet Curing Corrective Action

3.7.2.11 Cold Weather Protection and Sealed Insulation Curing

3.7.2.12 Cold Weather Protection Corrective Action

3.7.2.13 Mixer Uniformity
  3.7.2.13.1 Stationary Mixers
  3.7.2.13.2 Truck Mixers

3.7.2.14 Mixer Uniformity Corrective Action

3.7.3 Reports

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for large projects containing mass concrete or mass and structural concrete, and major projects where the government retains the responsibility for concrete mixture proportioning. This section was originally developed for USACE Civil Works projects.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1 GENERAL

NOTE: The content of this specification is such that guidance given in EM 1110-2-2000, "Standard Practice for Concrete" is applicable.

1.1 UNIT PRICES

NOTE: If Section 01 20 00 PRICE AND PAYMENT PROCEDURES is included in the project
specifications, this paragraph title (UNIT PRICES) should be deleted from this section and the remaining appropriately edited subparagraphs below should be inserted into Section 01 20 00.

Consult the concrete materials design memorandum to choose the appropriate cementitious materials and admixtures for measurement and payment.

When silica fume is used in the project, the Specifier should include both bid items, "Silica Fume, Dry" and "Silica Fume, Slurry", to give the Contractor the option of supplying the material in dry form or in slurry form.

NOTE: Repeat this bid item and its respective subparagraphs for each bid item of concrete, renumbering the bid items appropriately.

1.1.1 Concrete for [______]

1.1.1.1 Payment

Payment will be made for costs associated with completing the concrete work for concrete placed in the [______]. However, these costs will not include the cost of the cement, pozzolan, [slag,] reinforcement, [water-reducing admixture,] [high range water reducer,] [silica fume,] and embedded parts that are specified to be paid for separately. No payment will be made for concrete, as such, that is placed in structures of which payment is made as a lump sum.

1.1.1.2 Measurement

Concrete will be measurement for payment based upon the actual volume of concrete within the pay lines of the structures as indicated on the drawings. Measure concrete placed against the sides of any excavation without the use of intervening forms only within the pay lines of the structure. Do not make deductions for rounded or beveled edges, space occupied by metal work, electrical conduits or reinforcing steel, nor for voids or embedded items that are either less than 0.14 cubic meters 5 cubic feet in volume or 0.09 square meter 1 square foot in cross section.

1.1.1.3 Unit of Measure

Unit of measure: cubic meters yards.

[1.1.2 Concrete in Blockouts

[1.1.2.1 Payment

Payment will be made for costs associated with concrete placed in the blockouts.

][1.1.2.2 Measurement

Concrete will be measurement for payment based upon the actual volume of
concrete placed in the blockouts as indicated on the drawings.

][1.1.2.3  Unit of Measure

Unit of measure:  cubic meters yards.

][1.1.3  Portland Cement

**************************************************************************
NOTE:  List all other cementitious materials (except pozzolan), such as portland-pozzolan cement, slag cement, or portland blast-furnace cement, separately similar to this bid item, and the bid items renumbered appropriately.
**************************************************************************

1.1.3.1  Payment

Payment will be made for costs associated with Portland cement, which includes the cost of required unloading, hauling, handling, and storage at the site, of all portland cement used in the work.

1.1.3.2  Measurement

Portland cement will be measured for payment based upon the number of tons of portland cement used unless specifically excepted, wasted, or used for the convenience of the Contractor. The quantity to be paid for will be determined by multiplying the approved batch weight in kg/cubic meter pounds/cubic yard of portland cement in each type of concrete used by the number of cubic meters yards of concrete types placed within the pay lines of the structure, as determined in accordance with the concrete bid items, and dividing by the product of the average specific gravity of the pozzolan multiplied by 1000 2,000.

1.1.3.3  Unit of Measure

Unit of measure:  tons (metric) (2000 lb).

1.1.4  Pozzolan (Except Silica Fume)

1.1.4.1  Payment

Payment will be made for costs associated with pozzolan, which includes the cost of required unloading, hauling, handling, and storage at the site, of all pozzolan used in the concrete bid items.

1.1.4.2  Measurement

Pozzolan, except silica fume, will be measured for payment based upon the number of cubic meters feet solid volume of pozzolan used unless specifically excepted, wasted, or used for the convenience of the Contractor. The quantity to be paid for will be determined by multiplying the approved batch weight in kg/cubic meter pounds/cubic yard of pozzolan in each type of concrete used by the number of cubic meters yards of concrete of the types placed within the pay lines of the structure, as determined in accordance with the concrete bid items, and dividing by the product of the average specific gravity of the pozzolan multiplied by 1000 kg/cubic meter 62.4 pounds/cubic foot. The average specific gravity is the average of the test results for all material accepted during the period covered by the payment.
1.1.4.3 Unit of Measure

Unit of measure: cubic meters feet solid volume.

1.1.5 Ground Granulated Blast-Furnace Slag

1.1.5.1 Payment

Payment will be made for costs associated with ground granulated blast-furnace slag, which includes the cost of required unloading, hauling, handling, and storage at the site, of all ground granulated blast-furnace slag used in the concrete bid items.

1.1.5.2 Measurement

Ground granulated blast-furnace slag will be measured for payment based upon the number of tons of ground granulated blast-furnace slag used excluding the amount specifically excepted, wasted, or used for the convenience of the Contractor. The quantity to be paid for will be determined by multiplying the approved batch weight in kg/cubic meter pounds/cubic yard of ground granulated blast-furnace slag in each type of concrete used by the number of cubic meters yards of concrete types placed within the pay lines of the structure, as determined in accordance with the concrete bid items, and dividing by 1000 2,000.

1.1.5.3 Unit of Measure

Unit of measure: tons (metric) (2000 lb).

1.1.6 Water-Reducing Admixture (WRA)

1.1.6.1 Payment

[Payment will be made for costs associated with water-reducing admixture (WRA) at the applicable contract unit price per cubic meter yard of concrete containing water-reducing admixture.] [Payment will be made for costs associated with water-reducing admixture (WRA) at the applicable contract unit cost of concrete containing water-reducing admixture for:

a. "Bid Item [____]a., first [____] cubic meters yards."

b. "Bid Item [____]b., all over [____] cubic meters yards."

1.1.6.2 Measurement

Water-reducing admixture (WRA) will be measured for payment based upon the actual volume of concrete containing the admixture and within the pay lines of the structures, as determined in accordance with the concrete bid items.

1.1.6.3 Unit of Measure

Unit of measure: cubic meters yards.

1.1.7 High-Range Water-Reducing Admixture (HRWR)

1.1.7.1 Payment

[Payment will be made for costs associated with high-range water-reducing
admixture (HRWR) at the applicable contract unit price per cubic meter yard of concrete containing water-reducing admixture. Payment will be made for costs associated with high-range water-reducing admixture (HRWR) at the applicable contract unit cost of concrete containing water-reducing admixture for:

a. "Bid Item [_____]a., first [_____] cubic meters yards."

b. "Bid Item [_____]b., all over [_____] cubic meters yards."

1.1.7.2 Measurement

High-Range water-reducing admixture (HRWR) will be measured for payment based upon the actual volume of concrete containing the admixture and within the pay lines of the structures, as determined in accordance with the concrete bid items.

1.1.7.3 Unit of Measure

Unit of measure: cubic meters yards.

[1.1.8 Silica Fume, Dry]

[1.1.8.1 Payment]

Payment will be made for costs associated with silica fume, dry, which includes price batching and recording equipment for dry silica fume used in the concrete bid items. Payment will be made at the contract price per kilogram hundredweight of dry silica fume for:

a. "Bid Item [_____]a., first [_____] kilograms hundredweight."

b. "Bid Item [_____]b., all over [_____] kilograms hundredweight."

[1.1.8.2 Measurement]

Silica fume, dry, will be measured for payment based upon the number of kilograms hundredweight of silica fume used in the concrete, excluding the amount wasted or used for the convenience of the Contractor. The quantity to be paid for will be determined by multiplying the weight in kilograms pounds of silica fume per cubic meter yard by the number of cubic meters yards of silica fume concrete placed within the pay lines of the structure as determined in accordance with the concrete bid items., divided by 100.

[1.1.8.3 Unit of Measure]

Unit of measure: kilograms hundredweight (100 pounds).

[1.1.9 Silica Fume, Slurry]

[1.1.9.1 Payment]

Payment will be made for costs associated with silica fume, slurry, which includes the cost of silica fume, slurry; providing admixtures such as HRWR admixtures that are a component of the slurry; and furnishing storage, batching, and recording equipment for silica fume, slurry, used in the concrete bid items. Payment for silica fume, slurry, will be made at the contract price per hundredweight of dry silica fume for:
a. "Bid Item [_____]a., first [_____] kilograms hundredweight."

b. "Bid Item [_____]b., all over [_____] kilograms hundredweight."

1.1.9.2 Measurement

Silica fume, slurry, will be measured for payment based upon the number of kilograms hundredweight of silica fume used in the concrete, excluding the amount wasted or used for the convenience of the Contractor. The quantity to be paid for will be determined by multiplying the weight in kilograms pounds of silica fume per cubic meter yard by the number of cubic meters yards of silica fume concrete placed within the pay lines of the structure as determined in accordance with the concrete bid items, divided by 100. The dry weight will be determined by supplier's certificate.

1.1.9.3 Unit of Measure

Unit of measure: kilograms hundredweight (100 pounds).

1.2 REFERENCES

**************************************************************************

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

1.3 SUBMITTALS

*****************************************************************************

NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.

*****************************************************************************
Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

1.4 QUALITY ASSURANCE

1.4.1 Government Preconstruction Testing

**************************************************************************
NOTE: Contact the Engineer Research and Development Center, 3909 Halls Ferry Road, Vicksburg, Mississippi 39180-6199, ATTN: CEERD-SC for guidance in filling in the blanks.
**************************************************************************

1.4.1.1 Aggregate Sources

The aggregate sources listed in paragraph COMMERCIAL CONCRETE AGGREGATE SOURCES, have been tested, and at the time testing was performed, these sources were capable of producing materials of the quality and quantity required for this project provided suitable processing is performed. Deliver samples from any source selected consisting of no less than [_____] kg pounds of each size of coarse aggregate and [_____] kg pounds of fine aggregate, taken under the supervision of the Contracting Officer in
accordance with COE CRD-C 100, to [_____] within 15 days after notice to proceed. Sampling and shipment of samples is the Contractor's expense. [_____] days will be required to complete evaluation of the aggregates. Testing will be performed by the Government in accordance with the applicable COE CRD-C or ASTM test methods. Tests to which aggregate may be subjected are listed in paragraph AGGREGATES. The material from the proposed source must meet the quality requirements of this paragraph to be used for the project. The Government test data and other information on aggregate quality of those sources listed in paragraph COMMERCIAL CONCRETE AGGREGATE SOURCES, and are available for review in the District Office. Quality assurance testing of aggregates by the Government does not relieve the Contractor of quality control requirements.

1.4.1.2 Cementitious Materials, Admixtures, and Curing Materials

Notify the Contracting Officer of the source, brand name, type, and quantity of all materials (other than aggregates) to be used in the manufacture and curing of the concrete at least 60 days in advance of submitting samples for mixture proportioning studies. Assist the Contracting Officer in obtaining samples of each material. Sampling and testing as determined appropriate will be performed by and at the expense of the Government. If cement or pozzolan are to be obtained from more than one source, state the estimated amount of cement or pozzolan to be obtained from each source and the proposed schedule of shipments in the notification. When pozzolan other than fly ash is used, it must be from one source.

1.4.1.3 Materials for Mixture-Proportioning Studies

**************************************************************************
NOTE: Contact the Engineer Research and Development Center, 3909 Halls Ferry Road, Vicksburg, Mississippi 39180-6199, ATTN: CEERD-SC to fill in the blanks. At the end of the following table, insert other cementitious materials, including silica fume, as appropriate.
**************************************************************************

At least [_____] days in advance of the time when placing of concrete is expected to begin, deliver samples of representative materials proposed for this project and meeting all the requirements of this specification to [_____] by the Contractor at its expense. Take samples of aggregates under the supervision of the Contracting Officer in accordance with COE CRD-C 100, accompanied by test reports indicating conformance with grading and quality requirements hereinafter specified. Provide samples of materials other than aggregates that are representative of those proposed for the project and submit accompanied by manufacturer's test reports indicating compliance with applicable specified requirements. Quantities of materials required are as follows:

<table>
<thead>
<tr>
<th>MATERIAL</th>
<th>QUANTITY</th>
</tr>
</thead>
<tbody>
<tr>
<td>150 mm 6 inch nominal maximum-size coarse aggregate</td>
<td>[_____] kg pounds</td>
</tr>
<tr>
<td>75 mm 3 inch nominal maximum-size coarse aggregate</td>
<td>[_____] kg pounds</td>
</tr>
</tbody>
</table>
Mixture-proportioning studies will be made by the Government.

1.4.2 Construction Testing by the Government

1.4.2.1 General

The Government will sample and test cementitious materials, admixtures, aggregates, and concrete during construction as considered appropriate to determine compliance with the specifications. Provide facilities and labor as may be necessary for procurement of representative test samples. Samples of aggregates will be obtained at the point of batching in accordance with COE CRD-C 100. Slump and air content will be determined in accordance with ASTM C143/C143M and ASTM C231/C231M, respectively, except the point of sampling will be as directed. Compression test specimens will be made and laboratory cured in accordance with ASTM C31/C31M and will be tested in accordance with ASTM C39/C39M.

1.4.2.2 Testing Aggregates

Testing performed by the Government will not relieve the Contractor of its responsibility for testing as appropriate for quality control. During construction, aggregates will be sampled for acceptance testing as delivered to the mixer to determine compliance with specification provisions. Provide necessary facilities and labor for the ready procurement of representative samples under Contracting Officer supervision. The Government will test such samples at its expense using appropriate COE CRD-C and ASTM methods.

1.4.2.3 Cementitious Materials

Furnish cement or pozzolan or both from a prequalified source or, if not, it (they) will be sampled at the mill, shipping point, or site of the work by the Contracting Office. A list of prequalified cement sources and prequalified pozzolan sources is available from the Director, U.S. Army Corps of Engineers, Engineer Research and Development Center - Structures Laboratory, 3909 Halls Ferry Road, Vicksburg, MS 39180-6199, ATTN: CEERD-SC. If tests prove that a material which has been delivered is unsatisfactory, promptly remove it from the site of the work. Cementitious materials that have not been used within 6 months after being tested will be retested by the Government at the expense of the Contractor when
1.4.2.4  Cement from Prequalified Sources

Deliver and use cement directly from a mill of a producer designated as a prequalified source for the type of cement being used. Samples of cement for quality-assurance testing will be taken at the project site or cement-producing plant by the Contracting Officer for testing at the expense of the Government. Furnish a copy of the mill tests from the cement manufacturer to the Contracting Officer for each lot.

1.4.2.5  Pozzolan from Prequalified Sources

Deliver and use pozzolan directly from a producer designated as a prequalified source. Samples of pozzolan for check testing will be taken at the project site by the Contracting Officer for testing at the expense of the Government. Furnish a copy of the test results from the pozzolan manufacturer to the Contracting Officer for each lot.

1.4.2.6  Cement from Nonprequalified Sources

**************************************************************************
NOTE: The Contractor's expense rate for excess testing of cement and pozzolan by the Government can be obtained from the Structures Laboratory, U.S. Army Engineer Waterways Experiment Station (CEWES--SC--MP), 3909 Halls Ferry Road, Vicksburg, MS 39180--6199.
**************************************************************************

Cement, if not from a prequalified source, will be sampled and tested by or under the supervision of the Contracting Officer and at Government expense. Do not use cement until notice has been given by the Contracting Officer that test results are satisfactory. In the event of failure, the cement may be resampled and tested at the request of the Contractor and at the Contractor's expense. When the point of sampling is other than at the site of the work, the fill gate or gates of the sampled bin will be sealed and kept sealed until shipment from the bin has been completed. The fill gate or gates of conveyances used in shipment will be sealed by or under the supervision of the Contracting Officer. Conveyances will not be accepted at the site of the work unless received with all seals intact. If tested cement is rehandled at transfer points, the extra cost of inspection will be at the Contractor's expense. The cost of testing cement excess to project requirements will also be at the Contractor's expense and will be deducted from payments due the Contractor at a rate of [_____] dollars per test.

1.4.2.7  Pozzolan from Nonprequalified Sources

Pozzolan, if not from a prequalified source, will be sampled at the source or at the site of the work and will be stored in sealed bins pending completion of acceptance tests. Pozzolan may be resampled at the site when determined necessary. All sampling and testing will be performed by and at the expense of the Government. Release for shipment and approval for use will be based on compliance with seven day lime-pozzolan strength requirements and other physical, chemical, and uniformity requirements for which tests can be completed by the time the seven day lime-pozzolan strength test is completed. Release for shipment and approval for use on this basis will be contingent on continuing compliance with the other
requirements of the specifications. If test results of a bin fail, the contents may be resampled and tested at the Contractor's expense. The Government will supervise or perform the unsealing and resealing of bins and shipping conveyances. If tested pozzolan is rehandled at transfer points, the extra cost of inspection will be at the Contractor's expense. The cost of testing excess pozzolan in excess of project requirements will be at the Contractor's expense at a rate of [_____] dollars per test. The amount will be deducted from payment to the Contractor.

[1.4.2.8  Ground Granulated Blast-Furnace Slag]

********************************************************************
NOTE: If any other cementitious materials, including silica fume, are to be allowed, an additional paragraph should be added similar to this paragraph, with the name of the cementitious material substituted for "Ground Granulated Blast-Furnace Slag".
********************************************************************

Ground granulated blast-furnace slag will be sampled and tests at the mill or shipping point by and at the expense of the Government to determine that the material meets the requirements of the specification under which it is furnished. Do not use ground granulated blast-furnace slag until notice of acceptance has been given by the Contracting Officer. Ground granulated blast-furnace slag will be subject to check testing from samples obtained at the project site, as scheduled, and such sampling will be by or under the supervision of the Contracting Officer and at Government expense. Remove material not meeting specifications promptly from the site of work.

[1.4.2.9  Chemical Admixtures]

Provide satisfactory facilities for ready procurement of test samples. All sampling and testing of a chemical admixture will be by and at the expense of the Government. Tests will be conducted using samples of materials proposed for the project.

1.5  DELIVERY, STORAGE, AND HANDLING

1.5.1  Cementitious Materials

1.5.1.1  Transportation

When bulk cement, pozzolan, dry silica fume, or ground granulated blast-furnace slag is not unloaded from primary carriers directly into weather-tight hoppers at the batching plant, accomplish transportation from the railhead, mill, or intermediate storage to the batching plant in weather-tight trucks, conveyors, or other means that will protect the material from exposure to moisture. Transportation facilities for dry bulk silica fume must be approved in advance.

1.5.1.2  Storage

Furnish cementitious materials in bulk except that cement used for finishing and patching may be packaged, and silica fume may be packaged or in slurry form. Immediately upon receipt at the site of the work, store all cementitious materials in separate dry, weather-tight, and properly ventilated structures. All storage facilities must permit easy access for inspection and identification. Maintain sufficient materials in storage to
complete any lift of concrete started. In order that cement may not become
unduly aged after delivery, use any cement that has been stored at the site
for 60 days or more before using cement of lesser age. Do not use silica
fume in slurry form that has been in storage at the project site for longer
than recommended by the manufacturer or that has been subjected to freezing
in the work and remove from the site.

1.5.1.3 Separation of Materials

Provide separate facilities for unloading, transporting, and handling each
cementitious material. Provide separate appropriate storage facilities for
each type of cement and each source of pozzolan, dry bulk silica fume, or
slag. Plainly mark the contents of each storage facility marked with a
large permanent sign posted near the loading port.

1.5.2 Aggregates Storage

Store fine aggregate and each size of coarse aggregate in separate size
groups adjacent to the batch plant and in such a manner as to prevent the
intermingling of size groups or the inclusion of foreign materials in the
concrete. Maintain sufficient fine and coarse aggregate at the site at all
times to permit continuous placement and completion of any lift of concrete
started.

PART 2 PRODUCTS

2.1 SYSTEM DESCRIPTION

Provide concrete composed of cementitious materials, water, fine and coarse
aggregates, and admixtures. Use cementitious materials that are [portland
cement], [portland cement in combination with pozzolan], [portland cement
in combination with [______]], [portland blast-furnace slag cement]
[portland cement in combination with ground granulated blast-furnace slag]
[portland cement in combination with silica fume] [portland-pozzolan
cement]. Use an air-entraining admixture [or an air-entraining admixture
plus] [a retarding admixture], [a WRA], [a HRWRA], [or an accelerating
admixture]. A retarding admixture may be used at the request of the
Contractor when approved. Do not use chemical admixtures other than those
listed above.

2.1.1 Proportioning Responsibility

**************************************************************************
NOTE: The last optional sentence should be used if
slow strength gain cementitious materials are to be
used.
**************************************************************************

The concrete mixtures will be proportioned by the Contracting Officer.
[Preliminary mixture-proportioning studies or thermal studies which include
mixture proportions are available for review in the District Office.]  
[Some mixtures, especially those containing higher amounts of pozzolans,
may have slow strength gain which may impact form design and form removal
time.]

2.1.2 Design Requirements

**************************************************************************
NOTE: See the concrete materials design memorandum
**************************************************************************
to select the optional cementitious materials.

The proportions of all material entering into each concrete mixture will be furnished to the Contractor. The proportions will be changed by the Contracting Officer as necessary. Make adjustments to the batch weights of aggregates and water as necessary to compensate for free moisture in the aggregates. Adjust the quantity of air-entrainment admixture to maintain the specified air content.

2.1.3 Air Content

Determine the air content by volume by ASTM C231/C231M. When the nominal maximum size of coarse aggregate is 37.5 mm 1-1/2 inches or larger, the air content of the sample measured in accordance with ASTM C231/C231M must be 5-1/2 ± 1-1/2 percent. When the nominal maximum-size coarse aggregate is 19 mm 3/4 inch, the air content must be 6 ± 1 percent. The specified air content must be present in the concrete when the concrete has been placed in the forms.

2.1.4 Slump

Determine slump in accordance with ASTM C143/C143M of 50 mm 2 inches ± 25 mm 1 inch for massive features and between 25 and 100 mm 1 and 4 inches for all others except where placement by pump is approved, in which case the slump must be 114 mm 4-1/2 ± 38 mm 1-1/2 inches. In addition, the range of each set of two consecutive tests for each mixture must be no more than 50 mm 2 inches. The above specified slump is that required at the forms.

2.1.5 Construction Tolerances

Make level and grade tolerance measurements of slabs as soon as possible after finishing. When forms or shoring are used, make the measurements prior to removal. Tolerances are not cumulative. The most restrictive tolerance controls. Do not allow tolerances to extend the structure beyond legal boundaries. Except as specified otherwise, plus tolerance increases the amount or dimension to which it applies, or raises a level alignment and minus tolerance decreases the amount or dimension to which it applied, or lowers a level alignment. A tolerance without sign means plus or minus. Where only one signed tolerance is specified, there is no limit in the other direction. Finish unformed finished surfaces subject to high-velocity flow (12 m/s) (40 fps) to meet the tolerances for A-HV surfaces specified in Table, "TOLERANCES FOR FINISHED FORMED CONCRETE SURFACES".

2.1.6 Tabulations and Definitions

The definitions of the terms used in the following tabulations are used as defined and used in ACI 117. Make level and grade tolerance measurements of slabs as soon as possible after finishing.
# Tolerances for Foundations

## (1) Lateral alignment

<table>
<thead>
<tr>
<th>Description</th>
<th>Tolerance</th>
</tr>
</thead>
<tbody>
<tr>
<td>As cast to the center of gravity as specified; 0.02 times width of footing in direction of misplacement but not more than</td>
<td>50 mm/2 inches</td>
</tr>
<tr>
<td>Supporting masonry construction</td>
<td>13 mm/1/2 inch</td>
</tr>
</tbody>
</table>

## (2) Level alignment

<table>
<thead>
<tr>
<th>Description</th>
<th>Tolerance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Top of footings supporting masonry</td>
<td>13 mm/1/2 inch</td>
</tr>
<tr>
<td>Top of other footings</td>
<td>+13 mm, -50 mm +1/2 inch, -2 inch</td>
</tr>
</tbody>
</table>

## (3) Cross-sectional dimensions

<table>
<thead>
<tr>
<th>Description</th>
<th>Tolerance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Horizontal dimensions of formed members</td>
<td>+50 mm, -13 mm +2 in., -1/2</td>
</tr>
<tr>
<td>Horizontal dimensions of unformed members cast against soil</td>
<td></td>
</tr>
<tr>
<td>600 mm 2 feet or less</td>
<td>+75 mm, -13 mm +3 in., -1/2 in.</td>
</tr>
<tr>
<td>Greater than 600 mm 2 feet but less than 1800 mm 6 feet</td>
<td>+150 mm, -13 mm +6 in.</td>
</tr>
<tr>
<td>Over 1800 mm 6 feet</td>
<td>+300 mm, -13 mm +12 in., -1/2 in.</td>

<td>Specified width 50 mm 2 inches or less</td>
</tr>
<tr>
<td>Specified width more than 50 mm 2 inches but not more than 300 mm 12 inches</td>
</tr>
<tr>
<td><strong>Sawcuts, joints, and weakened plane on slab</strong></td>
</tr>
<tr>
<td>Lateral, gradual</td>
</tr>
<tr>
<td>Lateral, abrupt</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>(6) Openings through members</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Cross-sectional size of opening</strong></td>
</tr>
<tr>
<td><strong>Location of centerline of opening</strong></td>
</tr>
</tbody>
</table>

### TOLERANCE FOR FINISHED FORMED CONCRETE SURFACES

<table>
<thead>
<tr>
<th>(1) Vertical alignment: Formed surfaces slope with respect to the specified plane</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vertical alignment of outside corner of exposed corner columns and control joint grooves in concrete exposed to view</td>
</tr>
<tr>
<td>All other conditions</td>
</tr>
</tbody>
</table>
### Tolerance for Finished Formed Concrete Surfaces

#### (2) Abrupt Variation:
The offset between concrete surfaces under adjacent pieces of formwork for the following classes of surface:

<table>
<thead>
<tr>
<th>Class</th>
<th>Variation in the direction of waterflow</th>
<th>Variation perpendicular to the direction of waterflow</th>
</tr>
</thead>
<tbody>
<tr>
<td>Class A-HV</td>
<td>+0, -3 mm</td>
<td>3 mm/1/8 inch</td>
</tr>
<tr>
<td>*Class A-HV,</td>
<td></td>
<td></td>
</tr>
<tr>
<td>perpendicular</td>
<td></td>
<td></td>
</tr>
<tr>
<td>to the direction</td>
<td></td>
<td></td>
</tr>
<tr>
<td>of waterflow</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Class A</td>
<td>3 mm/1/8 inch</td>
<td></td>
</tr>
<tr>
<td>Class B</td>
<td>6 mm/1/4 inch</td>
<td></td>
</tr>
<tr>
<td>Class C</td>
<td>6 mm/1/4 inch</td>
<td></td>
</tr>
<tr>
<td>Class D</td>
<td>25 mm/1 inch</td>
<td></td>
</tr>
</tbody>
</table>

*Includes any high-velocity flow surface.

#### (3) Gradual Variation:
Surface finish tolerances as measured by placing a freestanding (unleveled), 1.5 m 5 foot straightedge for plane surface or curved template for curved surface anywhere on the surface and allowing it to rest upon two high spots within 72 hr after concrete placement. The gap at any point between the straightedge or template and the surface must not exceed:

<table>
<thead>
<tr>
<th>Class</th>
<th>Maximum Gap</th>
</tr>
</thead>
<tbody>
<tr>
<td><em>Class A (including Class A-HV)</em></td>
<td>3 mm/1/8 inch</td>
</tr>
<tr>
<td>Class B</td>
<td>6 mm/1/4 inch</td>
</tr>
<tr>
<td>Class C</td>
<td>13 mm/1/2 inch</td>
</tr>
<tr>
<td>Class D</td>
<td>25 mm/1 inch</td>
</tr>
</tbody>
</table>

*Includes any high-velocity flow surface.

### Tolerances for Cast-in-Place, Vertically Slipformed Building Elements

#### (1) Translation and Rotation from a Fixed Point at the Base of the Structure:

<table>
<thead>
<tr>
<th>Height Range</th>
<th>Translation and Rotation</th>
</tr>
</thead>
<tbody>
<tr>
<td>30 m 100 feet or less</td>
<td>50 mm/2 inches</td>
</tr>
<tr>
<td>Greater than 30 m 100 feet, 1/600 times the height but not more than</td>
<td>205 mm/8 inches</td>
</tr>
</tbody>
</table>

#### (2) Lateral Alignment

| Between adjacent elements | 50 mm/2 inches |

#### (3) Cross-sectional Dimensions

<table>
<thead>
<tr>
<th>Wall Thickness</th>
<th>+19 mm, -10 mm</th>
</tr>
</thead>
<tbody>
<tr>

</table>

2.2 MATERIALS

2.2.1 Cementitious Materials

**************************************************************************
NOTE: See the appropriate concrete aggregates design memorandum or thermal study to select the proper requirements for cementitious materials options, pozzolan, and silica fume.
**************************************************************************

2.2.1.1 Portland Cement

Provide portland cement conforming to ASTM C150/C150M, Type [____], [low-alkali when used with aggregates listed to require it in paragraph COMMERCIAL CONCRETE AGGREGATE SOURCES below, or when directed if a nonlisted source is permitted.] [including the heat of hydration requirement at 7 days] [including false-set requirement]. [In lieu of low-alkali cement, the Contractor may use a combination of portland cement that does not meet the low-alkali requirement with a pozzolan or slag provided the following requirement is met. The expansion of the proposed combination must be equal to or less than the expansion of a low-alkali cement meeting the requirements of this paragraph when tested in general conformance with ASTM C441/C441M. Run expansion tests concurrently at an
independent laboratory that is nationally recognized to perform such tests. The Government reserves the right to confirm the test results and to adjust the percentage of pozzolan or slag in the combination to suit other requirements.] [Provide white portland cement meeting these requirements except that it may be Type I, Type II, or Type III [low alkali].] [Type III may be used only in specific areas of the structure, when approved in writing.]

[2.2.1.2 Pozzolan Other than Silica Fume

Provide pozzolan other than silica fume conforming to ASTM C618, Class C or F, including low alkali [multiple factor,] [drying shrinkage,] [uniformity,] [and] [moderate] [severe] sulfate resistance requirements] of Table 2A. Uniformity Requirements (for entrained air) must apply to all fly ash. [Table 1A., Supplementary Optional Chemical Requirement for Maximum Alkalies, applies when used with aggregates listed to require low-alkali cement].

][2.2.1.3 Ground Granulated Blast-Furnace Slag

Provide ground granulated blast-furnace slag conforming to ASTM C989/C989M, Grade [______].

][2.2.1.4 Silica Fume

**************************************************************************
NOTE: Include optional Table 2 in ASTM C1240 when used with aggregates listed to require low-alkali cement. Other requirements in Table 4 may be specified if necessary. Refer EM 1110-2-2000 for guidance.
**************************************************************************

Silica fume may be furnished as a dry, densified material or as a slurry. Silica fume, unprocessed, or before processing into a slurry or a densified material, must conform to ASTM C1240 with [Table 2 and] the Specific Surface Area and Uniformity Requirements in Table 4 invoked. Provide the services of a manufacturer's technical representative, experienced in mixture proportioning, placement procedures, and curing of concrete containing silica fume. The manufacturer's representative must be available for consultation by both the Contractor and the Contracting officer during mixture proportioning, planning, and production of silica-fume concrete and onsite immediately prior to and during at least the first placement of concrete containing silica fume, and at other times if directed.

]2.2.1.5 Temperature of Cementitious Materials

The temperature of the cementitious materials as delivered to the site must not exceed 65 degrees C 150 degrees F.

2.2  Admixtures

All chemical admixtures furnished as liquids must be in a solution of suitable viscosity for field use as determined by the Contracting Officer.

2.2.2.1 Air-Entraining Admixtures

Provide air-entraining admixture conforming to ASTM C260/C260M and
consistently entrain air in the specified ranges under field conditions.

2.2.2.2 [Accelerating Admixture]

Do not use calcium chloride. Use accelerators that meet the requirements of ASTM C494/C494M, Type C [(or Type E)].

2.2.2.3 Retarding Admixture

******************************************************************************

NOTE: A retarding admixture should not be used where high early strength is desirable so that form stripping may proceed expeditiously. Before listing items consult the concrete materials design memorandum to determine areas where retarders may be necessary.
******************************************************************************

Provide retarding admixture meeting the requirements of ASTM C494/C494M, Type B, or D, except that the 6-month and 1-year compressive strength tests are waived. The admixture may be added to the concrete mixture only when approved[, except for the following structural items where a retarding admixture are not to be used: [______]]. Do not use Type D as the reason to reduce the cementitious material content unless used in mixture proportioning studies.

2.2.2.4 Water-Reducing Admixture

Provide a water-reducing admixture meeting the requirements of ASTM C494/C494M, Type A [or D], except that the 6-month and 1-year compressive strength tests are waived. The admixture may be added to the concrete mixture only when its use is approved or directed and after mixture proportioning studies.

2.2.2.5 High-Range Water-Reducing Admixture (HRWRA)

Use high-range water-reducing admixture that meets the requirements of ASTM C494/C494M, Type F [or G], except the 6-month and 1-year strength requirements are waived.[ The admixture may be used only after mixture proportioning studies and when approved.] [Provide the services of a manufacturer's technical representative experienced in mixture proportioning and placement procedures of concrete containing HRWRA. The technical representative must be available for consultation during mixture proportioning and on-site for the first placement of concrete containing HRWRA.]

2.2.2.6 Expansive Admixture

******************************************************************************

NOTE: Delete this paragraph and paragraph BLOCK-OUT CONCRETE in Part 3 if block-out concrete is not used.
******************************************************************************

Submit manufacturer's descriptive literature and certification for fluidifier to be used as expansive admixture in block-out concrete, 60 days prior to its use. Use expansive admixture in block-out concrete conforming to ASTM C937.
2.2.3 Curing Materials

2.2.3.1 Sheet Materials

Provide sheet curing materials conforming to ASTM C171, type optional, except do not use polyethylene sheet. Submit a manufacturer's certificate certifying that the materials comply with the requirements of ASTM C171, if sheet curing is used.

2.2.3.2 Membrane-Forming Curing Compound

Provide membrane-forming curing compound conforming to ASTM C309, Type 1D or 2, except a styrene acrylate or chlorinated rubber compound meeting ASTM C309, Class B, requirements may be used for surfaces that are to be painted or are to receive subsequent coatings, or floors that are to receive adhesive applications of resilient flooring. Select curing compound selected that is compatible with any subsequent paint, roofing, coating, or flooring specified.

2.2.3.3 Burlap

Provide burlap for curing purposes conforming to AASHTO M 182.

2.2.4 Water

Use water for washing aggregates and for mixing and curing concrete that is free from injurious amounts of oil, acid, salt, alkali, organic matter, or other deleterious substances and in compliance with COE CRD-C 400.

2.2.5 Aggregates

**************************************************************************

NOTE: See the concrete materials design memorandum to select the aggregate composition options.

This note may be disregarded for regions where Alkali-Silica Reactivity (ASR) is not a concern. Some aggregate sources may exhibit an ASR potential. ASR is a potentially deleterious reaction between alkalis present in concrete and some siliceous aggregates, reference EM 1110-2-2000 paragraph 2-3b(6) and appendix D. Use of cementitious materials meeting the low alkali requirement may be effective in some applications, and insufficient in others. In regions where imposing the low alkali requirement has not been effective in controlling ASR, additional effort for evaluation and mitigation may be required. In which case, the alternate procedures to proportion cementitious materials to meet the low alkali requirement in paragraph PORTLAND CEMENT should not be used with the following requirements. Where ASR is known or suspected to pose a concern for concrete durability, it is recommended that aggregates proposed for use in concrete be evaluated to determine ASR potential and an effective mitigation. EM 1110-2-2000, provides recommendations for evaluating and mitigating ASR in concrete mixtures.
Section 32 13 14.13 CONCRETE PAVING FOR AIRFIELDS AND OTHER HEAVY DUTY PAVEMENTS, paragraph ALKALI-SILICA REACTIVITY, provides a specification method for the Contractor to evaluate and mitigate ASR in concrete mixtures. The expansion limits specified in Section 32 13 14.13 are requirements for pavements and exterior slab construction. For structural concrete applications the measured expansion must be less than 0.10 percent. It may not be economical or practical to specify different test limit requirements for use on the same project. In which case the lower limit required by the application should be used.

The designer may use the specification method in UFGS Section 32 13 14.13 by incorporating the relevant paragraphs into this specification, or may use the following requirements (retain either the 0.10 or the 0.08 percent expansion limits as appropriate) included in the set of brackets highlighted thus "[.]".

**************************************************************************

2.2.5.1 Aggregate Composition

[Provide fine aggregate consisting of natural sand, manufactured sand, or a combination of natural and manufactured sands. Provide coarse aggregate consisting of gravel, crushed gravel, crushed stone, air-cooled blast-furnace slag, or a combination thereof.] "[Test and evaluate fine and coarse aggregates proposed for use in concrete for alkali-aggregate reactivity in accordance with ASTM C1260. Evaluate fine and coarse aggregates separately and in combination, which matches the Contractor's proposed mix design proportioning. All results of the separate and combination testing must have a measured expansion less than 0.10 (0.08) percent at 16 days after casting. Should the test data indicate an expansion of 0.10 (0.08) percent or greater, reject the aggregate(s) or perform additional testing using ASTM C1260 and ASTM C1567. Perform additional testing using ASTM C1260 and ASTM C1567 using the low alkali portland cement in combination with ground granulated blast furnace (GGBF) slag, or Class F fly ash. Use GGBF slag in the range of 40 to 50 percent of the total cementitious material by mass. Use Class F fly ash in the range of 25 to 40 percent of the total cementitious material by mass.]"

2.2.5.2 Quality of Aggregates

**************************************************************************

NOTES: The tests selected should be those which are applicable to the concrete to be used in the project. These tests may include those in the following list in addition to others not listed. See EM 1110-2-2000 for schedule of tests.

A list of properties and test values are unique to each project and should be taken from the concrete materials design memorandum. Delete the quality tests not required in the design memorandum.

Use petrographic examination to identify deleterious
substances in aggregates. List deleterious substances individually with respective limits.

Deliver aggregates to the mixer meeting the following requirements:

2.2.5.3 Grading

**NOTES:** The Designer should invoke the optional requirement limiting the amount of material passing the 75-µm No. 200 sieve when manufactured sand is specified and may invoke the option when natural sand is specified. If the limitation is invoked here, it must be listed for fine aggregate in paragraph AGGREGATES above.

See the concrete materials design memorandum for the
approved gradings. Delete gradings not required.

2.2.5.3.1 Fine Aggregate

Deliver fine aggregate to the mixers with a grading such that the individual percent retained on any sieve does not vary more than 3 percent from the percent retained on that sieve in a fixed grading selected by the Contractor with the approval of the Contracting Officer. The fixed grading may be selected at the start of concrete placement and based upon 30 days fine aggregate production or selected after the first 30 days of concrete placement. The minimum individual percent retained on the 2.36 mm (No. 8) sieve must be 5 percent and on all smaller sieves[, except the 75 µm (No. 200),] must be 10 percent. In addition to the grading limits, the fine aggregate, as delivered to the mixer, must have a fineness modulus of no less than 2.25 nor more than 2.85. Also control the grading of the fine aggregate so that the fineness moduli groups (average of the current test and the previous two tests) of the fine aggregate as delivered to the mixer do not vary more than 0.10 from the target fineness modulus of the fixed grading selected by the Contractor and approved by the Contracting Officer. The range of each group must not exceed 0.20. Determine the fineness modulus in accordance with COE CRD-C 104. At the option of the Contractor, fine aggregate may be separated into two or more sizes or classifications, but control the uniformity of grading of the separate sizes so that they may be combined throughout the job in fixed proportions established during the first 30 days of concrete placement. The selected fixed grading must be within the following limits, except any individual test result may be outside these limits if within the allowable 3 percent variation from the selected grading.

2.2.5.3.2 Coarse Aggregate

Rescreen coarse aggregate just prior to delivery to the concrete batch plant bins. The grading of the coarse aggregate within the separate size groups must conform to the following requirements as delivered to the mixer.
### Particle Shape

The quantity of flat and elongated particles in the separate size groups of coarse aggregate, as determined by ASTM D4791, using a value of 3 for width-thickness ratio and length-width ratio must not exceed 25 percent in any size group.

### Nominal Maximum-Size of Aggregate

Use nominal maximum-size of coarse aggregate in the various parts of the work in accordance with the following tabulation except as directed. The NMSA may be changed for sections requiring a special quality of concrete as directed.

<table>
<thead>
<tr>
<th>FEATURES</th>
<th>NOMINAL MAXIMUM-SIZE AGGREGATE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sections 190 mm 7-1/2 inches or less in width or slabs 100 mm 4 inches or less in thickness or any section with a clear distance between reinforcement less than 55 mm 2-1/4 inches</td>
<td>19 mm3/4 inch</td>
</tr>
<tr>
<td>Sections over 190 mm 7-1/2 inches or slabs at least 100 mm 4 inch in thickness. However, do not use this size in any section in which the clear distance between reinforcement is less than 55 mm 2-1/4 inch</td>
<td>40 mm1-1/2 inch</td>
</tr>
</tbody>
</table>
### FEATURES

<table>
<thead>
<tr>
<th>NOMINAL MAXIMUM-SIZE AGGREGATE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unreinforced sections over 300 mm 12 inches in width and reinforced sections over 450 mm 18 inches in width or slabs 255 mm 10 inches or greater in thickness. However, do not use this size in any section in which the clear distance between reinforcing bars is less than 115 mm 4-1/2 inches</td>
</tr>
<tr>
<td>Massive sections exceeding 1.8 m 6 feet in width and slabs 600 mm 24 inches in thickness, in which the clear distance between reinforcing bars is at least 225 mm 9 inches</td>
</tr>
</tbody>
</table>

### 2.2.5.6 Moisture Content

Do not place fine aggregate in bins at the batch plant until it is in a stable state of moisture content. Reach a stable moisture content when the variation in the percent of total moisture tested in accordance with ASTM C566 and when sampled at the same location will not be more than 0.5 percent during 1 hour of the 2 hours prior to placing the material in the batch plant bins and the variation in moisture content when sampled at the same location must not be more than 2.0 percent during the last 8 hour period that the aggregate remains in the stockpile. Deliver coarse aggregate to the mixers with the least amount of free moisture and the least variation in free moisture practicable under the job conditions. Under no conditions deliver coarse aggregate to the mixer "dripping wet".

### 2.2.5.7 Commercial Concrete Aggregate Sources

**NOTE: The list of sources and required tests will be taken from the concrete materials design memorandum.**

Concrete aggregates may be furnished from any source capable of meeting the quality requirements stated in paragraph AGGREGATES above. The following sources were evaluated during the design phase of the project in [_____] and were found at that time capable of meeting the quality requirements when suitably processed. No guarantee is given or implied that any of the following listed sources are currently capable of producing aggregates that meet the required quality stated above. A Design Memorandum containing the results of the Government investigation and test results is available for review in the [_____] District Office. Contact [_____] at [_____] to arrange for review of the memorandum. Consider test results and conclusions valid only for the sample tested and do not take as an indication of the quality of all material from a source nor for the amount of processing required.

a. List of Sources
b. Selection of Source - After the award of the contract, designate in writing only one source or combination of sources from which the Contractor proposes to furnish aggregates. If the Contractor proposes to furnish aggregates from a source or sources not listed in subparagraph "a.", LIST OF SOURCES, above, designate only a single source or single combination of sources for aggregates. Regardless of the source selected, provide samples for quality-assurance testing as required by paragraphs GOVERNMENT PRECONSTRUCTION TESTING and MATERIALS FOR MIXTURE-PROPORTIONING STUDIES IN part 1. If a source for coarse or fine aggregate so designated by the Contractor does not meet the quality requirements stated above, do not submit for approval other sources but furnish the coarse or fine aggregate, as the case may be, from one or a combination of the sources listed at no additional cost to the Government.

2.2.5.8 Government Furnished Concrete Aggregate Source

NOTE: The Specification Writer should ascertain that restoration of the pit or quarry site is specified under other sections.

2.2.5.8.1 Location

The deposits are [owned] [controlled] by the Government and are made available to the Contractor free of charge for production of aggregate required under this contract. Within the designated area, a supply of material is available from which concrete aggregate meeting the requirement of these specifications can be produced with suitable processing. The Government guarantees that a sufficient amount of material of suitable quality for production of all of the concrete aggregate required is available within the deposit and that concrete aggregates of suitable quality can be produced with a properly designed and operated plant [without hand-picking or similar operations]. However, the amount of work involved or the amount of unsatisfactory materials required to be wasted to produce a sufficient quantity of suitable concrete aggregate is the responsibility of the Contractor, and the Government will not be held liable for costs resulting from such work or waste. Produce the concrete aggregate from the following sites as shown:
[2.2.5.8.2 Explorations]

The deposits listed have been explored by the Government to determine the character and extent of the materials available. The locations of the explorations are shown in the contract drawings. The logs of the exploratory holes are also shown in the drawings. Samples of materials secured are available for inspection at [______]. The results of explorations are furnished for information only. These data are the result of limited explorations and tests conducted by and for the Government and are accurate to the extent of the scope of the investigations conducted. The Government will not be responsible for any deduction, interpretation, or conclusion drawn therefrom by the Contractor.

[2.2.6 Nonshrink Grout]

**************************************************************************
NOTE: Grade of nonshrink grout will be specified based on the application, exposure conditions, and manufacturer's recommendation.
**************************************************************************

Use nonshrink grout for use in setting base plates and machinery conforming to ASTM C1107/C1107M, Grade [______], and is a commercial formulation suitable for the application proposed. Submit descriptive literature of the grout proposed for use containing certified laboratory test results showing that it meets ASTM C1107/C1107M 60 days prior to its use together with a certificate from the manufacturer stating that the grout is suitable for the application or exposure for which it is being considered. In addition, a detailed plan for review, showing equipment and procedures for use in mixing and placing the grout.

[2.2.7 Packaged Dry Repair Materials]

Provide packaged dry rapid-hardening cementitious materials for concrete repairs that is a commercial formulation conforming to ASTM C928/C928M requiring only the addition of water.

[2.2.8 Bonding Agents]

Submit descriptive literature and certification in advance of their use. Bonding agents must meet the following requirements:

[2.2.8.1 Latex Bonding Agent]

Provide latex agents for bonding fresh to hardened concrete conforming to ASTM C1059/C1059M, Type II.
2.2.8.2 Epoxy Resin

Provide epoxy resins for use in repairs conforming to ASTM C881/C881M, Type V, Grade I or II.

2.2.9 Surface Retarder

Provide surface retarder conforming to COE CRD-C 94.

2.3 PLANT AND EQUIPMENT

**************************************************************************
NOTE: See the concrete materials design memorandum or EM 1110-2-2000 for the plant size requirements.
**************************************************************************

Provide batching, mixing, conveying, and placing systems with a capacity of at least [_____] cubic meters yards per hour. Submit the methods and description of the equipment proposed for transporting, handling, and depositing the concrete for review, 60 days before concrete placement begins. Include site drawings or sketches with locations of equipment and placement site.

2.3.1 Batch Plant

**************************************************************************
NOTE: See EM 1110-2-2000, and the concrete materials design memorandum for selection of automatic or semiautomatic plant.
**************************************************************************

Submit details and data on the concrete plant, within 60 days prior to assembly, to the Contracting Officer for conformance review with the requirements of paragraph PLANT AND EQUIPMENT. Batch plant must meet the following requirements:

2.3.2 Location

The concrete plant [will] [may] be located at the site of the work in the general area indicated on the drawings, [or may be located offsite].

2.3.3 Bins and Silos

Provide separate bins, compartments, or silos for each size or classification of aggregate and for each of the cementitious materials. Provide compartments of ample size and constructed so that the various materials will be maintained separately under all working conditions. Separate all compartments containing bulk cement, pozzolan, ground granulated blast-furnace slag, or silica fume from each other by a free-draining air space. Clearly mark all filling ports with a permanent sign stating the contents.

2.3.4 Batching Equipment

2.3.4.1 Batchers

Weigh aggregate in separate weigh batchers with individual scales. Weigh each bulk cement and/or other cementitious materials on a separate scale in a separate weigh batcher. Measure water by weight or by volume. If
measured by weight, do not weigh cumulatively with another ingredient. Measure ice separately by weight. Batch admixtures separately and batch by weight or by volume in accordance with the manufacturer's recommendations.

2.3.4.2 Water Batcher

Provide a suitable water-measuring and batching device that will be capable of measuring and batching the mixing water within the specified tolerances for each batch. Use mechanism for delivering water to the mixers that is free from leakage when the valves are closed. Interlock the filling and discharge valves for the water batcher so that the discharge valve cannot be opened before the filling valve is fully closed. When a water meter is used, provide a suitable strainer ahead of the metering device.

2.3.4.3 Admixture Dispensers

Provide a separate batcher or dispenser for each admixture. Equip each plant with the necessary calibration devices that will permit convenient checking of the accuracy of the dispensed volume of the particular admixture. Use batching or dispensing devices capable of repetitively controlling the batching of the admixtures to the accuracy specified. Use piping for liquid admixtures that are free from leaks and properly valved to prevent backflow or siphoning. Include a device or devices that will detect and indicate the presence or absence of the admixture or provide a means of visually observing the admixture in the process of being batched or discharged in the dispensing system. Ensure each system is capable of ready adjustment to permit varying the quantity of admixture to be batched. Interlock each dispenser with the batching and discharge operations so that each admixture is added separately to the batch in solution in a separate portion of the mixing water or in fine aggregate in a manner to ensure uniform distribution of the admixtures throughout the batch during the required mixing period. Store and handle admixtures in accordance with the manufacturers recommendations.

2.3.4.4 Moisture Control

Provide plant which is capable of ready adjustment to compensate for the varying moisture content of the aggregates and to change the weights of the materials being batched. Provide a moisture meter complying with the provisions of COE CRD-C 143 for measurement of moisture in the fine aggregate. Arrange the sensing element so that the measurement is made near the batcher charging gate of the fine aggregate bin or in the fine aggregate batcher.

2.3.4.5 Scales

Provide facilities for the accurate measurement and control of each of the materials entering each batch of concrete. Use weighing equipment and controls conforming to the applicable requirements of NIST HB 44, except that the accuracy must be within 0.2 percent of the scale capacity. Provide standard test weights and any other auxiliary equipment required for checking the operating performance of each scale or other measuring device. Make tests at the frequency required in paragraph TESTS AND INSPECTIONS in PART 3, and in the presence of a Government quality assurance representative. Include a visible indicator for each weighing unit that indicates the scale load at all stages of the weighing operation and shows the scale in balance at zero load. Arrange weighing equipment so that the concrete plant operator can observe the indicators.
2.3.4.6 Operation and Accuracy

[Start weighing operation of each material automatically when actuated by a single starter switch and end automatically when the designated amount of each material has been reached. These requirements can be met by providing an automatic batching system as defined in NRMCA CPMB 100.] [Start weighing operation of each material automatically when actuated by one or more starter switches and end when the designated amount of each material has been reached. These requirements can be met by providing a semiautomatic or automatic batching system as defined by NRMCA CPMB 100.]

Provide equipment to permit the selection of [_____] preset mixes each by the movement of not more than two switches or other control devices. Cumulative weighing will not be permitted. Construct and arrange weigh batchers so that the sequence and timing of batcher discharge gates can be controlled to produce a ribboning and mixing of the aggregates, water, admixtures, and cementitious materials as the materials pass through the charging hopper into the mixer. Include provisions to facilitate the inspection of all operations at all times. Deliver materials from the batching equipment within the following limits of accuracy:

<table>
<thead>
<tr>
<th>MATERIAL</th>
<th>PERCENT</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cementitious materials</td>
<td>± 1</td>
</tr>
<tr>
<td>Water</td>
<td>± 1</td>
</tr>
<tr>
<td>Aggregate smaller than 37.5 mm 1-1/2 inch size</td>
<td>± 2</td>
</tr>
<tr>
<td>Aggregate larger than 37.5 mm 1-1/2 inch size</td>
<td>± 3</td>
</tr>
<tr>
<td>Chemical admixtures</td>
<td>± 3</td>
</tr>
</tbody>
</table>

2.3.4.7 Interlocks

Interlock batchers and mixers so that:

a. The charging device of each batcher cannot be actuated until all scales have returned to zero balance within ± 0.2 percent of the scale capacity and each volumetric device has reset to start or has signaled empty.

b. The charging device of each batcher cannot be actuated if the discharge device is open.

c. The discharge device of each batcher cannot be actuated if the charging device is open.

d. The discharge device of each batcher cannot be actuated until the indicated material is within the allowable tolerances.

e. One admixture is batched automatically with the water.

f. Each additional admixture is batched automatically with a separate portion of the water or with the fine aggregate.

g. The mixers cannot be discharged until the required mixing time has elapsed.
2.3.4.8 Recorder

Provide an accurate recorder or recorders conforming to the following detailed requirements:

a. Produce a graphical or digital record on a single visible chart or tape of the weight or volume of each material in the batchers at the conclusion of the batching cycle. Produce record prior to delivery of the materials to the mixer. After the batchers have been discharged, show the return to empty condition.

b. House graphical recording or digital printout unit completely in a single cabinet that is capable of being locked.

c. Mark the chart or tape so that each batch may be permanently identified and so that variations in batch weights of each type of batch can be readily observed. Provide chart or tape which is easily interpreted in increments not exceeding 0.5 percent of each batch weight.

d. Show time of day at intervals of no more than 15 minutes.

e. The recorder chart or tape will become the property of the Government.

f. Place recorder in a position convenient for observation by the concrete plant operator and the Government inspector.

g. The recorded weights or volumes when compared to the weights or volumes actually batched must be accurate within ± 2 percent.

2.3.4.9 Batch Counters

Include devices for automatically counting the total number of batches of all concrete batched and the number of batches of each preset mixture.

2.3.4.10 Rescreening Plant

Locate, arrange, and operate rescreening plant in a manner that all coarse aggregate will be routed through the plant and that its operation will ensure delivery to the mixers of graded coarse aggregate free from excessive variation and conforming to the size groups and grading of paragraph AGGREGATES above and with moisture content conforming to the provisions of paragraph MOISTURE CONTENT above. Coarse aggregate may be rescreened and delivered to the batch plant bins one size group at a time or two or more adjacent size groups at a time. Simultaneous rescreening of nonadjacent size groups is not permitted. Waste all material passing the bottom screen of the smallest size of coarse aggregate being screened.

2.3.4.11 Washing Plant

Wash all coarse aggregates immediately prior to entering the rescreening plant. Provide rewashing plant containing water nozzles and vibrating screens to remove foreign materials and coatings from aggregate particles. Use water for washing meeting the requirements of paragraph WATER above.

2.3.4.12 Trial Operation

Not less than 7 days prior to commencement of concrete placing, make a test of the batching and mixing plant in the presence of the Contracting Officer.
to check operational adequacy. Produce the number of full-scale concrete batches required in trial runs as directed, do not exceed 20, and proportion as directed. Waste or use all concrete produced in these tests for purposes other than inclusion in structures covered by this specification. Correct all deficiencies found in plant operation prior to the start of concrete placing operations. No separate payment will be made to the Contractor for labor or materials required by provisions of this paragraph. Notify the Contracting Officer of the trial operation not less than 7 days prior to the start of the trial operation.

2.3.4.13 Protection

Protect weighing, indicating, recording, and control equipment against exposure to dust, moisture, and vibration so that there is no interference with proper operation of the equipment.

2.3.5 Laboratory Areas

**************************************************************************

NOTE: The editor should use the alternate sentence and fill in the correct Section number unless a laboratory building is to be government furnished.

**************************************************************************

Provide a room in the plant to house the moisture and grading testing equipment for aggregate and to provide working space. Provide another room for testing fresh concrete and for fabricating and initial curing of concrete test specimens in accordance with ASTM C31/C31M. The size, arrangement, and location of these rooms will be subject to approval. Provide electricity, air conditioning, heat, and water as required for use in these laboratory areas.

[2.3.6 Plant Layout Drawings

**************************************************************************

NOTE: The paragraph should be included in projects for which "onsite" plant is a requirement. The wording should be modified as necessary to suit the particular requirements of each project. Drawings submitted in compliance with this paragraph will enable the Contracting Officer to determine in advance of erection whether or not the plant meets the requirements of these specifications.

**************************************************************************

Submit drawings, in triplicate, showing the layout of the plant the Contractor proposes to use on the work for review. Show the locations of the principal components of the construction plant; offices; shop and storage building; housing facilities, if any; and storage areas and yards which the Contractor proposes to construct at the site of the work and elsewhere. Also furnish for review drawings, in triplicate, showing the general features of his aggregate processing plant; aggregate transporting; storage and reclaiming facilities; aggregate rinsing and dewatering plant, if required; coarse aggregate rescreening plant, if required; concrete batching and mixing plant; concrete conveying and placing plant; and when precooling of concrete is required, the cooling plant. Appropriately show the capacity of each major feature of the plant including the rated capacity of the aggregate production plant in tons (metric) (2000 lb) per hour of fine and coarse aggregates; rated capacity of the aggregate...
transporting, storage and reclaiming facilities; volume of aggregate storage; capacity of cement and pozzolan storage; rated capacity of the concrete batching and mixing plant in cubic meters yards per hour; rated capacity of the concrete transporting and placing plant in cubic meters yards per hour; and when used rated capacity of plant for precooling of concrete. Submit drawings in triplicate showing any changes in plant made during design and erection or after the plant is in operation for review. Two sets of the drawings will be retained and one set will be returned to the Contractor with comments.

2.3.7 Mixers

******************************************************************************
NOTE: See the concrete materials design memorandum for information on mixer selection and concrete mixers. Truck mixers are not allowed for mixing or transporting concrete with less than 50 mm 2 in. slump or greater than 37 mm 1-1/2 in. nominal maximum size aggregate (NMSA).
******************************************************************************

Provide stationary mixers [or truck mixers]. Each mixer must combine the materials into a uniform mixture and discharge this mixture without segregation. Do not charge mixers in excess of the capacity recommended by the manufacturer on the nameplate. Excessive over-mixing requiring introduction of additional water will not be permitted. Maintain mixers in satisfactory operating condition, and keep mixer drums free of hardened concrete. Replace mixer blades or paddles when worn down more than 10 percent of their depth when compared with the manufacturer's dimension for new blades. Should any mixer at any time produce unsatisfactory results, discontinue its use promptly until it is repaired or replaced. Submit the make, type, capacity, and number of the concrete mixers proposed for use, 60 days prior to installation for review by the Contracting Officer for conformance with the requirements of paragraph PLANT AND EQUIPMENT.

2.3.7.1 Stationary Mixer Uniformity Requirements

******************************************************************************
NOTE: The option for the government to perform the initial mixer evaluation may be invoked.
******************************************************************************

Adjust the size of the batch, the mixing time, the charging sequence, and other factors to provide concrete that meets the uniformity limits specified herein and in paragraph MIXER UNIFORMITY IN PART 3. Perform all testing in accordance with COE CRD-C 55. When regular testing is performed, the concrete must meet the limits of any five of the six uniformity requirements. When abbreviated testing is performed, the concrete must meet only those requirements listed for abbreviated testing. The initial mixer evaluation test is a regular test and perform prior to the start of concrete placement. Use concrete proportions for the evaluation that contains the largest size aggregate on the project and as directed. Regular testing consists of performing all six tests on three batches of concrete. The range for regular testing is the average of the ranges of the three batches. Abbreviated testing consists of performing the three required tests on a single batch of concrete. The range for abbreviated testing is the range for one batch. If more than one mixer is used and all are identical in terms of make, type, capacity, condition, speed of rotation, etc., the results of tests on one of the mixers applies.
to the others, subject to approval. Perform mixer evaluations as specified herein. [However, the initial evaluation will be performed by the Government. Provide labor and equipment as directed to assist the Government in performing any evaluation made by the Government.]

</table>

[2.3.7.2 Truck Mixers]

Provide truck mixers and the mixing of concrete therein conforming to the requirements of ASTM C94/C94M. A truck mixer may be used for complete mixing (transit-mixed) or to finish the partial mixing done in a stationary mixer (shrink-mixed). Equip each truck with two counters from which it is possible to determine the number of revolutions at mixing speed and the number of revolutions at agitating speed. Do not use truck mixers to mix or agitate concrete with greater than 37.5 mm 1-1/2 inch nominal maximum-size aggregate or concrete with a slump of 50 mm 2 inches or less. Determine the acceptability of truck mixers by uniformity tests in accordance with ASTM C94/C94M.

[2.3.8 Sampling Facilities]

Provide suitable facilities and labor for obtaining representative samples of concrete in accordance with ASTM C172/C172M for Contractor quality control (QC) and Government quality control (QA) testing.

2.3.9 Coarse Aggregate

NOTE: The automatic sampling plant should be required for aggregates in concrete containing larger than 75 mm 3 inch NMSA. For aggregates in concrete containing 75 mm 3 inch NMSA, a cost analysis should be made before specifying the automatic sampling plant. The automatic sampling plant should not be specified for aggregates in concrete containing 75 or 150 mm 3 or 6 inch NMSA. Note that the quarry sloping screens on the automatic plant will require slightly larger screens than those used for tests by ASTM C136/C136M for comparable results.
Provide suitable facilities for readily obtaining representative samples of coarse aggregate for test purposes immediately prior to the material entering the mixer. [Include automatic equipment capable of obtaining, sieving, and weighing samples of the coarse aggregate as follows:

<table>
<thead>
<tr>
<th>AGGREGATE SIZE (mm)</th>
<th>APPROXIMATE SIZE OF SAMPLE (kg) (lb)</th>
</tr>

Provide equipment that is capable of running a complete sieving, of any required sample, without the necessity of intermittent loading. Design the assembly to permit selection, screening, and weighing of any individual sample in 10 minutes or less. Provide equipment designed by a company engaged in the design and manufacture of aggregate sieving devices. Provide equipment that will accomplish the desired purpose. Use sieves that meet the applicable requirements of ASTM E11, except for the frame size requirements. Arrange equipment so that all controls will be enclosed and operable from a single position commanding a view of the screen device and the scale or scales. Provide communication from the batch plant operation to this control area. The Contractor is responsible for charging of the assembly as directed, disposal of waste material, and proper service and maintenance of the assembly. Provide each sieve with individual controls for frequency and angle. Run correlation tests with equipment as used for ASTM C136/C136M before concrete placement begins and at least every 60 days while concrete is being placed. The correlation test will determine the optimum angle, volume of feed, and the frequency for each sieve.]

2.3.10 Transporting Equipment

Design, operate, and maintain transporting equipment so that it does not cause or permit segregation or loss of material. Do not drop concrete vertically more than 1.5 m 5 feet except where suitable equipment is provided to prevent segregation and where specifically authorized.

2.3.10.1 Buckets

Use bottom-dump buckets conforming to the following requirements: the interior hopper slope must be no less than 70 degrees from the horizontal; the minimum dimension of the clear gate opening must be at least five times the nominal maximum size of the aggregate, and the area of the gate opening...
must not be less than 0.2 square meters 2 square feet; the bucket gates must be grout-tight when closed, the double clamshell type, and manually, pneumatically, or hydraulically operated; and design the gate-opening mechanism to close the gates automatically when the control is released or when the air or hydraulic line is broken. If gate actuation is dependent on integral air or hydraulic reservoirs, the capacity of the reservoirs must be sufficient to open and close the gates three times without recharging the reservoir.

2.3.10.2 Trucks

Use truck mixers or agitators for transporting central-mixed concrete conforming to the applicable requirements of ASTM C94/C94M. Do not use truck mixers to transport concrete with larger than 37.5 mm 1-1/2 inch nominal maximum-size aggregate or 50 mm 2 inch or lower slump. Nonagitating trucks may be used for transporting central-mixed concrete over a smooth road when the hauling time is less than 15 minutes and the slump is less than 75 mm 3 inches. Bodies of nonagitating trucks must be smooth, watertight, metal containers specifically designed to transport concrete, shaped with rounded corners to minimize segregation, and equipped with gates that will permit positive control of the discharge of the concrete.

2.3.10.3 Chutes

When concrete can be placed directly from a truck mixer, agitator, or nonagitating truck, the chutes supplied by the truck manufacturer as standard equipment may be used. Use a discharge deflector when required by the Contracting Officer. Separate chutes and other similar equipment are not permitted for conveying concrete except when specifically approved and do not increase slump to accommodate their use.

2.3.10.4 Belt Conveyors

Design and operate belt conveyors to assure a uniform flow of concrete from mixer or delivery truck to final place of deposit without segregation of ingredients or loss of mortar and provide with positive means for preventing segregation of the concrete or loss of mortar at the transfer point(s) and the point of placing. Do not exceed idler spacing of 900 mm 36 inches. Use a minimum belt speed of 90 m 300 feet per minute and a maximum of 230 m 750 feet per minute. Belt width must be a minimum of 600 mm 24 inches if the NMSA is 150 mm 6 inches and must be a minimum of 400 mm 16 inches if the NMSA is 75 mm 3 inches or less. The NMSA required in mixture proportions furnished by the Government will not be changed to accommodate the belt width.

2.3.10.5 Pump Placement

Concrete may be conveyed by positive-displacement pump when approved. Pump placement will be approved only for areas where placement by bucket or conveyor is difficult or impractical. Provide piston or squeeze-pressure type pumping equipment. Provide rigid-steel pipe or heavy-duty flexible hose pipeline. Do not use aluminum pipe. Use pipe with an inside diameter at least 3 times the nominal maximum size of the coarse aggregate in the concrete to be pumped but no less than 100 mm 4 inches.
3.1 PREPARATION FOR PLACING

3.1.1 Vibrators

Keep an adequate number of vibrators on hand to meet placing requirements, and spare vibrators available to maintain production in the event of breakdown. Make adequate air pressure available for air vibrators and adequate voltage for electric vibrators. Use vibrators of the proper size, frequency, and amplitude for the type of work being performed in conformance with the following requirements:

<table>
<thead>
<tr>
<th>APPLICATION</th>
<th>HEAD DIAMETER (mm) (inch)</th>
<th>FREQUENCY VPM</th>
<th>AMPLITUDE (mm) (inch)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Thin walls, beams, etc.</td>

<td>5,500 - 8,500</td>
<td>1.0 - 2.00.04 - 0.08</td>
</tr>
</tbody>
</table>

Use frequency and amplitude within the range indicated in the tabulation as determined in accordance with paragraph TESTS AND INSPECTIONS below.

3.1.2 Embedded Items

Before placing concrete, take care to determine that all embedded items are securely fastened in place as indicated in the drawings or required. Provide embedded items that are free of oil and other foreign matter such as loose coatings of rust, paint, and scale. The embedding of wood in concrete will be permitted only when specifically authorized or directed. Provide any air or water lines or other materials embedded in structures, as authorized construction expedients, conforming to the above requirements and upon completion of their use backfill with concrete or mortar as directed. Welding will not be permitted on embedded or otherwise exposed metals which are in contact with concrete surfaces. Tack welding of or to embedded items will not be permitted.

3.1.3 Concrete on Earth Foundations

Place concrete on earth foundations that are clean, damp, and free from frost, ice, and standing or running water. Prior to placement of concrete, compact the earth foundation satisfactorily in accordance with the provisions of Section 31 00 00 EARTHWORK.

3.1.4 Concrete on Rock Foundations

Place concrete on rock surfaces that are clean and free from oil, standing or running water, ice, mud, drummy rock, coatings, debris, and loose, semidetached, overhanging, or unsound fragments. Clean faults or joints to a satisfactory depth and to firm rock on the sides as directed by the Contracting Officer. Immediately before concrete is placed, clean all rock surfaces thoroughly by the use of air-water jet, high-pressure water jet, or sandblasting as described in the paragraph below. Keep all rock surfaces continuously wet for at least 24 hours immediately prior to placing concrete thereon. Cover all approximately horizontal surfaces.
immediately before the concrete is placed with a **13 mm 1/2 inch** layer of mortar composed of the same sand and cementitious materials used in the concrete. The sand-cementitious materials ratio and the water-cementitious material ratio of the mortar must be approximately the same as those used in the concrete mixture. Cover mortar with concrete before the mortar has reached its initial time of setting.

### 3.1.5 Construction Joint Treatment

Submit the method and equipment proposed for joint cleanup and waste disposal, for review 30 days before concrete placement begins.

#### 3.1.5.1 Joint Preparation

Prepare concrete surfaces to which other concrete is to be bonded for receiving the next lift or adjacent concrete by cleaning by sandblasting, high-pressure water jet, or air-water cutting. Surface cutting by air-water jets will not be permitted for concrete surfaces congested with reinforcing steel or if they are relatively inaccessible. If, for any other reason, it is considered undesirable to disturb the surface of a lift before it has hardened, the use of sandblasting or high-pressure water jet after hardening will be required. Regardless of the method used, the resulting surface must be free from all laitance and inferior concrete so that clean, well-bonded coarse aggregate particles are exposed uniformly over the lift surface. Apply joint treatment method such that the edges of the larger particles of aggregate are not undercut. Where joint preparation occurs more than 2 days prior to placing the next lift or where the work in the area subsequent to the joint preparation causes dirt or debris to be deposited on the surface, clean the surface as the last operation prior to placing the next lift. Keep the surface of the construction joint continuously wet for the first 12 hours of the 24 hours prior to placing concrete, except that the surface must be damp with no free water at the time of placement.

#### 3.1.5.2 Air-Water Cutting

Perform air-water cutting of a construction joint at the proper time, generally between 4 and 12 hours after placement and only on horizontal construction joints. This period may be modified if a retarder is used to prolong the setting of the cement at surface of the concrete. Use an air pressure of **620 to 760 kPa 90 to 110 psi** in the jet, and use sufficient water pressure to bring the water into effective influence of the air pressure. When approved a surface retarder complying with the requirements of **COE CRD-C 94** may be applied to the surface of the lift to prolong the period of time during which air-water cutting is effective. Prior to receiving approval, furnish samples of the material to be used and demonstrate the method to be used in its application. After cutting, wash and rinse the surface until the wash water is no longer cloudy. If air-water cutting does not produce acceptable results, prepare the surface by high-pressure water jet or sandblasting.

#### 3.1.5.3 High-Pressure Water Jet

A stream of water under a pressure of not less than **21 MPa 3,000 psi** may be used for cleaning. Delay its use until the concrete is sufficiently hard so that only the surface skin or mortar is removed and there is no undercutting of coarse-aggregate particles. If the high-pressure water jet is incapable of a satisfactory cleaning, clean the surface by sandblasting.
3.1.5.4 Wet Sandblasting

This method of joint preparation may be used when the concrete has reached sufficient strength to prevent undercutting of coarse aggregate particles. Continue the operation until all accumulated laitance, coatings, stains, debris, and foreign materials are removed. Then wash the surface of the concrete thoroughly to remove all loose material. This method may be used on both horizontal and vertical surfaces.

3.1.5.5 Waste Water Disposal

**************************************************************************
**************************************************************************

Use a method in disposing of waste water employed in cutting, washing, and rinsing of concrete surfaces such that the waste water does not stain, discolor, or affect exposed surfaces of the structures, or damage the environment of the project area. The method of disposal must meet all requirements of Section 01 57 19 TEMPORARY ENVIRONMENTAL CONTROLS.

3.2 TRANSPORTING AND PLACING

3.2.1 Transporting

Methods and equipment for conveying and depositing the concrete into the form are subject to approval. Provide transporting system with sufficient capacity to supply concrete at a rate to prevent cold joints forming during placement. A properly designed and sized elephant trunk and rigid drop chute bottom section which will prevent free-fall within the elephant trunk and rigid drop chute will be used if concrete is to drop more than 1.5 m 5 feet. If concrete is to be placed through installed horizontal or sloping reinforcing bars, discharge the concrete into a pipe or elephant trunk that is long enough to extend through the reinforcing bars to within 1.5 m 5 feet of the placing surface. In no case will concrete be discharged to free fall through the reinforcing bars.

3.2.1.1 Transporting by Bucket

Provide indicating and signaling devices to control the identification of types or classes of concrete as they are mixed and discharged into buckets for transfer to the forms. Identify each type or class of concrete visually by placing a colored tag or marker on a bucket as it leaves the mixing plant so that the concrete may be positively identified in the forms and placed in the structure in the desired position.

3.2.1.2 Transporting by Pump

The nominal maximum-size coarse aggregate will not be reduced or mixture proportions changed to accommodate a pump except as specifically determined appropriate. The distance and height to be pumped must not exceed limits recommended by the pump manufacturer. Supply concrete to the pump continuously. When pumping is completed, eject concrete remaining in the pipeline without contamination of concrete in place. After each operation clean the equipment thoroughly and waste flushing water outside the forms.
3.2.1.3 Transporting by Belt Conveyor

Methods and equipment for transporting the concrete by belt conveyor into the form are subject to approval.

3.2.2 Placing

Provide placing system with sufficient capacity to supply concrete at a rate which will prevent cold joints in any placement. Work concrete into the corners and angles of the forms and around all reinforcement and embedded items without permitting the material to segregate. Deposit concrete as close as possible to its final position in the forms, and in so depositing, there must be no vertical drop greater than 1.5 m 5 feet except where suitable equipment is provided to prevent segregation and where specifically authorized. Regulate depositing of concrete so that it will be effectively placed and consolidated in horizontal layers not exceeding 1.5 m 5 feet in thickness with a minimum of lateral movement. Deposit amount of concrete such that it can be readily and thoroughly consolidated and do not exceed 3 cubic meters 4 cubic yards in one pile. All concrete-placing equipment and methods are subject to approval. Concrete placement will not be permitted when, in the opinion of the Contracting Officer, weather conditions prevent proper placement and consolidation.

3.2.2.1 Time Interval Between Mixing and Placing

Place concrete mixed in stationary mixers and transported by nonagitating equipment within 30 minutes after it has been mixed, unless otherwise authorized. When concrete is truck mixed or when a truck mixer or agitator is used for transporting concrete mixed by stationary mixers, deliver the concrete to the site of the work, and complete discharge within 1 hour after introduction of the cement to either the water or aggregate.

3.2.2.2 Hot-Weather Placing

**************************************************************************

NOTE: See EM 1110-2-2000 for the proper placing temperature.
**************************************************************************

The temperature of the concrete when deposited in the forms during hot weather must not exceed [_____] degrees C F except as further required above. An approved retarding admixture may be used in accordance with paragraph RETARDING ADMIXTURE to facilitate placing and finishing. Cool steel forms and reinforcement and conveying and placing equipment if necessary to assist in maintaining specified concrete-placing temperature. Measure the temperature of the fresh concrete in accordance with ASTM C1064/C1064M. Submit a description of the materials and methods proposed for protection of the concrete 60 days in advance of anticipated need date for review, when concrete is to be placed under hot-weather conditions.

3.2.2.3 Cold Weather Placing

The temperature of the concrete when deposited in the forms must not be less than 5 degrees C 40 degrees F. The ambient temperature of the placement area and all surfaces to receive concrete must be above 0 degrees C 32 degrees F. Materials entering the mixer must be free from ice, snow, and frozen lumps. Closely regulate heating of mixing water or aggregates.
necessary to keep the concrete temperature above 5 degrees C 40 degrees F so that the concrete temperature does not exceed 15 degrees C 60 degrees F. An accelerator may be used when approved in advance.

[3.2.2.4 Special Temperature-Controlled Concrete]

**************************************************************************

NOTE: See the appropriate concrete materials design memorandum or thermal study to fill in blanks
**************************************************************************

Special temperature control is applicable to concrete in the following structures: [_____] [_____] [______]. Regardless of requirements specified above, the concrete must have a temperature of no more than [_____] degrees C F and no less than 5 degrees C 40 degrees F when measured at least 20 minutes after mixing. Heating of the mixing water or aggregates will not be permitted until the temperature of the concrete has decreased to 7 degrees C 45 degrees F. Heat materials in such a manner that they will be free from ice, snow, and frozen lumps before entering the mixer. Submit methods and equipment for review and comment 60 days in advance of anticipated date required for use, when special temperature controls are required.

[3.2.2.5 Concrete Lifts]

**************************************************************************

NOTE: The required construction joints should be shown in the drawings.
**************************************************************************

The depth of concrete placed in each lift will be as shown in the drawings. Deposit all concrete in approximately horizontal layers about 0.5 m 1-1/2 feet in thickness in stepped progression at such a rate that the formation of cold joints will be prevented. Place slabs in one lift, unless 0.8 m 2.5 foot or more deep. Where 2.3 m 7.5 foot or greater lift depths are permitted, furnish approved cantilever forms that are jointed or hinged approximately midheight to facilitate placement against surfaces sloping more than 10 degrees from vertical. At the beginning of the placing of a lift, retract the top half of a hinged or jointed form to such a position that it does not interfere with the operation of buckets placing concrete adjacent to the form. Use a minimum of five successive horizontal layers in stepped progression for 2.3 m 7.5 foot lifts. Where 1.5 m 5 foot lifts are required, use a minimum of three successive horizontal layers in stepped progression. Place each new layer of concrete on the oldest exposed layer. Do not exceed 12 m 40 feet maximum exposed bulkhead face of concrete between adjacent monoliths except as otherwise approved. Submit a lift drawing and bill of materials for each lift of concrete. (Show only one lift on a drawing). These drawings must be to scale and show all embedded items in sufficient detail for the proper installation and prosecution of the work. Identify all embedded electrical and/or mechanical items. The drawings must not be less than 594 by 841 mm 22 by 34 inches in size and use a sufficiently large scale to clearly show all details of the structure covered by these drawings. Include a note on each lift drawing indicating all contract drawings from which the lift drawing was prepared. Submit [_____] copies of each drawing for review at least 60 days prior to scheduling the lift for placement.
3.2.2.6 Consolidation

Immediately after placing, consolidate each layer of concrete by internal vibrating equipment. Do not use vibrators to cause concrete to flow for significant distances within the forms. Hand spading may be used if necessary together with internal vibration along formed surfaces permanently exposed to view. Do not use form vibrators unless forms are specifically designed for this use and unless specifically approved. Insert vibrator vertically at uniform spacing over the entire area of placement. Use distance between insertions that is approximately 1.5 times the radius of action of the vibrator. The vibrator must penetrate rapidly to the bottom of the layer and at least 150 mm 6 inches into the preceding unhardened layer if such exists. Hold it stationary until the concrete is consolidated and then withdraw slowly. Consolidate slabs 200 mm 8 inches or less in depth by approved methods.

3.2.2.7 Placing Concrete in Unformed Curved Sections

Finish the unformed portion of the ogee crest, spillway bucket, and similar features by placing concrete slightly above grade, consolidating and striking off to grade by accurate screeding. Screeding may be accomplished by semimechanical devices or by a mechanical screed that consolidates and screeds the surface in one operation. Ribs embedded in the fresh concrete as guides for screeds will not be permitted.

3.2.2.8 Placing Concrete Underwater

Deposit concrete, described in Bid Item [____], through water by a tremie or concrete pump. Submit the methods and equipment used in advance of placement for review. Concrete buckets may be used only to charge the hopper on top of the tremie. Do not lower concrete buckets under water and discharge the concrete subaqueously. Ensure tremie is watertight and sufficiently large to permit a free flow of concrete. Keep discharge end of the pump line or tremie pipe submerged continuously in the concrete after placement starts. Effect underwater seal in a manner that will not produce undue contamination of the concrete or turbulence in the water. Placement must proceed without interruption until the concrete has been brought to the required height. Do not move tremie or pump lines horizontally during a placing operation, unless removed, moved, and properly restarted, and provide a sufficient number of tremies or pump lines so that the maximum horizontal flow will be limited to 4.5 m 15 feet.

3.3 FINISHING

3.3.1 Unformed Surfaces

The ambient temperature of spaces adjacent to surfaces being finished must be no less than 5 degrees C 40 degrees F. In hot weather when the rate of evaporation of surface moisture, as determined by use of Figure 2.1.5 of ACI 305R, may reasonably be expected to exceed 1.0 kg/square meter 0.2 psf per hour, make provisions for windbreaks, shading, fog spraying, or evaporation retarding film in advance of placement to prevent plastic shrinkage cracks, and take such protective measures before, during, and immediately after finishing as operations require. All unformed surfaces of concrete that are not to be covered by additional concrete or backfill must have a float finish, unless a trowel finish is specified, and must be true to elevation as shown on the drawings. Bring surfaces to receive additional concrete or backfill to the elevation shown and leave true and regular. Slope exterior surfaces for drainage unless otherwise shown in...
the drawing or directed. Make joints carefully with a jointing or edging tool. Protect finished surfaces from stains or abrasions. Consolidate concrete thoroughly before finishing operations commence or before leaving it for future concrete or backfill placement.

3.3.1.1 Float Finish

Surfaces to receive a float finish must be screeded and darbied or bullfloated to bring the surface to the required finish level with no coarse aggregate visible. Do not add water, cement, or mortar to the surface during the finishing operation. Floating may be performed by use of suitable hand floats or power-driven equipment. Use aluminum or magnesium hand floats. After the water sheen has disappeared, float the concrete, while still green but sufficiently hardened to bear a man's weight without deep imprint, to a true even plane.

3.3.1.2 Trowel Finish

**************************************************************************

NOTE: Refer to the appropriate design memorandum for surfaces to be trowel finished. Be sure these are shown in the drawings.

**************************************************************************

Apply a trowel finish to the following surfaces [_______]; [_______]; [_______]. First, give concrete surfaces a float finish. After surface moisture has disappeared, trowel the surface to a smooth, even, dense finish, free from blemishes, including trowel marks. In lieu of hand finishing, an approved power finishing machine may be used in accordance with the directions of the machine manufacturer. A final hard steel troweling must be done by hand. Make joints carefully with a jointing or edging tool. Protect finished surfaces from stains or abrasions. Protect surface or edges likely to be injured during the construction period from damage.

3.3.1.3 Broom Finish

**************************************************************************

NOTE: Refer to the appropriate design memorandum for surfaces to be broom finished. Be sure these are shown in the drawings.

**************************************************************************

Apply a broom finish to the following surfaces: [_______]; [_______]; [_______]. The concrete surface to be broom finished must first be given a float finish. The surface must then be broomed with a [stiff fiber-bristle broom] [hair broom in a direction transverse to that of the traffic].

3.3.1.4 Abrasive Aggregate Finish

**************************************************************************

NOTE: Refer to the appropriate design memorandum for surfaces to receive the abrasive aggregate finish. Be sure this is shown in the drawings.

**************************************************************************

Apply an abrasive aggregate finish to the following surfaces: [_______]; [_______]; [_______]. First, give concrete surface a float finish. Sprinkle abrasive aggregate uniformly over the surface immediately after floating, at a rate of no less than 1.22 kg/square meter 1/4 psf. Refloat the
surface and then trowel to a smooth even finish that is uniform in texture and appearance including trowel marks. Immediately after curing, remove cement coating or laitance covering the abrasive aggregate by wire brushing, rubbing with abrasive stone, or sandblasting to expose the abrasive particles.

3.3.1.5 High Velocity Finishes

****************************************************************************************

NOTE: Refer to the appropriate design memorandum for surfaces to receive high velocity finishes. Be sure these are shown in the drawings.

****************************************************************************************

Unformed surfaces subjected to high velocity flow (12 m/s) (40 fps) must receive a trowel finish.

3.3.2 Formed Surface Repair

********************************************************************************

NOTE: Refer to EM 1110-2-2000 for direction on class of finish. Please note that definitions for class of finish have been changed recently. Class of finish must also be shown in the drawings. Paragraph CONSTRUCTION TOLERANCES, in PART 2, presents surface tolerances. Section 03 30 00 CAST-IN-PLACE CONCRETE presents materials for each class.

********************************************************************************

After removal of forms, remove all ridges, lips, and bulges on surfaces permanently exposed. Complete all repairs within 48 hours after form removal.

3.3.2.1 Classes A, A-HV, & B Finishes

For surfaces listed in Section 03 30 00 CAST-IN-PLACE CONCRETE, paragraph [______], and as shown in the drawings to have classes A, A-HV, and B finishes, repair surface defects as follows: chip defective areas, voids, and honeycombs smaller than 10 000 square mm 16 square inches in area and less than 13 mm 1/2 inches deep; bug holes exceeding 13 mm 1/2 inch in diameter and fill with dry-packed mortar; ream holes left by removal of tie rods and fill with the below specified material; define defective and unsound concrete areas larger than described by 13 mm 1/2 inch deep dovetailed saw cuts in a rectangular pattern with lines parallel to the formwork, remove the defective concrete by chipping and repair the void with replacement concrete. Brush-coat the prepared area with an epoxy resin meeting the requirements of ASTM C881/C881M, Type V; a latex bonding agent meeting the requirements of ASTM C1059/C1059M, Type II; or a neat cement grout after dampening the area with water. Fill the void with replacement concrete in accordance with the paragraph MATERIAL AND PROCEDURE FOR REPAIRS below.

3.3.2.2 Class C Finish

For surfaces listed in Section 03 30 00 CAST-IN-PLACE CONCRETE, paragraph [______], and as shown in the drawings, repair defects as follows: chip defective areas, voids, and honeycombs smaller than 15 000 square mm 24 square inches and less than 50 mm 2 inches deep; bug holes exceeding 38 mm
1-1/2 inches in diameter and fill with dry-packed mortar; and ream holes left by removal of the tie rods and fill with dry-packed mortar. Define defective and unsound concrete areas larger than 15,000 square mm 24 square inches and deeper than 38 mm 1-1/2 inches by 13 mm 1/2 inch deep dovetailed saw cuts in a rectangular pattern, remove the defective concrete by chipping, and repair the void with replacement concrete. Brush-coat the prepared area with an epoxy resin meeting the requirements of ASTM C881/C881M, Type V; a latex bonding agent meeting the requirements of ASTM C1059/C1059M, Type II; or a neat cement grout after dampening the area with water. Fill the void with replacement concrete in accordance with the paragraph below.

3.3.2.3 Class D Finish

For surfaces listed in Section 03 30 00 CAST-IN-PLACE CONCRETE, paragraph [____], and as shown in the drawings to have class D finish, repair surface defects as follows: define defective areas, voids, and honeycombs greater than 30,000 square mm 48 square inches in area or more than 50 mm 2 inches deep by 13 mm 1/2 inch deep dovetailed saw cuts in a rectangular pattern, remove the defective concrete by chipping and repair the void with replacement concrete. Brush-coat the prepared area with an epoxy resin meeting the requirements of ASTM C881/C881M, Type V; a latex bonding agent meeting the requirements of ASTM C1059/C1059M, Type II; or a neat cement grout after dampening the area with water. Fill the void with replacement concrete in accordance with the following paragraph.

3.3.2.4 Material and Procedure for Repairs

Use cement in the dry-packed mortar or replacement concrete that is a blend of the cement used for production of project concrete and white portland cement properly proportioned so that the final color of the mortar or concrete will match adjacent concrete. Use trial batches to determine the proportions required to match colors. Provide dry-packed mortar consisting of one part cement to two and one-half parts fine aggregate. Use fine aggregate for production of project concrete. Remix the mortar over a period of at least 30 minutes without addition of water until it obtains the stiffest consistency that will permit placing. Compact mortar thoroughly into the prepared void by tamping, rodding, ramming, etc. and struck off to match adjacent concrete. Produce replacement concrete using project materials and proportion as directed by the Contracting Officer. Thoroughly compact it into the prepared void by internal vibration, tamping, rodding, ramming, etc. and strike off and finish to match adjacent concrete. Use forms to confine the concrete. If an expanding agent is used in the repair concrete, confine the repair thoroughly on all sides including the top surface. Do not use metal tools to finish permanently exposed surfaces. Cure repaired areas for 7 days. The temperature of the in situ concrete, adjacent air, and replacement mortar or concrete must be above 5 degrees C 40 degrees F during placement, finishing, and curing. Packaged materials meeting the requirements of ASTM C928/C928M may be used in lieu of dry-packed mortar when approved. Other methods and materials for repair may be used only when approved in writing. Repairs of the so called "plaster-type" will not be permitted.

3.3.3 Grout-Cleaned Finish

**************************************************************************
NOTE: See the appropriate design memorandum and EM 1110-2-2000 for surfaces to receive a grout cleaned finish. Be sure this is shown in the drawings.

SECTION 03 70 00 Page 58
Give the surfaces of [_____] a grout-cleaned finish as hereinafter described, as approved by the Contracting Officer and after all required curing, cleaning, and repairs have been completed. Moisture cure surfaces to be grout-cleaned for the required period of time before application of the grout-cleaned finish. Delay grout-cleaning until near the end of construction on all surfaces not to be painted to achieve uniformity of appearance and reduce the chance of discoloring caused by subsequent construction operations. The temperature of the air adjacent to the surface must be no less than 5 degrees C and 72 hours following the application of the finish. Complete finish for any area in the same day, and make the limits of a finished area at natural breaks in the finished surface. Wet surface to receive grout-cleaned finish thoroughly to prevent absorption of water from the grout but have no free water present. Then coat the surface with grout. Apply grout as soon as the surface of the concrete approaches surface dryness and vigorously and thoroughly rub over the area with clean burlap pads, cork floats, or stones to fill all voids. Compose grout of one part portland cement as used on the project, to two parts by volume of well-graded sand passing a 600-µm (No. 30) sieve mixed with water to the consistency of thick paint. Use white cement for all or part of the cement as approved to give the desired finish color. Apply uniform coating, completely filling all pits, air bubbles, and surface voids. While the grout is still plastic, remove all excess grout by working the surface with a rubber float, burlap pad, or other means. Then, after the surface whitens from drying (about 30 minutes at normal temperature), rub vigorously with clean burlap pads. Immediately after rubbing is completed, moist cure the finished surface continuously for 72 hours. Use burlap pads for this operation consisting of burlap stretched tightly around a board to prevent dishing the mortar in the voids.

3.4 CURING AND PROTECTION

Submit the curing media and methods to be used for review 30 days before concrete placement begins.

3.4.1 Curing Time

<table>
<thead>
<tr>
<th>Cement Type</th>

</table>
Begin curing immediately after placing. Provide all equipment needed for curing and protection of the concrete on hand and ready to install before actual concrete placement begins. Use curing medium and method, or the combination of media and methods, as approved in accordance with paragraph SUBMITTALS, SD-03 Product Data, submittal item "Curing".

### 3.4.2 Moist Curing

NOTE: This requirement is for hot weather curing only and has to be used under certain conditions only. Thermal cracking can occur when the difference in temperature between the interior concrete is more than 11 degrees C 20 degrees F higher than the surface temperature of a concrete placement. Tepid water is water at a temperature no more than 11 degrees C 20 degrees F cooler than the surface of the concrete placement. For massive placements, thermal insulation should be provided to reduce the temperature gradient between the interior and exterior of the placement.

[Moist cure concrete containing silica fum.] Moist cure horizontal and nearly horizontal surfaces by ponding, by covering with a minimum uniform thickness of 50 mm 2 inches of continuously saturated sand, or by covering with saturated nonstaining burlap or cotton mats. Rinse burlap and cotton mats to remove soluble substances before using. Moist cure other surfaces when approved or directed. Maintain concrete that is moist cured continuously, not periodically, wet for the duration of the entire curing period. Use water for curing complying with the requirements of the paragraph WATER in PART 2. If the water, sand, mats, etc. cause staining or discoloration of permanently exposed concrete surfaces, clean the surfaces by an approved method. When wood forms are left in place during curing, keep the forms continuously wet except for sealed insulation curing in cold weather. When steel forms are left in place on vertical surfaces during curing of concrete, [when using high-strength concrete] [when concrete being cured has a water-cement ratio less than 0.40] [placements with a minimum dimension greater than 600 mm 2 feet] carefully break loose the forms from the hardened concrete and continuously introduce curing water into the void. The temperature of the water should be tepid. Allow horizontal construction joints to dry sufficiently to remove free water immediately prior to placing the next lift.

### 3.4.3 Membrane Curing

Membrane curing may be used on surfaces that are not specified or directed to receive moist curing and that are not to receive a grout-cleaned finish. Do not use membrane-forming curing compound on surfaces that
contain protruding steel reinforcing, that are heated by free steam, that will have additional concrete bonded to them, or that are to be grout-cleaned.

3.4.3.1 Pigmented Curing Compound

Pigmented compound conforming to ASTM C309, Type 2, Class A, may be used on surfaces that will not be exposed to view when the project is completed. Only pigmented compound of the styrene acrylate or chlorinated rubber formulation conforming to ASTM C309, Class B, requirements may be used on surfaces that are to be painted or to receive bituminous roofing or water proofing or floors that are to receive adhesive applications of resilient flooring. Select curing compound for such use that is compatible with any subsequent paint, roofing, coating, or flooring specified elsewhere in the contract.

3.4.3.2 Nonpigmented Curing Compound

Nonpigmented compound conforming to ASTM C309, Type ID, containing a fugitive dye may be used on surfaces that will be exposed to view when the project is completed. The reflective requirements of ASTM C309 are waived. [Shield surfaces cured with nonpigmented compound from direct rays of the sun for 3 days.]

3.4.3.3 Application

Apply curing compound to formed surfaces immediately after the forms are removed. Moisten surfaces thoroughly with water, and apply the curing compound as soon as free water disappears. Apply curing compound to unformed surfaces as soon as free water has disappeared provided steps have been taken when necessary to prevent premature loss of free water due to excessive evaporation as described in paragraph UNFORMED SURFACES above. Apply curing compound in a two-coat continuous operation by motorized power-spraying equipment or pressure-tank equipment operating at a minimum pressure of 520 kPa 75 psi with provisions for continuous agitation. The application equipment must be approved in advance. Do not use hand-operated pressure applicators ("garden sprayers") except in small, isolated areas as approved. Apply compound at a uniform coverage of no more than 10 square meters/L 400 square feet/gallon for each coat. Apply the second coat perpendicular to the first coat. Respray concrete surfaces that have been subjected to rainfall within 3 hours after the curing compound has been applied by the method and at the coverage specified. Protect all concrete surfaces on which the curing compound has been applied for the duration of the entire curing period from pedestrian and vehicular traffic and from any other influence that will disrupt the continuity of the curing membrane.

3.4.4 Sheet Curing

The only concrete that may be cured using sheet should be horizontal or nearly horizontal finished surfaces such as roof slabs, uncolored floors or the first course of two-course floors, or
floors that are to be covered with tile or resilient flooring.

The following concrete surfaces may be cured using sheets: [_____]; [_____]; [_____]. Use sheets only on horizontal or near horizontal surfaces. Use sheets complying with the requirements of ASTM C171, except do not use polyethylene sheet. Wet all surfaces thoroughly and completely cover with waterproof paper, or polyethylene-coated burlap. Lay covering with light-colored side up. Lap covering no less than 100 mm 4 inches and tape to form a continuous cover with completely closed joints. Use weighted sheet to prevent displacement so that it remains in contact with the concrete during the specified length of curing. Fold coverings down over exposed edges of slabs and secure by approved means. Repair sheets immediately or replace if tears or holes appear during the curing period.

3.4.5 Sealed Insulation Curing

Between dates listed in paragraph COLD WEATHER PROTECTION below where cold weather protection is provided entirely by insulation, seal all joints in the insulation to retard moisture loss and maintain a seal throughout the curing period.

3.4.6 Protection

NOTE: Add more sophisticated requirements for vibration control where appropriate.

No fire or excessive heat is permitted near or in direct contact with concrete at any time. Do not operate vibratory earth compaction equipment or pile-driving equipment within 30 m 100 feet horizontally of concrete less than 5 days old. Blasting is not permitted within 30 m 100 feet horizontally of concrete less than 90 days old. Blasting plans must be approved by the Contracting Officer. Keep all galleries, conduits, and other openings through the concrete closed or sealed during the entire construction period. Protect the surface of the concrete from rain or snow during placing.

3.4.7 Cold Weather-Protection

NOTE: The editor must insert the insulating value and the calendar dates in the appropriate blanks. The values will be taken from the thermal study that was performed during design of the structure. The paragraph may be revised or expanded to provide varying insulating values and dates for various concrete features of the project in accordance with the thermal study.

Between [_____] of each year and [_____] of the following year, cover all concrete [less than 30 days old] [immediately after placing] for a period of [_____] days with insulation that provides an R value no less than [_____] square meter degree Celsius per watt hour square foot degree Fahrenheit per BTU. Submit a description of the materials and methods proposed for protection of the concrete, 60 days in advance of anticipated
need date for review, when concrete is to be placed under cold-weather conditions.

a. Maintain insulation in such a condition that the R value does not diminish during the period of protection. Protect edges and corners of the placement with a double layer of the insulation specified above for a minimum distance of 0.6 m 2 feet in all directions.

b. Insulate concrete placed prior to the starting date from the starting date until it reaches an age of [_____] days. Insulate concrete placed after the starting date continuously during and subsequent to placement [until it reaches an age of [_____] days or] until the end of the protection period [, whichever comes first].

c. Insulate forms in such a manner that the combined form-insulation system has a thermal resistance (R value) no less than that specified. Keep insulation and the combined form-insulation system in place for at least 5 days after placement of the concrete. After 5 days, forms and insulation on vertical surfaces may be removed for periods not to exceed 4 hours in a 24 hour period to allow forms to be moved, and insulation on horizontal surfaces may be removed for periods not to exceed 8 hours in a 24 hour period to allow reinforcement to be installed, insulation to be installed, lift joints to be prepared, etc. provided that suitable precautions are taken to prevent the concrete from being subjected at any time to ambient temperatures of minus 7 degrees C 20 degrees F or below.

d. Insulate the first 1.8 m 6 feet of all steel protruding from insulated concrete with material having an R value as stated. Insulate all form bolts and metal ribs on the forms in a like manner. During the period of protection there must be no holes or openings in the insulation or between the insulation and concrete which permit ambient air to penetrate the insulation except as noted for construction purposes. Give special attention to seams, corners, and edges to prevent holes or openings in the insulation.

3.5 BASE PLATES AND BEARING PLATES

3.5.1 Setting of Plates

After being plumbed and properly positioned, provide full bearing column base plates, bearing plates for beams and similar structural members, and machinery and equipment base plates using nonshrink grout. The space between the top of the concrete bearing surface and the bottom of the plate must not be less than 1/24 of the width of the plate or 13 mm 1/2 inch, whichever is greater. Concrete surfaces must be clean, free of oil, grease, and laitance, and damp. Metal surfaces must be clean and free of oil, grease, and rust.

3.5.2 Nonshrink Grout

Use nonshrink grout conforming to the requirement of paragraph NONSHRINK GROUT. Water content must be the minimum that will provide a flowable mixture and completely fill the space to be grouted without segregation, bleeding, or reduction of strength.

3.5.2.1 Mixing and Placing

Perform mixing and placing in conformance with the material manufacturer's
instructions and as specified. Dry-mix ingredients thoroughly before adding water. After adding water, mix the batch for 3 minutes. Size batches to allow continuous placement of freshly mixed grout. Discard grout not used within 30 minutes after mixing. Fill the space between the top of the concrete or masonry bearing surface and the plate with the grout. Use forms consisting of wood or other suitable material for retaining the grout and remove after the grout has hardened. If Grade "A" grout is used, form all surfaces, including top surfaces, to provide restraint. Work placed grout to eliminate voids; however, avoid overworking and breakdown of the initial set. Do not retemper or subject grout to vibration from any source. Where clearances are unusually small, make placement under pressure with a grout pump. Maintain temperature of the grout, and of surfaces receiving the grout, at 20 to 30 degrees C (65 to 85 degrees F) until after setting.

3.5.2.2 Treatment of Exposed Surfaces

Those types of grout containing metallic aggregate, Grade B or C grout, must, after setting, have exposed surfaces under cut back 1 inch from the edge of the base plate and immediately cover with a thick coat of mortar proportioned by weight of one part portland cement, two parts sand, and sufficient water to make the mixture placeable. The parg coat must have a smooth, dense finish. The exposed surface of other types of nonshrink grout must have a smooth, dense finish.

3.5.2.3 Curing

Cure grout and parg coats in conformance with paragraph CURING AND PROTECTION above.

[3.6 BLOCK-OUT CONCRETE]

[3.6.1 Composition and Proportions]

Provide block-out concrete composed of portland cement, water, fine and coarse aggregate, and admixtures. The concrete mixture proportions, including admixture, will be provided by the Contracting Officer. Use an expansive admixture to cause the blockout concrete to expand to fit snugly in the space that confines it. Use expansive admixture conforming to the requirements of ASTM C937 for grout fluidifier. Waste any block-out concrete not placed within 30 minutes after contact of the cement and admixture. Confine block-out on all sides to provide restraint.

[3.6.2 Placing Block-out Concrete]

Provide block-outs as shown on the plans for the embedment of gate seal seats, gate guides, bulkhead guides, beams embedded for bulkhead seals, crane rails, and other embedded metalwork as appropriate. Prior to installation of embedded items, clean the block-outs or recesses in accordance with applicable requirements of the paragraph on construction joint treatment. After installation of embedded items and prior to placing any forms, clean all surfaces of the block-outs or recesses and surfaces of items to be embedded thoroughly of all loose material, oil, grease, and other contaminants which might reduce the bond between the surfaces of the blockouts or recesses and new concrete. Exercise extreme caution in placing block-out concrete to avoid distortion or displacement of the embedded items.
3.7 TESTS AND INSPECTIONS

3.7.1 General

Perform the following inspection and tests as described, and, based upon the results of these inspections and tests, take the action required and submit reports as required. When, in the opinion of the Contracting Officer, the concreting operation is out of control, cease concrete placement. The laboratory performing the tests must be onsite and conform with the requirements given in ASTM C1077. The individuals who sample and test concrete or the constituents of concrete as required in this specification will have demonstrated a knowledge and ability to perform the necessary test procedures equivalent to the ACI minimum guidelines for certification of Concrete Field Testing Technicians, Grade I. The Government will inspect the laboratory, equipment, and test procedures prior to start of concreting operations and at least once per year thereafter for conformance with ASTM C1077. The individual who performs the inspection will have demonstrated a knowledge and ability equivalent to the ACI minimum guidelines for certification of Concrete Transportation Construction Inspector (CTCI) [Concrete Construction Inspector (CCI)].

3.7.2 Testing and Inspection Requirements

3.7.2.1 Fine Aggregate

**************************************************************************

NOTE: If the optional requirement to limit the amount of material passing the 75 µm No. 200 sieve was invoked in paragraph AGGREGATES in PART 2, the requirement to perform ASTM C117 must be invoked in subparagraph a.
**************************************************************************

3.7.2.1.1 Grading

At least once during each shift when the concrete plant is operating, there make one sieve analysis and fineness modulus determination in accordance with ASTM C136/C136M [, ASTM C117] and COE CRD-C 104 for the fine aggregate or for each fine aggregate if it is batched in more than one size or classification. The location at which samples are taken may be selected by the Contractor as the most advantageous for control. However, the Contractor is responsible for delivering fine aggregate to the mixer within specification limits. Record the results on a sheet on which are also shown the specification limits applicable to the project.

3.7.2.1.2 Fineness Modulus Control Chart

Group results for fineness modulus in sets of three consecutive tests, and plot the average and range of each group on a control chart. Draw the upper and lower control limits for average 0.10 units above and below the target fineness modulus, and the upper control limit for range 0.20 units above the target fineness modulus.

3.7.2.1.3 Corrective Action for Fine Aggregate Grading

When the amount passing any sieve is outside the specification limits, resample and retest the fine aggregate immediately. If there is another failure for any sieve, report the fact immediately. Whenever a point on the fineness modulus control chart, either for average or range, is beyond
one of the control limits, double the frequency of testing. If two consecutive points are beyond the control limits, consider the process out of control and stop concreting. Notify the Contracting Officer, and take immediate steps to rectify the situation. After two consecutive points have fallen within the control limits, testing at the normal frequency may be resumed.

3.7.2.1.4 Moisture Content Testing

When in the opinion of the Contracting Officer the electric moisture meter is not operating satisfactorily, perform at least four tests for moisture content in accordance with ASTM C566 during each 8-hour period of mixing plant operation. Select times for the tests randomly within the 8-hour period. Make an additional test whenever the slump is shown to be out of control or excessive variation in workability is reported by the placing foreman. When an electric moisture meter is operating satisfactorily, make at least two direct measurements of moisture content per week to check the calibration of the meter. Use results of tests for moisture content to adjust the added water in the control of the batch plant.

3.7.2.1.5 Moisture Content Corrective Action

Whenever the moisture content of the fine aggregate changes by 0.5 percent or more, adjust the scale settings for the fine-aggregate batcher and water batcher (directly or by means of a moisture compensation device).

3.7.2.2 Coarse Aggregate

3.7.2.2.1 Grading

At least once during each shift in which the concrete plant is operating, perform a sieve analysis in accordance with ASTM C136/C136M for each size of coarse aggregate. The location at which samples are taken may be selected by the Contractor as the most advantageous for production control. However, the Contractor is responsible for delivering the aggregate to the mixer within specification limits. A test record of samples of aggregate taken at the same locations must show the results of the current test as well as the average results of the five most recent tests including the current test. The Contractor may adopt limits for control coarser than the specification limits for samples taken other than as delivered to the mixer to allow for degradation during handling. When facilities are available to test samples five times as large as those required in ASTM C136/C136M, averaging is not permitted.

3.7.2.2.2 Corrective Action for Grading

When the amount passing any sieve is outside the specification limits, resample and retest the coarse aggregate immediately. If the second sample fails on any sieve, report that fact. Where two consecutive averages of five tests (or two consecutive tests where large samples are used) are outside specification limits, consider the operation out of control, and report that fact, stop concreting, and take immediate steps to correct the grading.

3.7.2.2.3 Coarse Aggregate Moisture Content

Make a test for moisture content of each size group of coarse aggregate at least once a shift. When two consecutive readings for smallest size coarse aggregate differ by more than 1.0 percent, increase frequency of testing to
that specified previously for fine aggregate.

3.7.2.2.4 Coarse Aggregate Moisture Corrective Action

Whenever the moisture content of any size of coarse aggregate changes by 0.5 percent or more, adjust the scale setting for the coarse aggregate batcher and the water batcher to compensate for this.

3.7.2.2.5 Particle Shape Testing

When directed, a problem exists in connection with aggregate particle shape, make tests in accordance with ASTM D4791. Testing frequency must not be less than one per day, when directed.

3.7.2.2.6 Particle Shape Corrective Action

When testing for particle shape is required, report two consecutive failures in the same sieve size immediately, and determine what corrective action is needed.

3.7.2.2.7 Material Finer than the 75-µm No. 200 Sieve

When in the opinion of the Contracting Officer, a problem exists in connection with the cleanliness of aggregate, make tests in accordance with ASTM C117. Testing frequency must be as directed.

3.7.2.2.8 Corrective Action for Material Finer than the 75-µm No. 200 Sieve

When material finer than the 75-µm No. 200 sieve exceeds 1.0 percent of the weight of the aggregate finer than 37.5 mm 1-1/2 inches or 0.5 percent of the weight of the aggregate coarser than 37.5 mm 1-1/2 inches, notify the Contracting Officer and initiate steps, such as washing or other corrective action, immediately.

3.7.2.3 Quality of Aggregates

**************************************************************************

NOTES: Tests should be those listed in paragraph QUALITY OF AGGREGATES.

Use petrographic examination to identify deleterious substances in aggregates. List deleterious substances individually with respective limits.

**************************************************************************

3.7.2.3.1 Frequency of Quality Tests

Prior to submitting samples for mixture proportioning studies and 30 days prior to the start of concrete placement, perform the tests for aggregate quality in the following list. In addition, after the start of concrete placement, perform tests for aggregate quality in accordance with the following frequency schedule. Take samples tested after the start of concrete placement immediately prior to entering the concrete mixer.

3.7.2.3.2 Corrective Action for Aggregate Quality

If the result of a quality test fails to meet the requirements for quality during submittal of samples for mixture-proportioning studies or immediately prior to start of concrete placement, change production procedures or materials and perform additional tests until the material meets the quality requirements prior to proceeding with either mixture-proportioning studies or starting concrete placement. After concrete placement commences, whenever the result of a test for quality fails the requirements, rerun the test immediately. If the second test fails the quality requirement, report the fact and take immediate steps to rectify the situation.

3.7.2.4 Scales

3.7.2.4.1 Weighing Accuracy

Check accuracy of the scales by test weights at least once a month for conformance with the applicable requirements of paragraph PLANT AND
EQUIPMENT. Also make such tests as directed whenever there are variations in properties of the fresh concrete that could result from batching errors.

3.7.2.4.2 Batching and Recording Accuracy

Check the accuracy of each batching and recording device once a week during a weighing operation by noting and recording the required weight, recorded weight, and the actual weight batched. Confirm that the calibration devices described in paragraph PLANT AND EQUIPMENT in PART 2, for checking the accuracy of dispensed admixtures, are operating properly.

3.7.2.4.3 Scales Corrective Action

When either the weighing accuracy or batching accuracy does not comply with specification requirements, do not operate the plant until necessary adjustments or repairs have been made. Correct discrepancies in recording accuracies immediately.

3.7.2.5 Batch-Plant Control

Control the measurement of all constituent materials including cementitious materials, each size of aggregate, water, and admixtures continuously. Adjust aggregate weights and amount of added water as necessary to compensate for free moisture in the aggregates. Adjust the amount of air-entraining agent to control air content within specified limits. Prepare a report indicating type and source of cement used, type and source of pozzolan or slag used, amount and source of admixtures used, aggregate source, the required aggregate and water weights per cubic meter yard, amount of water as free moisture in each size of aggregate, and the batch aggregate and water weights per cubic meter yard for each class of concrete batched during plant operation.

3.7.2.6 Concrete

3.7.2.6.1 Air Content

Make at least two tests for air content on randomly selected batches of each concrete mixture produced during each 8 hour period of concrete production. Make additional tests when excessive variation in workability is reported. Make tests in accordance with ASTM C231/C231M. Plot the average of each set of two tests for each mixture on control charts on which the average percent and upper and lower limits are set in accordance with paragraph MATERIALS FOR MIXTURE PROPORTIONING STUDIES, in PART 1, for each NMSA. Plot the range between two consecutive tests for each mixture on a control chart on which the upper control limit is 3.0 percent. Normally take samples for air content at the mixer, however the Contractor is responsible for delivering the concrete to the forms at the proper air content. Take samples at the placement site as often as required, depending on the Contractor's delivery method, to determine any air loss.

3.7.2.6.2 Air Content Corrective Action

Whenever points on the control chart approach the upper or lower control limits, an adjustment should be made in the amount of air-entraining admixture batched. If a single test result is outside the specification limit, immediate adjustment is mandatory. As soon as practical after each adjustment, make another test to verify the correction of the adjustment. Whenever a point falls above the upper control for range, calibrate the dispenser to ensure that it is operating correctly and with good
reproducibility. Whenever two consecutive points either for average or range are outside the control limits, notify the Contracting Officer.

3.7.2.6.3 Slump Testing

Make at least two slump tests in accordance with ASTM C143/C143M on each concrete mixture produced during each 8-hour period or less of concrete production each day. Make additional tests when excessive variation in workability is reported. Plot the result of each test for each mixture on a control chart on which the upper and lower limits are set as specified in paragraph SLUMP. Plot the range on a control chart on which the upper control limit is 50 mm 2 inches. Take samples for slump at the mixer, however the Contractor is responsible for delivering the concrete to the placement site at the stipulated slump. If the Contractor's materials or transportation methods cause slump loss between the mixer and the placement, take samples at the placement site as often as required by the Contracting Officer.

3.7.2.6.4 Slump Corrective Action

Whenever points on the control chart approach the upper or lower control limits, make an adjustment in the batch weights of water and fine aggregate. The adjustments are to be made so that the total water content does not exceed that amount specified in the mixture proportions provided based on the free water available with the aggregates and that amount of water batched. If the adjustments to the batch weights of water and aggregates do not satisfactorily produce the required slump, the Contracting Officer may adjust the mixture proportions if the fine-aggregate moisture content is stable and within the required limits. When a single slump is outside the control limits, such adjustment is mandatory. As soon as practical after each adjustment, make another test to verify the correctness of the adjustment. Whenever two consecutive individual slump tests, made during a period when there was no adjustment of batch weights, produce a point on the control chart for range above the upper control limits, consider the slump to be out of control, halt the concreting operation, and undertake additional testing for aggregate moisture content required, and take action immediately to correct the problem.

3.7.2.6.5 Compression Test Cylinders

Make at least one set of test cylinders each shift on each different concrete mixture placed during the shift. Make additional sets of test cylinders, as directed, when the mixture proportions are changed or when low strengths have been detected. Develop a random sampling plan for approval by the Contracting Officer prior to start of construction. Assure that sampling is done in a completely random and unbiased, not just haphazard, manner. Provide a set of test cylinders for structural concrete containing Type I or Type II portland cement only consisting of four cylinders, two to be tested at 7 days and two at 28 days. Provide a set of test cylinders for all other concrete consisting of six cylinders, two to be tested at 7 days, two at 28 days, and two at 90 days. In addition, for all concrete except that containing Type I or Type II portland cement only, every 2 months make four additional cylinders and test two at 6 months of age and test two at 12 months of age. Mold and cure all test specimens in accordance with ASTM C31/C31M and test in accordance with ASTM C39/C39M. Report all compressive strength tests immediately. Keep quality control charts for individual strength tests, moving average for strength and moving average for range for each mixture. The charts must be similar to
those found in ACI 214R.

3.7.2.7 Inspection Before Placing

Inspect foundation or construction joints, forms, and embedded items in sufficient time prior to each concrete placement in order to certify that they are ready to receive concrete. Report results of each inspection in writing.

3.7.2.8 Concrete Placement

3.7.2.8.1 Placing Inspection

The placing foreman must supervise all placing operations, must determine that the correct quality of concrete or grout is placed in each location as directed, and is responsible for measuring and recording concrete temperatures and ambient temperature hourly during placing operations, weather conditions, time of placement, volume yardage placed, and method of placement.

3.7.2.8.2 Placing Corrective Action

Do not permit placing to begin until an adequate number of vibrators in working order with competent operators are available is verified. Do not continue placing if any pile of concrete is inadequately consolidated. If any batch of concrete fails to meet the temperature requirements, take immediate steps to improve temperature controls.

3.7.2.9 Vibrators

3.7.2.9.1 Vibrator Testing and Use

Determine frequency and amplitude of each vibrator in accordance with COE CRD-C 521 prior to initial use and at least once a month when concrete is being placed. Make additional tests as directed when a vibrator does not appear to be adequately consolidating the concrete. Determine the frequency while the vibrator is operating in concrete with the tachometer being held against the upper end of the vibrator head while almost submerged and just before the vibrator is withdrawn from the concrete. Determine the amplitude with the head vibrating in air. Take two measurements, one near the tip and another near the upper end of the vibrator head, and average these results. Report make, model, type, and size of the vibrator and frequency and amplitude results in writing.

3.7.2.9.2 Vibrator Corrective Action

Remove any vibrator not meeting the requirements of paragraph PREPARATION FOR PLACING above immediately from service and repair or replace.

3.7.2.10 Curing

3.7.2.10.1 Moist Curing Inspections

At least twice each shift, and twice per day on nonwork days, inspect all areas subject to moist curing. Note and record the surface moisture condition.
3.7.2.10.2 Moist Curing Corrective Action

When a daily inspection report lists an area of inadequate moistness, take immediate corrective action, and extend the required curing period for those areas by one (1) day.

3.7.2.10.3 Membrane Curing Inspection

Do not apply curing compound until the Contractor's authorized representative has verified that the compound is properly mixed and ready for spraying. At the end of each operation, estimate the quantity of compound used by measurement of the container and the area of concrete surface covered and compute the rate of coverage in square meters/L square feet per gallon. Note whether or not coverage is uniform.

3.7.2.10.4 Membrane Curing Corrective Action

When the coverage rate of the curing compound is less than that specified or when the coverage is not uniform, spray the entire surface again.

3.7.2.10.5 Sheet Curing Inspection

At least once each shift and once per day on nonwork days, inspect all areas being cured using sheets. Note and record the condition of the covering and the tightness of the laps and tapes.

3.7.2.10.6 Sheet Curing Corrective Action

When a daily inspection report lists any tears, holes, or laps or joints that are not completely closed, repair the tears and holes promptly or replace the sheets, close the joints, and extend the required curing period for those areas by one day.

3.7.2.11 Cold Weather Protection and Sealed Insulation Curing

At least once each shift and once per day on nonwork days inspect all areas subject to cold weather protection. Inspect the protection system for holes, tears, unsealed joints, or other incongruities which could result in damage to the concrete. Take special attention at edges, corners, and thin sections. Note, correct, and report any deficiencies.

3.7.2.12 Cold Weather Protection Corrective Action

When a daily inspection report lists any holes, tears, unsealed joints, or other incongruities, correct the deficiency immediately and extend the period of protection for one (1) day.

3.7.2.13 Mixer Uniformity

**************************************************************************
NOTE: The optional phrases should be used if the Contractor is to perform the initial test. Correlate with paragraph PLANT AND EQUIPMENT in PART 2.
**************************************************************************

3.7.2.13.1 Stationary Mixers

[Prior to the start of concrete placing and] once every 3 months when
concrete is being placed, or once for every 57,000 cubic meters 75,000 cubic yards of concrete placed, whichever results in the longest time, determine interval uniformity of concrete mixing in accordance with paragraph PLANT AND EQUIPMENT in PART 2. [The initial and] every fourth set of tests must be regular tests performed on three batches of concrete. Intermediate uniformity tests must be abbreviated tests performed on a single batch of concrete. If the mixer fails the abbreviated test, perform a regular test immediately. Whenever adjustments in a mixer or increased mixing time are required because of failure of a uniformity test, reevaluate the mixer by a regular test after the adjustments have been completed. If the Contractor proposes to reduce a mixing time, perform a regular test to evaluate the proposed time. Perform additional testing when directed when there is visible evidence of possible improper mixer performance. Report results of all uniformity tests in writing.

3.7.2.13.2 Truck Mixers

Prior to the start of concrete placing and at least once every 6 months when concrete is being placed, determine uniformity of concrete in accordance with ASTM C94/C94M. Select truck mixers randomly for testing. When satisfactory performance is found in one truck mixer, the performance of mixers of substantially the same design and condition of the blades may be regarded as satisfactory. Report results of tests in writing.

3.7.2.14 Mixer Uniformity Corrective Action

When a mixer fails to meet mixer uniformity requirements, either increase the mixing time, change batching sequence, reduce batch size, or make adjustments to the mixer until compliance is achieved.

3.7.3 Reports

Report all results of tests or inspections conducted informally as they are completed and in writing daily. Prepare a weekly report for the updating of control charts covering the entire period from the start of the construction season through the current week. During periods of cold weather protection, make daily reports of pertinent temperatures. These requirements do not relieve the Contractor of the obligation to report certain failures immediately as required in preceding paragraphs. Confirm such reports of failures and the action taken in writing in the routine reports. The Contracting Officer has the right to examine all contractor quality control records.

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for strengthening of masonry walls and is intended for use in defining those requirements for procurement of structural strengthening using fiber reinforced polymer (FRP) composite systems.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1  GENERAL

NOTE: In general, reinforced masonry is defined as masonry construction that contains vertical bar reinforcement, horizontal bar reinforcement, mortar, and grout combined so that the component materials will act together to resist the design loading conditions. Under certain circumstances, joint reinforcement may be designed as structural reinforcement to resist applied loads, but is typically used only to resist shrinkage cracking in concrete masonry.

Masonry not meeting the above definition but bonded
together with mortar and containing, if necessary, the minimum amount of reinforcement for crack control and vertical stiffeners, is classified as non-reinforced or unreinforced masonry (URM).

The project drawings should show all necessary details, architectural and structural, including wall sections, masonry bond and pattern, control joint locations, joint dimensions, reinforcement locations, anchors, bond beam and special units, masonry dimensions, and FRP composite details to complement this section.

It may be useful to include the SUMMARY article at the beginning of this specification section:

[1.1 SUMMARY]

This section includes design, performance, and construction requirements for strengthening masonry walls by adding near-surface fiber reinforced polymer (FRP) bars in mortar joints. The scope includes assessment of existing masonry conditions, including cracks, and providing (furnishing and installing) materials, labor, equipment and other items necessary for masonry strengthening as indicated.

[1.2 REFERENCES]

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

AMERICAN CONCRETE INSTITUTE (ACI)

AMERICAN CONFERENCE OF GOVERNMENTAL INDUSTRIAL HYGIENISTS (ACGIH)

ACGIH 0116  (2016) TLVs and BEIs

ASTM D882  (2012) Tensile Properties of Thin Plastic Sheeting

ASTM D4501  (2001; R 2014) Adhesive Bonds Between Rigid Substrates by the Block-Shear Method

ICC EVALUATION SERVICE, INC. (ICC-ES)

U.S. NATIONAL ARCHIVES AND RECORDS ADMINISTRATION (NARA)

29 CFR 1910.1200 Hazard Communication
1.3 PRE-INSTALLATION MEETING

NOTE: Add requirements for Special Inspector qualifications, observations, and testing of this FRP composite system to Section 01 45 35 SPECIAL INSPECTIONS.

Prior to commencement of work, arrange and conduct a meeting between the Contracting Officer, Contractor, and the Special Inspector to discuss the project requirements.

a. Review the requirements of the Specification and overall project requirements.

b. Review and discuss all aspects of the project, including containment, environmental control, surface preparation, strengthening system application, quality assurance, schedule requirements, and safety.

c. Request clarification of ambiguities and advise the Contracting Officer of potential conflicts and/or any technical requirements that appear improper or inappropriate.

1.4 SUBMITTALS

NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air
Force projects, or choose the second bracketed item for Army projects.

For non-Design-Build type contracts, Shop Drawings and Design Data should be provided by the Government.

**************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.] [for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-08 Manufacturer's Instructions
1.5 QUALITY ASSURANCE

1.5.1 Quality Control Plan

Submit a quality control plan for installation and curing of materials, personnel safety, installer certification, application and inspection of the FRP system, structural paste/adhesive curing provisions, means to assure clean, dry masonry surfaces, quality control samples and cleanup. Indicate the testing that will be performed and identify the party or parties responsible for this testing.

1.5.2 Regulatory Requirements

a. Submit certification that structural pastes/adhesives proposed for use meet Federal VOC regulations and those of the local Air Pollution Control Districts having jurisdiction over the geographical area in which the project is located.

b. Use bonding materials that do not release volatile organic compounds (VOC) into the air in excess of the most restrictive of NIOSH RELs, OSHA PELs or ACGIH TLVs for worker or occupant exposure during installation and/or over the useful life of the structure. If VOCs exceed any of these exposure limits during installation or use, provide additional ventilation for the duration of the excess outgassing. At no time will they exceed STEL, even if additional ventilation or air supply is provided; provide the necessary equipment to comply with these requirements. Once cured, the FRP composite system must not exhibit any detectable odor at a distance of 300 mm one foot from the FRP surface.

c. Inform workers, having access to the work area, of the contents of the applicable safety data sheets (SDS) and of potential health and safety hazard and protective controls associated with materials used on the project. Submit data sheets for all materials to be used at the job site in accordance with OSHA and 29 CFR 1910.1200. Train workers in the safe handling and application, and the exposure limit, for each material that the worker will use or otherwise be exposed to during the course of the project. Instruct personnel having a need to use respirators and masks in the use and maintenance of such equipment.

1.5.3 Qualifications

1.5.3.1 System Manufacturer Experience

Submit a certified list of a minimum five successfully completed FRP composite strengthening projects completed with the manufacturer's composite system. Include the following information, at a minimum:

a. The dates of work
b. Type, description and amount of work performed
c. Point of contact for an owner representative to include:
1.5.3.2 Contractor Qualifications

Submit a list of a minimum of five FRP composite strengthening projects completed by the Contractor on masonry surfaces, with a minimum of three of those jobs using the manufacturer's composite system. Include the following information, at a minimum:

a. The dates of work
b. Type, description and amount of work performed
c. Point of contact for an owner representative to include:
   (1) Name
   (2) Address
   (3) Company/Agency name
   (3) Telephone number

1.5.3.3 Contractor's Field Representative Qualifications

Provide a Field Representative who will be present on site during installation of the FRP system. Submit the name of the Contractor's Field Representative that will perform the actual work supervision and a list of a minimum of five FRP composite strengthening projects supervised by that Field Representative, at least three of which use the manufacturer's composite system. Include the following information, at a minimum:

a. The dates of work
b. Type, description and amount of work performed
c. Point of contact for an owner representative to include:
   (1) Name
   (2) Address
   (3) Company/Agency name
   (3) Telephone number

1.5.3.4 Applicators

1.5.3.4.1 Applicator Training

Submit certification for the FRP composite applicators who have completed, as a minimum, a course provided by the FRP manufacturer which includes hands-on application of FRP systems to masonry substrates. Submit the course syllabus.

Train workers in the safe handling and application, and the exposure limit, for each material that the worker will use or otherwise be exposed to during the course of the project.

1.5.3.4.2 Experience

Only assign qualified applicators meeting these requirements and those having prior experience in the specified application preparation to perform the work described herein.

1.5.4 Laboratory
NOTE: If rectangular FRP shapes are specified to be used, the laboratory should have experience using test method ASTM D3039/D3039M. If FRP bars are specified, ASTM D3916 should be cited.

Provide a testing laboratory experienced in testing FRP materials and having performed [ASTM D3039/D3039M] [ASTM D3916] wall tests for at least three different Contractors prior to this contract.

1.6 DELIVERY, STORAGE, AND HANDLING

1.6.1 FRP Reinforcing Bars and Shapes

NOTE: FRP reinforcing bars are susceptible to surface damage. Puncturing their surface can significantly reduce the strength capacity of the FRP reinforcements. In the case of glass FRP rods, the surface damage can cause a loss of durability due to infiltration of alkalis.

Comply with the following handling guidelines to minimize damage to the FRP bars and workers handling them:

a. Handle FRP reinforcing bars with work gloves to avoid personal injuries from either exposed fibers or sharp edges;

b. Do not store the FRP bars on the ground. Place pallets under the bars to keep them clean and to provide easy handling;

c. Avoid high temperatures, ultraviolet rays, and chemical substances because they can damage FRP bars;

d. Occasionally, bars become contaminated with form releasing agents or other substances. Substances that decrease bond should be removed by wiping the bars with solvents before placing them in the masonry;

e. It may be necessary to use a spreader bar so that the FRP bars can be hoisted without excessive bending.

f. Conduct construction activities in such a way that potential damage to the FRP bars and shapes is minimized.

1.6.2 Structural Pastes/Adhesives

1.6.2.1 Labeling

Deliver structural pastes/adhesives in original factory-sealed containers with the manufacturer's labels intact and legible with verification of product nomenclature, manufacturer's name, product identification and batch number, date of manufacture and shelf life or expiration date. Do not use adhesive materials that have exceeded the shelf life.

1.6.2.2 Storage

Store all structural paste/adhesive materials in a covered, well-ventilated area and protected from exposure to any detrimental conditions including:
airborne contaminants, dirt, dust, sunlight, temperatures lower than 4 degrees C 40 degrees F or greater than 38 degrees C 100 degrees F, rainfall, sparks or flame and in accordance with the manufacturer's requirements.

1.7  PROJECT/SITE CONDITIONS

1.7.1  Environmental Requirements

Do not install the FRP composite if the ambient air temperature or substrate surface temperature is outside the range recommended by the system manufacturer. Submit manufacturer's requirements for ambient, surface, and component temperatures at the time of mixing of the structural paste/adhesive.

Do not install the FRP composite when surface moisture is present on the substrate or when rainfall or condensation is anticipated in the work areas.

a. When the air or substrate temperature is outside the prescribed range, do not proceed with work unless other measures approved by the Contracting Officer are employed.

b. Do not apply structural pastes/adhesives to cold or frozen surfaces. When the surface temperature of the masonry surface falls below a minimum level, as specified by the FRP system manufacturer, cease work until both the air and masonry temperature rise above the specified minimum. Do not use supplemental sources of heat to raise the air or masonry surface temperature unless approved by the FRP composite system manufacturer.

c. When the surface temperature of the masonry and/or the air temperature rises above the maximum level, as specified by the FRP system manufacturer, cease work until both the air temperature and masonry temperature cool below the specified maximum.

d. Unless they have been formulated for such applications, do not apply structural pastes/adhesives to damp or wet surfaces.

e. Should the potential for adverse temperatures occur during installation, stop the application of FRP until temperatures return to within the range specified in the Manufacturer's Instructions. Obtain written approval of the FRP manufacturer and the Contracting Officer before using supplemental heating or cooling sources.

f. Should the potential for direct contact by rain, dust, dirt, excessive sunlight, high humidity, or vandalism occur during installation, provide temporary protection, such as tents and/or plastic screens, until the construction pastes/adhesives have cured. Cure the structural paste/adhesive before removal of temporary protection or allowing the structure to be exposed to new loads. In the event of suspected damage to the FRP system during installation, notify the Contracting Officer as soon as possible. Should the damage be caused by the Contractor's negligence, perform repairs at no additional cost to the Government.

1.7.2  Existing Conditions

As-built drawings of the structure [are attached] [can be accessed at [_____]].
1.8 WARRANTY

Furnish manufacturer's standard warranty for FRP composite system installation, including the FRP composite system [design,] installation, bond to the substrate, and interlaminar bond, as well as mechanical property retention, and bar-adhesive compatibility. Provide a warranty period of not less than 5 years from the date of Government's acceptance.

PART 2 PRODUCTS

2.1 SYSTEM DESCRIPTION

2.1.1 System Definition

Provide an FRP systems that consists of procured composite rods and shapes, manufactured in the system supplier's facility and shipped to the job site, and a structural paste/adhesive to bond the precured rods and shapes into grooves cut in the masonry surface. Ensure that materials supplied for the work of this section are from a single system manufacturer. Substitution of FRP rods or shapes, and substitution of structural pastes/adhesives that differ from those which comprise the approved manufacturer's FRP system are not allowed.

2.1.2 Performance Requirements

**************************************************************************
NOTE: Provide the parameters of strength or force that must be provided by the FRP system application. The following variables must be considered in determining the enhanced performance requirements: the load on the wall, the size of the wall, the wall aspect ratio, wall openings, etc.
**************************************************************************

Provide the FRP composite system with [seismic] [wind] [and] [blast] strengthening for [clay brick] [concrete] masonry walls by [[_____]percent] [the quantity indicated on the Drawings]. Provide a system that transfers [seismic] [wind] [and] [blast] loading, in concert with the existing masonry, to the building foundation.

2.1.3 FRP Composite System Design Requirements

2.1.3.1 Design Basis

Design the FRP composite system in conformance with ACI 440.2R and ACI 440.7R to provide [seismic] [wind] [and] [blast] strengthening for clay brick and concrete masonry walls. Design walls with the FRP system to fail by cracking through the masonry units and mortar prior to debonding or rupture of the FRP composite system.

2.1.3.2 Shop Drawings

Submit complete FRP composite system shop drawings for each installation of the composite system including details of the fiber reinforcement type, dimensions, end details, proposed connections to the diaphragms and adjacent walls, and locations to be applied as specified. Include calculations prepared by or on behalf of the Contractor to determine the layout of the FRP materials to be installed.
2.1.3.3 Design Calculations

Submit design calculations for the FRP composite system stamped by a registered professional civil or structural engineer. Submit calculations conforming to requirements set forth in the ICC ES AC125; Acceptance Criteria based on tension force and strain limits.

2.2 MATERIALS

**************************************************************************
NOTE: The values listed in the following tables should be those values and assumptions that were used in developing the preliminary rehab/strengthening design. Those items in Table 1 below will be the minimum acceptable property values for the FRP bars and shapes to be installed. Those items in Table 2 will be the minimum acceptable properties for the structural paste/adhesive.

For tests with two methods listed, the first refers to round shapes such as FRP bars and the second pertains to rectangular cross-sectional shapes.

The arbitrary selection of a fiber reinforcement and an adhesive material from different manufacturers or systems can lead to failure of the installed FRP system due to possible matrix-reinforcement incompatibility.
**************************************************************************

2.2.1 FRP Composite System

2.2.1.1 System Materials

Provide an FRP system consisting of [glass] [carbon] [aramid] [rods] [rectangles] [grids] with a resin matrix of [vinyl ester] [polyester] [epoxy] [urethane] [specialty resin] binder and an [epoxy] [urethane] [_____] structural adhesive. Formulate the structural paste/adhesive for use as an embedding material to bond masonry and FRP materials and, once cured, protect the FRP shapes from the environment. Provide a structural paste/adhesive that is suitable for use in both non-load bearing and load bearing applications.

2.2.1.2 System Submittals

2.2.1.2.1 Wall Test Reports

Submit results of testing, performed by an independent testing facility, on walls that are representative of the actual configuration and loading conditions for this contract to demonstrate structural equivalency of the proposed system to the properties specified herein. Currently, no standard tests exist; therefore, submit testing for approval by the Contracting Officer. Include the following information in the test report:

a. FRP System nomenclature
b. Testing facility name
c. Testing facility address
d. Testing facility telephone number
e. Testing facility point of contact  
f. Test wall substrate material  
g. Test wall aspect ratio  
h. FRP orientation and frequency/location  
i. FRP composite shape and cross-sectional area  
j. Cyclic in-plane test results in accordance with ICC ES AC125 to include the following:  
   (1) Description of test setup  
   (2) Rate and method of loading  
   (3) Deformation and strain measurements  
   (4) Modes of failure  

2.2.1.2.2 Manufacturer's Installation Instructions  
Submit manufacturer's printed installation instructions for the FRP Composite System, including the following:  

a. Brand name  
b. Catalog number  
c. Names of manufacturer for each material to be used. Include with instructions the estimated quantity of each material to be used on the job.  
d. Detailed mixing and application instructions to include:  
   (1) Mixing instructions  
   (2) Curing times between coats or layers  
   (3) Application procedures for surface coatings  
   (4) Cold weather installation to include the minimum application temperature recommended by the FRP system manufacturer or 4 degrees C 40 degrees F whichever is higher. Advise the minimum Shore Hardness for application at temperatures below 4 degrees C 40 degrees F for approval by the Contracting Officer.  
   (5) Hot weather installation to include the maximum application temperature recommended by the FRP system manufacturer or 38 degrees C 100 degrees F whichever is lower. Advise the minimum Shore Hardness for application at temperatures above 38 degrees C 100 degrees F for approval by the Contracting Officer.  
   (5) Inclement weather installation  
   (6) Application procedures of top coating material  

2.2.2 FRP Rods and Shapes  
2.2.2.1 Material Properties  
Provide FRP [rods] [shapes] conforming to the material properties listed in Table 1.

2.2.2.2 Rods and Shapes Submittals

a. Submit a sample FRP bar, 300 mm 12 inches long.

b. Submit material property test reports indicating the following physical properties of the FRP bar or shape.

(1) Tensile strength, as determined in accordance with ASTM D3916 for FRP rods or ASTM D3039/D3039M for flat or rectangular shaped FRP reinforcement.

(2) Design elastic modulus by the strength and rupture strain values. Determine ultimate tensile strength and rupture strain values by subtracting three standard deviations from the average values of 20 or more tensile tests.

c. Submit product data with documented evidence that the [rods] [shapes] meet the requirements of Table 1.

2.2.3 Structural Paste/Adhesive Material

2.2.3.1 Material Properties

Provide structural paste/adhesive that conforms to the material properties listed in Table 2.

2.2.3.2 Structural Paste/Adhesive Material Submittals

a. Submit a sample plate of cured structural paste/adhesive 75 x 75 mm 3 x 3 inches.

b. Submit test results of shore hardness tests at 3 and at 24 hours in ten degree intervals between 4 and 38 degrees C 40 and 100 degrees F for structural pastes/adhesives used. Also submit system environmental durability test results conducted and reported by an independent testing facility. Include the following information in test reports:

(1) FRP System nomenclature
(2) Testing facility name
(3) Testing facility address
(4) Testing facility telephone number
(5) Testing facility point of contact
(6) Freeze-thaw test results
(7) 2000 hour UV exposure test results
(8) Fire resistance test results
(9) Seven day exposure at 100 percent humidity test results
(10) 3000 hour test results for ozone exposure, for alkali exposure, for salt water immersion, and for 60 degrees C 140 degrees F exposure

c. Submit product data with documented evidence that the structural paste/adhesive meets the requirements of Table 2.

2.2.4 Accessories

Provide all other materials as needed for the proper installation of the complete composite system as specified.

2.3 MIXES

Perform mixing of structural paste/adhesive materials in accordance with the FRP system manufacturer's recommended procedure. Ensure that adhesive components are at a proper temperature and mixed in the correct ratio until there is a complete mixing of components and a uniform color. Mix each batch of adhesive materials in quantities sufficiently small to ensure that the mixed structural paste/adhesive can be used within its pot life. Do not use mixed structural paste/adhesive that exceeds its pot life, as defined by the system manufacturer.

PART 3 EXECUTION

3.1 EXAMINATION

Examine existing conditions to assess the quality of the masonry substrate, identify potential obstructions, and verify dimensions/geometries shown on shop drawings.

Ensure that other scheduled masonry repairs are complete and cured prior to starting the work of this Section. Provide mortar surfaces, to which the FRP system is to be applied, that are free of loose and unsound materials and other conditions that would inhibit bond, such as oil, efflorescence and moisture.
3.2 PREPARATION

3.2.1 Protection

Coordinate the work to minimize exposure of building occupants, other personnel, and visitors to dust, mists, and odors from preparation, FRP system application and clean-up operations.

3.2.2 FRP Material Verification

Prior to starting the project and together with the Special Inspector, ensure that delivered FRP materials meet the specified requirements. This will require the following laboratory testing by the Special Inspector.

a. Determine the tensile strength and tensile modulus of elasticity for each batch of FRP bars or shapes used. Reject materials that do not meet the minimum requirements of Table 1.

b. Determine the gel time, pot life, and cured hardness of the structural paste/adhesive. Determine the tensile strength, bond strength, modulus of elasticity, and elongation of the structural paste/adhesive. Reject materials that do not meet the minimum requirements of Table 2.

3.2.3 Surface Preparation

3.2.3.1 Surface

**************************************************************************
NOTE: Select the bracketed option that accurately describes the masonry condition prior to the start of the Work of this Section.
**************************************************************************

[The mortar joints to receive FRP composite are relatively sound structurally.] [There are known problems associated with the condition of the original masonry and the masonry substrate that can compromise the integrity of the FRP system.] [Remove areas of loose or spalling mortar material and repoint in accordance with Section 04 03 00 UNIT MASONRY CLEANING AND RESTORATION.]

3.2.3.2 Subsurface

Do not apply FRP systems to masonry substrates containing corroded reinforcing steel. Note evidence of localized cracking and/or spalling at grouted cells and rust stains and report them to the Contracting Officer. Do not proceed with Work until the cause(s) of the corrosion is(are) addressed and the corrosion-related deterioration repaired.

3.2.3.3 Obstructions

Prior to installing the FRP system, modify or remove obstructions and embedded objects that affect performance of the FRP system. Obtain Contracting Officer's approval before performing such modifications and removals.
3.3 FRP SYSTEM INSTALLATION

3.3.1 General

Do not make modifications to the manufacturer's installation procedures or to the design and shop drawings without the written approval of the Contracting Officer.

3.3.2 Embedment Slot Preparation

Lay out embedment slot locations on the wall surface at the specified locations. Prepare containment to catch dust and masonry chips generated during the embedment slot cutting/grinding.

3.3.2.1 Slot Cutting

Using a grinder or saw with a blade manufactured to cut substrate, cut slots in the masonry to the width and depth recommended by the FRP manufacturer. Take special care to avoid local fracture of the masonry.

3.3.2.2 Slot Finishing

Provide masonry slot surfaces to receive FRP composite that are free from fins, and protrusions that may prevent the FRP [bars] [shapes] from being embedded to the specified depth in the wall. Dry the contact surfaces as recommended by the FRP system manufacturer. Evaluate moisture content in accordance with ACI 503.1-503.4 standard specification applicable to the application. Provide contact surfaces that have no loose particles, paint, oil, dirt, dust, efflorescence, mildew or free moisture on them at the time of application. Do not use solvent or chemical cleaning methods to clean surfaces. Clean contact surfaces by hand using wire brushes or by using compressed air. [Using masking tape or other suitable adhesive tape, fix a strip at each edge of the slots.]

3.3.3 Cutting FRP Bars and Shapes

Perform cutting of the FRP bars with a high-speed grinding cutter or a fine blade saw. Do not shear FRP bars.

3.3.4 Application of Structural Paste/Adhesive

Mix the structural paste/adhesive according to the specifications prescribed by the manufacturer. Place a layer of structural paste/adhesive uniformly in the slots cut in the masonry substrate. Depending on the type of structural paste/adhesive used, ventilate work areas during structural paste/adhesive application so that worker exposure to chemical substances will not exceed limits as established by ACGIH 0116, or as required by a more stringent applicable local regulation. Ventilate interior work zones having a volume of 280 cubic meters 10,000 cubic feet or less with a minimum of two air exchanges per hour. Maintain ventilation in larger work zones by means of mechanical exhaust. Exhaust solvent vapors outdoors, away from air intakes and workers. Temporarily seal return air inlets in the work zone before start of work and maintain until the structural paste/adhesive has cured.

3.3.5 FRP Reinforcing Bar/Shape Installation

Press the FRP reinforcing bar/shape into the slot so that the surface of
the [bar] [shape] is fully embedded in the paste/adhesive and does not protrude to the surface of the wall. Completely fill the slot with the structural paste/adhesive to encapsulate the bar and strike the surface even with the surface of the masonry.

3.3.6 Curing

Maintain structural paste/adhesive curing temperatures within the required temperature range designated by the manufacturer for the formulation used for the manufacturer specified time. Protect the composite system from contact by moisture for a minimum period of 24 hours.

3.3.7 Finish

Once cure is complete, remove any masking tape applied around the edges of the slots taking care not to damage the structural paste/adhesive. [[Stain] [Paint] the structural paste/adhesive according to the Shop Drawings in accordance with the manufacturer's instructions.]

3.3.8 Movement Joints

3.3.8.1 Control Joints

Maintain all control joints. Do not bridge existing control joints with the FRP composite.

3.3.8.2 Expansion Joints

Maintain all expansion joints. Do not bridge existing expansion joints with the FRP composite.

3.4 FIELD QUALITY CONTROL

3.4.1 General Requirements

Maintain quality control (QC) programs and criteria provided in the pre-construction submittals. Comply with the approved quality control plan. Submit inspection and progress reports daily to the Contracting Officer.

3.4.2 Field Testing During Construction

3.4.2.1 Mixed Structural Paste/Adhesive Hardness and Curing

3.4.2.1.1 Sample Preparation

**************************************************************************
NOTE: The required resin samples are a minimum of 6 mm 0.25-inch in thickness, whereas FRP placed on a wall is much thinner, typically 3 mm 1/8-inch or less. During initial stages of curing, thicker cross sections tend to be softer than thin ones. There is, therefore a variation in the required hardness to account for this phenomenon.
**************************************************************************

During installation, prepare two samples of mixed structural paste/adhesive per shift from two, separate, [nonconsecutive batches] [tube sets] of structural paste/adhesive. Provide structural paste/adhesive samples that
are a minimum of 6 mm 1/4-inch thick and 50 mm 2-inches in diameter for testing, by the Special Inspector, to evaluate curing progress.

3.4.2.1.2 Curing and Hardness Evaluation

Evaluate relative curing progress of the resin on the job site by measuring the hardness of the resin sample at 3 hours and 24 hours of cure in accordance with provisions of ASTM D2240. Take measurements at a minimum of three different points distributed over the surface of the structural paste/adhesive at least 6 mm 0.25 inch apart from each other.

3.4.2.1.3 Field Testing Report by Special Inspector

Report the mean hardness value obtained, structural paste/adhesive identification, manufacturer, and batch number, structural paste/adhesive mixing date and time, test date and time minimum air temperature during the curing evaluation time, and the type and serial number of the durometer used. Report whether the shore hardness measurements exceed the minimum hardness values submitted by the materials manufacturer, based on the lowest air temperature during the curing period evaluated.

3.4.2.1.4 Resolution of Noncompliances

In the event that curing does not meet the minimum values submitted by the materials manufacturer, take remedial measures as specified in paragraph REMEDIAL MEASURES.

3.4.2.2 In-Place Structural Paste/Adhesive Hardness

3.4.2.2.1 Testing Frequency

During installation, perform a minimum of one test on each 152 m 500 linear feet or portion thereof of FRP bar installed at 3 hours after installation and at 24 hours after installation.

3.4.2.2.2 Curing Evaluation

Evaluate relative curing progress of the in-place FRP resin using the Shore hardness test described in ASTM D2240. The shore hardness measurements must exceed the minimum hardness values submitted by the materials manufacturer based on the minimum substrate temperature observed during the evaluation period.

3.4.2.2.3 Field Testing Report

Report both the individual and mean hardness values obtained, the locations where each hardness test was performed, the FRP application date, test date and time, air and substrate temperature when the FRP was applied, air and substrate temperature during the testing period, and the type and serial number of durometer used. Report whether the shore hardness measurements exceed the minimum hardness values submitted by the materials manufacturer, based on the lowest air temperature during the curing period evaluated.

3.4.2.2.4 Resolution of Noncompliances

In the event that curing does not meet the minimum values submitted by the materials manufacturer, take remedial measures as specified in paragraph REMEDIAL MEASURES.
3.4.2.3 Remedial Measures

For strengthened sections where testing indicates that the installed composite system has material properties below the minimum specified values, remove the installed FRP composite and replace it with FRP composite meeting or exceeding the minimum specified values. Remove unacceptable FRP composite, repair damaged masonry as a result of the FRP removal, and install replacement FRP composite at no cost to the Government.

3.4.3 Inspection

**************************************************************************

NOTE: Add requirements for special inspection of masonry strengthening using FRP Bars to Section 01 45 35 SPECIAL INSPECTIONS, including aspects of the work to be observed and documented, frequency, and record keeping.

Include in Section 01 45 35 the extent of observation of field testing to be performed by the Special Inspector.

**************************************************************************

Provide a Special Inspector, who is trained and certified by the FRP system manufacturer and approved by the Contracting Officer, to perform inspections in accordance with this specification, SECTION 01 45 35 SPECIAL INSPECTIONS, and ICC ES AC178. Provide a Special Inspector who is not be an employee of the Contractor nor financially associated with the Contractor beyond the inspection contract.

3.4.4 Record Maintenance

Retain samples of mixed structural paste/adhesive and maintain a record of the placement of each batch. Submit the record at the end of the project.

3.5 ADJUSTING AND CLEANING

3.5.1 Repairs

Repair all defects according to the FRP maintenance and repair procedure provided by the system manufacturer.

3.5.2 Work Area Clean Up

Upon completion of the work, remove staging, scaffolding, and containers from the site or destroy them in an approved manner. Remove FRP composite, structural paste/adhesive, and other deposits on adjacent surfaces. Leave the project site cleaned to equal or better condition to that prior to the start of the job. Place cloths, cotton waste and other debris, which might constitute a fire hazard, in closed metal containers and remove at the end of each day. Store, transport, and dispose of adhesives properly as indicated on the SDS sheets. Contain masonry dust and chips and dispose of properly, as required by local authorities. Contain material to be disposed of at the site until proper disposition is achieved.

3.6 MAINTENANCE

Submit procedures to properly maintain the installed FRP system and written manufacturer recommended repair procedures for damage to the in-place FRP
system.

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for strengthening of masonry walls and is intended for use in defining those requirements for procurement of structural strengthening using fiber reinforced polymer (FRP) composite systems.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1 GENERAL

NOTE: In general, reinforced masonry is defined as masonry construction containing vertical bar reinforcement, horizontal bar reinforcement, mortar, and grout combined so that the component materials will act together to resist the design loading conditions. Under certain circumstances, joint reinforcement may be designed as structural reinforcement to resist applied loads, but is typically used only to resist shrinkage cracking in concrete masonry.

Masonry not meeting the above definition, but bonded
together with mortar and containing, if necessary, the minimum amount of reinforcement for crack control, is classified as unreinforced masonry (URM).

The project drawings should show all necessary details, architectural and structural, including wall sections, masonry bond and pattern, control joint locations, joint dimensions, reinforcement locations, anchors, bond beam and special units, masonry dimensions, and FRP composite details to complement this section.

The masonry to be strengthened with surface-applied FRP composites should first be assessed for suitability. Considerations include the extent of repairs that might be required to provide a suitable surface for achieving bond, the effect of reduced vapor permeability of the masonry, and the design requirements for covering the composite surface, both for visual aesthetics and fire resistance (when required). The presence of efflorescence or corrosion may inhibit bond of the FRP composite. Simply cleaning the staining addresses the symptom only and does not correct the cause of the problem.

**************************************************************************
[1.1 SUMMARY

**************************************************************************

NOTE: It may be useful to include this SUMMARY Article at the beginning of this Specification Section.

**************************************************************************

This section includes design, performance, and construction requirements for strengthening masonry walls by adding near-surface fiber reinforced polymer (FRP) bars in mortar joints. The scope includes assessment of existing masonry conditions, including cracks, and providing (furnishing and installing) materials, labor, equipment and other items necessary for masonry strengthening as indicated.

]1.2 REFERENCES

**************************************************************************

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.
The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

**AMERICAN CONCRETE INSTITUTE (ACI)**

ACI 440.3R (2012) Guide Test Methods for Fiber-Reinforced Polymer (FRP) for Reinforcing or Strengthening Concrete Structures

**AMERICAN CONFERENCE OF GOVERNMENTAL INDUSTRIAL HYGIENISTS (ACGIH)**

ACGIH 0116 (2016) TLVs and BEIs

**ASTM INTERNATIONAL (ASTM)**

1.3 PRE-INSTALLATION MEETING

**************************************************************************
NOTE: Add requirements for Special Inspector qualifications, observations, and testing of this FRP composite system to Section 01 45 35 SPECIAL INSPECTIONS.
**************************************************************************

Prior to commencement of work, arrange and conduct a meeting between the Contracting Officer, Contractor, and the Special Inspector to discuss the project requirements.

a. Review the requirements of the Specification and overall project requirements.

b. Review and discuss all aspects of the project, including containment, environmental control, surface preparation, strengthening system application, quality assurance, schedule requirements, and safety.

c. Request clarification of ambiguities and advise the Contracting Officer of potential conflicts and/or any technical requirements that appear improper or inappropriate.

1.4 SUBMITTALS

**************************************************************************
NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's
Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.

**************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

1.5 QUALITY CONTROL

1.5.1 Quality Control Plan

Submit a Quality Control Plan for installation and curing of FRP materials, including personnel safety, installer certification, application and inspection of the FRP system, location and placement of splices, curing provisions, means to assure dry surfaces, quality assurance samples and cleanup.

1.5.2 Regulatory Requirements

Submit Safety Data Sheets (SDS) to demonstrate that the composite system will not release volatile organic compounds (VOC) into the air in excess of the most restrictive of NIOSH RELs, OSHA PELs or ACGIH TLVs for worker or occupant exposure during installation and/or over the useful life of the structure. If VOCs exceed any of these exposure limits during installation or use, provide additional ventilation for the duration of the excess outgassing. Ensure that at no time will they exceed STEL, even if additional ventilation or air supply is provided. Provide the necessary equipment to comply with these requirements. Once cured, ensure the FRP composite system does not exhibit detectable odor at a distance of 300 mm one foot from the FRP surface.

Submit certification that resins proposed for use meet Federal VOC regulations and those of the local Air Pollution Control Districts having jurisdiction over the geographical area in which the project is located.
1.5.3 Qualifications

1.5.3.1 Manufacturer Qualifications

Submit documentation that the FRP composite system manufacturer has used the proposed materials system on a minimum of ten completed strengthening projects. Certification submittal must include: the dates of work, type, description and amount of work performed, as well as a point of contact for the Contractor doing the work, and an owner representative identified by name, address and telephone number.

1.5.3.2 Contractor Qualifications

Submit documentation that the Contractor has completed a minimum of five FRP composite strengthening projects on masonry surfaces and a minimum of three of those jobs using the manufacturer's composite system. Certification submittal must include the dates of work, type, description and amount of work performed, the FRP system installed for each project, and the name and telephone number of a contact person or owner for whom the work was completed.

1.5.3.3 Installers' Qualifications

1.5.3.3.1 Training

a. FRP composite applicators must have completed, as a minimum, a certification course provided by the FRP manufacturer or as an alternative, a list of experience, which includes hands-on application of FRP systems to masonry substrates.

b. A field representative who has completed the course of instruction and has completed a minimum of ten FRP composite strengthening projects, three (3) using the manufacturer's composite system, must be present onsite during all installation of the FRP system. Submit the Field Representative Qualifications, including the name of the person who will perform the actual work supervision and a list of a minimum of ten completed FRP composite strengthening projects of similar applications using the manufacturer's composite system. Include the dates of work, type, description and amount of work performed, and the name and telephone number of a contact person or owner for whom the work was completed.

c. Inform workers having access to the work area of the contents of the applicable safety data sheets (SDS) and of potential health and safety hazards and protective controls associated with materials used on the project. Provide SDS that are in accordance with 29 CFR 1910.1200. The work area is one that may receive mists and odors from the FRP system application and curing operations. Train workers in the safe handling and application of FRP materials and the exposure limit for each material that the worker will use or otherwise be exposed to during the course of the project. Instruct personnel having a need to use respirators and masks in the use and maintenance of such equipment.

1.5.3.3.2 Experience

Assign only qualified applicators meeting these requirements and those having prior experience in the specified surface preparation and coating applications to perform the work described herein. Submit a listing of past application projects completed by the applicators, including the dates
of work, type, description and amount of work performed, and the name and telephone number of a contact person or owner for whom the work was completed.

1.5.3.3 Laboratory Qualifications

**************************************************************************
NOTE: Due to the sensitivity of ASTM D3039/D3039M, not all testing laboratories are capable of performing this test. The testing laboratory used must have a history of performing ASTM D3039/D3039M tests prior to the contract.
**************************************************************************

Submit documentation that the laboratory has experience in testing FRP materials and has performed ASTM D3039/D3039M wall tests for at least three different Contractors prior to this contract. Include the results of the wall tests in the laboratory certification of qualifications.

1.6 DELIVERY, STORAGE, AND HANDLING

1.6.1 Labeling

Deliver polymer resin materials in original factory-sealed containers with the manufacturer's labels intact and legible with verification of product nomenclature, manufacturer's name, product identification and batch number, date of manufacture and shelf life or expiration date. Do not use polymer resin materials that have exceeded the shelf life.

1.6.2 Storage

Store materials in a covered, well-ventilated area protected from exposure to detrimental conditions including: airborne contaminants, dirt, dust, sunlight, temperatures lower than 4 or greater than 38 degrees C or greater than 100 degrees F, rainfall, sparks or flame and in accordance with the manufacturer's requirements. Store polymer resins and hardeners in a separate area from construction materials that can absorb odors.

1.7 PROJECT/SITE CONDITIONS

1.7.1 Environmental Requirements

1.7.1.1 Application Temperature

1.7.1.1.1 Cold Surfaces

Do not apply primers, saturating resins and adhesives to cold or frozen surfaces. When the surface temperature of the masonry surface falls below a minimum level, as specified by the FRP system manufacturer, stop work until both the air and masonry temperature rise above the specified minimums. Do not use supplemental sources of heat to raise the air or masonry surface temperature unless approved by the FRP composite system manufacturer.

1.7.1.1.2 Hot Surfaces

When the surface temperature of the masonry and/or the air temperature rise above the maximum level, as specified by the FRP system manufacturer, stop work until both the air temperature and masonry temperature cool below the
1.7.1.3  Wet or Damp Surfaces

Unless they have been formulated for such applications, do not apply resins and adhesives to damp or wet surfaces.

1.7.1.2  Environmental Temperature

Should the potential for adverse temperatures occur during installation, stop the application of FRP until temperatures return to within the range specified in the Manufacturer's Instructions. Obtain approval from the FRP manufacturer and the Contracting Officer before using supplemental heating or cooling sources.

1.7.1.3  Other Environmental Factors

Provide temporary protection from direct contact by rain, dust and dirt, excessive sunlight, and high humidity during installation and until the resins have cured. Provide and install tents and/or plastic screens as required to protect the FRP system as it cures. Assure resins are cured before removal of temporary shoring or allowing the structure to be exposed to new loads. In the event of suspected damage to the FRP system during installation, notify the Contracting Officer.

1.7.2  Existing Conditions

As-built drawings of the structure [are attached] [can be accessed at [______]].

1.8  WARRANTY

Furnish a warranty for FRP composite system installation. Ensure the warranty covers the FRP composite system [design,] installation, bond to the substrate, and interlaminar bond, as well as mechanical property retention, and fabric-resin compatibility. Furnish the warranty for a period of not less than 5 years from the date of Government's acceptance.

PART 2  PRODUCTS

******************************************************************************

NOTE: FRP system forms can be categorized based on how they are delivered to the work site and installed. Externally applied FRP composite systems come in a variety of forms including wet lay-up systems, prepreg systems, and precured systems.

Wet lay-up FRP systems consist of dry unidirectional or multi-directional fiber sheets or fabrics that are impregnated onsite with a saturating resin. The saturating resin is used to bond the sheets to the masonry surface. Wet lay-up systems are saturated with resin and cured in place and in this sense are analogous to cast-in-place concrete. For dry lay-up systems, the fabric is placed on the wall and then saturated in-place with resin and cured in place.

Prepreg FRP systems consist of unidirectional or multidirectional fiber sheets or fabrics that are
preimpregnated with a saturating resin in the supplier's facility. Prepreg systems are bonded to the concrete surface with or without an additional resin application, depending upon specific system requirements. Prepreg systems are saturated offsite and, like wet lay-up systems, are cured in place. Prepreg systems usually require heat for cure.

Precured FRP systems consist of composite shapes (plates, strips, ribbons, and bars configured as an open mesh grid or solid laminate) manufactured in the system supplier's facility and shipped to the job site. Typically, an adhesive is used to bond the precured shapes to the masonry surface.

A single system manufacturer should supply all materials and system components (reinforcements, resins and adhesives) for a specific job. The arbitrary selection of a fiber reinforcement and a resin/matrix material can lead to failure of the FRP composites system due to matrix-reinforcement incompatibilities and are, therefore, not allowed.

2.1 SYSTEM DESIGN AND PERFORMANCE

2.1.1 Design Requirements

NOTE: The resin system used in the FRP composite system seals up the surface of the wall where it is applied and can impede air and moisture migration through a wall. If the wall should not be sealed tight, full coverage of the wall with the FRP system should be avoided thus allowing normal air and water vapor transmission.

a. Design the FRP composite system in conformance with ACI 440.7R to provide [seismic] [wind] [and] [blast] strengthening for [clay] [and] [concrete] masonry walls.

b. Submit complete shop drawings for each installation of the composite system showing details of fiber architecture, fiber type, dimensions, number and thickness of layers, direction of fiber layers, sequence of layer applications, lap splices, joint and end details, anchorage of the FRP composite system, proposed connections to diaphragms and adjacent walls, and locations to be applied as specified.

c. Submit design calculations for the FRP composite system, prepared by or on behalf of the Contractor and stamped by a licensed professional engineer, for approval of the Contracting Officer. Develop an FRP layout that does not adversely affect moisture permeation through the masonry walls. Include a hygrothermal analysis of the wall system in its environment to assess the impact of reducing air and vapor transmission by the application of the proposed FRP system.
2.1.2 Performance Requirements

**************************************************************************
NOTE: Provide the parameters of strength or force that must be provided by the FRP composite application. The following variables must be considered in determining the enhanced performance requirements: the load on the wall, the size of the wall, the wall aspect ratio, wall openings, etc.
**************************************************************************

Provide the FRP composite system with [seismic] [wind] [and] [blast] strengthening for [clay] [concrete] masonry walls to provide the flexure and shear demand indicated [on the Drawings][on the shop drawings]. Provide a system that transfers [seismic] [wind] [and] [blast] loading in concert with the existing masonry to the building foundation.

2.2 FRP SYSTEM

2.2.1 General Requirements

Ensure that all FRP system components are provided by a single manufacturer of FRP systems. Do not substitute the submitted reinforced FRP composite system or any of its components during the course of the project.

Assure that delivered FRP materials meet the specified requirements prior to starting the project. Submit certificates of compliance. Reject all materials that do not meet the minimum requirements, as specified in Table 1 and by the Contracting Officer. In addition, determine the setting time, pot life, and curing hardness of the resins.

2.2.2 FRP Composite System

**************************************************************************
NOTE: Select the appropriate system from the three choices below and delete the others.
**************************************************************************

[2.2.2.1 Wet Lay-up System

A wet lay-up FRP system consists of [glass] [carbon] [aramid] fiber in [an epoxy] [a polyester] [a polyurethane] resin.

][2.2.2.2 Prepreg System

A prepreg FRP system consists of [glass] [carbon] [aramid] fiber in an uncured polymer resin.

][2.2.2.3 Precured System

A precured FRP system consists of [glass] [carbon] [aramid] fiber, fabricated as [strips] [plates] [ribbons] [bars] in [an open mesh grid] [a solid laminate] configuration with a resin matrix of [vinyl ester] [polyester] [epoxy] [polyurethane] [specialty resin] applied to the surface of the masonry wall using [a polyurethane] [an epoxy] structural adhesive.

]2.2.3 FRP Composite System Properties
NOTE: The values listed in the following table should be provided by the design engineer and be based on the values and assumptions that were used in developing the design. The items in Table 1 below will be the minimum acceptable property values for the FRP system to be installed and potential FRP systems submitted which do not meet these minimums should be rejected.

2.2.3.1 Property Requirements

Table 1 lists the minimum allowable gross laminate properties for the cured [glass] [carbon] [aramid] [hybrid] reinforced FRP composite system.

Proposed FRP systems must utilize the same primary fiber reinforcement type (e.g., carbon fiber, aramid fiber, or E-glass fiber) as the specified system.

2.2.3.2 FRP System Submittals

2.2.3.2.1 Product Data Sheets

Submit manufacturer's product data sheets indicating physical, mechanical, and chemical characteristics of materials used in the FRP system application and certification from the system manufacturer of the guaranteed material and section properties for the supplied material.

2.2.3.2.2 System Material Sample

The required system sample material submittal is an FRP plate 300 x 300 mm 12 x 12 inch or plate of equivalent area when one of the fiber reinforcing dimensions is less than 300 mm 12 inches.

2.2.3.2.3 System Properties

Submit documented evidence that the proposed system meets the requirements of Table 1. Determine elastic modulus by the strength and rupture strain values. Determine ultimate tensile strength and rupture strain values by subtracting three standard deviations from the average values of 20 or more tensile tests. Provide test report.

2.2.3.2.4 System Durability

System environmental durability test results conducted and reported by an independent testing facility. Include the following information in the report:

(1) FRP System nomenclature
(2) Testing facility name
(3) Testing facility address
(4) Testing facility telephone number
(5) Testing facility point of contact
(6) Freeze-thaw test results
(7) UV test results
(8) Fire resistance test results
2.2.3.2.5 System Performance

Test results by an independent testing facility on walls which are representative of the actual configuration and loading conditions for this contract, showing the following information:

(1) FRP System nomenclature
(2) Primer/filler system nomenclature
(3) Coating/finishing system nomenclature
(4) Testing facility name
(5) Testing facility address
(6) Testing facility telephone number
(7) Testing facility point of contact
(8) Test wall substrate material
(9) Test wall aspect ratio
(10) FRP fiber orientation and fiber density
(11) FRP composite application process
(12) Cyclic in-plane test results in accordance with ICC ES AC125 to include the following:

(a) Description of test setup.
(b) Rate and method of loading.
(c) Deformation and strain measurements.
(d) Modes of failure.

2.2.3.2.6 System Installation Instructions

Submit manufacturer's printed installation instructions, including the following:

(1) Brand name
(2) Catalog numbers
(3) Names of manufacturers for each material to be used. Include with instructions the estimated quantity of each material to be used on the job.
(4) Detailed mixing and application instructions to include:

(a) Mixing instructions
(b) Curing times between coats or layers
(c) Application procedures for surface coatings
(d) Cold weather installation to include the minimum application temperature recommended by the FRP system manufacturer or 4 degrees C 40 degrees F whichever is higher. Application at temperatures below 4 degrees C 40 degrees F must be approved by the Contracting Officer and the minimum Shore hardness for the lower temperatures will be provided.
(e) Hot weather installation to include the maximum application temperature recommended by the FRP system manufacturer or 38 degrees C 100 degrees F whichever is lower. Application at temperatures above 38 degrees C 100 degrees F must be approved by the Contracting Officer and the minimum Shore hardness for the higher temperatures will be provided.
(f) Inclement weather installations
(g) Application procedures of top coating material
2.3 COMPONENTS

2.3.1 Primer/Filler

Provide a primer/filler, for the protective seal coat and for filling voids, that consists of a thickened [epoxy] [polyester].

2.3.2 Finish and Coating

Perform final finish and apply architectural coatings as prescribed in architectural specifications and drawings [____].

a. Finish coat compatibility letter from FRP manufacturer: Submit letter from FRP system manufacturer stating that the finish coating is compatible with the FRP System.

b. Finish coat compatibility letter from finish coat manufacturer: Submit letter from finish coat manufacturer stating that the finish coating is compatible with the FRP System.

[2.3.2.1 Flame Spread/Fire Protection

**************************************************************************
NOTE: Include the following paragraph unless the FRP materials are installed on the exterior of a structure, or if a flame barrier is installed between living space and the FRP materials system, or unless stated otherwise by the local fire building code.
**************************************************************************

Meet requirements for Class 1 fire rating in accordance with ASTM E84 and meet or exceed local building code requirements for flame spread and smoke generation.

2.4 MIXES

Mix [Resins] [Adhesive] in accordance with the FRP system manufacturer's recommended procedure. Assure that [resin] [adhesive] components are at a proper temperature and are mixed in the correct ratio until there is a complete mixing of components and a uniform color. Mix each batch of [resin] [adhesive] in quantities sufficiently small to ensure that the mixed [resin] [adhesive] can be used within the [resin] [adhesive] pot life. Do not use mixed [resin] [adhesive] that exceeds its pot life, as defined by the system manufacturer.

2.5 ACCESSORIES

Provide anchors for the FRP system as prescribed by the FRP system manufacturer and designated in the Shop Drawings. Submit two of each type of anchor to be used.

PART 3 EXECUTION

3.1 EXAMINATION

3.1.1 Verification

Examine existing conditions to assess the quality of the masonry substrate,
identify potential obstructions, and verify dimensions/geometries shown on shop drawings.

3.1.2 Surface Moisture

Ensure that all surfaces to receive the strengthening system are as dry as recommended by the FRP system manufacturer. Evaluate moisture content in accordance with the requirements of ACI 503.1-503.4 standard specification applicable to the application.

3.2 PREPARATION

3.2.1 Protection

Protect building occupants, other Contractor personnel, and visitors from exposure to FRP system dust and mists from preparation, FRP system application and clean-up operations.

3.2.2 Worksite Ventilation

Ventilate work areas during FRP application so that worker exposure to chemical substances does not exceed limits established by ACGIH 0116, or required by a more stringent applicable local regulation. Ventilate interior work zones having a volume of 280 cubic m 10,000 cubic ft or less at a minimum of 2 air exchanges per hour. Maintain ventilation in larger work zones by means of mechanical exhaust. Exhaust solvent vapors outdoors, away from air intakes and workers. Temporarily seal return air inlets in the work zone before start of work until the polymer resin has cured.

3.2.3 Substrate Repair

3.2.3.1 Surface Conditions

**************************************************************************
NOTE: If the masonry surface to be treated has been inspected and found to not need repair, select the first bracketed option. If the masonry surface to be treated has been inspected and found to have distress that requires repair, but the repairs have not be identified, select the second bracketed option. Select the third and fourth bracketed options only when these repair approaches have been determined to be appropriate and applicable to the masonry surface to be treated.
**************************************************************************

[The area to receive FRP composite is relatively sound structurally.] [There are known problems associated with the condition of the original masonry and the masonry substrate that can compromise the integrity of the FRP system.] [Fill surface cracks greater than 1.6 mm 1/16-inch to a minimum depth of 25 mm 1 inch.] [Remove areas of loose or spalling masonry material.]

3.2.3.2 Sub-Surface Conditions

Do not apply externally bonded FRP systems to areas of substandard masonry exhibiting lack of structural integrity (such as signs of corroded embedded steel elements, excessive cracking and spalling, excessive deflections,
etc.). Stop work in these areas, notify the Contracting Officer, and indicate the locations and type of masonry distress. Do not proceed with work until directed to do so by the Contracting Officer.

3.2.4 Surface Preparation

3.2.4.1 Surface Cleaning

Remove loose and unsound materials and other conditions that would inhibit bond, such as laitance, dust, dirt, oil, curing compound, existing paint or coatings, efflorescence, and other matter that could interfere with the bond of the FRP system to the masonry or repaired surfaces to which the FRP system is to be applied.

3.2.4.2 New Masonry Preparation

Unspoiled new masonry only requires wire brushing to remove loose surface particles.

3.2.4.3 Old Clay Masonry Preparation

Prepare surface of older clay masonry using hand tools, power tools or water blasting techniques. Do not use abrasive blasting.

3.2.4.4 Old Concrete Masonry Preparation

Concrete masonry may be blasted using a light blast abrasive or cleaned using hand tools, power tools or water blasting techniques.

3.2.4.5 Cleaned Surface Protection

After the cleaning operations are complete, protect the surface prior to FRP installation so that no materials that may interfere with bond are redeposited on the surface. Apply the FRP composite system to the prepared wall within 72 hours of performing the surface preparation.

3.2.5 Mortar Joint Preparation

3.2.5.1 Tooled Mortar Joints

Fill tooled mortar joints with putty or another epoxy-based paste to make mortar joints flush with the masonry units. Ensure that localized out-of-plane variations between masonry units do not exceed 1.6 mm 1/16-inch or the tolerances recommended by the FRP system manufacturer, whichever is smaller. Smooth localized out-of-plane variations in the masonry units using putty as needed. It is not necessary to screed filler onto the surface to fill all bug holes. Fill larger holes greater than 6 mm 1/4 inch in diameter and other voids with putty.

3.2.5.2 Untooled Mortar Joints

Grind or chisel untooled mortar joints that protrude beyond the masonry surface or other protuberances or irregularities flush with the surface.

3.2.5.3 Putty/Filler

Ensure putty/filler used is compatible with the masonry and the FRP strengthening system and complies with the FRP system manufacturer's specifications. Use putty or another epoxy-based paste with adequate
bonding properties to masonry only to fill voids and smooth surface discontinuities prior to application of other materials. Allow putty to cure to the degree specified by the FRP manufacturer before applying subsequent materials. Grind rough edges or trowel lines of cured putty smooth prior to continuing the installation.

3.2.6 Obstructions, Corners and Non-Planar Surfaces

Obstructions, re-entrant corners, concave surfaces and embedded objects can affect the performance of the FRP system. Modify surfaces scheduled to receive RFP system until localized out-of-plane variations between masonry units do not exceed 1.6 mm 1/16-inch or the tolerance recommended by the FRP system manufacturer, whichever is smaller. Movable obstructions and embedded objects may need to be removed prior to installing the FRP system. [Give special care to re-entrant corner detailing and concave surface detailing to ensure that the bond of the FRP system to the substrate is maintained.]

3.3 FRP INSTALLATION

3.3.1 General

Do not install the FRP composite if environmental conditions are outside the permitted range defined by the FRP system manufacturer.

3.3.2 Primer

*******************************************************************************
NOTE: Wet lay-up systems typically require a primer to saturate and penetrate the masonry surface and enhance the bond strength of the FRP system. Adhesives used with pre-cured systems, depending upon its chemistry, may not require use of a primer.
*******************************************************************************

a. Mix primers according to the FRP system manufacturer's installation instructions. Assure resin components are at a proper temperature and mixed in the Manufacturer's prescribed mix ratio for its prescribed mixing time until there is a uniform and complete mixing of components.

b. Apply primers to areas on the masonry surface where the FRP system is to be placed. Place primer uniformly on the prepared surface at the manufacturer's specified rate of coverage. Allow primer to cure to the degree specified by the FRP manufacturer before applying subsequent materials.

3.3.3 System Installation

3.3.3.1 Wet Lay-Up and Prepreg Systems

Install the FRP system in strict accordance with the FRP system manufacturer's recommendations. Apply sufficient saturating resin to achieve full saturation of the fibers in accordance with the manufacturer's specifications. Release or roll out entrapped air between layers before the resin sets. Place successive layers of saturating resin and fiber materials before complete cure of the previous layer of resin. Handle
sheet and fabric materials in a manner to maintain the fiber straightness and orientation. Remove and repair fabric kinks, folds, or other forms of severe waviness.

Precured Systems

Install the FRP system in strict accordance with the FRP system manufacturer's recommendations. Uniformly apply adhesives to the prepared surfaces where pre-cured systems are to be placed. Apply adhesives at a rate recommended by the FRP manufacturer to ensure full bonding of successive layers. Release or roll out entrapped air between layers before the adhesive sets.

3.3.4 Splices

Locate splices in accordance with the approved Shop Drawings. [Stagger lap splices unless noted otherwise in the Shop Drawings and by the Contracting Officer.] [Lap splices are not permitted except as shown in the Shop Drawings.]

3.3.5 Curing of Resins

Inspect the primer and FRP resin to ensure proper cure according to the manufacturer's recommendation. Do not modify resin chemistry in the field.

3.3.6 Surface Finish - Coating Application

**************************************************************************
NOTE: Determine what finishes are required for appearance, fire protection, UV protection, etc. If coatings will be used, keep the following two paragraphs.
**************************************************************************

3.3.6.1 Preparation

Apply paints and coatings prior to final resin cure for best results. After the FRP resin has cured, the coating can be applied by performing a light dust blast of 30-mesh silica sand (or equivalent method) to break the gloss finish in preparation of a finish coating. Remove dust and residue from all surfaces by flushing with clean water before applying the coating. Ensure all surfaces are dry before applying the surface finish coating.

3.3.6.2 Multiple Coats

Use coatings compatible with the FRP strengthening system and applied in accordance with the manufacturer's recommendations. Apply two finish layers of coating according to the coating manufacturer's instructions prior to full cure of the FRP system.

3.3.7 Installation Procedure Modification

Installation procedures may be modified to achieve maximum results, subject to approval by the Contracting Officer prior to implementation.
3.3.8 Interface with Wall Features

3.3.8.1 Weeps

Maintain all weeps. Do not cover existing weeps with the FRP composite and prevent resin from entering weeps.

3.3.8.2 Movement Joints

[3.3.8.2.1 Control Joints

Maintain all concrete masonry control joints. Ensure that the FRP composite does not bridge existing control joints.

][3.3.8.2.2 Expansion Joints

Evaluate design loads to determine whether or not to maintain existing clay masonry expansion joints.

][3.3.8.3 Diaphragms

Anchor the FRP system into the floor, ceiling and roof diaphragms in accordance with the Shop Drawings. Ensure anchorage does not create local stresses that may locally fracture the walls when deflection occurs due to out-of-plane loading.

3.4 FIELD QUALITY CONTROL

Comply with the approved Quality Control Plan.

3.4.1 Laboratory Testing During Construction

3.4.1.1 Witness Panels

3.4.1.1.1 Wet Lay-up and Prepreg

Fabricate witness panels onsite using installation procedures identical to the method used to install the FRP system to the masonry surfaces. Fabricate two witness panels for each day of production or one for each 46 square m 500 square feet of production whichever is more. From a standard polymer resin mix, saturate a 300 x 300 mm 12 x 12 inch piece of fabric according to specified fiber-resin ratio. On a smooth, flat, level surface covered with polyethylene sheeting or 0.4 mm 16-mil plastic film, prime the surface with polymer resin and then prepare the witness panel by placing two layers of saturated fabric oriented in the same direction on the flat surface. Apply an additional topping of polymer resin and cover the completed sample with plastic film and squeegee out all bubbles. Store samples in a sample box at the work site and do not move them for a minimum 48 hours after casting. Mark the panels with the date of fabrication, location of application, number of plies and primary fiber direction. Ship the samples within two weeks of fabrication to the pre-approved testing laboratory for evaluation.

3.4.1.1.2 Precured

Witness panel samples for precured sheet and strip material are the width of the procured sheet and a length sufficient to achieve 92,900 square mm 144 square inches in total area taken randomly from the material received at the job site.
3.4.1.2 Witness Panel Testing

Determine lap splice strength, tension strength, and elastic modulus of FRP materials. Test not fewer than two (2) coupons from each witness panel in the laboratory in accordance with ASTM D3039/D3039M. If one coupon from a witness panel fails to meet the minimum strength specified in Table 1, test five additional coupons from the witness panel with the failed coupon. If a second one fails, test five coupons from all panels for that day of production. Take appropriate remedial measures to ensure integrity of the FRP system applied for the day the failed witness panels were prepared. In addition, test a minimum of five coupons from each witness panel for the remainder of the job or until ten successive witness panels are tested with no coupon failures. Then two coupon tests per witness panel may be resumed. The Contracting Officer may waive or alter the frequency of testing.

3.4.1.3 Witness Panel Test Report

Prepare a laboratory report to document the mechanical properties of the witness panels, in accordance with ASTM D3039/D3039M. Submit a copy of the report to the Contracting Officer and Special Inspector for review.

3.4.2 Field Testing

3.4.2.1 Mixed Resin Hardness

**************************************************************************
NOTE: The term "resins" include primers, saturating resins, binders, and adhesive components.

The required resin samples are a minimum of 6 mm 1/4-inch in thickness, whereas FRP placed on a wall is much thinner, typically 3 mm 1/8-inch or less. During initial stages of curing, thicker cross sections tend to be softer than thin ones. There is, therefore a variation in the required hardness to account for this phenomenon.
**************************************************************************

3.4.2.1.1 Mixed Resin Hardness Sample Preparation

Prepare two samples of each mixed resin, primers, binders, saturants, and adhesives, per day from two, separate, nonconsecutive batches of each. The required resin sample size is a minimum of 6 mm 1/4-inch thick and 50 mm 2 inches in diameter. Retain the mixed resin samples for testing to evaluate curing progress.

3.4.2.1.2 Mixed Resin Hardness Testing

Evaluate relative curing progress of the resin on the job site by measuring the hardness of the resin sample at 24 hours and 48 hours of cure in accordance with provisions of ASTM D2240. Ensure the polymer resin exceeds the Shore hardness reported by the manufacturer evaluated at the lowest air temperature for the curing time period. Take measurements at a minimum of three different points distributed over the resin specimen's surface at least 6 mm 1/4-inch apart from each other.
3.4.2.1.3 Mixed Resin Hardness Test Report

Report the mean hardness value obtained, resin identification and manufacturer, resin batch number, resin mixing date and time, test date and time, air temperature when the resin was mixed, air temperature when the testing was performed, the minimum air temperature for the curing period, and the type and serial number of durometer used. Submit test reports as specified.

3.4.2.1.4 Resolution of Noncompliance

In the event that measured hardness is less than the manufacturer's reported hardness for the temperature range, comply with paragraph REMEDIAL MEASURES under paragraph IN-PLACE FRP HARDNESS.

3.4.2.2 In-Place FRP Hardness

3.4.2.2.1 In-Place FRP Hardness Testing

Evaluate relative curing progress of the in-place FRP resin at 24 hours and at 48 hours using the Shore Hardness test in ten-degree intervals between 4 and 38 degrees C (40 and 100 degrees F) for both neat resin and for FRP laminate on masonry substrate, as described in ASTM D2240. Perform a minimum of five tests on each 9 square m (100 square ft) of wall or portion thereof with FRP composite applied to it. Ensure the Shore Hardness exceeds the manufacturer's values for the time period measured and the lowest air temperature during that time period. Submit minimum Shore Hardness values for fully cured resin and fully cured FRP laminate on masonry substrate.

3.4.2.2.2 In-Place FRP Hardness Test Report

Report both the individual and mean hardness values obtained, the locations where each hardness test was performed, the FRP application date, test date and time, air temperature when the FRP was applied, air temperature when testing performed, and the type and serial number of durometer used.

3.4.2.2.3 Remedial Measures

In the event that hardness is less than the manufacturer's reported hardness for the temperature range, take remedial measures as follows. Where testing indicates that the installed composite system does not meet the minimum specified hardness values, immediately halt the FRP installation and notify the Contracting Officer. Remove the affected, installed FRP composite at no expense to the Government and replace with FRP composite meeting or exceeding the minimum hardness values.

3.4.2.3 Adhesion Strength

3.4.2.3.1 Adhesion Testing

a. Using the method described by ACI 440.3R or ASTM D4541 conduct direct tension adhesion testing of cored samples. Perform a minimum of three tests for each day of production or for each 46 square m (500 square ft) of FRP application, whichever is less. Perform pull-off tests on each area of fiber sheet installed on a single day. Perform tests on each type of masonry substrate or for each surface preparation technique used.
b. Allow the FRP system to cure a minimum of 24 hours before execution of the direct tension pull-off test. Select locations for the pull-off tests that are representative and on flat surfaces. If possible, conduct the tests on areas of the FRP system subjected to relatively low stress during service. The minimum acceptable value for any single tension test is 1.2 MPa 175 psi. The minimum acceptable average adhesion strength of the three tests at each location is 1.38 MPa 200 psi. Acceptable tension adhesion tests exhibit failure of the masonry substrate, indicated by a layer of masonry, on at least 80 percent of the underside of the test puck following the test.

3.4.2.3.2 Adhesion Strength Test Report

Report the adhesive strength values for each test and the average strength for each day's production. Report the type of failure for each. Report percentage of masonry on the FRP surface adhered to the test puck to the Contracting Officer.

3.4.2.3.3 Resolution of Noncompliances

In the event that the adhesive strength does not meet the minimum allowable strength, take remedial measures. Halt FRP installation and notify the Contracting Officer. Remove affected, installed FRP composite. Clean the substrate surface and apply FRP composite that meets or exceeds the minimum specified values.

3.4.2.3.4 Repair After Adhesion Test

After testing, fill the hole in the FRP composite with putty and smooth it. Apply a 100 mm 4-inch or more overlapping sheet patch of equivalent plies over the location where the sample was taken.

3.4.3 INSPECTION

Provide full inspection of the surface preparation and composite system application to ensure full compliance with the specified requirements.

3.4.3.1 Special Inspector

**************************************************************************
NOTE: Modify Section 01 45 35 SPECIAL INSPECTIONS to include the inspection requirements of ICC ES AC178. Include in Section 01 45 35 the extent of observation of field testing to be performed by the Special Inspector.

Ensure that the following information is included in Section 01 45 35 SPECIAL INSPECTIONS:

Inspect the FRP composite overlay during and immediately following application of the composite. Inspect FRP systems and all associated work as required by the applicable codes and as described in the QC plan. Observe all aspects of onsite preparation and material application including surface preparation, resin component mixing, application of primer, application of resin and fiber sheet, curing of composite, and the application of protective coatings. Require
compliance with the design drawings and specifications.

Include in daily inspection records:

a. Date and time of installation;
b. Ambient temperature, relative humidity, and general weather observations;
c. Surface temperature of the masonry receiving the FRP composite system;
d. Surface dryness;
e. Surface preparation methods;
f. Surface cleanliness;
g. Type of auxiliary heat source, if applicable;
h. Fiber or pre-cured laminate batch number(s) and location in structure;
i. Batch numbers, mix ratios, mixing times, and mixed color of all resins, including primers, putties, saturants, adhesives, and coatings mixed for the day;
j. Observations of progress of cure of resins;
k. Conformance with installation procedures;
l. Pull-off test results: bond strength, failure mode, and location;
m. FRP system properties from witness panel tests, if required;
n. Location and size of any delaminations or air voids;
o. General progress of work.

**************************************************************************

Provide a Special Inspector, trained and certified by the FRP system manufacturer and approved by the Contracting Officer, to perform inspections in accordance with Section 01 45 35 SPECIAL INSPECTIONS and ICC ES AC178. Provide a Special Inspector who is not an employee of the Contractor or is financially associated with the Contractor beyond the inspection contract.

3.4.3.2 Void Detection

After allowing at least 24 hours for initial resin cure to occur, perform a visual and acoustic tap test inspection of the layered surface. Other methods for detecting voids may be employed provided that all parties concerned agree upon these methods prior to the submission of bids or proposals. Together with the Special Inspector, mark voids requiring corrective action in accordance with the specified FRP maintenance and repair procedure. Acoustic Guided Wave (AGW) inspection technology has been shown to be an objective method for detecting voids.

3.4.3.3 Delaminations

Together with the Special Inspector, evaluate the cured FRP system for delaminations and air voids between multiple plies or between the FRP system and the masonry. Use inspection methods capable of detecting delaminations of 1300 square mm 2 square inches or greater. Submit identification of delaminations and other anomalies for evaluation. Acoustic Guided Wave (AGW) inspection technology has been shown to be an objective method for detecting delaminations.
3.4.3.3.1 Wet Lay-Up and Prepreg Systems

NOTE: Determine and correct the cause of delamination prior to application of the patch.

a. Small delaminations and air voids less than 1300 square mm 2 square inches each are permissible, so long as the delaminated area is less than 5 percent of the total laminate area and there are no more than 10 such delaminations or air voids per 0.93 square m 10 square ft.

b. Delaminations and air voids less than 16,000 square mm 25 square inches may be repaired by resin injection or ply replacement, depending upon the size and number of delaminations and their locations. With the Contractor's Engineer of Record, determine the cause of the delamination and an appropriate repair. Obtain the Contracting Officer's approval of the repair method.

c. For large delaminations and air voids, greater than 16,000 square mm 25 square inches, determine the cause of the defect and design an appropriate repair using the Contractor's Engineer of Record. Obtain the Contracting Officer's approval of the repair method.

3.4.3.3.2 Pre-Cured Systems

For pre-cured FRP systems, evaluate each delamination and air void and, with the Contractor's Engineer of Record, design an appropriate repair. Obtain the Contracting Officer's approval of the repair method.

3.4.3.4 Fiber Orientation

Together with the Special Inspector, evaluate fiber or pre-cured laminate orientation by visual inspection during application. Evaluate for fiber waviness, a localized appearance of fibers that deviate from the general straight-fiber line in the form of kinks or waves. Report fiber or pre-cured laminate misalignment of more than 5 degrees from that specified on the design drawings (approximately 80 mm/m 1 in/ft) to the Contracting Officer.

3.4.3.5 Record Retention

Retain the records of inspection and witness panels throughout the warranty period. Retain samples of mixed resin and maintain a record of the placement of each batch. Upon completion of repairs, re-inspect the laminate to verify that the repair was properly accomplished. Evaluate the FRP systems and accept/reject based on conformance or nonconformance with the design drawings and specifications. Include FRP system material properties, as-built fiber orientation, presence of delaminations, cure of resins, and adhesion to substrate in the evaluation. Submit these records upon completion of the project.
3.5 ADJUSTING AND CLEANING

3.5.1 Identification and Repair of Defects

3.5.1.1 Repair Methods for Application Defects

Repair defects spanning more than 5 percent of the surface area according to the FRP maintenance and repair procedure that is prepared by the system manufacturer and submitted for approval. There are two types of repairs; resin injection and removal followed by reapplication of the FRP system.

3.5.1.2 Tears in the Reinforcing Fibers

Repair tears in the reinforcing fibers that cross fiber rows greater than 50 mm 2 inches in length by adding additional plies of FRP material.

3.5.1.3 Adhesion Defects

Review and get approval of anchor details for correcting deficient adhesion from the Contracting Officer prior to installation. Should the Contracting Officer determine that anchors are inappropriate, remove the FRP composite and replace with new composite meeting the minimum adhesion requirements.

3.5.2 Work Area Clean Up

Upon completion of the work, remove staging, scaffolding, and containers from the work site or destroy them in an approved manner. Remove FRP composite, resin, and other deposits on adjacent surfaces and leave the entire job cleaned to equal or better condition to that prior to the start of the job. Place cloths, cotton waste and other debris, which might constitute a fire hazard, in closed metal containers removed at the end of each day. Dispose of resins and adhesives properly as indicated on the SDS sheets. Store and transport resins and adhesives as indicated in SDS directions. Contain and dispose of spent abrasive blast media properly as required by local authorities. Contain material to be discarded at the site until properly disposed of.

3.6 MAINTENANCE PROCEDURES

Submit procedures to properly maintain the installed FRP system and written manufacturer recommended repair procedures for damage to the in-place FRP system.

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for restoration and cleaning of masonry in historic structures.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1 GENERAL

NOTE: Where the words "as indicated" are used, ensure that sizes, positions and other designated information are indicated on the design drawings.

The following publications, from the United States Department of the Interior – National Park Service, provide useful guidance in the restoration of historic masonry and may be included as addenda to the specifications.

1.1 REFERENCES

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

1.2 DEFINITIONS

Terms are defined below as applicable to this project.

1.2.1 Aggregates

The sand component of mortar.

1.2.2 Biocides

A chemical treatment that inhibits, deters, or controls organic growth. Such growth is typically removed by cleaning following biocide treatment.

1.2.3 Binder

The component of mortar that binds together the aggregate particles into a cohesive material.

1.2.4 Dispersed Lime Crack Injection

A repair method in which dispersed lime material is injected into small cracks ranging in width from hairline to 3.2 mm 1/8 in by use of needle or syringe.

1.2.5 Consolidant

A chemical product meant to strengthen loose or deteriorated stone.
1.2.6 Dutchman

A repair method in which deteriorated stone is removed in part and replaced with salvaged, harvested or new stone to make a seamless patch.

1.2.7 Harvested

Units removed from inconspicuous areas of the building.

1.2.8 In situ

A term referencing a repair procedure in which the masonry units and mortar remain in place and are repaired without removal from the wall system.

1.2.9 Joint Sealant

A flexible, chemical product that is used to create a weather-tight seal at the boundary of masonry units with other units or dissimilar materials.

1.2.10 Lead Flashing

An extruded lead material that is inserted into joints to assist in precluding water entry into the masonry.

1.2.11 Lime Wash

A protective surface treatment comprised of calcium hydroxide particles in suspension in water, along with small amounts of calcium carbonate, silica particles and other minerals.

1.2.12 Mockup

Specific area on the building approved by Contracting Officer to demonstrate the ability to apply, match and install specified materials.

1.2.13 Mortar

A mixture of binders, aggregates, and pigments used for reconstruction, repointing or stucco applications.

1.2.14 New Elements

New, non-historic materials added to masonry structures to aid in their ability to resist loads (typically seismic) or to resist water infiltration.

1.2.15 Patch

The use of substitute repair materials to treat damaged or deteriorated masonry units in situ.

1.2.16 Remediate

An intervention of a historic masonry structure and its component materials with the intent to maintain the original fabric to the greatest extent possible.

1.2.17 Remove

Specifically for historic masonry materials, the term means to detach an
item from existing construction to the limits indicated.

1.2.18 Replace

To reinstall an item in its original position (or where indicated) after remedial treatment, or to duplicate and reinstall an entire item with new material; with the original item serving as the pattern for creating the duplicate.

1.2.19 Repoint

To remove existing mortar joints to the specified depth and replace with a mortar that matches in color, texture, and performance with water vapor transmission, bond, hardness, and flexibility compatible with original mortar, as assessed in accordance with ASTM C1713.

1.2.20 Retool

A repair method in which a chisel is used to re-create the surrounding stone texture finish by removing loose pieces of stone.

1.2.21 Stucco

A mixture of binders and aggregates, sometimes including animal hair or fibers used for the repair treatment of existing stucco.

1.2.22 Surface Treatment

The application of traditional materials or contemporary chemical products to the surface of masonry to provide protection to the masonry units and mortar and/or reduce water infiltration.

1.2.23 Test Panel

Specific area on the building approved by the Contracting Officer to demonstrate individual applicator competency and workmanship proficiency prior to the start of restoration work.

1.2.24 Tuckpointing

Often called skim-coating, an American practice of surface repairing mortar joints without the required removal of existing deteriorated mortar beneath. This practice is not recommended for mortar joint repair work on historic masonry. There is also an acceptable British form of tuckpointing practice that involves careful thin penciling of smaller joints within larger ones to give the wall the appearance of an ashlar finish.

1.2.25 Water Repellent

A surface-applied chemcial intended to reduce liquid water entry into a masonry wall without significantly affecting the vapro transmission properties of the original material.

1.2.26 Wall System

A term used to address the fact that masonry structures are comprised of different materials but function holistically, requiring that all restoration and cleaning process take into account the implications of the treatment to the adjacent materials and the building as a whole.
1.2.27 Masonry Treatment Requirement (MTR)

Defined treatments that are required by the specification (contract) documents for project specific repairs to masonry.

1.2.28 Saturated Surface Dry (SSD)

Condition of the wall surface after water has been applied sufficient to saturate more than the surface, then allowed to dry until the surface is dry but the body of the masonry still has moisture.

1.3 ADMINISTRATIVE REQUIREMENTS

1.3.1 Pre-Installation Meeting

Prior to beginning the work of this Section, convene a meeting with the Contracting Officer's Representative(s) to review the requirements of the Quality Control Plan, Project Training Program, installation procedures, location of required mockup areas, and all job conditions and processes. All subcontracting firms involved with this work must participate in this meeting.

1.4 SUBMITTALS

**************************************************************************

NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item.
Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.]} Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

1.5 QUALITY CONTROL

1.5.1 Quality Control Plan

[Prior to beginning restoration and cleaning work, submit a written Quality Control Plan.][Include a separate section in the overall project Quality Control Plan specifically addressing this restoration and cleaning work.] Do not proceed without written approval of the Quality Control Plan. At a minimum, include the following items in the Quality Control Plan:

a. Describe methods of dust containment during the work specific to the work of this section.

b. Describe the methods of protecting surrounding masonry, windows, doors, roof, and building trim as well as surrounding landscape. Provide drawings of protection when requested.

c. Describe the work procedures, materials, and proposed tools to use for each Masonry Treatment Requirement (MTR) specified.

d. Describe the sequence of each MTR.

e. Describe how each MTR sequence and the overall construction schedule changes with weather variations and how completed work will be protected.

f. Describe the methods for surveying original layout and collecting datum points and plumb lines for rebuilding masonry.

g. Describe the methods for shoring and providing a safe working environment.

h. Describe the methods for select deconstruction of individual masonry units and tools/methods for cleaning the masonry for reuse.

i. Describe the method and approach to mortar joint removal.

j. Describe the method and approach for assuring repair material compatibility with original materials.

k. Describe the method and approach to cleaning mortar, coating, smears and old patching materials from the masonry surfaces.

l. Describe, in detail, the procedures relating to techniques and tools proposed for masonry matching.

m. Describe the complete masonry removal and matching procedures; include equipment, approach, length of time the masonry will be out of the wall, documentation on mapping the location, and where (on-site or in shop) the masonry units will be repaired.

n. Describe the procedure for matching of different colors at different locations.

o. Describe the procedure for mixing and matching of repair materials.

p. Describe the methods and system by which the use of reclaimed masonry units can be utilized.
q. Describe the methods for setting masonry back into its original position and maintaining the original bond patterns and joint width.

r. Describe the methods of transition points where replacement/preservation work will meet the original historic work.

s. Describe the on-site project training program. Provide the opportunity for workers to be trained in each masonry treatment requirement (MTR) as work proceeds.

1.5.2 Qualifications

1.5.2.1 Historic Masonry Consultant

a. Secure the services of a historic masonry consultant with a minimum of 10 years experience applying NPS Hist Prop as they relate to the work in this section.

b. Submit a resume that describes five relevant projects within that period and include how NPS Hist Prop was applied to the work of similar scope and scale and what jurisdiction or agency was involved in approving the work.

c. The consultant's services include:
   
   (1) Investigating the condition of the masonry materials and mortar.
   
   (2) Arranging for material analysis in the laboratory
   
   (3) Recommending appropriate cleaning methods and materials
   
   (4) Recommending restoration options.
   
   (5) Providing project specific specifications.
   
   (6) Providing an on-site training program.
   
   (7) Providing quality control services during construction.
   
   (8) Recommending appropriate repair and restoration materials.

1.5.2.2 Masonry Firm

a. The firm performing the masonry work must have a minimum of five years experience on relevant projects.

b. The firm must have completed work similar in material, design, and extent to that indicated for this Project and demonstrate a record of successful in-service performance.

c. Proven implementation of NPS Hist Prop and related Preservation Briefs are required.

d. Submit a resume that describes the required experience.

1.5.2.3 Field Supervisor

Retain an experienced full-time supervisor on the project site at all times.
when masonry restoration is in progress. A single individual must be responsible for supervising the historic masonry restoration work throughout the duration of the project.

Submit a resume that describes the required experience.

1.5.2.4 Masonry Applicator

a. Employ craftspeople who are experienced with and specialize in restoration work of the types they will be performing.

b. All masonry restoration treatments must be performed by a craftsperson that is familiar with historic masonry construction and has worked on historic masonry projects for at least five years.

c. Only skilled technicians who are familiar and experienced with the materials and methods specified may be used.

d. Submit resumes for all historic masonry applicators, demonstrating the required experience.

1.5.3 Project Training Definition and Use

In addition to five years demonstrable experience on masonry restoration projects, offer workers project training certificate(s) within the framework of ASTM E2659. Project training certificates are earned by individual workers and issued with the understanding that they are for limited time use, enforceable only to this specific project and for a specific MTR. It is not necessary, nor a requirement of this specification, that all restoration workers obtain all project training certificates offered. Rather it is desirable that workers be trained for each project specific task they will perform to ensure the highest quality results from the cleaning and restoration program.

1.5.4 Mortar Analyst

Laboratory mortar analysis equipment should be operated by and results analyzed by trained personnel experienced with analysis of historic masonry mortar.

1.5.5 Documentation

Submit digital photographic documentation of the all phases of masonry restoration, including prior to the start of restoration work.

Provide thorough photo documentation of the project and project details and targeted areas.

1.5.6 Cleaning and Restoration Methods

1.5.6.1 General Procedure

a. Submit the cleaning and restoration methods, and materials selected for a specific structure for approval before work starts.

b. Take into account the total construction system of the building to be worked upon, including different masonry and mortar materials, as well as non-masonry elements which may be affected by the work.
c. Utilize mockups to identify the appropriate cleaning and restoration treatment and materials and set the standard for each project task.

d. Demonstrate the correct execution of the approved cleaning and restoration methods and materials during the on-site workmanship training program within the framework of ASTM E2659.

1.5.6.2 Cleaning Products and Procedures

1.5.6.2.1 General Cleaning Requirements

a. Establish cleaning products and procedures during the mockup process.

b. Select the least aggressive method used to achieve the desired level of cleanliness.

c. Where chemical products are selected for cleaning, use them in accordance with the manufacturer's instructions.

1.5.6.2.2 Cleaning Mock-Ups

a. Demonstrate the materials, equipment, and methods to be used in cleaning in a test section approximately 1 meter by 1 meter = 3 feet by 3 feet.

b. Locate test patches in inconspicuous areas of the building. The areas tested are subject to approval by the Contracting Officer. The areas tested must exhibit soiling characteristics representative of those larger areas to be cleaned.

c. Adjust the cleaning process as required and the test section rerun until an acceptable process is obtained.

d. Conduct tests on areas to be stripped of paint.

e. Allow tested areas to dry before a determination is made on the effectiveness of a particular treatment.

1.5.7 Masonry Restoration Products and Procedures

1.5.7.1 General Restoration Requirements

a. Do not use masonry or mortar in the work until the mock-ups and the represented material and workmanship have been submitted and approved.

b. Demonstrate the methods and quality of workmanship to be performed in each masonry treatment requirement (MTR). Provide a mock-up for each MTR indicated.

1.5.7.2 General Restoration Mock-Up Requirements

a. Throughout restoration, retain approved mock-up panels in undisturbed condition, suitably marked, as a standard for judging completed work.

b. Review manufacturer's product data sheets to determine suitability of each product for each surface.

c. Apply products using manufacturer-approved application methods, determining actual requirements for application.
d. Obtain approval as to the preservation treatment approach, design, and workmanship to include, but not limited to the verification of all material applications and finishes as specified to the requirements of color, texture, profiles, and finishes before proceeding with work.

1.5.7.2.1 Mock-ups

May be performed on inconspicuous sections of actual construction under the same weather conditions expected the remainder of the work.

a. Location and number as directed[, but no more than [_____]].

b. Size: 1 m by 1 m 3 feet by 3 feet or as appropriate for the repair specified.

c. Repair unacceptable work.

1.5.7.3 Restoration Mock-Ups

1.5.7.3.1 Repointing

Repoint mortar joints, minimum acceptable mock up dimensions: twelve feet in length - 2/3 horizontal joints and 1/3 vertical joints. Demonstrate method for cutting out mortar joints, preparing wall for repointing, mixing mortar, installing mortar and curing the mortar. Prepare and place repointing mortar in accordance with NPS TPS Brief 2 and in compliance with NPS Hist Prop.

1.5.7.3.2 Retooling Stone Masonry In Situ

*******************************************************************************
NOTE: Common historic finish textures include, but are not limited to, corduroy and point chisel finishes.
*******************************************************************************

Demonstrate treatment technique and methods to retool three deteriorated stone faces in situ in all known historic profile textures identified.

1.5.7.3.3 Masonry Removal and Replacement

Fully remove masonry and replace to specified dimensions and texture. Select size of masonry units representing typical conditions. Return one masonry unit to same location, set to surrounding profile joint width and bond pattern. Set masonry unit using specified mortar. Confirm with Contracting Officer’s Representative that the replacement masonry units meet specification requirements for matching and that sufficient quantity required for the work have been identified. Leave one stone dry-set into opening set on wood shims for evaluation and approval of preparation conditions.

1.5.7.3.4 Repair Material

1.5.7.3.4.1 Patching

Apply repair material on at least two masonry units for repair. Include one masonry unit on which to demonstrate proficiency in removing previous patching material and repairing with new substitute repair material.
Include the removal of metal anchors at two locations and fill in the holes with repair material on the second masonry unit (where applicable).

1.5.7.3.4.2 Dutchman

Undertake dutchman repairs in two locations, including one that is only cut and prepared for application. Demonstrate the quality of the stone insert, as well as the workmanship and techniques to be performed in the dutchman repairs. Do not proceed with other dutchman repairs until the technique has been approved.

1.5.7.3.5 Crack Repair

Repair one crack, 600 mm 2 feet in length, using mortar. Repair one crack, 600 mm 2 feet in length, using dispersed hydrated lime injection technique with appropriate repair material.

1.5.7.3.6 Surface Treatments

Install a minimum 1.5 square meter 16 square foot mockup for each surface treatment on each substrate to be treated. For stucco, demonstrate the means for installing each coat; including mechanical support systems such as wood or metal lath. For water repellents and/or consolidants, demonstrate the equipment and installation procedure. Allow 48 hours for limewash applications to dry to their final color and appearance.

1.5.7.3.7 New Masonry Elements

**************************************************************************
NOTE: Consideration of new elements on a historic structure should only be undertaken once the addition is approved by the Contracting Officer. New accessories are intended to provide structural strengthening or facilitate weather protection.
**************************************************************************

Install new components in a manner demonstrating their final installation on the structure.

1.6 DELIVERY, STORAGE, AND HANDLING

a. Furnish cement in suitable bags used for packaging cements.

b. Provide packages with labeling that clearly defines contents, manufacturer, and batch identification.

c. Provide detergents, masonry cleaners, paint removers, solvents, epoxies and other chemicals used for masonry cleaning in sealed containers that legibly show the designated name, formula or specification number, quantity, date of manufacture, manufacturer's formulation number, manufacturer's directions including any warnings and special precautions, and name of manufacturer.

d. Store materials in weathertight structures which will protect all materials from moisture and contaminants.

e. Store accessories to avoid contamination and deterioration.

f. Do not use admixtures which have been in storage onsite for six months.
or longer, or which have been subjected to freezing, unless retested and proven to meet the specified requirements.

1.7 PROJECT/SITE CONDITIONS

1.7.1 Environmental Requirements

a. Do not place materials when weather conditions adversely affect the quality of the finished product.

b. Do not place masonry or mortar when the air or surface temperature is below 5 degrees C (40 degrees F) in the shade and will remain so for at least 48 hours after completion of the work. Heated enclosures may be used to overcome ambient weather restrictions, where such enclosures are feasible.

c. Do not place masonry or mortar when air or surface temperature is above 35 degrees C (90 degrees F) with a wind speed above 13 kilometers per hour and will remain so for at least 48 hours after completion of the work.

d. Do not place masonry or mortar when air or surface temperature is above 38 degrees C (100 degrees F) with or without wind and will remain so for at least 48 hours after completion of the work.

e. Do not produce or place materials during periods of rain or other precipitation. Stop material placements, and protect all in-place material from exposure, during periods of rain or other precipitation.

f. Clean masonry surfaces when air temperatures are above 5 degrees C (40 degrees F) and will remain so until masonry has dried out, but for not less than 7 days after completion of the work.

g. Do not perform work in wind conditions that may blow materials onto surfaces not intended to be treated.

1.7.2 Masonry Installation Requirements

a. Phase work during hot weather by performing work on the shady side(s) of the building during daylight hours and on the daylight side(s) of the building during cooler evening hours to prevent premature evaporation of the water from the mortar.

b. Do not use frozen materials or materials mixed or coated with ice or frost. Do not apply materials to frozen surfaces; allow complete thawing prior to installation.

c. Do not lower the freezing point of mortar by the use of admixtures or anti-freeze agents. Do not add chlorides or admixtures containing greater than 0.2 percent chlorides to the mortar, per TMS MSJC.

d. Prevent mortar from staining the face of the masonry or other exposed surfaces. Immediately remove mortar that comes in contact with such surfaces. Cover partially completed work when work is not in progress. Protect sills, ledges and projections from mortar droppings. Building damage resulting from work of this Section is the Contractor's responsibility. Restore damaged areas to the satisfaction of the Owner at no expense to the Owner. Do not apply products under conditions outside product manufacturer's requirements.
1.8 WARRANTY

1.8.1 Cleaning Warranty

Warrant cleaning procedures for a period of two years against harm to substrate (masonry and mortar) or to adjacent materials including, but not limited to discoloration of substrate from improper procedures or usage, chemical damage from inadequate rinse procedures, and abrasive damage from improper procedures.

1.8.2 Repair Warranty

Warrant repair procedures, including repointing, for a period of two years against: discoloration or mismatch of new mortar to adjacent original historic mortar, discoloration or damage to masonry from improper mortar clean-up, loss of bond between masonry and mortar, fracturing of masonry edges from improper mortar joint preparation procedures or improper mortar formulation, and occurrence of efflorescence from improper repair procedures.

PART 2 PRODUCTS

2.1 CLEANING MATERIALS

2.1.1 General Requirements

Selection of appropriate cleaning products requires a clear understanding of the masonry materials to be cleaned, a rationale for the cleaning, and an understanding of the anticipated level of cleanliness expected from the cleaning program. Overly aggressive cleaning methods and materials can cause subtle, long-term damage to masonry units. Use products that have a minimum 5 year performance record on relevant projects. Select the products predicated on long-term negative effects to the masonry rather than current level of cleanliness of the comparable structure.

2.1.2 Paint Removers

a. Provide chemical paint removers that are water soluble, low toxicity products, effective for removal of paint on masonry without altering, damaging, or discoloring the masonry surface.

b. Provide commercially available poulticing materials designed to adhere to and peel off paint without damaging the underlying masonry or project specific mixtures that include absorbent materials and cleaning solutions which can be demonstrated to do no harm to the masonry.

2.1.3 Chemical Cleaners

**************************************************************************
NOTE: Chemical cleaners range from acidic to alkaline in their chemical makeup. Selected products must be suitable for the type of masonry units to be cleaned.
**************************************************************************

a. Provide commercially available products that have a proven record of cleaning masonry without altering, damaging or discoloring the masonry
units, mortar or surrounding materials.

b. Provide the associated pre and post treatment material to neutralize the long term effects of the chemicals.

2.1.4 Biocides

Provide commercially available biocides with accompanying product literature containing information on the product as well as the expected service life of the material and any detrimental effects it may have on the masonry or mortar.

2.1.5 Liquid Strippable Masking Agent

Provide manufacturer's standard liquid, film-forming, strippable masking material for protecting glass, metal, and polished stone surfaces from the damaging effect of acidic and alkaline masonry cleaners.

2.1.6 Cleaning Implements

Furnish brushes that contain natural or nylon fiber bristles only. Do not use metallic wire brushes. Use scrapers and application paddles made of wood with rounded edges. Metallic tools are not permitted.

2.1.7 Water

**************************************************************************
NOTE: Filtering and neutralizing pH is rarely conducted for masonry cleaning, except for statues or museum pieces.
**************************************************************************

Obtain potable water from a local source. [Filter to remove minerals resulting in a neutral pH, prior to application.]

2.2 REPAIR MATERIALS

**************************************************************************
NOTE: Use materials, physical and chemical properties, and composition of masonry and mortar in renovation work that match the original existing masonry and mortar to be repaired, unless samples and testing determine that existing mixtures and materials are faulty or nonperforming. Match masonry materials used for repair and renovation to the original existing historic materials as closely as possible in composition, color, texture, strength, size, finishing and porosity. Refer to ASTM C1713 for matching mortar.
**************************************************************************

2.2.1 General

Use repair materials of one type and from one source, when used in repair treatments that will have surfaces exposed in the finished structure.

2.2.2 Mortar and Stucco

**************************************************************************
NOTE: Mortar types L and K are not included in ASTM C270. Type L mortar uses only hydrated lime or lime putty as binder. Type K mortar has typical proportions in the range of 1 part cement, 2 to 3 parts lime, and 2 1/4 to 3 times the combined cement and lime components as sand.

2.2.2.1 Testing and Matching

a. Take test specimens of existing mortar and stucco from a sound and intact representative portion of the structure, at locations indicated [or ][by the Contracting Officer's Representative] and assess in accordance with ASTM C1713 and ASTM C1324.

b. Subject a part of the historic mortar sample to petrographic examination and differential thermal analysis, or X-ray diffraction, or analytical chemistry to determine the binder components.

c. Aggregate Analysis

(1) Separate aggregate of the mortar sample from the binder [by taking the crushed mortar sample and either gently blowing away the fine binder material, placing the crushed sample in a centrifuge, or chemically separating the aggregate from the binder].

(2) Rinse the separated aggregate clean with water and dry. [Examine the aggregate with a magnifying glass, and record the component materials as to range of materials, sizes, colors, as well as the presence of other materials.]

(3) Perform sand analysis using a sieve analysis of the aggregate as part of the ASTM C1324 process.

d. Match the replacement mortar and stucco to the original existing material in color, texture and tooling.

2.2.2.2 Replacement Mortar and Stucco

Provide replacement mortar and stucco that will:

a. Coexist with the old in a sympathetic, supportive and, if necessary, sacrificial capacity.

b. Have greater vapor permeability and be softer (measured in compressive strength) than the masonry units.

(1) Measure water vapor transmission in accordance with ASTM E96/E96M.

(2) Prepare ASTM E96/E96M water vapor transmission specimens with thickness similar to that expected in service, or a maximum of 13 mm 1/2 inch, whichever is thinner.

c. Be as vapor permeable, and as soft, or softer, (measured in compressive strength) than the existing historic mortar or stucco.

2.2.2.3 Binder Content
NOTE: Historic mortars can represent four different binder types, or combination of them, depending on the time period of construction. A building constructed in the early 1800s is likely built with a straight lime putty binder type because the discovery of natural cement binder types had not occurred until the early 1820s. A building constructed in 1940 might be built with portland cement (1871) and hydrated lime (1930s). The historic binder types include: non-hydraulic lime (fat lime, lime putty or hydrated lime); hydraulic lime (feebly, NHL 2, moderately, NHL 3.5, and imminently, NHL 5.0); natural cement; and portland cement. The binder types are all derived from limestone. Each successive type is fired at higher temperatures in a kiln to the point of vitrification or liquid phase (1204-1540 degrees C) when Portland cement is developed. Lime can be slaked into a hydrate powder or putty form by adding water due to the lower firing temperatures (900-1093 degrees C), while cement products must be crushed mechanically into a powder form before use. Each binder type has its own unique performance properties in relation to historic masonry units and the building wall design. A mortar formula made from lime putty (low compressive strength) will accommodate building movement in load-bearing masonry much more effectively than a portland cement formula of much higher compressive strength. Identify performance characteristics of the replacement mortar carefully based upon evaluation of the existing historic mortar.

******************************************************************************************************************************************

Provide binder type or mixture of mortar (and stucco) with a cement, lime, or combination thereof consistent with the original existing mortar (and stucco) content in order to provide uniform durability, weathering characteristics, and the same, or better, life-cycle performance expectations.

2.2.2.4 Repointing Mortar

******************************************************************************************************************************************

NOTE: If mortar testing is performed prior to project bidding and the compatible mortar type is known, select from the following choices. Otherwise, delete the following paragraph and allow mortar to be determined by the above described testing.

******************************************************************************************************************************************

[Pre-blend repointing mortar in single containers in a factory-controlled environment.][Repointing mortar may be site mixed, Type S, Type N, Type L, Type O and Type K.][Use lime for repointing mortar that conforms to ASTM C207, Type S, or ASTM C1489 or unless otherwise specified.]
2.2.2.5 Admixtures

Do not use admixtures in the mortar or stucco unless specifically approved in writing by the Contracting Officer.

2.2.3 Crack Injection

**************************************************************************
NOTE: Dispersed hydrated lime (specified herein) is suitable for injection of cracks up to 3.2 mm 1/8 inch wide for architectural purposes (sealing, restoring appearance, preventing moisture infiltration) but has low bond and is not the best material for structural repairs. Masonry injection grouts (not specified herein) may be more suitable for structural repairs.
**************************************************************************

a. Comply with the dispersed hydrated lime manufacturer's written instructions.

b. Inject cracks that are no greater than 3 mm 1/8 inch in width and masonry is soundly bonded but cracked.

c. Inject the full length of the cracks unless specifically instructed otherwise.

2.2.4 Replacement Masonry Materials

2.2.4.1 Clay Brick

a. Provide replacement brick matching color, shape, size, texture, appearance, and thermal expansion properties of the existing historic brick.

b. Test brick in comparison to the original existing historic brick using ASTM C67/C67M.

c. Do not use reclaimed brick unless approved by Contracting Officer.

d. Provide brick meeting the requirements of ASTM C216 Grade SW, including a rating of "not effloresced", unless otherwise specified.

2.2.4.2 Stone

a. Provide replacement stone matching type, color, shape, size, texture, finish-profile, and compressive strength of the existing historic stone units.

b. Test replacement stone in comparison to the existing historic stone using ASTM C170/C170M.

2.2.4.3 Terra Cotta

a. Provide replacement terra cotta matching color, shape, size, texture and finish-profile of the existing historic terra cotta units.

b. Test replacement terra cotta in comparison to the existing historic terra cotta using ASTM C34.
2.2.4.4 Architectural Precast Stone

a. Provide replacement architectural precast stone matching color, shape, size, texture and finish-profile of the existing historic architectural precast stone units.

b. Test replacement architectural precast stone in comparison to the existing historic architectural precast stone using ASTM C1364.

2.2.5 Surface Treatments

2.2.5.1 General

Provide commercially available coatings with water vapor permeability of 0.98 or greater, as measured in accordance with ASTM E96/E96M, including silanes and siloxanes.

2.2.5.2 Consolidants

Provide commercially available consolidants designed to strengthen loose or deteriorated stone without damaging intact stone or reducing water vapor permeability below 0.98, as measured in accordance with ASTM E96/E96M.

2.2.5.3 Water Repellents

Provide commercially available water repellents designed to preclude water droplet entry into the masonry walls without reducing water vapor permeability below 0.98, as measured in accordance with ASTM E96/E96M.

2.2.6 Miscellaneous Materials

2.2.6.1 Cementitious Grout

Use cementitious grout, recommended by the manufacturer for the application, to bond steel anchors to masonry.

2.2.6.2 Metal Attachments

a. Provide threaded or deformed stainless steel anchors for spall repairs, size as indicated.

b. Provide other plates, angles, anchors, and embedments conforming to ASTM A36/A36M, prime painted with inorganic zinc primer.

2.2.6.3 Lead Flashing

Provide commercially available lead flashing conforming to GSA HPTP 07656-01.

2.3 EQUIPMENT

2.3.1 Cleaning Equipment

Provide cleaning equipment that does not cause staining, erosion, marring, or other damage or changes in the appearance of the surfaces to be cleaned.

2.3.1.1 Sandblasting

Use of sandblasting equipment is not allowed for cleaning masonry surfaces.
2.3.1.2 Water Blasting

a. Provide water blasting equipment including a trailer-mounted water tank, pumps, high-pressure hose, wand with safety release cutoff control, nozzle, and auxiliary water re-supply equipment.

b. Do not operate the equipment at a pressure which will cause etching or other damage to the masonry surface or mortar joints. Operate the equipment at a discharge capacity of 0.38 to 3.0 MPa 55 to 400 psi and 9.5 to 11.4 L/m 2.5 to 3 gpm for general surface cleaning operations.

c. Provide water tank and auxiliary re-supply equipment of sufficient capacity to permit continuous operations.

d. Provide protective covers and barriers as required to prevent over-spray onto adjacent surfaces.

2.3.1.3 Alternative Blasting Equipment

a. Alternative blasting methods require equipment designed to discharge sponges, walnut shells, ice, soda and other friable materials.

b. Operate equipment in accordance with manufacturer's recommendations and maintain in good working order.

c. Do not operate equipment at a pressure which will cause etching or other damage to the masonry surface or mortar joints.

d. Determine discharge capacity on a case by case basis during the mockup test panel demonstration and approval process.

e. Provide protective covers and barriers as required to prevent over-spray onto adjacent surfaces.

2.3.2 Spray Equipment

a. Provide spray equipment for chemical cleaners with low-pressure tanks or chemical pumps suitable for chemical cleaner indicated, and equipped with stainless steel, cone-shaped spray-tip.

b. Disperse water through a fan-shaped spray tip at an angle of not less than 15 degrees.

c. Deliver water at a pressure not greater than 3.0 MPa 400 psi and at a volume between 9.5 and 11.4 L/m 2.5 and 3 gpm.

d. Deliver heated water at flow rates indicated maintaining between 60 and 82 degrees C 140 and 180 degrees F.

2.3.3 Drilling Equipment

a. Use standard small, powered, handheld masonry drills, commonly used for drilling small holes in concrete and masonry to drill holes in masonry for patch anchors and other applications.

b. Use drills in rotary mode only. Do not use impact type drills.
2.3.4 Compressed Air Supplies
   a. Use compressed air equipment that delivers clean, oil and moisture free
      compressed air at the surface to be cleaned. Use a minimum of two
      in-line air filters to remove oil and moisture from the air supply.
   b. Test the compressed air supply during each shift for the presence of
      oil and moisture.

2.3.5 Material Handling and Associated Equipment
2.3.5.1 Mixing, Transporting, and Placing Job Materials
   a. Provide equipment used for mixing, transporting, placing, and confining
      masonry and mortar placements capable of satisfactorily mixing material
      and supporting uninterrupted placement operations.
   b. Provide equipment used for mixing, conveying, and placing of materials
      that is clean, free of old materials and contaminants, and in
      conformance with material manufacturer's recommendations.

2.3.5.2 Associated Equipment
   Provide associated equipment, such as mixer timing equipment, valves,
   pressure gauges, pressure hoses, other hardware, and tools, as required to
   ensure a continuous supply of material and operation control.

2.4 Mortar Mix
2.4.1 General
   a. Proportion materials appropriately with regard to the effect of
      moisture content on the individual components (cement, sand and lime).
   b. Batch materials using volumetric measurement devices and consistently
      consolidate the material in these devices to ensure the uniformity of
      the mortar. Do not batch by shovel counts.

2.4.2 Batching
   a. Utilize a calibrated measuring device for batching Portland cement.
   b. Utilize a calibrated measuring device for batching hydrated lime or
      lime putty.
   c. Utilize a calibrated measuring device for batching the sand.

2.4.3 Cement and Lime Proportions
   a. Fill the measuring device with portland cement, hydrated lime or lime
      putty.
   b. Briskly strike the bottom of the measuring device against the ground a
      minimum of ten times and then strike the top flush.

**************************************************************************
NOTE: Dry hydrate lime experiences a significant
volumetric loss when converted to a wet paste during
mixing. Volume changes that occur when dry hydrated
lime is converted to a wet paste can cause sizable errors in proportioning mortar formulations. Because mortar ingredients are often measured dry in restoration work, the most likely error is over-sanding. A given amount of hydrated lime occupies far more volume as a dry powder than it does after mixing with water. Thus, when lime is measured as a dry powder, less is actually put into the mixture than is used if the lime is measured as putty. When wetted, dry hydrate lime will typically contract, on average, to 75 percent of the original dry volume. Using a nominal 1:2:9 mixture (Type O) cement/lime/sand, the variation caused by wet verses dry measure of the lime results in a 1:1.5:9 mixture. This ratio exceeds the allowable sand content in ASTM C270 of 2.5 to 3 times the binder, and is 3.75 times the cement plus lime; thus an unintended over-sanded mixture results. To avoid this problem an additional amount of dry hydrate lime (25 percent) must be added to all formulations during the proportioning stage. Volume loss occurs when dry hydrate lime is mixed to a paste that is more than 42 percent solid. Note: Portland cement does not experience this volumetric loss when converted to a wet paste during mixing.

**************************************************************************

c. For dry hydrate lime, fill the measuring device using a minimum of three lifts, strike the bottom of the measuring device against the ground a minimum of ten times for each lift and then strike the top flush. Mix dry hydrate lime to a wet paste that is 40 to 42 percent solid.

d. For lime putty briskly strike the bottom of the measuring device against the ground a minimum of ten times and then strike the top flush. No additional lime is required when measuring from putty.

2.4.4 Sand Proportions

a. Proportion sand when the sand is in saturated surface dry (SSD), loose damp condition.

b. Proportion the sand by filling a measuring device using a minimum of three lifts, striking the sides a minimum of ten times, and then striking the top flush.

PART 3 EXECUTION

3.1 EXAMINATION

a. Undertake masonry renovation only after complete evaluation and analysis of the areas to be repaired are completed, including sampling and testing of the existing mortar to determine its composition and qualities. Do not start repair work until conditions that have caused masonry deterioration have been identified and corrected.

b. Use the gentlest means to perform the work and take the greatest of care to ensure that the historic materials are not damaged in the process of the work, as established by mock-ups and testing.
c. In addition to requirements in this Section, comply with NPS Hist Prop.

3.1.1 Field (In Situ) Mortar Examination

a. Detect cracks, degradation and de-bonding from the surrounding masonry.

b. Determine previous surface coating treatments that may be contributing to the current conditions.

c. Compare the bedding mortar with the pointing mortar and determine the cross-sectional characteristics of the wall.

d. Determine the level of moisture movement in the in situ mortar, and if the mortar or masonry units are handling the brunt of the water movement through the wall.

**************************************************************************
NOTE: Mortar shear strength may be needed for structural masonry walls that resist in-plane loads (wind or seismic).
**************************************************************************

e. Evaluate in situ mortar joint shear strength in accordance with ASTM C1531.

3.1.2 Taking and Preparation of Samples

a. Take and analyze samples of unweathered original historic mortar and different types of mortar in the structure in order to match the new mortar to be used for repointing.

b. Remove three or four samples of each type of mortar to be matched with a hand chisel from several locations on the building. Mortar samples to be intact pieces with a minimum size of 28 grams/1 ounce.

c. Set aside the largest sample for comparison with the repointing mortar.

d. Place the remaining samples in labeled, sealed sample bags for transport to the laboratory for evaluation per Part 2 of this Specification.

3.2 PREPARATION

3.2.1 Protection

a. Protect persons, motor vehicles, adjacent surfaces, surrounding buildings, equipment, and landscape materials from chemicals used and runoff from cleaning and paint removal operations.

b. Erect temporary protection covers, which will remain in operation during the course of the work, over pedestrian walkways and at personnel and vehicular points of entrance and exit.

c. Protect the interior of buildings from the weather, cleaning, and repair operations at all times.

d. Do not expose workers to chemical substances in excess of the limits established by ACGIH 0100. Comply with more stringent regulations.
where applicable.

3.2.2 Surface Preparation

a. Do not proceed with cleaning until mock-ups have been approved.

b. Do not proceed with repointing or stucco until existing mortar and stucco have been analyzed and suitable repair materials have been determined.

c. Do not proceed with restoration work until the cause of observed distresses have been identified and corrected.

d. Do not proceed with surface treatments until all other restoration work has been completed.

3.2.3 Equipment and Techniques Demonstration

a. Demonstrate equipment and techniques of operation in an approved location.

b. Assemble dependable and sufficient equipment, appropriate and adequate to accomplish the work specified, at the work site with sufficient lead time before the start of the work to permit inspection, calibration of weighing and measuring devices, adjustment of parts, and the making of any repairs that may be required.

c. Maintain the equipment in good working condition throughout the project.

3.3 MASONRY CLEANING

3.3.1 General

a. Exercise caution against over-cleaning of surfaces, which may be detrimental, and which may remove desirable historic surface details or patinas. For example, if cleaning reveals unexpected joint painting or historic signage; suspend the cleaning action, protect the exposed area and notify the Contracting Officer.

b. Do not damage or mar historic materials in the process of cleaning.

c. Perform cleaning per NPS TPS Brief 1.

d. Protect open joints to prevent water and cleaner intrusion into the interior of the structure.

e. Protect non-masonry materials and severely deteriorated masonry by approved methods prior to initiation of cleaning operations.

f. Remove all organic and inorganic contaminants from the surface and pores of the substrate, without causing any short or long-term negative consequences.

g. Clean surfaces evenly with no evidence of streaking or bleaching.

h. Do not affect the density, porosity, or color of the existing masonry or mortar.

i. Maintain a neutral pH on surface of cleaned masonry units.
j. Use the gentlest methods possible for cleaning historic masonry to achieve the desired results.

k. Proceed with cleaning in an orderly manner, working from top to bottom of each scaffold width and from one end of each elevation to the other.

l. Perform cleaning in a manner which results in uniform coverage of all surfaces, including corners, moldings, interstices and which produces an even effect without streaking or damage to masonry.

m. Use the following sequence of methods to determine the least aggressive, effective cleaning method:

(1) Water with non-metallic brushes (cold water).
(2) Water with mild soap
(3) Water with stronger soap
(4) Water with stronger soap plus ammonia
(5) Water with stronger soap plus vinegar (but not on calcareous masonry)
(6) Stronger chemical cleaners, only when above methods are determined to be ineffective by the Contracting Officer

3.3.2 Chemical Cleaners

a. Do not use chemical cleaners without approval from the Contracting Officer.

b. Do not use acidic chemical cleaners on limestone, marble, concrete and other calcareous (calcium containing) masonry materials. If chemical cleaners are used on such materials, use alkaline based cleaners with neutralizing afterwashes.

3.3.3 Paint Removal

a. Prior to removal, test existing paint for lead in accordance with Section 02 83 00 LEAD REMEDIATION.

b. Clean areas where paint is to be removed with water and detergent solution to remove surface dirt. Rinse and allow to dry.

c. Remove paint and other coatings from masonry surfaces in areas indicated prior to general cleaning.

d. Do not damage or mar masonry in the process of paint removal.

e. Apply chemical paint removers in accordance with manufacturer's instructions.

f. Protect surrounding painted surfaces from exposure to chemical paint removers to avoid damage.

g. Remove paint containing lead in accordance with Section 02 83 00 LEAD REMEDIATION.
3.3.4 Water Cleaning

3.3.4.1 Pressure Spraying

a. Spray apply water to masonry surfaces to comply with requirements indicated by test patches for location, purpose, water temperature, pressure, volume, and equipment.

b. Unless otherwise indicated, wash the surface with clean, low pressure water (pressure of less than 0.38 MPa 55 psi and 9.5 to 11.4 L/m 2.5 to 3 gpm discharge) and hold spray nozzle not less than 300 mm 12 inches from surface of masonry.

c. Apply water side to side and top to bottom in overlapping bands to produce uniform coverage.

3.3.4.2 Hand Scrubbing

a. Scrub surfaces to be cleaned to remove surface contaminants.

b. Pre-wet surfaces and use hand-held natural bristle or nylon brushes.

c. Do not use wire brushes.

3.3.4.3 Rinsing

a. Rinse scrubbed surfaces clean of all contaminants and cleaning solutions with water in a low-to-moderate pressure spray, working from top to bottom of each treated area.

b. Remove all traces of contaminants and cleaning solutions.

3.3.5 Chemical Cleaning

3.3.5.1 General

a. Chemical cleaning is the use of any product in addition to water, including detergents, ammonia, vinegar, and bleach.

b. Use gentlest means possible to achieve the desired result as determined by test patches.

c. Proceed in an orderly manner, working from top to bottom of each scaffold width and from one end of each elevation to the other.

d. Provide uniform coverage of all surfaces, including corners, moldings, interstices and produce an even effect without streaking or damage to masonry.

e. Do not apply chemical cleaners to the same masonry surfaces more than twice.

3.3.5.2 Surface Prewetting

a. Wet masonry surfaces to be cleaned with chemical cleaners with water using a low pressure spray before application of any cleaner.

b. Prewet walls working from top to bottom, except work bottom to top on one-story walls.
c. Do not prewet masonry surface prior to applying biocides.

3.3.5.3 Acidic Chemical Cleaning

******************************************************************************
NOTE: Buffered acidic cleaners are generally safer for masonry substrates.
******************************************************************************

a. Apply acidic chemical cleaners according to manufacturer's instructions.
b. Do not apply acidic chemical cleaners to masonry with high calcium content (e.g. marble, limestone).
c. Apply acidic cleaners to masonry surfaces by low pressure spray 0.35 MPa 50 psi max., roller, or brush.
d. Leave cleaner on masonry surface for the time period recommended by the manufacturer.
e. Employ manual scrubbing by brushes as indicated by test patches for the specific location.
f. Rinse cleaned surfaces with a low-to-moderate pressure spray of water to remove all traces of chemical cleaner.

3.3.5.4 Alkaline Chemical Cleaning

3.3.5.4.1 Prewash Phase

a. Apply alkaline chemical cleaners to masonry surfaces according to manufacturer's instructions, by low pressure spray 0.35 MPa 50 psi max., roller, or brush.
b. Leave cleaner on masonry surface for the time period recommended by the manufacturer.
c. Employ manual scrubbing by brushes as indicated by test patches for the specific location.
d. Rinse cleaned surfaces with a low-to-moderate pressure spray of water.

3.3.5.4.2 Afterwash Phase

a. Immediately after rinsing of alkaline cleaned surfaces, apply a neutralizing afterwash to the cleaned masonry areas.
b. Apply neutralizing afterwash according to manufacturer's instructions, by low pressure spray 0.35 MPa 50 psi max., roller, or brush.
c. Leave afterwash on masonry surface for the time period recommended by manufacturer.
d. Rinse cleaned surfaces with a low-to-moderate pressure spray of water to remove all traces of chemical cleaners.
3.3.5.5 Rinsing and pH Testing

a. Determine the pH of masonry surfaces that have been chemically cleaned using pH monitoring pencils or papers.

b. Rinse chemically cleaned masonry, using a low pressure spray, until a neutral pH (7) reading is obtained from the masonry unit surface.

3.4 MASONRY REPAIR

**************************************************************************
NOTE: Provide missing information; if a reference is added, revise paragraph REFERENCES accordingly.
**************************************************************************

3.4.1 General

a. Match repaired surfaces with adjacent existing surfaces in all respects.

b. Demonstrate the materials, methods and equipment proposed for use in the repair work in mock-ups, as specified in PART 2.

c. Use products in accordance with the manufacturer's instructions.

d. Proceed with masonry repair only after the cause of deterioration has been corrected.

e. Assist Historic Masonry Consultant with performing field investigation to determine the causes and extent of degradation. Utilize the following techniques.

(1) Employ a field microscope to closely assess the conditions at the surface of the mortar and masonry units. Detect cracks and assess for degradation and debonding from the surrounding masonry. Detect previous surface coating treatments on the mortar and masonry that may be contributing to the current conditions.

(2) Employ a boroscope to examine mortar deeper in the joint. Compare the bedding mortar with the pointing mortar and ascertain the cross-sectional characteristics of the wall.

(3) Employ moisture meters to determine the level of moisture in the mortar and masonry, and if the mortar or masonry units are handling the brunt of the water movement through the wall. Infrared thermography, employed by a trained investigator, can provide additional information on the moisture conditions.

(4) Employ RILEM tubes using the method of RILEM II.4 or water penetration testing in accordance with ASTM C1601 to determine the rate of water uptake into the masonry.

(5) To access the physical characteristics of hard mortar, use a spring loaded or pendulum impact device to determine surface hardness as an indicator of relative compressive strength. For evaluating softer mortars, mortar integrity deeper in the wall, and the condition of the masonry units, use a drill resistance tool by an experienced consultant.

(6) Utilize technologies such as ground penetrating radar or metal...
detection equipment to map metal reinforcement and embedments in the wall.

(7) Use flat jack or jacks and rams to gather information on in situ compressive stress (ASTM C1196, masonry compressive response ASTM C1197, and mortar joint shear strength ASTM C1531).

3.4.2 Repointing Masonry

Repoint masonry in accordance with NPS TPS Brief 2, using ASTM E2260 as a reference guide.

3.4.2.1 Wall Preparation

a. Remove old caulking, grout, or non-original mortar from previously repaired joints to a minimum depth of 2.5 times the width of the joint. Cut all joints (unless otherwise noted) back to sound, solid, back up material. Leave a clean, square face at the back of the joint to provide for maximum contact of repointing mortar.

b. Shallow or feather edging is not permitted. Remove loose particles from joints. Clean joints, followed by blowing with filtered, dry, compressed air or vacuum.

c. Cut out existing horizontal mortar joints (bed joints) that are filled with a hard Portland mortar using a diamond blade that is narrower than the joint width. Cut out the middle one-third of the mortar joint using a rotary power saw. Remove the remaining mortar from the masonry joints by hand using masonry chisels or pneumatic carving tools.

d. Do not use rotary power saws to cut out vertical joints (head joints). Remove all vertical head joints by hand using a pneumatic carving tool, or hammer and chisel.

e. Remove existing historic lime-based mortar using only small-headed chisels that are no wider than half the width of the existing masonry joints. Pneumatic air carving chisels are permitted as are specially designed mortar removal reciprocating tools (i.e. Arbortech Saw).

f. Do not widen the existing masonry joints. Do not chip or spall the surrounding masonry edges in the process of mortar removal. Damage to surrounding masonry units resulting from rotary blade over running is not permitted. Damages to adjacent materials exceeding 3.2 mm/1/8 inch in size are the responsibility of the contractor and must be repaired by removal and replacement of damaged materials.

g. Permit applicators to be trained at the project site in this masonry treatment requirement.

3.4.2.2 Presoaking Masonry / Mortar Consistency / Lifts

a. Use the same mortar as the repointing mortar for setting the replacement masonry.

b. Soak exposed surfaces of historic masonry adjacent to joint with water prior to repointing.

c. Allow time for excess water to run off and evaporate prior to repointing. Joint surfaces must be damp but free from standing water.
d. Maintain a water sprayer on site at all times during the repointing process.

e. The mortar material must resemble the consistency of brown sugar during installation. This drier consistency enables the material to be tightly packed into the joint, allows for cleaner work, and prevents shrinkage cracks as the mortar cures.

f. Allow mixed repointing mortar to stand for not less than one-half hour and not more than one and one-half hours for pre-hydration to reduce post-curing shrinkage. After this time, water can be added to small batches by hand to bring the mortar to a stiff yet workable consistency. Use repointing mortar within two and one-half hours after initial mixing and within one hour after adding water to bring the mortar to a working consistency. Retempering of the mortar to replace evaporated water is permitted within these time frames.

g. Point joints in layers or "lifts" where the joints are deeper than 32 mm 1-1/4 inch. Apply in layers not less than 1/2 the depth but not more than 32 mm 1-1/4 inch or until a uniform depth is formed.

3.4.2.3 Compression / Joint Finish / Curing

a. Compress each layer thoroughly.

b. When mortar is thumbprint hard at the surface of the wall, finish the joints to match the original historic joint profile.

c. For Type L mortar:

(1) Allow water evaporation from the freshly repointed walls in order to initiate the carbonation process in high lime content mortars. The carbonation of lime mortar initially requires wet-and-dry cycles, which can be created by water misting the joints after the mortar application when dry weather conditions prevail. Finish the joint profile before these cycles are started.

(2) Depending on the environmental conditions (temperature and humidity), carry out water misting until a full nine alternating wet-and-dry cycles are completed.

(3) Adjust curing methods to ensure that the repointing mortar is damp without eroding the surface of the mortar.

3.4.2.4 Protection

a. Keep the mortar from drying out too quickly or from becoming too wet.

b. Protect mortar from direct sun and high winds for the first 72 hours after installation or from driving rain for the first 24 hours, using plastic sheeting if necessary. Do not create a greenhouse effect by sealing off air movement in an attempt to protect the wall with plastic. Allow for air circulation to facilitate the carbonation process.

3.4.3 Retooling Stone Masonry In situ

a. Scale off all loose pieces of original stone from masonry intended to
remain in place, including surface material in powder or granular form and detachments of planer elements, spalls and chips.

b. Assess all stone on building by sounding (tapping with a small hammer) or by using impact echo (for massive stones), surface penetrating radar, or infrared thermography in order to distinguish fully intact stone from those in which delamination may be hidden or pieces of unstable material may not be immediately visible.

c. Remove and replace stone units that are designated for retooling in situ, but develop a solid stone substrate that is no longer in plane or plumb with the surrounding stone masonry surfaces after chiseling is complete.

3.4.4 Masonry Removal and Replacement

a. Before removing any deteriorated masonry units, establish bonding patterns, levels and coursings. Remove masonry that has deteriorated or is damaged beyond repair, as determined through investigation and evaluation. Carefully demolish or remove entire units from joint to joint, without damaging surrounding units in a manner that permits replacement with full-size units. Support and protect remaining masonry work that surrounds removal area. Maintain flashing, reinforcement, lintels, and adjoining construction in an undamaged condition. Notify Contracting Officer of unforeseen detrimental conditions including voids, cracks, bulges, and loose masonry units in existing masonry backup, rotted wood, rusted metal, and other deteriorated items. Remove as many whole masonry units as possible without damage.

b. Remove mortar, loose particles, and soil from masonry by cleaning with hand chisels, non-metallic brushes, and water.

c. Remove sealants by cutting close to masonry units with utility knife and cleaning with solvents. Clean surrounding masonry areas by removing mortar, dust, and loose particles in preparation for replacement.

d. Replace removed masonry with masonry units removed from inconspicuous areas of the building, where possible, or with new masonry units matching the existing units. Butter vertical joints for full width before setting and set units in full bed of mortar, unless otherwise indicated. Remove mortar used for laying/setting masonry units before mortar sets to the repointing depth of the surrounding area. Repoint new mortar joints in repaired area to comply with requirements for repointing at existing masonry units.

e. If a few isolated masonry units are to be replaced, remove each without disturbing the surrounding masonry. Remove deteriorated masonry units and mortar requiring replacement by hand chiseling. Do not damage adjoining masonry units during the removal of deteriorated units and mortar.

f. Test the new element for fitting into its space without mortar. Use wedges made from non-expanding, non-corrosive material such as plastic to support and align the new unit, cover them with at least 38 mm 1-1/2 inches of mortar when pointing is complete.

g. Cover the four sides of the space with sufficient mortar to ensure that
there will be no air spaces when the new unit is set. Fill the back of the space with mortar only if it matches existing construction.

h. Line up and set the new unit by tapping it into place with a wooden or rubber mallet. Align the face of new unit with that of existing masonry.

i. Repoint joints to match the rest of the wall after new units have been properly installed and adjusted.

j. Clean replacement areas with a non-metallic brush and water to remove excess mortar.

3.4.5 Material Repair

Repair or replace original historic masonry materials only if surfaces are extensively deteriorated (surface missing to a depth of 100 mm 4 inches or more) or are threatening the safety of the structure or individuals. If additional damage is found, notify the Contracting Officer. Repairs and replacements must match the materials, colors, and finish of the existing historic masonry as closely as possible.

3.4.5.1 Selective Demolition

a. Remove unsound, weak, or damaged masonry and mortar in areas as indicated.

b. Remove loose particles, laitance, spalling, cracked, or debonded masonry and mortar and foreign materials with hand tools unless otherwise noted.

c. Clean surfaces prepared for repair free of dust, dirt, masonry chips, oil or other contaminants, rinsed with water, and dried before repair work is begun.

d. Protect surfaces of the structure, and surfaces adjacent to the work area from damage which may result from removal, cleaning, and repair operations.

3.4.5.2 Application of Substitute Repair Materials

**************************************************************************
NOTE: Use repair materials as a last resort after all other repair treatments are determined to be ineffective or cost prohibitive.
**************************************************************************

a. Place repair materials to rebuild spalled or damaged areas to match the original surface finish, level, texture, bonding patterns, color and porosity. Match the finished appearance of the substitute repair material patch with the adjacent existing surface. Apply samples to the masonry units in situ.

b. Do not install repair material in thicknesses exceeding 50 mm 2 inches. Utilize a Dutchman repair approach or replacement unit for masonry repairs in excess of 50 mm 2 inches.

c. Remove loose mortar and masonry prior to installation of the repair material. "Sound" the masonry with a hammer to verify its integrity.
If necessary, cut away an additional 12.7 mm 1/2 inch of the masonry substrate to ensure the surface to be repaired is solid and stable.

d. Remove all deteriorated stone, mortar, sealant residue, and previous repair materials back to sound substrate using hammer and chisel or power equipment. Finish edges square to a minimum depth of 12.7 mm 1/2 inch. Do not feather edges. Roughen substrate surface to achieve surface roughness required by manufacturer for good bond, but do not overly damage the substrate surface.

e. Remove sealant residue. Cut out used anchors, threaded rod anchors and/or dowels within the damaged masonry area. Any anchors that are free of rust, solidly embedded, and do not project beyond the solid masonry surface may remain.

f. Using clean water and a non-metallic scrub brush, clean dust from surface and pores of the substrate.

g. Pre-wet the substrate with water prior to the application of the repair material to prevent the substrate from drawing out the moisture too quickly. Re-wet the surface with water again immediately before applying the repair material. Use methods approved by the repair material manufacturer to deliver the substitute repair work as demonstrated.

h. Follow manufacturers' instructions pertaining to the placement of materials. If the manufacturer requires that installers of a specified product be trained, provide this documentation to the Contracting Officer. Training certificates previously issued by product companies for the application of specified products cannot be substituted for the Project Training "Substitute Repair Material Certificate" on this project.

i. Masonry and Material Repair Finishes and Color

(1) Match the exposed surfaces of masonry and substitute material repair finish, color, texture, and surface detail with the original surface. Mechanical finishing and texturing may be required to produce the required finish and appearance.

(2) Conceal bond lines between the repaired area and adjacent surfaces.

(3) Replicate all surface details, including tooling and machine marks.

(4) Use low-impact energy type equipment in finishing and texturing, which will not weaken the patch or damage the patch bond and the adjacent masonry.

3.4.5.3 Patch Anchors

a. Provide patch anchors to ensure that the patch is tied to the existing masonry structure at a frequency of at least one patch anchor per 2580 square mm 4 square inches of patch plan surface area; specific locations for patch anchors must be as indicated.

b. Use small handheld, low-speed rotary masonry drills to produce holes in the existing masonry, within the limits for the patch anchor installation.
(1) Drill holes into the existing substrate material of the masonry using rotary (non-hammer) drills making holes with a diameter of 3 mm 1/8 inch larger than the anchor diameter and a depth of 101 mm 4 inches, except as otherwise indicated or directed.

(2) Drill holes must not penetrate completely through the masonry, and must provide at least 25 mm 1 inch of cover around the drill hole.

(3) Clean holes by water blasting to remove drill dust and other debris and then blow dry with filtered, dry, compressed air.

(4) Condition drill holes in accordance with the epoxy adhesive manufacturer's recommendations.

c. Clean anchors to remove all contaminants which may hinder epoxy bond.

d. Pressure inject adhesive into the back of the drilled holes.

(1) Fill holes without spilling excess grout when the anchors are inserted.

(2) Insert anchors immediately into the holes.

(3) Set back anchors from the exterior face at least 25 mm 1 inch.

(4) Install anchors without breaking or chipping the exposed masonry surface.

(5) Use socked or screen tube anchors where voids exist in the masonry units or between the wythes.

3.4.5.4 Cleanup

a. Protect masonry surfaces from excess grout adhesive and spills.

b. Leave the surface of the masonry in a clean and uncontaminated condition.

3.4.6 Dutchman Repairs

*********************************************************************************************************************************************
NOTE: A Dutchman repair is a process of removing damaged stone to a specified depth and inserting a new piece of stone to fit in the opening to create the appearance of a seamless patch. The process involves careful and precise removal of select deteriorated stone material, usually in a larger stone.
*********************************************************************************************************************************************

a. Select stone for Dutchman repairs from the following three sources listed in order of priority:

(1) Stone harvested from the same elevation and stone type.

(2) Approved salvaged stone.

(3) New stone made from a similar stone type.
b. Fit the new piece into place with tolerances of no more than plus or minus 1.6 mm 1/16-inch.

c. Provide supporting rods of stainless steel as necessary for the extent of the repair and the location.

d. Closely blend repairs in with the surrounding original materials.

3.4.7 Crack Injection with Dispersed Hydrated Lime (DHL)

3.4.7.1 General

a. Notify the Contracting Officer as to when and where the installation will occur at least 48 hours prior to start.

b. Provide samples to the Government representative from the dispenser during the course of the injection.

c. Apply in accordance with the manufacturer's instructions.

3.4.7.2 Application of DHL

a. Drill 3.2 mm 1/8-inch diameter, downward-sloping injection holes. For transverse cracks less than 3.2 mm 1/8 inch wide, drill holes through center of crack at 25 to 40 mm 1 to 1.5 inches on center.

b. Clean out drill holes and cracks with compressed air and potable water. Remove dirt and organic matter, loose material, sealants, and failed crack repair materials.

c. Inject Dispersed Hydrated Lime using hypodermic needles or pressure ports through holes sequentially, beginning at one end of area and working to opposite end. Do not exceed 0.069 MPa 10 psi injection pressure. Where possible begin at lower end of injection area and work upward. Inject Dispersed Hydrated Lime until it extrudes from adjacent holes. After Dispersed Hydrated Lime has set, remove excess material and patch injection holes and surface of cracks with appropriate surface treatment.

3.4.7.3 Tools and Equipment

Do not use tools and equipment that have not been cleaned of set dispersed hydrated lime.

3.4.8 Surface Treatments

3.4.8.1 Stucco

******************************************************************************
NOTE: The correct finish is project specified. Specify the desired finish as appropriate for the project... Possible finishes include; tight-trowel, smooth; wet/damp sponge; or dry wood float. In rare cases, a pebble-dash finish may be required where screened aggregates are cast into the wet finish coat and pressed back with a wood float or left exposed. Historic stuccos may also include animal hair for reinforcement. Ox or cattle hair is the preferred choice, but horse or goat hair may be used.
******************************************************************************
3.4.8.2 Limewashes

a. Apply limewash using fiber brushes in three thin coats on saturated surface dry (SSD) raw masonry surfaces.

b. Do not allow the material to dry out before it has had a chance to absorb into the masonry surfaces.

c. Work from top to bottom of the wall working from the dry-edge.

d. Allow six hours drying time between coats

e. Where colors are desired, use natural earth pigments.

f. Verify all applications, materials and colors through mock ups panels applied to the substrate prior to the start of the work.

3.4.8.3 Water Repellents Infiltration

NOTE: Water proofing, for the purposes of this specification, is considered any continuous chemical coating designed to sit on the surface of the masonry and preclude water movement through the pore structure of the masonry units, mortar or at their intersection. Historic Masonry structures were typically intended to manage moisture movement by allowing water vapor transmission through the pores and by allowing the dew point to move in the wall. While water proofing may preclude water ingress into the masonry system, it also precludes water vapor egress and is therefore not acceptable.

Water repellents are designed to resist water infiltration through the pore structure of masonry while allowing water vapor transmission. Unfortunately, evidence exists that some water
repellents do not perform as advertised and can impede vapor transmission. Only when all other water infiltration control methods have been considered carefully and disqualified, and the extreme decision has been reached to potentially risk a loss of historic material, will water repellents be allowed.

Application of water proofing is not allowed.

Application of water repellents may be performed upon Contracting Officer approval of the recommendation and justification, by the historic masonry consultant, that no other means will control water infiltration. Apply water repellents per manufacturer's instructions.

3.4.8.4 Stone Consolidants

Use of stone consolidants requires Contracting Officer approval of the historic masonry consultants recommendation, including justifying data. Apply stone consolidants per manufacturer's instructions.

3.5 INSTALLATION OF NEW ELEMENTS

Evaluate new materials and components for both functional and aesthetic impacts on historic structures.

3.5.1 Structural Upgrades

For mechanical anchors used to reinforce masonry structures, provide design by a registered professional structural engineer. Strengthening measures must take into account the current loads and stresses in the structure and the nature in which the building has historically managed thermal and other environmental changes or cycles.

Submit manufacturers literature, design analysis and detail drawings for the proposed additional materials.
3.5.2 Joint Sealant and Lead Flashing

NOTE: Joint sealant is a flexible material that may be found in historic structures as a replacement for the original material used in construction. Typically, it is used in lieu of mortar around windows and in masonry joints and in masonry joints between stone elements at vulnerable areas such as copings and sills.

a. Test existing sealants for asbestos and PCBs before performing demolition.

b. Provide joint sealing as specified in Section 07 92 00 JOINT SEALANTS.
   (1) Augmentation with lead flashing is allowed for upward facing joints exposed to weather.
   (2) Install sealants and lead flashing in accordance with manufacturer's recommendations.

3.6 FINAL CLEANING

a. No sooner than 72 hours after completion of the repair work and after joints are sealed, wash down faces and other exposed surfaces of masonry with water applied with a soft bristle brush, then rinse with clean water.

b. Discolorations that cannot be removed by these procedures, are considered defective work.

c. Perform cleaning work when temperature and humidity conditions allow the surfaces to dry rapidly.

d. Protect adjacent surfaces from damage during cleaning operations.

3.7 PROTECTION OF WORK

Protect work against damage from subsequent operations.

3.8 DEFECTIVE WORK

Repair or replace defective work as directed by Contracting Officer, using approved procedures.

3.9 FINAL INSPECTION

Following completion of the work, inspect the structure for damage, staining, and other distresses. Inspect the patches for cracking, crazing, delamination, unsoundness, staining and other defects. Inspect the finish, texture, color and shade, and surface tolerances of the patches to verify that all requirements have been met. Repair surfaces exhibiting defects as directed.

a. Following completion of the work, inspect the structure for damage, staining, and other distresses.
(1) Inspect patches for cracking, crazing, delamination, unsoundness, staining and other defects.

(2) Inspect finish, texture, color and shade, and surface tolerances of the patches to verify that all requirements have been met.

b. Repair surfaces exhibiting defects as directed by Contracting Officer.

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for reinforced and nonreinforced masonry. This includes reinforced single wythe masonry walls, cavity walls, masonry veneer, composite walls, partition walls and other masonry wall types.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).
Masonry not meeting the above definition but bonded together with mortar and containing, if necessary, the minimum amount of reinforcement for crack control and vertical stiffeners, is classified as unreinforced masonry.

Masonry design must comply with UFC 3-301-01 Structural Engineering. Following are some pertinent modifications to the 2012 ICC IBC from that UFC standard.

a. Masonry may be designed by allowable stress design or strength design, but empirical design is not permitted.

b. Masonry must be designed as reinforced unless the element is isolated from the structure so that vertical and lateral forces are not imparted to the element.

c. Coupling beams must be designed in accordance with paragraph 14.4.5.3 of ASCE 7-16.

d. Shear walls are required to be in running bond construction.

e. Below-grade masonry walls and elevator shaft masonry walls must be grouted solid.

f. Corrugated metal brick ties are not permitted.

g. Horizontal joint reinforcement is required to be continuous around corners and through wall intersections, unless the intersecting walls are separated. Splicing of joint reinforcement in accordance with TMS MSJC provides continuity.

h. Concrete masonry control joint spacing and placement are required to comply with NCMA TEK 10-2C or 10-3.

i. Clay brick masonry expansion joint spacing, placement, and size are required to comply with BIA Technical Notes 18 and 18A.

j. The lateral deflection for framing supported brick veneer is required to be limited to L/600.

k. Details for masonry veneer/steel stud wall assemblies should comply with BIA Technical Note 28B.

UFC 3-301-01 Appendix B also provides the following "best practices".

a. The base of masonry veneer should be placed on a shelf angle or a foundation ledge that is at least
100 mm 4 inches lower than the base of the steel stud wall. The width of this shelf angle or foundation ledge must accommodate the masonry veneer and cavity, and should not be less than two-thirds of the veneer thickness plus the minimum air space.

b. Shelf angles should be hot-dip galvanized structural steel members. Angles should be provided approximately 3 m 10 feet long segments, with gaps between segments. Gaps should be detailed to allow for thermal expansion and contraction of the steel in angle runs and at building corners. At building corners, corner pieces with each leg no less than 1.2 m 4 feet in length should be detailed, where possible. Limit deflection of horizontal legs of shelf angles to 1.6 mm 1/16 inch at the end of the horizontal leg. Include rotation of the shelf angle support in the deflection limit calculation.

Masonry design in DOD buildings must comply with UFC 3-301-01, Seismic design of Buildings. Following are some pertinent modifications to the 2012 ICC IBC from that UFC standard.

a. Design anchors in masonry in accordance with TMS MSJC. Additionally, at least one of the following must be satisfied.

b. Design anchors to be governed by the tensile or shear strength of a ductile steel element.

c. Design anchors for the maximum load that can be transmitted to the anchors from a ductile attachment, considering both material overstrength and strain hardening of the attachment.

d. Design anchors for the maximum load that can be transmitted to the anchors by a non-yielding attachment.

e. Design anchors for the maximum load obtained from design load combinations that include E, with E multiplied by Omega_0.

f. Post-installed anchors in masonry must be prequalified for seismic applications in accordance with approved qualification procedures.

g. Reinforcement must be continuous around wall corners and through wall intersections, unless the intersecting walls are separated. Reinforcement that is spliced in accordance with applicable provisions of TMS MSJC is considered continuous.

h. Only include horizontal reinforcement that is continuous in the wall or element in computing the area of horizontal reinforcement. Intermediate bond beam steel properly designed at control joints is considered continuous.
i. Where concrete abuts structural masonry, and the joint between the materials is not designed as a separation joint, the joint must conform to the requirements of ASCE 7-16 Section 14.4.3.1.

Masonry design must meet the requirements of the following UFCs if applicable: UFC 3-340-01 "Design and Analysis of Hardened Structures to Resist conventional Weapons Effects; UFC 3-340-02 "Structures to Resist the Effects of Accidental Explosions"; and UFC 4-023-03 "Design of Buildings to Resist Progressive Collapse"

Show the following information on the project drawings:

1. Locations and dimensions of each type of masonry work; wall sections and anchor details.

2. Color, texture, and size of brick and color of mortar if other than natural gray.

3. Bond pattern if other than running bond.

4. All flashing locations and details.

5. Control joint and expansion joint locations and details.

6. Special brick shapes if required.

7. Compressive strength (f'c) of units, mortar, grout, or entire assembly and fy of reinforcement.

8. Reinforcement lateral tie, splice, and bond beam details.

9. Size and location of any pipes, ducts, door and window framing, or other embedded items.

10. Equivalent thickness, in accordance with ACI216.1, or UL assembly for fire rated walls.

1.1 REFERENCES

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also
use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

1.3 QUALITY ASSURANCE

1.3.1 Masonry Mock-Up Panels

**************************************************************************

NOTE: A sample panel is a small element of constructed masonry units, usually 1.22 m x 1.22 m 4 ft x 4 ft. A mock-up is a wall segment constructed to show all materials used in the construction as well as typical workmanship. Mock-up panels will be required for structures having over 185 square meters 2,000 square feet of exterior wall area, including openings, and for smaller structures where appearance is important. The list of items to be shown by the sample panel will be edited to provide only the representative items. Typical installation of electrical conduit and boxes may be illustrated by the sample panel when deemed appropriate.

**************************************************************************

1.3.1.1 Mock-Up Panel Location

After material samples are approved and prior to starting masonry work, construct a mock-up panel for each type and color of masonry required. At least 48 hours prior to constructing the panel or panels, submit written notification to the Contracting Officer. Do not build-in mock-up panels as part of the structure; locate mock-up panels where directed. Construct portable mock-up panels or locate in an area where they will not be disrupted during construction.

1.3.1.2 Mock-Up Panel Configuration

Construct mock-up panels L-shaped or otherwise configured to represent all of the wall elements. Construct panels of the size necessary to demonstrate the acceptable level of workmanship for each type of masonry represented on the project. Provide a straight panel or a leg of an L-shaped panel of minimum size 2.5 m 8 feet long by [1.2] [1.8] m [4] [6] feet high.

1.3.1.3 Mock-Up Panel Composition

Show full color range, texture, and bond pattern of the masonry work. Demonstrate mortar joint tooling; grouting of reinforced vertical cores, collar joints, bond beams, and lintels; positioning, securing, and lapping of reinforcing steel; positioning and lapping of joint reinforcement (including prefabricated corners); and cleaning of masonry work during the construction of the panels. Also include installation or application procedures for anchors, wall ties, CMU control joints, brick expansion joints, insulation, flashing, brick soldier, row lock courses and weeps. Include a [a masonry bonded corner] [a stacked bond corner] [a bond beam corner] [and] [parging] [and] [installation of electrical boxes and conduit]. When the panel represents reinforced masonry, include a 610 by 610 mm 2 by 2 foot opening placed at least 610 mm 2 feet above the panel base and 610 mm 2 feet away from all free edges, corners, and control joints. Provide required reinforcing around this opening as well as at wall corners and control joints.
1.3.1.4 Mock-Up Panel Construction Method

Where anchored veneer walls or cavity walls are required, demonstrate and receive approval for the method of construction; i.e., either bring up the two wythes together or separately, with the insulation and appropriate ties placed within the specified tolerances across the cavity. Demonstrate provisions to preclude mortar or grout droppings in the cavity and to provide a clear open air space of the dimensions shown on the drawings. Where masonry is to be grouted, demonstrate and receive approval on the method that will be used to bring up the masonry wythes; support the reinforcing bars; and grout cells, bond beams, lintels, and collar joints using the requirements specified herein. When water-repellent is specified to be applied to the masonry, apply the approved product to the mock-up panel. Construct panels on a properly designed concrete foundation.

1.3.1.5 Mock-Up Panel Purpose

The completed panels is used as the standard of workmanship for the type of masonry represented. Do not commence masonry work until the mock-up panel for that type of masonry construction has been completed and approved. Protect panels from the weather and construction operations until the masonry work has been completed and approved. Perform cleaning procedures on the mockup and obtain approval of the Contracting Officer prior to cleaning the building. After completion of the work, completely remove the mock-up panels, including all foundation concrete, from the construction site.

1.3.2 Special Masonry Inspector Qualifications

Refer to Section 01 45 35 SPECIAL INSPECTIONS for qualifications and responsibilities of the masonry special inspector.

1.4 DELIVERY, STORAGE, AND HANDLING

Deliver, store, handle, and protect material to avoid chipping, breakage, and contact with soil or contaminating material. Store and prepare materials in already disturbed areas to minimize project site disturbance and size of project site.

1.4.1 Masonry Units

Cover and protect masonry units from precipitation. Conform to handling and storage requirements of TMS MSJC.

a. Pack glazed brick, glazed structural clay tile, and prefaced concrete masonry units in the manufacturer's standard paper cartons, trays, or shrink wrapped pallets with a divider between each unit. Do not stack pallets. Do not remove units from cartons until cartons are placed on scaffolds or in the location where units are to be laid.

b. Mark prefabricated lintels on top sides to show either the lintel schedule number or the number and size of top and bottom bars.

1.4.2 Reinforcement, Anchors, and Ties

Store steel reinforcing bars, coated anchors, ties, and joint reinforcement above the ground. Maintain steel reinforcing bars and uncoated ties free of loose mill scale and loose rust.
1.4.3 Cementitious Materials, Sand and Aggregates

Deliver cementitious and other packaged materials in unopened containers, plainly marked and labeled with manufacturers' names and brands. Store cementitious material in dry, weathertight enclosures or completely cover. Handle cementitious materials in a manner that will prevent the inclusion of foreign materials and damage by water or dampness. Store sand and aggregates in a manner to prevent contamination and segregation.

1.5 PROJECT/SITE CONDITIONS

Conform to TMS MSJC for hot and cold weather masonry erection.

1.5.1 Hot Weather Procedures

When ambient air temperature exceeds 38 degrees C 100 degrees F, or exceeds 32 degrees C 90 degrees F and the wind velocity is greater than 13 km/h 8 mph, comply with TMS MSJC Article 1.8 D for: preparation prior to conducting masonry work; construction while masonry work is in progress; and protection for newly completed masonry.

1.5.2 Cold Weather Procedures

When ambient temperature is below 4 degrees C 40 degrees F, comply with TMS MSJC Article 1.8 C for: preparation prior to conducting masonry work; construction while masonry work is in progress; and protection for newly completed masonry.

PART 2 PRODUCTS

2.1 SYSTEM DESCRIPTION

2.1.1 Design - Specified Compressive Strength of Masonry

The specified compressive strength of masonry, f'm, is [_____] [as indicated for each type of masonry] [indicated in a schedule in this Specification].

2.1.2 Performance - Verify Masonry Compressive Strength

**************************************************************************

NOTE: The Unit Strength Method can be used for clay masonry with units conforming to ASTM C216, ASTM C62, or ASTM C652, with bed joints not exceeding 16 mm 5/8 inch, and with grout conforming to ASTM C476, where grout compressive strength is at least equal to f'm. It can also be used for concrete masonry with units conforming to ASTM C90 or ASTM C55, with bed joints and grout same as clay masonry. The Prism Test Method must be used when the Unit Strength Method, which is conservative, is insufficient to verify compliance and when the above-listed parameters are not met. The Prism Test Method may be used at any time, at the Contractor's option.

**************************************************************************

Verify specified compressive strength of masonry using the "Unit Strength Method" of TMS MSJC. Submit calculations and certifications of unit and
mortar strength.

Verify specified compressive strength of masonry using the "Prism Test Method" of TMS MSJC when the "Unit Strength Method" cannot be used. Submit test results.

2.2 MANUFACTURED UNITS

2.2.1 General Requirements

Do not change the source of materials, which will affect the appearance of the finished work, after the work has started except with Contracting Officer's approval. Submit test reports from an approved independent laboratory. Certify test reports on a previously tested material as the same materials as that proposed for use in this project. Submit certificates of compliance stating that the materials meet the specified requirements.

2.2.2 Clay or Shale Brick

**************************************************************************

NOTE: The manufacturer's name and color number or color range will be indicated on the drawings along with the following note: "Colors or color ranges indicated are for identification purposes only and are not intended to limit selection of similar color or color range from other manufacturers."

Grade SW brick provides a high degree of resistance to frost action and deterioration by weathering. Grade MW brick provides a moderate degree of resistance and is only suitable for exterior use in certain parts of the country. Refer to ASTM C216.

Types FBS and HBS brick are for general use where normal size variation and chippage is acceptable. Types FBX and HBX permit less variation in size and chippage and are; therefore, more expensive. Types FBA and HBA permit larger variations for special architectural effect.

Bricks of various sizes are available and, if for architectural reasons, other sized bricks are included in the design, specify the size by listing the specified (not nominal) dimensions and not by name because names can vary. If larger units are required, change the specified dimensions. Nominal dimensions should not be used as they may result in confusion with specified size.

**************************************************************************

2.2.2.1 General

2.2.2.1.1 Sample Submittal

Submit brick samples as specified, showing the color range and texture of clay or shale brick. Limit units used on the project to those that conform to the approved sample. Submit sample of colored mortar with applicable masonry unit and color samples of three stretcher units and one unit for
each type of special shape.

2.2.2.1.2 Uniformity

[Manufacture bricks at one time and from the same run. ]Deliver clay or shale brick units factory-blended to provide a uniform appearance and color range in the completed wall.

[2.2.2.1.3 Recycled Content

**************************************************************************
NOTE: Use of materials with recycled content, calculated on the basis of post-industrial and post-consumer percentage content, contributes to meeting the requirements of Section 01 33 29 SUSTAINABILITY REQUIREMENTS AND REPORTING. Designer must verify that products meeting the indicated minimum recycled content are available, preferably from at least three sources, to ensure adequate competition. Use this paragraph if choosing recycled content.
**************************************************************************

Provide clay units containing a minimum of [0] [5] [_____] percent post-consumer recycled content, and a minimum of [10] [20] [_____] percent post-industrial recycled content.

]2.2.2.1.4 Efflorescence Test

**************************************************************************
NOTE: Delete this paragraph in areas where efflorescence has not been a problem. Efflorescence is generally the result of poor design and detailing. Properly covered or flashed walls are generally free of efflorescence. Efflorescence testing is generally not required.
**************************************************************************

Test clay brick that will be exposed to weathering for efflorescence in accordance with ASTM C67/C67M. Schedule tests far enough in advance of starting masonry work to permit retesting if necessary. Units meeting the definition of "effloresced" are subject to rejection.

2.2.2.2 Solid Clay or Shale Brick

**************************************************************************
NOTE: Specify ASTM C216 facing brick where aesthetic value is a prime consideration or to match existing construction. ASTM C216 may be replaced with ASTM C62 for projects where brick conforming to ASTM C62 provides aesthetic appearance that does not detract from the design, is generally available and predominantly used in the area, and the specific brick will blend with existing or adjacent architecture.
**************************************************************************

If larger units, such as closure size (92 mm x 92 mm x 194 mm 3-5/8 inch x 3-5/8 inch x 7-5/8 inch) or utility size (92 mm x 92 mm x 295 mm 3-5/8 inch x
3-5/8 inch x 11-5/8 inch) brick, are required, change the specified dimensions. Consider the use of closure or utility size brick when it is architecturally acceptable. The cost per square foot of wall is generally less when using larger units. Use paragraph titled "Closure or Utility Brick" below.

Compressive strength of the brick units only needs to be specified when it is used structurally; a veneer wythe is nonstructural. Commonly available face brick are produced to much higher compressive strength than the minimum required by ASTM C216.

Provide solid clay or shale brick that conforms to ASTM C216, Type [FBS] [FBA] [FBX] [ASTM C62]. Provide brick with minimum compressive strength of [_____] MPa psi. Where brick cores, recesses, or deformation would be exposed to view, provide 100 percent solid units. Provide brick with texture and color tange to match the brick [on display at [_____]] [indicated].

Provide brick with specified sizes.

[a. Modular size, 92 mm 3-5/8 inches thick, 57 mm 2-1/4 inches high, and 194 mm 7-5/8 inches long.

[b. Closure size, 92 mm 3-5/8 inches thick, 92 mm 3-5/8 inches high, and 194 mm 7-5/8 inches long.

[c. Utility size, 92 mm 3-5/8 inches thick, 92 mm 3-5/8 inches high, and 295 mm 11-5/8 inches long.

] 2.2.2.3 Hollow Clay or Shale Brick

Provide hollow clay or shale brick that conforms to ASTM C652, Type [HBS] [HBX] [HBA] [HBB].

[a. Provide brick size of [_____] mm inches thick, [_____] mm inches high, and [_____] mm inches long.

b. Where vertical reinforcement is shown in hollow brick, provide hollow brick designed to provide precise vertical alignment of the cells, with

SECTION 04 20 00 Page 20
minimum cell dimension of 64 mm 2-1/2 inches.

c. Provide hollow brick with minimum compressive strength of [_____] MPa psi.

2.2.2.4 Refractory Brick

Provide brick units that comply with ASTM C27, low-duty type, [_____] mm inches thick, [_____] mm inches high, and [_____] mm inches long.

2.2.2.5 Glazed Brick and Glazed Structural Clay Facing Tile

**************************************************************************

NOTE: Indicate the designation of ceramic glazed brick and glazed structural clay facing tile on the project drawings, or use the schedule to indicate locations. Delete the schedule if it is not used.

ASTM C1405 applies to brick units fired with a glaze in a single process; ASTM C126 applies to brick units fired then fired again with a glaze. ASTM C126 also applies to hollow facing tiles. For both standards, specify Grade SS (select) for walls laid in stack bond; Grade S (standard) is supplied if nothing is specified. Type I indicates a single glazed face while Type II is double faced. Type I is the default.

Normally, prefaced ASTM C1634 concrete masonry units will be specified as a Contractor's option to ceramic glazed structural clay facing units. Structurally, the units will be considered as equal.

**************************************************************************

Provide [ceramic glazed brick] [glazed facing tile] indicated as [____], conforming to ASTM C1405 [ASTM C126], Type I, Grade [SS] [S], glaze as indicated. In two-faced walls, Type II units may be used for the base course. Provide all shapes and sizes for a complete installation. Use bullnose units along sills and caps and at vertical external corners including door jambs, window jambs, and other such openings. Provide coved base units to meet finished floor surfaces where ceramic tile floor occurs.

a. Where backs of units will be exposed in unfinished rooms, provide smooth backs, free from glaze. Where backs of units will receive plaster, provide scored, combed, or otherwise roughened backs.

b. Provide unit surfaces, to receive mortar, reasonably free from glaze and suitable for receiving mortar.

c. Provide tile for fire rated walls with the percent of solid required for that rating.

**************************************************************************

NOTE: Appropriate information should be indicated. Include this schedule for information when it is not convenient to indicate on the project drawings. Select colors from manufacturer's standard colors.

**************************************************************************
d. Structural Clay Facing Tile Schedule

<table>

2.2.2.6 Salvaged Brick

**************************************************************************
NOTE: Use of salvaged/recovered materials contributes to meeting the requirements of Section 01 33 29 SUSTAINABILITY REQUIREMENTS AND REPORTING.

Include bracketed wording if bricks will be in structures used for children or residences. Indicate on drawings locations where salvaged brick is acceptable.
**************************************************************************

Use [lead-free] salvaged bricks and other masonry units in place of new bricks or masonry units as indicated. [Wash bricks salvaged from foundries or industrial buildings with appropriate metal-dust removing cleaner.] When using salvaged brick, select salvaged exterior face bricks from exterior locations.

Provide salvaged bricks that meet standards of new bricks otherwise used in application, and cleaned of all mortar prior to use. Submit documentation certifying products are from salvaged/recovered sources. Indicate relative dollar value of salvaged content products to total dollar value of products included in project.

2.2.2.7 Flue Linings and Thimbles

Provide units that comply with ASTM C315, and are free from fractures. Provide sizes and shapes as indicated.

2.2.3 Concrete Units

2.2.3.1 Aggregates

**************************************************************************
NOTE: Where sufficient evidence based on previous construction experience indicates concrete masonry units manufactured from aggregate from a specific source may be subject to excessive popouts and/or staining, contract specifications may be written to exclude such aggregate. Delete this article when the concrete units will not be exposed to view.
**************************************************************************

Test lightweight aggregates, and blends of lightweight and heavier aggregates in proportions used in producing the units, for stain-producing iron compounds in accordance with ASTM C641, visual classification method. Do not incorporate aggregates for which the iron stain deposited on the filter paper exceeds the "light stain" classification.

Use industrial waste by-products (air-cooled slag, cinders, or bottom ash),
ground waste glass and concrete, granulated slag, and expanded slag in aggregates.

2.2.3.2 Concrete Masonry Units (CMU)

**************************************************************************
NOTE: Concrete units may be produced in three weight classifications. It is important that the weight classification desired be designated.

Low alkali cement maybe specified for use in CMU if efflorescence caused by the use of available cement is a problem. However, these cements are difficult to obtain in some regions where sulfates are not an issue. Also, alkali-silica reactivity (ASR) is not as big an issue in concrete masonry units as it is in cast-in-place concrete. If efflorescence is not a problem, or if the CMU will not be exposed to weather, delete the first sentence.

Specify lightweight aggregate where required for fire-resistant or "U" value purposes. Coordinate with structural and mechanical designers. Otherwise, unit density is at the option of the contractor, including single wythe, grouted walls.

For single-wythe, concrete masonry unit exterior walls, specify water-repellant admixture for both the masonry units and the mortar.

See addition information regarding use of recycled content materials in Section 01 33 29 SUSTAINABILITY REQUIREMENTS AND REPORTING.
**************************************************************************

[2.2.3.2.1 Cement]
Use only cement that has a low alkali content and is of one brand.

)2.2.3.2.2 Recycled Content

Provide units with a minimum of [5] [10] [_____] percent post-consumer recycled content, or a minimum of [20] [40] [_____] percent post-industrial recycled content, based on mass, cost, or volume.[Units may contain post-consumer or post-industrial recycled content.]

2.2.3.2.3 Size

Provide units with specified dimension of [_____] mm inches wide, [_____] mm inches high, and [_____] mm inches long.

2.2.3.2.4 Surfaces

[For units that are to be plastered or stuccoed, provide surfaces that are sufficiently rough to provide bond.] [[Elsewhere, provide][Provide] units with exposed surfaces that are smooth and of uniform texture.]
2.2.3.2.5 Weather Exposure

Provide concrete masonry units with water-repellant admixture added during manufacture where units will be exposed to weather.

2.2.3.2.6 Unit Types

**************************************************************************
NOTE: The weight of concrete masonry units is not important except as it effects porosity, the heavier the block the less porous it will be. Direct design and production of masonry units towards reducing shrinkage, porosity, and absorption. However, heavier units will effect masons' production rates as they prefer the lightest possible units to lay. Proper vibration and autoclave curing of CMU in the manufacturing process will provide better quality units. Admixture to densify units is recommended. Specify loading-bearing type masonry units in exterior walls or interior walls subject to moist environments. Only specify Non-Load-bearing Units for interior partitions.
**************************************************************************

a. Hollow Load-Bearing Units: ASTM C90, lightweight [or medium weight] [or normal weight]. Provide load-bearing units for exterior walls, foundation walls, load-bearing walls, and shear walls.

b. Hollow Non-Load-Bearing Units: ASTM C129, lightweight [or medium weight] [or normal weight]. Load-bearing units may be provided in lieu of non-load-bearing units.

c. Solid Load-Bearing Units: ASTM C90, lightweight [or medium weight] [or normal weight] units. Provide solid units as indicated.

2.2.3.2.7 Jamb Units

Provide jamb units of the shapes and sizes to conform with wall units. Solid units may be incorporated in the masonry work where necessary to fill out at corners, gable slopes, and elsewhere as approved.

Provide sash jamb units with a 19 by 19 mm 3/4 by 3/4 inch groove near the center at end of each unit.

2.2.3.3 Architectural Units

**************************************************************************
NOTE: Where architectural units are used, local sources should be checked to determine available shapes, sizes, patterns, and colors. Desired unit pattern should be clearly indicated. Delete integral coloring if units will be painted or if natural color is satisfactory. Concrete masonry veneer wythes should be 100 percent solid units to minimize trapping water which could lead to damage from freezing, mildew, and efflorescence.
**************************************************************************

Provide architectural units with patterned face shell: [fluted] [vertical
scored] [split ribbed] [____].

Provide units that are integrally colored during manufacture, with color [____].

2.2.3.4 Patterned, Decorative Screen Units

**************************************************************************

NOTE: Manufacturer's catalogs will be consulted for patterned units that are locally available. Optional designs of patterned units will be shown as necessary for competitive bidding.

Concrete masonry units conforming to applicable requirements of ASTM C129 are suitable for interior nonload-bearing screens, and may be specified where required.

**************************************************************************

Provide patterned, decorative screen units that conform to [ASTM C90] [ASTM C129]. Provide units that have uniform through-the-wall pattern, color, and texture.

2.2.3.5 Fire-Rated Concrete Masonry Units

**************************************************************************

NOTE: The thickness of fire-rated walls as well as the required fire rating will be indicated on the drawings. Such walls will be shown as continuous from floor to deck above. Sections and details of these walls will clearly indicate the extent of such walls. Solid grouted hollow concrete units and concrete brick masonry 150 mm 6 inches or greater in thickness will be considered a 4-hour fire-rated wall regardless of aggregate type.

**************************************************************************

For indicated fire-rated construction, provide concrete masonry units of minimum equivalent thickness for the fire rating indicated and the corresponding type of aggregates indicated in TABLE I. Units containing more than one of the aggregates listed in TABLE I will be rated by linear interpolation based on the percent by dry-rodred volume of each aggregate used in manufacturing the units.

<table>

</tr>
</tbody>
</table>

Determine equivalent thickness in accordance with ACI 216.1. Where walls are to receive plaster or be faced with brick, or otherwise form an assembly; include the thickness of plaster or brick or other material in the assembly in determining the equivalent thickness. Submit calculation results.

2.2.3.6 Prefaced Concrete Masonry Units

**************************************************************************
NOTE: Bullnose units will be specified only in cases where sharp corners are considered objectionable, such as in heavy traffic areas. If bullnose units are specified, the locations of use will be detailed on the drawings and/or listed in this paragraph.
**************************************************************************

Prefaced concrete masonry units [may] [may not] be provided in lieu of ceramic glazed structural clay facing tile units. Where prefaced concrete masonry units are provided, concrete masonry unit backing may be omitted when the nominal thickness of the prefaced concrete masonry units is the same as the total indicated nominal thickness of the facing tile plus the backing.

a. Provide prefaced concrete masonry units conforming to ASTM C744 using masonry units conforming to ASTM C90, with the facing turned over the edges and ends of the unit at least 9.5 mm 3/8 inch in the direction of the thickness of the unit to form a lip at least 1.6 mm 1/16 inch thick. Limit variation in color and texture to that in the approved sample.

b. Provide all shapes and sized for a complete installation. Use bullnose units along sills and caps and at vertical external corners including door jambs, window jambs, and other such openings with a bullnose radius of 25 mm 1 inch. Cove base units to meet finished floor surfaces where ceramic tile floor occurs.

2.2.3.7 Concrete Brick

**************************************************************************
NOTE: ASTM C1634 concrete brick are used for high strength and resistance to moisture penetration. Split face brick (solid concrete facing units), where required by design, should be added to this paragraph. A particular color and texture may be specified when locally available and competitively

SECTION 04 20 00 Page 26
priced. Sizes may be specified for brick or split face brick where required by the design.

ASTM C55 concrete brick are used for lesser strength and moisture resistance, and where appearance is of low importance.

ASTM C73 sand-lime brick may be used on the interior or exterior. Where limited to interior use, Grade MSW may be specified as an option to Grade SW.

2.2.3.7.1 Common Concrete Brick

Provide common concrete brick conforming to ASTM C55. Common concrete brick may be used where necessary for filling out in concrete masonry unit construction.

2.2.3.7.2 Concrete Brick for Facing

Provide concrete brick for exposed applications that conforms to ASTM C1634. Submit samples as specified.

2.2.3.7.3 Sand-Lime Brick

Provide calcium-silicate (sand-lime) that conforms to ASTM C73, Grade SW, approximately 92 mm thick, 57 mm high, 194 mm long 3-5/8 inches thick, 2-1/4 inches high, and 8 inches long or modular, with smooth surfaces and natural color.

2.2.4 Precast Concrete Units

NOTE: Architectural Cast Stone is a refined architectural concrete building unit manufactured to simulate natural cut stone and may be specified in lieu of precast concrete. It exceeds minimum requirements for compressive strength and weathering qualities essential for common installations and may be a suitable replacement for natural cut limestone, brownstone, sandstone, bluestone, granite, slate, keystone, travertine, and other natural building stones. When specified for use in climates that experience freeze-thaw, its durability can be demonstrated by field performance of similar products in similar exposures for many years, or it can be tested by a modified version of ASTM C666, Procedure A, per Cast Stone Institute literature. Cast stone masonry products may be used as architectural feature, trim, and ornament, facing or other non-structural use in buildings and other structures.

2.2.4.1 General

a. Provide precast concrete trim, lintels, copings, splashblocks and sills that are factory-made units in a plant regularly engaged in producing precast concrete units. Unless otherwise indicated, provide precast
concrete with minimum [28] [20] MPa [4,000] [3000] psi compressive strength, conforming to Section 03 30 00 CAST-IN-PLACE CONCRETE using 13 mm 1/2 inch to No. 4 nominal-size coarse aggregate, and with reinforcement required for handling of the units. Maintain minimum clearance of 19 mm 3/4 inch between reinforcement and faces of units.

b. Unless precast-concrete items have been subjected during manufacture to saturated-steam pressure of at least 827 kPa 120 psi for at least 5 hours, either damp-cure for 24 hours or steam-cure and then age under cover for 28 days or longer. In precast concrete members weighing over 35 kg 80 pounds provide built-in loops of galvanized wire or other approved provisions for lifting and anchoring.

c. Fabricate units with beds and joints at right angles to the face, with sharp true arises and with drip grooves on the underside where units overhang walls. Form exposed-to-view surfaces free of surface voids, spalls, cracks, and chipped or broken edges and with uniform appearance and color. Unless otherwise specified, provide units with a smooth dense finish.

d. Prior to installation, wet and inspect each unit for crazing. Items showing evidence of dusting, spalling, crazing, or having surfaces treated with a protective coating will be rejected.

e. Submit specified factory certificates.

f. Provide architectural cast stone masonry trim, copings, heads, and sills that are manufactured in a plant by a producer regularly engaged in producing cast stone. Provide cast stone units that comply with ASTM C1364. Submit test reports and three exemplars of the same cast stone product installed in similar projects in similar climatic conditions.

2.2.4.2 Precast Concrete Lintels

**************************************************************************
NOTE: Insert strength of concrete; precast lintels usually range from 17 to 25 MPa 2500 to 3500 psi. Alternatively, reinforced masonry lintels may be designed in conformance with TMS MSJC.
**************************************************************************

Provide precast concrete lintels, unless otherwise shown, of a thickness equal to the wall and reinforced with minimum two No. 4 bars for the full length. Provide top and bottom bars for lintels over 914 mm 36 inches in length. Provide at least 200 mm 8 inches bearing at each end. Label the top of lintels and clearly mark each lintel to show location in the structure. Design reinforced lintels in conformance with ACI 318M ACI 318 for flexural and shear strength, using concrete with a minimum 28 day compressive strength of [_____] MPa psi. Limit lintel deflection due to dead plus live load to L/600 or 7.6 mm 0.3 inches.

2.2.4.3 Precast Concrete Sills and Copings

**************************************************************************
NOTE: Lug sills, which are longer than the window opening, eliminate the vulnerable head joint that occurs at the end of slip sills, which are the same length as the window opening.
**************************************************************************
Cast sills and copings washes. For windows having mullions, cast sills in sections with head joints at mullions and a 6 mm 1/4 inch allowance for mortar joints. Roughen the ends of sills, except a 19 mm 3/4 inch wide margin at exposed surfaces, for bond. Provide rounded nosings on treads of door sills. [Reinforce sills with not less than two No. 15 No. 4 bars.]

2.2.5 DIMENSION STONE UNITS

NOTE: The stone specified herein is for structures requiring a limited quantity of cut stone. Where previous experience indicates difficulty in obtaining precast concrete trim of the specified quality, stone may be specified as a Contractor's option.

Provide dimension stone for trim, sills, lintels, and copings cut to the design shown and conforming to:

<table>
<thead>
<tr>
<th>Stone</th>
<th>Specification</th>
<th>Finish Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limestone</td>
<td>ASTM C586</td>
<td>Standard buff color with a smooth machine finish free from tool marks</td>
</tr>
<tr>
<td>Sandstone</td>
<td>ASTM C616/C616M</td>
<td>Standard grade, buff, gray, or buff brown, with a smooth finish free from clay pits and tool marks</td>
</tr>
<tr>
<td>Granite</td>
<td>ASTM C616/C615M</td>
<td>Commercial grade of medium or moderately coarse grain, with a light or medium gray or light pink color</td>
</tr>
</tbody>
</table>

Provide a smooth machine finish on washes, 4-cut finish on treads, and 6-cut or equivalent machine finish on other exposed surfaces. Except when supported by a steel member, provide lintels 100 mm 4 inches or more in thickness from face to back edge and of the depth required to support the masonry over the opening. Fabricate stone with beds and joints at right angles to the face, and with sharp, true arises. Provide copings and sills with washes, and where overhanging the walls, with drips cut on the underside. Submit samples as specified.

2.3 EQUIPMENT

NOTE: The requirement for spare vibrator may be deleted on small projects.

2.3.1 Vibrators

Maintain at least one spare vibrator on site at all times.

2.3.2 Grout Pumps

Pumping through aluminum tubes is not permitted.
2.4 MATERIALS

2.4.1 Mortar Materials

**************************************************************************
NOTE: Refer to ASTM C270 for specifying mortar, which allows mortar to be specified by proportions (ASTM C270 Table 1) or properties (ASTM C270 Table 2) but not both. Acceptable cementitious materials are listed in the standard, though not all are appropriate for all applications. For instance, some cements are used for high early strength or for sulfate resistance. See Table Hydraulic Cements for Masonry Mortar below for comparable designations between different cement specifications. Also, ASTM C270 Appendix X1 contains guidance on selection and use of mortar for unit masonry by location (exterior, interior, above grade, below grade) and building segment type (wall, partition, foundation, etc.).

Mortar that complies with ASTM C1714 for Unit Masonry, meets the requirements of ASTM C270. These mortars are preblended dry in a factory and delivered to the job-site in packages (bags or silos or trucks).

A good rule of thumb is to specify the weakest mortar that will perform adequately, not the strongest. In accordance with TMS MSJC, mortar in masonry elements that are part of the seismic force-resisting system in Seismic Design Category D or higher must be Type S or Type M, and must use portland cement/lime or mortar cement as their cementitious material (masonry cement is not permitted). Therefore, these masonry members must be indicated on the Drawings. Type O mortar should not be used in new construction.

Laboratory testing of mortar is only required for acceptance of mortar mixes under the property specifications of ASTM C270. Field testing of mortars, conducted under ASTM C780, is used to verify consistency of materials and procedures, not mortar strength. While field testing of mortar strength is not recommended, it can provide information about degree of quality control exercised during mortar production at the construction site if compared to preconstruction test values. However, compressive test results for mortar are evaluated after 28 days, so mortar-aggregate ratio testing per ASTM C780, which can take as little as four hours, may be more useful for evaluating mortar consistency. Observation of mortar mixing, to verify proper proportioning, is the best evaluator of mortar consistency and quality.

For white mortar, specify white cement. For colored mortar, white cement or gray cement may be
specified, depending on the desired color. Color is achieved by adding pigments at the time of mixing or by selecting preblended colored cementitious materials or preblended colored mortar materials. Excessive use of pigments to achieve mortar color may reduce both compressive and tensile strengths of masonry. Conformance to maximum percentages indicated will limit loss of strength to acceptable amounts. Due to their fine particle size, coloring pigments increase water demand.

Where efflorescence is a concern, techniques for minimizing its occurrence are described in ASTM C1400. Techniques include: minimizing water penetration into the wall, such as by use of overhangs; facilitating drainage of water in the wall; avoiding contact between dissimilar masonry units; and minimizing potential efflorescence compounds in the wall materials.

2.4.1.1 Cementitious Materials

NOTE: See Section 01 33 29 SUSTAINABILITY REQUIREMENTS AND REPORTING and include additive options unless designer determines that justification for non-use exists. Supplementary cementitious materials are often included as ingredients in mortar that conforms to ASTM C595 blended cements or ASTM C1157 hydraulic cements. See "Hydraulic Cements for Masonry Mortar" table below for different ASTM C150, C595, and C1157 cements that are allowed in masonry mortar by ASTM C270. For example, high-early strength cement may be used when constructing in cold weather. Contractors select cementitious materials based on performance, availability, and familiarity, and the Contracting Officer should be aware that more than one cement designation can satisfy the same need, such as high early strength.

</tbody>
</table>

* Type IT(S<70) cements are ternary blended cements with less than 70 percent by mass slag cement content. For this table, this includes ternary blended cements with pozzolans and limestone (no slag cement) as the non-portland ingredients.

** Type IT cements with between 5 and 15 percent (by mass) limestone content are not permitted to be used in sulfate exposure applications, pending results of research.

+ Air-entrained counterparts for cements listed are also allowed in masonry mortar per the proportioning requirements of ASTM C270.

---

Provide cementitious materials that conform to those permitted by ASTM C270.

### 2.4.1.2 Hydrated Lime and Alternates

**NOTE:** Higher lime content increases workability and water retentivity. Allowable lime materials include ASTM C207 hydrated lime and ASTM C5 quicklime.

Provide lime that conforms to one of the materials permitted by ASTM C207 for use in combination with portland cement, hydraulic cement, and blended hydraulic cement. Do not use lime in combination with masonry cement or mortar cement.

### 2.4.1.3 Colored Mortar

---

**SECTION 04 20 00 Page 32**
NOTE: Indicate on the drawings locations of colored mortar. Maximum allowable pigment dosages are based on ASTM C270 Appendix X1 and TMS MSJC Article 2.6 A.2. When pigments that comply with ASTM C979 are used at maximum permitted dosage, 28-day strength of colored mortar is not less than 90 percent of the control mix and water-cementitious materials ratio is no more than 110 percent of the control mix.

Use mortar pigment that conforms to ASTM C979/C979M. Add pigment to mortar to produce a uniform color matching [______]. Furnish pigments in accurately pre-measured and packaged units that can be added to a measured amount of cementitious materials or supply pigments via preblended cementitious materials or dry mortar mix.

a. In masonry cement or mortar cement, do not exceed [5][_____] percent of cement weight for mineral oxide pigment; do not exceed [1][_____] percent of cement weight for carbon black pigment.

b. In cement-lime mortar mix, do not exceed [10][_____] percent of cementitious materials' weight for mineral oxide pigment; do not exceed [2][_____] percent of cementitious materials' weight for carbon black pigment.

2.4.1.4 Admixtures for Masonry Mortar

NOTE: Admixtures can improve performance of mortar and are specified for beneficial purposes, but potential negative side effects include an increased risk of efflorescence, reduced strength of mortar, and corrosion of embedded steel items. Admixtures that comply with ASTM C1384 have limited negative side effects and meet the minimum requirements for improvement in performance of the desired attribute, such as rate of set, water-repellency, or bond.

Showers, kitchens, and single-wythe concrete masonry unit exterior walls should be built with concrete block containing integral water-repellent admixture. When water repellents are used in concrete masonry, the mortar should contain a compatible water-repellent admixture. A complementary material from the same manufacturer and of the same brand is designed to be compatible with the block admixture.

In cold weather, use a non-chloride based accelerating admixture that conforms to ASTM C1384, unless Type III portland cement is used in the mortar.

In showers and kitchens, use mortar that contains a water-repellent admixture that conforms to ASTM C1384. Provide a water-repellent admixture, conforming to ASTM C1384 and of the same brand and manufacturer as the block's integral water-repellent, in the mortar used to place concrete masonry units that have an integral water-repellent admixture.
2.4.1.5  Aggregate and Water

Provide aggregate (sand) and water that conform to materials permitted by ASTM C270.

2.4.2  Grout and Ready-Mix Grout Materials

------------------------------------------------------------------------------------------------------------------------
NOTE: Acceptable cements for masonry grout are listed in ASTM C476 and are summarized in Table "Hydraulic Cements for Masonry Grout Construction in ASTM C476" below. Check the local availability of specific cements as all cements are not available everywhere. Per ASTM C476, other acceptable cementitious materials for masonry grout are fly ash and slag and small quantities of lime. Note that masonry cement and mortar cement are not permitted to be used in grout. When high-early strength cement, such as Type III Portland cement, is used for cold weather construction, the protection period for grouted masonry may be reduced.

<table>
<thead>
<tr>
<th>Cement specification*</th>
<th>General Purpose</th>
<th>High early strength</th>
<th>Moderate sulfate resistance</th>
<th>High sulfate resistance</th>
</tr>
</thead>
<tbody>

<td>GU</td>
<td>HE</td>
<td>MS</td>
<td>HS</td>
</tr>
</tbody>
</table>

* Air-entrained counterparts for these cements listed are also allowed in masonry grout. However, use of air-entrainment is not recommended when the grout will be used to bond reinforcement to the masonry units.

**
------------------------------------------------------------------------------------------------------------------------
2.4.2.1  Cementitious Materials for Grout

Provide cementitious materials that conform to those permitted by ASTM C476.

2.4.2.2  Admixtures for Grout

------------------------------------------------------------------------------------------------------------------------
NOTE: Admixtures, including air entrainment, may contribute to efflorescence and may adversely affect the strength of the mix or the protection of embedded steel items. Admixtures that comply with C494/C494M Type F or G water reducing admixtures and

SECTION 04 20 00 Page 34
viscosity-modifying admixtures are permitted, but others, such as integral waterproofing compounds, accelerators, and others, require approval from purchaser.

When concrete masonry and clay brick units are highly absorbent, a grouting aid admixture may be desirable to reduce early water loss, promote bonding, and produce slight expansion to help ensure complete filling of cavities.

Water-reducing admixtures that conform to ASTM C494/C494M Type F or G and viscosity-modifying admixtures that conform to ASTM C494/C494M Type S are permitted for use in grout. Other admixtures require approval by the Contracting Officer.

In cold weather, a non-chloride based accelerating admixture may be used subject to approval by the Contracting Officer; use accelerating admixture that is non-corrosive and conforms to ASTM C494/C494M, Type C.

2.4.2.3 Aggregate and Water

Provide fine and coarse aggregates and water that conform to materials permitted by ASTM C476.

2.5 MORTAR AND GROUT MIXES

NOTE: Some preblended mortars may require special mixing procedures. If so, follow manufacturers published recommendations.

Indicate seismic force-resisting masonry elements on the Drawings.

2.5.1 Mortar Mix

a. Provide mortar Type [N] [S] [M] unless specified otherwise herein. [Do not use masonry cement in the mortar.] [Do not use air-entrainment in the mortar.]

b. Use ASTM C270 Type [S] [M] cement-lime mortar or mortar cement mortar for seismic-force-resisting elements indicated.[

c. Provide mortar that conforms to ASTM C270. Use Type [M] [S] [N] mortar [for foundation walls] [, basement walls,] [and in piers].][

d. Provide Type N or S mortar for non-load-bearing, non-shear-wall interior masonry.][

e. Provide approved commercial fire clay mortar or refractory cement (calcium-aluminate) mortar for fire brick and flue liners.]

[c][d][e][f]. For field-batched mortar, measure component materials by volume. Use measuring boxes for materials that do not come in packages, such as sand, for consistent batching. Mix cementitious materials and aggregates between 3 and 5 minutes in a mechanical batch.
mixture with a sufficient amount of water to produce a workable consistency. Do not hand mix mortar unless approved by the Contracting Officer. Maintain workability of mortar by remixing or retempering. Discard mortar that has begun to stiffen or is not used within 2-1/2 hours after initial mixing.

[d][e][f][g]. For preblended mortar, follow manufacturer's mixing instructions.

2.5.2 Grout and Ready Mix Grout Mix

**************************************************************************

NOTE: Grout strength must be at least as great as the specified compressive strength of masonry (f’m) but not less than 14 MPa 2000 psi at 28 days. Revise specification when grout compressive strength is required to be in excess of 14 MPa 2000 psi.

Choice of fine or coarse grout depends on width of grout space and pour height; tabulated limitation can be found in TMS MSJC. The Contractor usually has the option to select grout type, but under special circumstances, the Engineer-of-Record may want to define grout type.

**************************************************************************

Use grout that conforms to ASTM C476, [fine] [coarse]. Use conventional grout with a slump between 203 and [279] mm 8 and [11] inches. Use self-consolidating grout with slump flow of 610 to 762 mm 24 to 30 inches and a visual stability index (VSI) not greater than 1. Provide minimum grout strength of [14][_____] MPa [2000][_____] psi in 28 days, as tested in accordance with ASTM C1019. Do not change proportions and do not use materials with different physical or chemical characteristics in grout for the work unless additional evidence is furnished that grout meets the specified requirements. Use ready-mixed grout that conforms to ASTM C476.

2.6 ACCESSORIES

2.6.1 Grout Barriers

Grout barriers for vertical cores that consist of fine mesh wire, fiberglass, or expanded metal.

2.6.2 Anchors, Ties, and Bar Positioners

**************************************************************************

NOTE: By definition, ties are connections between masonry wythes, anchors connect masonry to the structure and connect veneer to its backing, and fasteners are for attachment of non-masonry items to masonry. The anchors and ties specified in this paragraph are primarily used to laterally tie masonry veneer to backup elements. Anchors and ties not incorporated in the design should be deleted. If special anchors or ties are required by the design, they will be specified to meet the necessary requirements. Standard anchors and ties can be used in cavities up to 114 mm 4.5 inches wide.

SECTION 04 20 00 Page 36
The required minimum zinc coating thicknesses for wire ties, anchors, and joint reinforcement are shown in the following table and are based on exposure:

<table>
<thead>
<tr>
<th>Exposure</th>
<th>Finish</th>
<th>Wt. of Coating in Gram Per Sq. Meter Oz. Per Sq. Foot</th>
</tr>
</thead>
<tbody>
<tr>
<td>Joint reinforcement, interior walls</td>
<td>ASTM A641/A641M</td>
<td>31 0.1</td>
</tr>
<tr>
<td>Wire ties or anchors</td>

<td>180 .60</td>
</tr>
</tbody>
</table>

2.6.2.1 General

a. Fabricate anchors and ties without drips or crimps. Size anchors and ties to provide a minimum of 16 mm 5/8 inch mortar cover from each face of masonry.

b. Fabricate steel wire anchors and ties from wire conforming to ASTM A1064/A1064M and hot-dip galvanize in accordance with ASTM A153/A153M.
c. Fabricate joint reinforcement in conformance with ASTM A951/A951M. Hot dip galvanize joint reinforcement in exterior walls and in interior walls exposed to moist environment in conformance with ASTM A153/A153M. Galvanize joint reinforcement in other interior walls in conformance with ASTM A641/A641M; coordinate with paragraph JOINT REINFORCEMENT below.

e. Submit two anchors, ties and bar positioners of each type used, as samples.

2.6.2.2 Wire Mesh Anchors

**************************************************************************
NOTE: Wire mesh anchors will only be used to connect interior non-bearing walls to other intersecting interior non-bearing masonry walls.
**************************************************************************

Provide wire mesh anchors of 6 mm 1/4 inch mesh galvanized hardware cloth, conforming to ASTM A185/A185M, with length not less than 305 mm 12 inches, at intersections of interior non-bearing masonry walls.

2.6.2.3 Wall Ties for Multi-Wythe Masonry Construction

**************************************************************************
NOTE: Wall ties will be specified to provide an option to the typically used continuous joint reinforcement to anchor the outer wythe to the inner wythe of multiple wythe masonry construction. Vertical spacing will normally be 400 mm 16 inches on center and horizontal spacing of the unit ties will normally be 600 mm 24 inches on center.
**************************************************************************

Rectangular ties may be used with either solid or hollow units. The maximum wall area per rectangular tie of wire size MW11 W1.7 is 0.25 m2 2-2/3 ft2; when the wire size is MW18 W2.8 the maximum wall area per tie is 0.42 m2 4.5 ft2. There are additional requirements for wall ties based on how the masonry is designed (veneer or engineered non-composite), spacing, and seismic design category of buildings with veneer.

Adjustable wall ties are normally used when constructing one wythe independent of the other. The preferred method of construction, however, is to bring the wythes up together. Delete the sentences pertaining to adjustable ties when they are not permitted.

**************************************************************************

Provide rectangular-shaped wall ties, fabricated of hot-dipped galvanized [
MW11W1.7][MW18W2.8] diameter steel wire. Provide rectangular wall ties no less than 100 mm 4 inches wide.

Provide adjustable type wall ties, if approved for use, that consist of two essentially U-shaped elements fabricated of minimum MW18 W2.8 diameter steel wire or pintle type ties that are inserted to eyes of horizontal joint reinforcement, hot-dip galvanized. Provide adjustable ties with double pintle legs and allows a maximum offset of 32 mm 1-1/4 inch between each element of the tie and maximum distance between connecting parts no more than 2 mm 1/16 inch. Form the pintle and eye elements so that both can be in the same plane. Wall ties may also be of a continuous type conforming to paragraph JOINT REINFORCEMENT.

2.6.2.4 Dovetail Anchors

Provide dovetail anchors of 5 mm 3/16 inch diameter steel wire, triangular shaped, and attached to a 12 gauge or heavier steel dovetail section. Use these anchors to connect the exterior masonry wythe as it passes over the face of concrete columns, beams, or walls. Fill cells immediately above and below these anchors unless solid units are used. Furnish dovetail slots, which are specified to be installed by others, in accordance with Section 03 30 00 CAST-IN-PLACE CONCRETE.

2.6.2.5 Adjustable Anchors

**************************************************************************
NOTE: Adjustable anchors will be used to anchor masonry to structural steel columns or beams. Such anchors will be either be detailed on the drawings, or the capacity requirements will be given in the specification and the contractor will be required to submit test data to verify compliance. Select the appropriate option.

Adjustable anchors may also be used to connect veneer to its backing. Adjustable anchors are required when the backing for the veneer is steel stud framing or concrete.
**************************************************************************

2.6.2.5.1 Anchorage to Structural Steel

Provide [hot-dip galvanized] [stainless steel] adjustable anchors for connecting masonry walls to the structural steel frame [as detailed on the drawings] [that have [_____] kg pounds capacity in both tension and compression for the span indicated when placed at [_____] mm inches on center; submit test data to verify compliance]. [Provide zinc-rich paint for touching up paint after welding galvanized anchors to structural steel.]

2.6.2.5.2 Anchorage of Veneer to Light Gauge Steel or Concrete Backing

Use one of the following types of adjustable anchors to connect veneer to light gauge steel or concrete backing:

a. sheet metal at least 22 mm 7/8 inch wide, 1.5 mm 0.06 inch thick, and with corrugations having a wavelength of 7.6 to 12.7 mm 0.3 to 0.5 inch and an amplitude of 1.5 to 2.5 mm 0.06 to 0.10 inch or bent, notched or punched to provide equivalent performance;
b. wire anchors of minimum size \( MW_{11} \ W_{1.7} \) with ends bent to form a minimum 50 mm 2 inches extension and without drips;

c. or wire pintle anchors used in conjunction with joint reinforcement.

Do not exceed 1.6 mm 1/16 inch clearance between connecting parts of the tie. Assemble adjustable anchors to prevent disengagement. Provide pintle anchors with one or more pintle legs of wire size \( MW_{18} \ W_{2.8} \) and an offset not exceeding 32 mm 1-1/4 inch.

2.6.2.6  Veneer Anchor Screws

******************************************************************************
NOTE: This paragraph should be edited to reflect the design option selected.
******************************************************************************

Provide screws for attachment of veneer anchors to cold-formed steel framing members of size [No. 12] [as indicated] [as required by design to provide the needed pullout load capacity but not less than No. 12]. Provide length of screws such that the screws penetrate the holding member by not less than 16 mm 5/8 inch.

2.6.2.7  Bar Positioners

Factory-fabricate bar positioners, used to prevent displacement of reinforcing bars during the course of construction, from 9 gauge steel wire or equivalent, and hot-dip galvanized. Bar positioners must be suitable for intended use and be corrosion resistant steel. Bar positioners not fully contained within the wythe must be hot-dip galvanized.

2.6.3  Joint Reinforcement

******************************************************************************
NOTE: Location of horizontal joint reinforcement should be shown on the drawings. Reinforcement will have one longitudinal wire in each mortar bed. Truss-type joint reinforcement will not be used. Adjustable joint reinforcement assemblies may be used in certain types of construction where it is feasible to construct one wythe independent of the other. If the type of design does not permit this type of construction, delete the sentences pertaining to adjustable joint reinforcement assemblies.
******************************************************************************

Various combinations of wire sizes are available and are usually designated as follows:

<table>
<thead>
<tr>
<th></th>
<th>Long. wires</th>
<th>Cross wires</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Standard</strong></td>
<td>3.8 mm9 gauge (0.1483 inch)</td>
<td>3.8 mm9 gauge (0.1483 inch)</td>
</tr>
</tbody>
</table>
Factory fabricate joint reinforcement in conformance with ASTM A951/A951M, welded construction. Provide ladder type joint reinforcement, having one longitudinal wire in the mortar bed of each face shell for hollow units and one wire for solid units and with all wires a minimum of 0.1483 inch gauge. Size joint reinforcement to provide a minimum of 5/8 inch cover from each face. Space crosswires not more than 16 inches. Provide joint reinforcement for straight runs in flat sections not less than 10 feet long. Provide joint reinforcement with factory formed corners and intersections. If approved for use, joint reinforcement may be furnished with adjustable wall tie features. Submit one piece of each type used, including corner and wall intersection pieces, showing at least two cross wires.

### 2.6.4 Reinforcing Steel Bars

**NOTE:** ASTM A615/A615M is typically used. Only use weldable bars if welding is unavoidable.

Provide reinforcing steel bars and rods conforming to ASTM A615/A615M or ASTM A996/A996M, Grade 60.

### 2.6.5 Concrete Masonry Control Joint Keys

**NOTE:** Control joint keys are generally not required vertically when the concrete masonry spans vertically and no shear transfer is required across control joints. Delete paragraph when not required. Control joints will be detailed on the drawings. When control joint keys are not required by design, such as at reinforced bond beams, the control joint detail will show the head joint completely filled with mortar for the width of the wythe; but joints will be flush, raked, or raked and sealed as required.

Provide control joint keys of a factory fabricated solid section of natural or synthetic rubber (or combination thereof) conforming to ASTM D2000 M2AA-805 with a minimum durometer hardness of 80 or polyvinyl chloride conforming to ASTM D2287 Type PVC 654-4 with a minimum durometer hardness of 85. Form the control joint key with a solid shear section not less than 5/8 inch thick and 3/8 inch thick flanges, with a tolerance of...
plus or minus 1.5 mm 1/16 inch, to fit neatly, but without forcing, in masonry unit jamb sash grooves.

2.6.6 Clay Masonry Expansion-Joint Materials

**************************************************************************
NOTE: Using interior low-VOC products contributes to meeting the requirements of Section 01 33 29 SUSTAINABILITY REQUIREMENTS AND REPORTING.
**************************************************************************

Provide backer rod and sealant, adequate to accommodate joint compression and extension equal to 50 percent of the width of the joint. Provide the backer rod of compressible rod stock of closed cell polyethylene foam, polyurethane foam, butyl rubber foam, or other flexible, nonabsorptive material as recommended by the sealant manufacturer. Provide sealant in conformance with Section 07 92 00 JOINT SEALANTS [with a maximum volatile organic compound (VOC) content of 600 grams/liter].

Submit one piece of each type of material used.

2.6.7 Through Wall Flashing and Weeps

**************************************************************************
NOTE: Require flashing in exterior masonry walls, including single-wythe construction, at all obstructions such as bond beams, sills, lintels, shelf angles, and concrete tie beams. The wall design and detailing must conform to National Concrete Masonry Association (NCMA) publications: TEK 19-2B, "Design for Dry Single-Wythe Concrete Masonry Walls"; TEK 19-4A, "Flash Strategies for Concrete Masonry Walls"; TEK 19-5A, "Lasing Details for Concrete Masonry Walls"; TEK 10-2C, "Control Joints for Concrete Masonry Walls"; and BIA Technical Notes 7 Water Penetration, Resistance. Show locations and details on project drawings. This is a regional requirement which must be used, when applicable, for NAVFAC SE projects; when appropriate, the requirements may be used for projects in other areas.

Copper may stain masonry and deteriorate in high chloride environments. Deformed copper may be specified only when mortar must bond to the flashing, such as under copings without dowels.

Through wall flashing of single wythe walls is not appropriate for all applications. Omit this section when design requires seismic shear resistance of the masonry wall.

**************************************************************************
2.6.7.1 General

Provide coated copper, copper or stainless steel sheet, self-adhesive rubberized sheet, or reinforced membrane sheet flashing [except that flashing indicated to terminate in reglets must be metal or coated-metal flashing] [and] [except that the material must be one which is not
adversely affected by dampproofing material.]

2.6.7.2 Coated-Copper Flashing

Provide 0.2 kg 7 ounce, electrolytic copper sheet, uniformly coated on both sides with acidproof, alkaliproof, asphalt impregnated kraft paper or polyethylene sheets.

2.6.7.3 Copper or Stainless Steel Flashing

Provide copper sheet, complying with ASTM B370, minimum 450 kg 16 ounce weight; or stainless steel, ASTM A167, Type 304 or 316, 0.4 mm 0.015 inch thick, No. 2D finish. [Where indicated, provide with factory-fabricated deformations that mechanically bond flashing against horizontal movement in all directions, where deformations consist of dimples, diagonal corrugations, or a combination of dimples and transverse corrugations.]

2.6.7.4 Reinforced Membrane Flashing

Provide polyester film core with a reinforcing fiberglass scrim bonded to one side. Provide membrane that is impervious to moisture, flexible, is not affected by caustic alkalis, and after being exposed for not less than 1/2 hour to a temperature of 0 degrees C 32 degrees F, shows no cracking when, at that temperature, it is bent 180 degrees over a 2 mm 1/16 inch diameter mandrel and then bent at the same point over the same size mandrel in the opposite direction 360 degrees.

2.6.7.5 Rubberized Flashing

Provide self-adhesive rubberized asphalt sheet flashing consisting of 0.8 mm 32-mil thick pliable and highly adhesive rubberized asphalt compound bonded completely and integrally to 0.2 8-mil thick, high density, cross-laminated polyethylene film to produce an overall thickness of 1 mm 40 mils. Provide rubberized, asphalt-based mastic and surface conditioner that are each approved by flashing manufacturer for use with flashing material.

2.6.7.6 Weep Ventilators

Provide weep ventilators that are prefabricated from stainless steel or plastic. Provide inserts with grill or louver-type openings designed to allow the passage of moisture from cavities and to prevent the entrance of insects, and with a rectangular closure strip to prevent mortar droppings from clogging the opening. Provide ventilators with compressible flanges to fit in a standard 10 mm 3/8 inch wide mortar joint and with height equal to the nominal height of the unit.

2.6.7.7 Single-Wythe Exterior Wall CMU Flashing System

In single-wythe exterior CMU walls, provide a system of CMU cell flashing pans and interlocking CMU web covers made from UV-resistant, high-density polyethylene. For exterior CMU walls, provide a flashing/weep system in open cores that do not receive grout. Cell flashing pans are to have integral weep spouts built into mortar bed joints that extend into the cell to prevent clogging with mortar.

2.6.7.8 Metal Drip Edge

Provide stainless steel drip edge, 0.4 mm 15-mil thick, hemmed edges, with
down-turned drip at the outside edge and upturned dam at the inside edge for use with membrane flashings.

2.6.8 RIGID BOARD-TYPE INSULATION

**************************************************************************
NOTE: Insert the appropriate thickness and R-Value to be used for the insulation. The total R-value for the insulation and the total thickness of the insulation must be coordinated to fit the space provided within the wall cavity. The thickness of the insulation must allow for not less than 19 mm 3/4 inch air space between the insulation and the facing veneer. This will limit the insulation thickness to 50 mm 2 inches in a 70 mm 2-3/4 inch cavity space. If greater insulation thickness is required the masonry wall must be designed to provide a larger cavity.

To assure adequate competition, an R-value should be chosen that allows several products to meet the specified thickness. The range of design R-values (in IP units) for foam insulations given by ASHRAE is 5 to 7 per inch. Verify range available from manufacturers. An aged R-value in SI units of 2 IP units of 11) can be readily achieved with 50 mm 2 inches of insulation.

Cellular plastic insulations (polystyrene, polyurethane and polyisocyanurate) are thermally efficient, however, certain precautions should be observed in their use due to high smoke development and toxicity of the smoke generated by the burning of these materials. Cellular plastic insulations should only be used in anchored veneer masonry walls where the insulation is completely isolated from the interior of the building by masonry, including all penetrations of the interior wythe.

**************************************************************************

Provide rigid board-type insulation as specified in Section 07 21 13 BOARD AND BLOCK INSULATION.

PART 3 EXECUTION

3.1 EXAMINATION

Prior to start of work, verify the applicable conditions as set forth in TMS MSJC, inspection.

3.2 PREPARATION

3.2.1 Stains

Protect exposed surfaces from mortar and other stains. When mortar joints are tooled, remove mortar from exposed surfaces with fiber brushes and wooden paddles. Protect base of walls from splash stains by covering adjacent ground with sand, sawdust, or polyethylene.
3.2.2 Loads

Do not apply uniform loads for at least 12 hours or concentrated loads for at least 72 hours after masonry is constructed. Provide temporary bracing as required.

3.2.3 Concrete Surfaces

Where masonry is to be placed, clean concrete of laitance, dust, dirt, oil, organic matter, or other foreign materials and slightly roughen to provide a surface texture with a depth of at least 3 mm 1/8 inch. Sandblast, if necessary, to remove laitance from pores and to expose the aggregate.

3.2.4 Shelf Angles

Adjust shelf angles as required to keep the masonry level and at the proper elevation.

3.2.5 Bracing

********************************************************************************
NOTE: TMS MSJC, Article 3.3 E Commentary references "Standard Practice for Bracing Masonry Walls Under Construction" for guidance on wall bracing requirements. Design wind pressure for bracing design is lower than that required by building code for long term building performance.********************************************************************************

Provide bracing and scaffolding necessary for masonry work. Design bracing to resist wind pressure as required by OSHA and local codes and submit bracing calculations, sealed by a registered professional engineer. Do not remove bracing in less than 10 days.

3.3 ERECTION

********************************************************************************
NOTE: Specify bond pattern for each type of masonry. Where more than one bond pattern is required, the drawings should indicate the location and extent of each bond pattern. Bond patterns for reinforced hollow masonry construction should be such that cores of units will be in vertical alignment. Perfect vertical alignment of cells may require special masonry units. Where stacked bond is specified in reinforced hollow masonry, provide horizontal reinforcing bars at maximum 1220 mm 4 foot intervals or horizontal joint reinforcement must be required in every other horizontal joint to provide mechanical bond between adjacent units. When veneer is specified to be laid in stack bond and the project is in Seismic Design Category E or higher, horizontal joint reinforcement consisting of a single wire size MW11 W1.7 is required at a maximum spacing of 460 mm 18 inches. The use of stacked bond is discouraged and should only be permitted for small wall areas to give an architectural feature, such as for a building entrance detail.********************************************************************************

SECTION 04 20 00 Page 45
3.3.1 General

a. Coordinate masonry work with the work of other trades to accommodate built-in items and to avoid cutting and patching. Lay masonry units in [running] [stacked] [the indicated] bond pattern. Lay facing courses level with back-up courses, unless the use of adjustable ties has been approved in which case the tolerances is plus or minus 13 mm 1/2 inch. Adjust each unit to its final position while mortar is still soft and has plastic consistency.

b. Remove and clean units that have been disturbed after the mortar has stiffened, and relay with fresh mortar. Keep air spaces, cavities, chases, expansion joints, and spaces to be grouted free from mortar and other debris. Select units to be used in exposed masonry surfaces from those having the least amount of chipped edges or other imperfections detracting from the appearance of the finished work.

c. When necessary to temporarily discontinue the work, step (rack) back the masonry for joining when work resumes. Toothing may be used only when specifically approved by the Contracting Officer. Before resuming work, remove loose mortar and thoroughly clean the exposed joint. Cover the top of walls subjected to rain or snow with nonstaining waterproof covering or membrane when work is not in process. Extend the covering a minimum of 610 mm 2 feet down on each side of the wall and hold securely in place.

d. Ensure that units being laid and surfaces to receive units are free of water film and frost. Lay solid units in a nonfurrowed full bed of mortar. Bevel mortar for veneer wythes and slope down toward the cavity side. Shove units into place so that the vertical joints are tight. Completely fill vertical joints between solid units with mortar, except where indicated at control, expansion, and isolation joints. Place hollow units so that mortar extends to the depth of the face shell at heads and beds, unless otherwise indicated. Mortar will be permitted to protrude up to 13 mm 1/2 inch into the space or cells to be grouted. Provide means to prevent mortar from dropping into the space below or clean grout spaces prior to grouting.

e. In multi-wythe construction with collar joints no more than 20 mm 3/4 inch wide, bring up the inner wythe not more than 400 mm 16 inches ahead of the outer wythe. Fill collar joints with mortar during the laying of the facing wythe, and do not lag the laying of the facing wythe by back-buttering each unit as it is laid.

3.3.1.1 Jointing

Tool mortar joints when the mortar is thumbprint hard. Tool horizontal joints after tooling vertical joints. Brush mortar joints to remove loose and excess mortar.

3.3.1.1.1 Tooled Joints

**************************************************************************
NOTE: Tooling any joint densifies the mortar bonding. Joints in exterior masonry walls exposed to weather will be tooled with an approved mortar jointer, typically a concave jointer. Other joints that are suitable for weathertight construction and
may be considered for architectural purposes are: Vee, Beaded, or Weathered types. Exposed to view or painted interior masonry walls will also be tooled, typically with a slightly concaved joint, but may also be tooled with other joint types as architecturally desired.

Tool mortar joints in exposed exterior and interior masonry surfaces [concave] [____], using a jointer that is slightly larger than the joint width so that complete contact is made along the edges of the unit. Perform tooing so that the mortar is compressed and the joint surface is sealed. Use a jointer of sufficient length to obtain a straight and true mortar joint. No exterior joints are to be left un-tooled.

3.3.1.1.2 Flush Joints

Flush cut mortar joints in concealed masonry surfaces and joints at electrical outlet boxes in wet areas. Finish flush cut joints by cutting off the mortar flush with the face of the wall. Point joints in unparged masonry walls below grade tight. For architectural units, such as fluted units, completely fill both the head and bed joints and flush cut.

3.3.1.1.3 Door and Window Frame Joints

On the exposed interior side of exterior frames, rake joints between frames and abutting masonry walls to a depth of 10 mm 3/8 inch. On the exterior side of exterior frames, rake joints between frames and abutting masonry walls to a depth of 10 mm 3/8 inch.

3.3.1.1.4 Joint Widths

a. Construct brick masonry with mortar joint widths equal to the difference between the specified and nominal dimensions of the unit, within tolerances permitted by TMS MSJC.

b. Provide 10 mm 3/8 inch wide mortar joints in concrete masonry, except for prefaced concrete masonry units.

c. Provide 10 mm 3/8 inch wide mortar joints on unfaced side of prefaced concrete masonry units and not less than 5 mm 3/16 inch nor more than 6 mm 1/4 inch wide on prefaced side.

d. Maintain mortar joint widths within tolerances permitted by TMS MSJC

3.3.1.2 Cutting and Fitting

Use full units of the proper size wherever possible, in lieu of cut units. Locate cut units where they would have the least impact on the architectural aesthetic goals of the facility. Perform cutting and fitting, including that required to accommodate the work of others, by masonry mechanics using power masonry saws. Concrete masonry units may be wet or dry cut. Before being placed in the work, dry wet-cut units to the same surface-dry appearance as uncut units being laid in the wall. Provide cut edges that are clean, true and sharp.
a. Carefully make openings in the masonry so that wall plates, cover plates or escutcheons required by the installation will completely conceal the openings and will have bottoms parallel with the masonry bed joints. Provide reinforced masonry lintels above openings over 300 mm 12 inches wide for pipes, ducts, cable trays, and other wall penetrations, unless steel sleeves are used.

b. Do not reduce masonry units in size by more than one-third in height and one-half in length. Do not locate cut products at ends of walls, corners, and other openings.

3.3.1.3 Unfinished Work

Rack back unfinished work for joining with new work. Tooothing may be resorted to only when specifically approved by the Contracting Officer. Remove loose mortar and thoroughly clean the exposed joints before laying new work.

3.3.1.4 Clay Masonry Expansion Joints

**************************************************************************
NOTE: Expansion joints in clay or shale masonry will be located and detailed on the drawings. The wall design and detailing must conform to BIA Technical Notes 18A Accommodating Expansion of Brickwork.
**************************************************************************

Provide clay masonry expansion joints as indicated. Construct by [leaving a gap] [filling with a compressible foam pad]. Ensure that no mortar or other noncompressible materials are within the joint. Install backer rod and sealant in accordance with Section 07 92 00 JOINT SEALANTS.

3.3.1.5 Control Joints

**************************************************************************
NOTE: Control joints will be located and detailed on the drawings. The wall design and detailing for movement control must conform to National Concrete Masonry Association (NCMA) publications: TEK 10-01A, and 10-02C or 10-03 or 10-04, as applicable. When control joint keys are required, it is the Contractor's option to use either special control joint units or sash jamb units with control joint keys. If one is preferred over the other in the design, edit this paragraph accordingly and provide specific details on the drawings. Standard industry practice is to discontinue horizontal reinforcement at control joints except at floor and roof diaphragms, where the reinforcement must be continuous. Where horizontal shear reinforcement is needed by design, however, the reinforcement must be continuous through the control joint. Select the appropriate option.
**************************************************************************

Provide control joints in concrete masonry as indicated. Construct by [raking out mortar within the head joint] [using special control-joint
units] [using sash jamb units with control joint key] [using open end stretcher units placed with the closed end at the joint] in accordance with the details shown on the Drawings. Form a continuous vertical joint at control joint locations, including through bond beams, by utilizing half blocks in alternating courses on each side of the joint. Interrupt the control joint key in courses containing continuous bond beam reinforcement. [Do not interrupt the horizontal reinforcement and grout at the control joint.] [Interrupt the horizontal reinforcement and grout in bond beams at the control joint except in bond beams at the floor and roof diaphragms.]

Where mortar was placed in the joint, rake both faces of the control joints to a depth of 19 mm 3/4 inch. Install backer rod and sealant on both faces in accordance with Section 07 92 00 JOINT SEALANTS.

3.3.1.6 Decorative Architectural Units

Place decorative masonry units with the patterned face shell properly aligned in the completed wall.

3.3.2 Clay or Shale Brick Masonry

******************************************************************************
NOTE: Specify type of bond required, if other than running bond is desired.
******************************************************************************

3.3.2.1 Brick Placement

Blend all brick at the jobsite from several cubes to produce a uniform appearance when installed. An observable "banding" or "layering" of colors or textures caused by improperly mixed brick is unacceptable. Lay brick facing with the better face exposed. Lay brick in running bond with each course bonded at corners, unless otherwise indicated. Lay molded brick with the frog side down. Do not lay brick that is cored, recessed, or has other deformations in a manner that allows those deformations to be exposed to view; lay 100 percent solid units in these areas. Completely fill head and bed joints of solid units with mortar. Lay hollow units with mortar joints as specified for concrete masonry units. [Lay fire brick by dipping each brick in a soft mixture of fire clay and water and then rubbing the brick into place with joints as thin as practicable or provide refractory mortar with joints not more than 10 mm 3/8 inch thick.]

Place exterior face of salvaged bricks towards the exterior.

3.3.2.2 Wetting of Units

******************************************************************************
NOTE: If clay, shale brick, or hollow brick is specified, include wetting requirements for units having an initial rate of absorption (IRA) of more than 0.155 gm per minute per square cm 1 gm per minute per square inch of bed surface.

IRA is measured in the laboratory and reported in test results. However, the IRA can increase under hot weather conditions in the field. The wax pencil test can approximate the field IRA condition.
******************************************************************************
Wet clay, shale brick, or hollow brick units having an initial rate of absorption of more than 0.155 gm per minute per square cm 1 gram per minute per square inch of bed surface in conformance with ASTM C67/C67M. Ensure that each unit is nearly saturated when wetted but surface dry when laid.

Test clay or shale brick daily on the job, prior to laying, as follows: Using a wax pencil, draw a circle the size of a quarter on five randomly selected bricks. Apply 20 drops of water with a medicine dropper to the surface within the circle on each brick. If the average time that the water is completely absorbed in the five bricks is less than 1-1/2 minutes, wet bricks represented by the five bricks tested.

3.3.2.3 Brick Sills

**************************************************************************
NOTE: Brick sills are more susceptible to freeze-/thaw damage and should be carefully considered in freezing climates.
**************************************************************************

Lay brick on edge, slope not less than 19 mm 3/4 inch downward to the outside, and project not less than 13 mm 1/2 inch beyond the face of the wall to form a wash and drip. Fill all joints solidly with mortar and tool.

3.3.2.4 Reinforced Brick Walls

**************************************************************************
NOTE: Multi-wythe walls with masonry headers are more susceptible to water penetration and efflorescence.
**************************************************************************

Show required length of reinforcing bar lap splices on the Drawings or by a schedule in the Specification. Required lap length of bars may be different depending on whether the masonry is designed by allowable stress or by strength.

**************************************************************************
Provide two wythes of brick separated by a [_____] mm inch wide continuous space filled with [grout] [bricks "floated" in grout] and reinforced as indicated. Bevel mortar beds away from grout space to prevent projection into grout space when bricks are shoved in place. Deeply furrowed bed joints will not be permitted. Lay exterior wythe of brick to the height of each grout pour in advance of interior wythe. Clean grout space and set reinforcing before laying interior wythe. Provide metal ties to prevent spreading of the wythes and to maintain vertical alignment of walls. Place reinforcement and grout in accordance with paragraph BAR REINFORCEMENT INSTALLATION and paragraph PLACING GROUT in this Section.

3.3.2.5 Chimneys

**************************************************************************
NOTE: If a chimney wall is 200 mm 8 inches or less in thickness, the space between the flue liner and brickwork should be kept clean and clear to avoid cracking the brickwork.
**************************************************************************
Construct chimneys of brick with clay flue linings of the sizes indicated. Extend flue linings from 300 mm 12 inches below the smoke inlet to 100 mm 4 inches above the chimney cap. Place thimbles as indicated, flush with inside of or up to 25 mm one inch into the flue lining. Set linings in fire clay mortar or refractory mortar and fill and smooth the joints on the inside. Set each section of flue lining before surrounding brickwork reaches top of flue lining section below. Build brickwork around lining, and [fill the space] [leave a 25 mm one inch airspace] between lining and brickwork [with grout]. [Seal top of airspace before installing chimney cap.] Do not cut linings after they are installed in chimney. Unless indicated otherwise, provide a chimney cap of air-entrained concrete. Slope cap to a minimum edge thickness of 50 mm 2 inches and reinforce with two rings of No. 3 gage galvanized steel wire.

3.3.2.6 Partitions

**************************************************************************
NOTE: Walls and partitions that serve as fire walls or fire-rated walls will be shown. Sections and details of these walls will clearly indicate the extent of such walls. Non-structural masonry partition walls will not be tied in any way to structural or exterior masonry walls. Isolation joints will be used at these intersections. When 100 mm 4 inch masonry partitions are not used, delete reference to these units and their intersections.
**************************************************************************

a. Construct partitions continuous from floor to underside of floor or roof deck where shown. Fill openings in firewalls around joists and other structural members as indicated or approved. Where suspended ceilings on both sides of partitions are indicated, the partitions other than those shown to be continuous may be stopped approximately 100 mm 4 inches above the ceiling level. Construct an isolation joint in the intersection between partitions and structural or exterior walls.

b. Tie interior partitions having 100 mm 4 inch nominal thickness units to intersecting partitions of 100 mm 4 inch units, 125 mm 5 inches into partitions of 150 mm 6 inch units, and 175 7 inches into partitions of 200 mm 8 inch or thicker units. Fill cells within vertical plane of ties solid with grout for full height of partition or solid masonry units may be used. Tie interior partitions over 100 mm 4 inches thick together with joint reinforcement. Provide joint reinforcement with prefabricated pieces at corners and intersections of partitions.

c. Double-Faced Bases or Partitions: Construct double-faced clay unit bases and partitions of two-unit construction. Bond units by overlapping from opposite faces of the wall, 50 mm for 150 mm 2 inches for 6 inch thick partitions and 100 mm for 200 mm 4 inches for 8 inch thick or greater. A single wythe prefaced concrete masonry base or partition may be made with double faced units.

3.3.3 Anchored Veneer Construction

**************************************************************************
NOTE: The air space behind the veneer should be a minimum of 25 mm 1 inch. The maximum distance
between the inside face of veneer and outside face of backing (concrete surface, masonry surface, or wood or steel stud face) should be 114 mm 4.5 inches, unless specially designed anchors are used. Coordinate cavity dimensions with standard lintel and shelf angle dimensions.

Bond pattern should be running bond unless there are compelling architectural reasons to select another pattern.

Adjustable assemblies are normally used when constructing one wythe independent of the other. If the design does not permit this type of construction, delete the reference pertaining to adjustable joint reinforcement assemblies. The preferred method of construction, however, is to bring the wythes up together. Typically, continuous joint reinforcement is used to tie the two wythes together as well as providing for shrinkage cracking control. Continuous joint reinforcement, used as wall ties, will typically be spaced not over 400 mm 16 inches on center vertically. Spacing of joint reinforcement will be shown on the contract drawings.

Refer to "Maximum Spacing and Wall Area for Veneer Anchors" table for required wall area per anchor, and maximum vertical and horizontal spacing of veneer anchors based on anchor type, wind loads, and seismic loads per TMS MSJC.

| Maximum Vertical Spacing | 635 mm 25 inch          | 635 mm 25 inch     | 635 mm 25 inch | 635 mm 25 inch |

**In Seismic Design Categories E and F, a continuous single wire joint reinforcement of wire size MW 11 W1.7 at a maximum vertical spacing of 457 mm 18 inch is required.**

For the additional anchors (ties) around openings, the maximum permitted spacing is reduced under high wind (over 1.92 kPa 40 psf) conditions and when the building's mean roof height does not exceed 18.3 m 60 feet; select the smaller spacing option when the veneer is subject to high winds.

**************************************************************************

a. Construct exterior masonry wythes to the thickness indicated on the drawings. Provide a minimum [_____] mm inch air space behind the masonry veneer. Provide means to ensure that the cavity space and flashings are kept clean of mortar droppings and other loose debris. Maintain chases and raked-out joints free from mortar and debris.

b. Place masonry [in running bond pattern.] [in stacked bond pattern.] [Place longitudinal reinforcement, consisting of at least one continuous hot-dip galvanized MW11 W 1.7 (9gauge) steel wire, in the veneer wythe when laid in stack bond.]

c. For veneer over stud framing, do not install veneer until the exterior sheathing, moisture barrier, veneer anchors and flashing have been installed on the backing. Take extreme care to avoid damage to the moisture barrier and flashing during construction of the masonry veneer. Repair or replace portions of the moisture barrier and flashing that are damaged prior to completion of the veneer. Provide a

---

SECTION 04 20 00 Page 53
continuous cavity as indicated.

d. For veneer with a masonry backup wythe, lay up both the inner and the outer wythes together except when adjustable joint reinforcement assemblies are approved for use. When both wythes are not brought up together, install through-wall flashings with the exterior wythe, securing the top edge of the flashing with a termination bar and sealant, or protect flashings that are installed with the interior wythe from damage until they are fully enclosed in the wall.

e. Provide anchors (ties) to connect the veneer to its backing in sufficient quantity to comply with the following requirements: maximum wall area per anchor (tie) of [_____] and maximum vertical spacing of [_____] and maximum horizontal spacing of [_____].. Provide additional anchors around openings larger than 406 mm 16 inch in either direction. Space anchors around perimeter of opening at a maximum of [0.91 m 3 feet][610 mm24 inches] on center. Place anchors within 305 mm 12 inches of openings. Anchors with drips are not permitted.

f. With solid units, embed anchors in mortar joint and extend into the veneer a minimum of 38 mm 1-1/2 inch, with at least 16 mm 5/8 inch mortar cover to the outside face.

g. With hollow units, embed anchors in mortar or grout and extend into the veneer a minimum of 38 mm 1-1/2 inch, with at least 16 mm 5/8 inch mortar or grout cover to outside face.

3.3.4 Composite Walls

Tie masonry wythes together with joint reinforcement or with unit wall ties. Embed wall ties at least 38 mm 1-1/2 inch into mortar of solid units and at least 13 mm 1/2 inch into the mortar of the outer face shell of hollow units. Provide at least one tie every 0.25 square m 2.67 square feet for wire size MW11 W1.7 and at least one tie every 0.42 square m 4.50 square feet for wire size MW18 W2.8. Space ties at a maximum of 900 mm 36 inches horizontally and 610 mm 24 inches vertically. Do not cross expansion joints or control joints with ties. Fill collar joints between masonry facing and masonry backup solidly with grout.

3.3.5 Reinforced, Single Wythe Concrete Masonry Units Walls

**************************************************************************
NOTE: For single-wythe, concrete masonry unit exterior walls, specify water-repellant application for the constructed masonry walls or specify integral water repellent admixture for both the masonry units and the mortar. Units with an impervious coating, such as glazed-faced units, do not require a water-repellent. This is a regional requirement which must be used, when applicable, for NAVFAC SE projects; when appropriate, the requirements may be used for projects in other areas.

Show required length of reinforcing bar lap splices on the Drawings or by a schedule in the Specification. Required lap length of bars may be different depending on whether the masonry is designed by allowable stress or by strength.

**************************************************************************
3.3.5.1 Concrete Masonry Unit Placement

a. Fully bed units used to form piers, pilasters, columns, starting courses on footings, solid foundation walls, lintels, and beams, and where cells are to be filled with grout in mortar under both face shells and webs. Provide mortar beds under both face shells for other units. Mortar head joints for a distance in from the face of the unit not less than the thickness of the face shell.

b. Solidly grout foundation walls below grade.

c. Stiffen double walls at wall-mounted plumbing fixtures by use of strap anchors, two above each fixture and two below each fixture, located to avoid pipe runs, and extending from center to center of each wall within the double wall. Adequately reinforce walls and partitions for support of wall-hung plumbing fixtures when chair carriers are not specified.

d. Submit drawings showing elevations of walls exposed to view and indicating the location of all cut CMU products.

3.3.5.2 Preparation for Reinforcement

Lay units in such a manner as to preserve the unobstructed vertical continuity of cores to be grouted. Remove mortar protrusions extending 13 mm 1/2 inch or more into cells before placing grout. Position reinforcing bars accurately as indicated before placing grout. Where vertical reinforcement occurs, fill cores solid with grout in accordance with paragraph PLACING GROUT in this Section.

3.3.6 Cavity Walls (Multi-Wythe Noncomposite Walls)

NOTE: Include dampproofing or air barrier requirements in geographic areas where these are required or as an acceptable practices. Now that masonry wall cavities are usually at least half full of rigid board insulation, and the backup wythe is usually completed before the brickwork is started, the wood strip method of keeping the cavities clean is neither practicable nor effective. A mortar divertingal placed at the bottom of the cavity will provide a path for water to drain through the weep holes. The specified method for concrete masonry unit and brick cavity wall is effective, but may be deleted if the specifier is reluctant to require it. Care must be taken (1) to prevent damage to mortar joints, especially adjacent to the washout holes, and (2) to prevent accumulation of water at the bottom of the wall. The cavities must be inspected to verify that they are clean and functional.

Refer to "Maximum Spacing and Wall Area for Ties" table for maximum wall area per tie, and maximum vertical and horizontal spacing of ties based on tie type per TMS MSJC.

For NAVFAC SE projects, use second bracketed statement in the eighth sentence.

Provide a continuous cavity as indicated. Bevel mortar beds away from cavity to prevent projection into cavity when bricks are shoved in place. Keep cavities clear and clean of mortar droppings. [At the bottom of cavity walls, in the course immediately above the through-wall flashing, temporarily omit one brick every 1200 mm 4 feet. Clean mortar droppings and debris out of the cavity through the temporary openings at least once each day masonry is laid, and more often when required to keep the cavities clean. Fill in the openings with bricks and mortar after the wall is complete and the cavity has been inspected and found clean.] [Dampproof cavity face of interior wythe in accordance with Section 07 11 13 BITUMINOUS DAMPPROOFING.]

Securely tie the two wythes together with horizontal joint reinforcement, or provide ties to connect the masonry wythes in sufficient quantity to comply with the following requirements: maximum wall area per tie of [____], and maximum vertical spacing of [____], and maximum horizontal spacing of [____]. Provide additional ties around openings larger than 405 mm 16 inches in either direction. Space ties around perimeter of opening at a maximum of 910 mm 3 feet on center. Place ties within 305 mm 12 inches of openings. Ties with drips are not permitted.

3.3.7 ANCHORAGE

NOTE: If spacing of anchors varies from that specified, edit these paragraphs accordingly.

For intersecting structural masonry walls, delete the types of anchorage that are not permitted for
3.3.7.1 Anchorage to Concrete

Anchor masonry to the face of concrete columns, beams, or walls with dovetail anchors spaced not over 400 mm 16 inches on centers vertically and 600 mm 24 inches on center horizontally.

3.3.7.2 Anchorage to Structural Steel

Anchor masonry to vertical structural steel framing with adjustable steel wire anchors spaced not over 400 mm 16 inches on centers vertically, and if applicable, not over 600 mm 24 inches on centers horizontally.

3.3.7.3 Anchorage at Intersecting Walls

Provide wire mesh anchors at maximum 400 mm 16 inches spacing at intersections of interior non-bearing masonry walls.

3.3.8 Lintels

3.3.8.1 Masonry Lintels

Construct masonry lintels with lintel units filled solid with grout in all courses and reinforced with a minimum of two No. 4 bars in the bottom course unless otherwise indicated. Extend lintel reinforcement beyond each side of masonry opening 40 bar diameters or 600 mm 24 inches, whichever is greater. Support reinforcing bars in place prior to grouting and locate 13 mm 1/2 inch above the bottom inside surface of the lintel unit.

3.3.8.2 Precast Concrete and Steel Lintels

Provide precast concrete and steel lintels as shown on the Drawings. Set lintels in a full bed of mortar with faces plumb and true. Provide steel and precast lintels with a minimum bearing length of 200 mm 8 inches unless otherwise indicated. In partially grouted masonry, provide fully grouted units under the full lintel bearing length, unless otherwise indicated.

3.3.9 Sills and Copings

NOTE: Coping and sills exceeding 1200 mm 4 feet
should be mechanically anchored and detailed on the project drawings. Where such anchors penetrate through-wall flashing, sealing of the penetration should be required.

**************************************************************************

Set sills and copings in a full bed of mortar with faces plumb and true. Slope sills and copings to drain water. Mechanically anchor copings and sills longer than 1200 mm 4 feet as indicated.

3.4 INSTALLATION

3.4.1 Bar Reinforcement Installation

3.4.1.1 Preparation

Submit detail drawings showing bar splice locations. Identify bent bars on a bending diagram and reference and locate such bars on the drawings. Show wall dimensions, bar clearances, and wall openings. Utilize bending details that conform to the requirements of ACI SP-66. No approval will be given to the shop drawings until the Contractor certifies that all openings, including those for mechanical and electrical service, are shown. If, during construction, additional masonry openings are required, resubmit the approved shop drawings with the additional openings shown along with the proposed changes. Clearly highlight location of these additional openings. Provide wall elevation drawings with minimum scale of 1 to 50 1/4 inch per foot. Submit drawings including plans, elevations, and details of wall reinforcement; details of reinforcing bars at corners and wall intersections; offsets; tops, bottoms, and ends of walls; control and expansion joints; lintels; and wall openings.

Clean reinforcement of loose, flaky rust, scale, grease, mortar, grout, and other coatings that might destroy or reduce its bond prior to placing grout. Do not use bars with kinks or bends not shown on the approved shop drawings. Place reinforcement prior to grouting. Unless otherwise indicated, extend vertical wall reinforcement to within 50 mm 2 inches of tops of walls.

3.4.1.2 Positioning Bars

**************************************************************************

NOTE: Positioning of bars will be shown on the drawings.

**************************************************************************

a. Accurately place vertical bars within the cells at the positions indicated on the drawings. Maintain a minimum clearance of 13 mm 1/2 inch between the bars and masonry units. Provide minimum clearance between parallel bars of 13 mm 1/2 inch between the bars and masonry units for coarse grout and a minimum clearance of 6 mm 1/4 inch between the bars and masonry units for fine grout. Provide minimum clearance between parallel bars of 25 mm 1 inch or one diameter of the reinforcement, whichever is greater. Vertical reinforcement may be held in place using bar positioners located near the ends of each bar and at intermediate intervals of not more than 192 diameters of the reinforcement or by other means to prevent displacement beyond permitted tolerances. As masonry work progresses, secure vertical reinforcement to prevent displacement beyond allowable tolerances.
b. Wire column and pilaster lateral ties in position around the vertical reinforcing bars. Place lateral ties in contact with the vertical reinforcement and do not place in horizontal mortar bed joints.

c. Position horizontal reinforcing bars as indicated. Stagger splices in adjacent horizontal bars, unless otherwise indicated.

d. Form splices by lapping bars as indicated. Do not cut, bend or eliminate reinforcing bars. Foundation dowel bars may be field-bent when permitted by TMS MSJC.

3.4.1.3 Splices of Bar Reinforcement

**************************************************************************
NOTE: The designer must determine the required lap splice lengths and indicate on the project documents. Required lap splice length may vary depending upon whether the masonry is designed by allowable stress or strength.
**************************************************************************

Lap splice reinforcing bars as indicated. When used, provide welded or mechanical connections that develop at least 125 percent of the specified yield strength of the reinforcement.

3.4.2 Placing Grout

**************************************************************************
NOTE: Mechanical consolidation of self-consolidating grout should not be performed because it may cause segregation. When placing self-consolidating grout, the properties listed in ASTM C476 should be verified.
**************************************************************************

3.4.2.1 General

Fill cells containing reinforcing bars with grout. Solidly grout hollow masonry units in walls or partitions supporting plumbing, heating, or other mechanical fixtures, voids at door and window jambs, and other indicated spaces. Solidly grout cells under lintel bearings on each side of openings for full height of openings. Solidly grout walls below grade, lintels, and bond beams. Units other than open end units may require grouting each course to preclude voids in the units.

Discard site-mixed grout that is not placed within 1-1/2 hours after water is first added to the batch or when the specified slump is not met without adding water after initial mixing. Discard ready-mixed grout that does not meet the specified slump without adding water other than water that was added at the time of initial discharge. Allow sufficient time between grout lifts to preclude displacement or cracking of face shells of masonry units. Provide a grout shear key between lifts when grouting is delayed and the lower lift loses plasticity. If blowouts, flowouts, misalignment, or cracking of face shells should occur during construction, tear down the wall and rebuild.

3.4.2.2 Vertical Grout Barriers for Multi-Wythe Composite Walls

In multi-wythe composite walls, provide grout barriers in the collar join
not more than 9 m 30 feet apart, or as required, to limit the horizontal flow of grout for each pour.

3.4.2.3 Horizontal Grout Barriers

Embed horizontal grout barriers in mortar below cells of hollow units receiving grout.

3.4.2.4 Grout Holes and Cleanouts

3.4.2.4.1 Grout Holes

Provide grouting holes in slabs, spandrel beams, and other in-place overhead construction. Locate holes over vertical reinforcing bars or as required to facilitate grout fill in bond beams. Provide additional openings spaced not more than 400 mm 16 inches on centers where grouting of hollow unit masonry is indicated. Fom such openings not less than 100 mm 4 inches in diameter or 75 by 100 mm 3 by 4 inches in horizontal dimensions. Upon completion of grouting operations, plug and finish grouting holes to match surrounding surfaces.

3.4.2.4.2 Cleanouts for Hollow Unit Masonry Construction

For hollow masonry units, provide cleanout holes at the bottom of every grout pour in cores containing vertical reinforcement when the height of the grout pour exceeds 1.6 m 5 feet 4 inches. Where all cells are to be grouted, construct cleanout courses using bond beam units in an inverted position to permit cleaning of all cells. Provide cleanout holes at a maximum spacing of 800 mm 32 inches where all cells are to be filled with grout.

Establish a new series of cleanouts if grouting operations are stopped for more than 4 hours. Provide cleanouts not less than 75 by 75 mm 3 by 3 inch by cutting openings in one face shell. Manufacturer's standard cutout units may be used at the Contractor's option. Do not cleanout holes until masonry work, reinforcement, and final cleaning of the grout spaces have been completed and inspected. For walls which will be exposed to view, close cleanout holes in an approved manner to match surrounding masonry.

3.4.2.4.3 Cleanouts for Multi-Wythe Composite Masonry Construction

Provide cleanouts for construction of walls that incorporate a grout filled cavity between solid masonry wythes, provide cleanouts at the bottom of every pour by omitting every other masonry unit from one wythe. Establish a new series of cleanouts if grouting operations are stopped for more than 4 hours. Do not plug cleanout holes until masonry work, reinforcement, and final cleaning of the grout spaces have been completed and inspected. For walls which will be exposed to view, close cleanout holes in an approved manner to match surrounding masonry.

3.4.2.5 Grout Placement

******************************************************************************

NOTE: The requirements listed are for normal grouting procedures. Other options, such as higher grout lifts, higher grout pours, or alternate methods of keeping the grout space clean, may be acceptable if proven through the process of constructing and examining a grout demonstration.

SECTION 04 20 00 Page 60
A grout pour is the total height of masonry to be grouted prior to erection of additional masonry. A grout lift is an increment of grout placement within a grout pour. A grout pour is filled by one or more lifts of grout. Maximum grout pour height is based on grout type (fine or coarse) and dimensions of grout space, per TMS MSJC Table 7. Fine grout has sand as the only aggregate while coarse grout uses both sand and pea gravel up to 10 mm 3/8 inch diameter. Coarse grout is preferred when grout will be placed in relatively large cross-sectional areas because shrinkage of the grout is reduced.

By following the TMS grout pour and lift recommendations and using grout of the proper consistency, grout placement occurs at a rate that does not cause displacement of masonry due to hydrostatic pressure of grout. Self-consolidating grout (SCG) attains its flow primarily from superplasticizing admixtures, not water, so it exerts a lower hydrostatic pressure than conventional grout during placement. Grout should be placed as rapidly as practical by methods that do not cause segregation and that minimize splatter on reinforcement and surrounding masonry. Conventional grout lifts should be consolidated (and reconsolidated) by mechanical vibration before the next lift is placed. SCG does not need to be consolidated.

******************************************************************************

A grout pour is the total height of masonry to be grouted prior to erection of additional masonry. A grout lift is an increment of grout placement within a grout pour. A grout pour is filled by one or more lifts of grout.

a. Lay masonry to the top of a pour permitted by TMS MSJC Table 7, based on the size of the grout space and the type of grout. Prior to grouting, remove masonry protrusions that extend 13 mm 1/2 inch or more into cells or spaces to be grouted. Provide grout holes and cleanouts in accordance with paragraph GROUT HOLES AND CLEANOUTS above when the grout pour height exceeds 1.6 m 5 feet 4 inches. Hold reinforcement, bolts, and embedded connections rigidly in position before grouting is started. Do not prewet concrete masonry units.

b. Place grout using a hand bucket, concrete hopper, or grout pump to fill the grout space without segregation of aggregate. Operate grout pumps to produce a continuous stream of grout without air pockets, segregation, or contamination.

c. If the masonry has cured at least 4 hours, grout slump is maintained between 250 and 275 mm 10 to 11 inches, and no intermediate reinforced bond beams are placed between the top and bottom of the pour height, place conventional grout in lifts not exceeding 3.9 m 12 feet 8 inches. For the same curing and slump conditions but with intermediate bond beams, limit conventional grout lift to the bottom of the lowest bond beam that is more than 1.6 m 5 feet 4 inches above the bottom of the lift, but do not exceed 3.9 m 12 feet 8 inches. If masonry has not
cured at least 4 hours or grout slump is not maintained between 250 and 275 mm 10 to 11 inches, place conventional grout in lifts not exceeding 1.6 m 5 feet 4 inches.

d. Consolidate conventional grout lift and reconsolidate after initial settlement before placing next lift. For grout pours that are 300 mm 12 inches or less in height, consolidate and reconsolidate grout by mechanical vibration or puddling. For grout pours that are greater than 300 mm 12 inches in height, consolidate and reconsolidate grout by mechanical vibration. Apply vibrators at uniformly spaced points not further apart than the visible effectiveness of the machine. Limit duration of vibration to time necessary to produce satisfactory consolidation without causing segregation. If previous lift is not permitted to set, dip vibrator into previous lift. Do not insert vibrators into lower lifts that are in a semi-solidified state. If lower lift sets prior to placement of subsequent lift, form a grout key by terminating grout a minimum of 38 mm 1-1/2 inch below a mortar joint. Vibrate each vertical cell containing reinforcement in partially grouted masonry. Do not form grout keys within beams.

e. If the masonry has cured 4 hours, place self-consolidating grout (SCG) in lifts not exceeding the pour height. If masonry has not cured for at least 4 hours, place SCG in lifts not exceeding 1.6 m 5 feet 4 inches. Do not mechanically consolidate self-consolidating grout. Place self-consolidating grout in accordance with manufacturer's recommendations.

f. Upon completion of each day's grouting, remove waste materials and debris from the equipment, and dispose of outside the masonry.

3.4.3 Joint Reinforcement Installation

**************************************************************************
NOTE: Location of horizontal joint reinforcement should be shown on the drawings with the maximum vertical spacing normally being 400 mm 16 inches. A 150 mm 6 inch lap splice length is sufficient for joint reinforcement whose only purpose is shrinkage control. Joint reinforcement that is used structurally may need longer lap splices.
**************************************************************************

Install joint reinforcement at 400 mm 16 inches on center unless otherwise indicated. Lap joint reinforcement not less than [150] [_____] mm [6] [_____] inches. Install prefabricated sections at corners and wall intersections. Place the longitudinal wires of joint reinforcement in mortar beds to provide not less than 16 mm 5/8 inch cover to either face of the unit.

3.4.4 Bond Beams

**************************************************************************
NOTE: Bond beams that are continuous over openings will be reinforced to serve as lintels.
**************************************************************************

Bond beams at floor lines and roofs, where the beam acts as a tension tie for the diaphragm, are typically reinforced continuously through masonry movement joints, and the mortar is raked back and
finished with backer rod and sealant. Intermediate bond beams are typically detailed with the reinforcement interrupted, but doweled, at control joints and again finished with raked back mortar, backer rod and sealant.

Interior control joints are raked to weaken the joint to focus cracks in the control joint and caulked so that 1) cracks don’t show and 2) provide a second line of defense should moisture try to travel through the cracks in the control joint.

Reinforce and grout bond beams as indicated and as described in paragraphs above. Install grout barriers under bond beam units to retain the grout as required, unless wall is fully grouted or solid bottom units are used. For high lift grouting in partially grouted masonry, provide grout retaining material on the top of bond beams to prevent upward flow of grout. Ensure that reinforcement is continuous, including around corners, except through control joints or expansion joints, unless otherwise indicated.

3.4.5 Flashing and Weeps

NOTE: Locate weeps and ventilators to ensure that in severe weather, wind driven water does not enter and drain into the interstitial space. Indicate acceptable locations on drawings.

Weep spacing of **610 mm 24 inches** is appropriate for open head joint weeps and weep vents. When smaller weeps are used, the spacing should be reduced to **406 mm 16 inches**.

Provide a flashing/weep system for open cores (non-grouted) of exterior single wythe CMU walls.

a. Install through-wall flashing at obstructions in the cavity and where indicated on Drawings. Ensure continuity of the flashing at laps and inside and outside corners by splicing in a manner approved by the flashing manufacturer. Ensure that the top edge of the flashing is sealed by [turning the flashing 13 mm 1/2 inch into the mortar bed joint of backup masonry] [attaching a termination bar and applying compatible sealant at the top edge of the termination bar] [lapping a minimum of 150 mm 6 inches under the weather resistive barrier] [securing the sheet metal flashing into a reglet cast into the concrete backup]. Terminate the horizontal leg of the flashing [by extending the sheet metal 13 mm 1/2 inch beyond the outside face of masonry and turning downward with a hemmed drip] [terminating the fabric flashing 13 mm 1/2 inch short of the outside face of masonry and adhering the flashing to a sheet metal drip edge] [extending the fabric flashing beyond the outside face of masonry and, when construction is complete, cutting the flashing flush with the face of masonry]. Provide sealant below the drip edge of through-wall flashing.

b. Wherever through-wall flashing occurs, provide weep holes to drain flashing to exterior at acceptable locations as indicated. Provide weeps of [open head joints][weep ventilators]. Locate weeps not more
than 600 mm 24 inches on centers in mortar joints of the exterior wythe directly on the horizontal leg of through-wall flashing over foundations, bond beams, and any other horizontal interruptions of the cavity. Place weep holes perfectly horizontal or slightly canted downward to encourage water drainage outward and not inward. Other methods may be used for providing weeps when spacing is reduced to 406 mm 16 inches on center and approved by the Contracting Officer. Maintain weeps free of mortar and other obstructions.

[ c. Install single-wythe CMU flashing system in bed joints of CMU walls where CMU cells are open. Install CMU cell pans with upturned edges located below face shells and webs of CMUs above and with weep spouts aligned with face of wall on the exterior side. Install CMU web covers so that they cover upturned edges of CMU cell pans at CMU webs and extend from face shell to face shell.]

3.5 APPLICATION

3.5.1 Insulation

**************************************************************************
NOTE: Specify taping or sealing of board joints when the insulation must act as the air or vapor barrier.
**************************************************************************

Insulate cavity walls (multi-wythe noncomposite masonry walls), where shown, by installing board-type insulation on the cavity side of the inner wythe. Apply board type insulation directly to the masonry or thru-wall flashing with adhesive. Neatly fit insulation between obstructions without impaling insulation on ties or anchors. Apply insulation in parallel courses with vertical joints breaking midway over the course below and in moderate contact with adjoining units without forcing. Cut to fit neatly against adjoining surfaces. [Tape or seal the joints between the boards.]

3.5.2 Interface with Other Products

**************************************************************************
NOTE: Label "wet locations" on the drawings.
**************************************************************************

3.5.2.1 Built-In Items

Fill spaces around built-in items with mortar. Point openings around flush-mount electrical outlet boxes in wet locations with mortar. Embed anchors, ties, wall plugs, accessories, flashing, pipe sleeves and other items required to be built-in as the masonry work progresses. Fully embed anchors, ties and joint reinforcement in the mortar. Fill cells receiving anchor bolts and cells of the first course below bearing plates with grout, unless otherwise indicated.

3.5.2.2 Door and Window Frame Joints

On the exposed interior and exterior sides of exterior frames, rake joints between frames and abutting masonry walls to a depth of 10 mm 3/8 inch.

3.5.2.3 Bearing Plates

**************************************************************************
NOTE: The bearing details must be shown on the drawings. The thermal effects must be considered for steel beams bearing on masonry to prevent cracking of masonry walls due to thermal expansion of steel framing members.

Set bearing plates for beams, joists, joist girders and similar structural members to the proper line and elevation with damp-pack bedding mortar, except where non-shrink grout is indicated. Provide bedding mortar and non-shrink grout as specified in Section 03 30 00 CAST-IN-PLACE CONCRETE.

3.5.3 Tolerances

Lay masonry plumb, true to line, with courses level within the tolerances of TMS MSJC, Article 3.3 F.

3.6 FIELD QUALITY CONTROL

3.6.1 Tests

3.6.1.1 Field Testing of Mortar

NOTE: Field testing of mortar should be limited or avoided. Better information can be obtained by observing mortar batching to confirm that proper proportions and mixing procedures have been followed. When field testing is required, verification of proportions is preferred to mortar compressive strength testing. Results are available in a matter of hours rather than days or weeks. Proportions of fresh mortars can be determined by running the mortar aggregate ratio test of ASTM C780 Appendix A4. Mortar compressive strength, tested in accordance with ASTM C780 Appendix 6, is not required or expected to meet the property requirements of ASTM C270 Table 2 and has more meaningful comparisons to preconstruction test values to evaluate consistency. Therefore, when mortar is tested for compressive strength, testing must be performed prior to construction as well as during construction. Frequency of testing, if any, depends on the size and complexity of the project. Modify paragraph below to advise required frequency of testing and type(s) of testing required.

Perform mortar testing at the following frequency: [_____] times per [______]. For each required mortar test, provide a minimum of three mortar samples. Perform initial mortar testing prior to construction for comparison purposes during construction.

Prepare and test mortar samples for mortar aggregate ratio in accordance with ASTM C780 Appendix A4. [Prepare and test mortar compressive strength specimens in accordance with ASTM C780 Appendix A6.]
3.6.1.2 Field Testing of Grout

**NOTE:** Field testing of grout involves measuring temperature, slump of conventional grout, slump flow of SCG, visual stability index of SCG, and compressive strength. Field testing of grout is not required when masonry compressive strength is verified by the prism test method.

Frequency of testing depends on the size and complexity of the project. Minimum requirements for testing frequency are provided in TMS MSJC Tables 1.19.1, 1.19.2, and 1.19.3 depending upon how the masonry is designed (prescriptive or engineered) and the Risk Category of the project. Modify paragraph below to advise required frequency of testing.

a. Perform grout testing at the following frequency: [_____] times per [______]. For each required grout property to be evaluated, provide a minimum of three specimens.

b. Sample and test conventional and self-consolidating grout for compressive strength and temperature in accordance with ASTM C1019.

c. Evaluate slump in conventional grout in accordance with ASTM C1019.

d. Evaluate slump flow and visual stability index of self-consolidating grout in accordance with ASTM C1611/C1611M.

[3.6.1.3 Clay Brick Efflorescence Test

**NOTE:** Delete this paragraph in areas where efflorescence has not been a problem. Efflorescence is generally the result of poor design and detailing and/or poor quality of construction. Properly covered and/or flashed walls with a good drainage and weep system are generally free of efflorescence. Efflorescence testing is generally not required.

Test clay brick that will be exposed to weathering for efflorescence in accordance with ASTM C67/C67M. Schedule tests far enough in advance of starting masonry work to permit retesting if necessary. Units meeting the definition of "effloresced" are subject to rejection.

[3.6.1.4 Prism Tests

**NOTE:** Prism testing will only be required for structures requiring masonry compressive strengths higher than those indicated by the conservative values derived by the Unit Strength Method. When the compressive strength of masonry can be verified by the Unit Strength method, prism testing normally will not be required. Delete this paragraph when
prism testing is not required. When prism test results are lower than the specified compressive strength, handling and testing of the prism specimens should be reviewed for compliance to the requirements contained in the ASTM standard.

Indicate the specified compressive strength of masonry in paragraph SYSTEM DESCRIPTION or on the Drawings.

Perform at least one prism test sample for each 465 square meters 5,000 square feet of wall but not less than three such tests for any building. Evaluate three prisms in each test. Fabricate, store, handle, and test prisms in accordance with ASTM C1314.

Seven-day tests may be used provided the relationship between the 7- and 28-day strengths of the masonry is established by the tests of the materials used. If the compressive strength of any prism falls below the specified value by more than 3.5 MPa 500 psi, take steps to assure that the load-carrying capacity of the structure is not jeopardized. If the likelihood of low-strength masonry is confirmed and computations indicate that the load-carrying capacity may have been significantly reduced, tests of cores drilled, or prisms sawed, from the area in question may be required. In such case, take three specimens for each prism test more than 3.5 MPa 500 psi below the specified value. Masonry in the area in question will be considered structurally adequate if the average compressive strength of three specimens is equal to or exceeds the specified value. Additional testing of specimens extracted from locations represented by erratic core or prism strength test results will be permitted.

3.6.1.5 Single-Wythe Masonry Wall Water Penetration Test

NOTE: Include masonry wall water penetration testing only for single-wythe masonry wall constructions where wall water penetration will impair mission-critical operations, create an immediate safety hazard, or have a detrimental impact on interior finishes. Testing evaluates the assembled wall test panel and does not assure compliant wall construction in the field. As an option additional testing may be performed on the actual wall construction in accordance with ASTM C1601.

Prior to start of field construction of the single-wythe concrete masonry wall, perform masonry wall water penetration test on mock-up wall assemblies consisting of the identical design, materials, mix, and construction methods as the actual wall construction and in accordance with ASTM E514/E514M. Prepare a minimum of three specimens and cure for minimum 28 days prior to testing. Construct panels by the same methods, processes, and applications to be used on the project's construction site. Spray test for 6 hours on each specimen. If water is visible on back of test panels during the test and areas of dampness on the backside of the test panels do not exceed 25 percent of the wall area, the panels will be considered to have passed. Dampness is defined as any area of surface darkening or discoloration due to moisture penetration or accumulation below the
observed surface.

Construct additional test panels for each failed test performed until three test panels pass the test. Factors that can affect test performance include materials, mixing, and quality of application and workmanship. Materials, mixing, and methods adjustments may be necessary in order to provide construction that passes the water penetration test. Document and record the test specimen construction materials and application and provide written test report in accordance with ASTM E514/E514M, supplemented by a detailed discussion of the specifics of test panel construction, application methods and processes used, quality of construction, and any variances or deviations that may have occurred between test panels during test panel construction. For failed test panels, identify in the supplemental report the variances, deficiencies or flaws that contributed to test panel failure and itemize the precautions to be taken in field construction of the masonry wall to prevent similar deficiencies and assure the wall construction replicates test panel conditions that pass the water penetration test. Submit the complete, certified test report, including supplemental report, to the Contracting Officer prior to start of single-wythe concrete masonry wall construction. Significant changes to materials, proportions, or construction techniques from those used in the passing water penetration test are grounds for performing new tests, at the discretion of the Contracting Officer.

3.6.2 Special Inspection

******************************************************************************
NOTE: The designer must indicate on the drawings all locations and all features for which special inspection and testing is required. This includes indicating the locations of all structural components and connections requiring inspection.
******************************************************************************

Perform special inspections and testing in accordance with Section 01 45 35 SPECIAL INSPECTIONS.

3.7 POINTING AND CLEANING

******************************************************************************
NOTE: Cleaning of masonry using water pressure may be necessary, but the pressure used should be the minimum required to successfully clean the masonry surface. Saturating the masonry wall in the cleaning process should be avoided.
******************************************************************************

After mortar joints have attained their initial set, but prior to hardening, completely remove mortar and grout daubs and splashings from masonry-unit surfaces that will be exposed or painted. Before completion of the work, rake out defects in joints of masonry to be exposed or painted, fill with mortar, and tool to match existing joints. Immediately after grout work is completed, remove scum and stains that have percolated through the masonry work using a low pressure stream of water and a stiff bristled brush. Do not clean masonry surfaces, other than removing excess surface mortar, until mortar in joints has hardened. Leave masonry surfaces clean, free of mortar daubs, dirt, stain, and discoloration, including scum from cleaning operations, and with tight mortar joints throughout. Do not use metal tools and metal brushes for cleaning.
3.7.1 Dry-Brushing Concrete Masonry

Dry brush exposed concrete masonry surfaces at the end of each day's work and after any required pointing, using stiff-fiber bristled brushes.

3.7.2 Clay Brick Surfaces

Clean exposed clay brick masonry surfaces to obtain surfaces free of stain, dirt, mortar and grout daubs, efflorescence, and discoloration or scum from cleaning operations. Perform cleaning in accordance with the approved cleaning procedure demonstrated on the mockup.

After cleaning, examine the sample panel of similar material for discoloration or stain as a result of cleaning. If the sample panel is discolored or stained, change the method of cleaning to ensure that the masonry surfaces in the structure will not be adversely affected. Water-soak exposed masonry surfaces and then clean with a proprietary masonry cleaning agent specifically recommended for the color and texture by the clay brick manufacturer and manufacturer of the cleaning product. Apply the solution with stiff fiber brushes, followed immediately by thorough rinsing with clean water. Use proprietary cleaning agents in conformance with the cleaning product manufacturer's printed recommendations. Remove efflorescence in conformance with the brick manufacturer's recommendations.

3.8 CLOSE-OUT TAKE-BACK PROGRAM

*****************************************************************
NOTE: Take-back programs refer to programs in which the product manufacturer "takes-back" scrap material and/or packaging associated with its product.
*****************************************************************

Collect information from manufacturer for take-back program options. Set aside [masonry units, full and partial] [scrap] [packaging] [_____] to be returned to manufacturer for recycling into new product. When such a service is not available, seek local recyclers to reclaim the materials. Submit documentation that includes contact information, summary of procedures, and the limitations and conditions applicable to the project. Indicate manufacturer's commitment to reclaim materials for recycling and/or reuse.

3.9 PROTECTION

*****************************************************************
NOTE: Covering masonry walls is required for protection from detrimental moisture intrusion, which can result in efflorescence, or as required by cold weather masonry construction provisions. In certain geographical areas, vertical reinforcement may be placed prior to installation of masonry units, which can significantly interfere with covering masonry walls.
*****************************************************************

Protect facing materials against staining. Cover top of walls with nonstaining waterproof covering or membrane to protect from moisture intrusion when work is not in progress. Continue covering the top of the
unfinished walls until the wall is waterproofed with a complete roof or parapet system. Extend covering a minimum of 600 mm 2 feet down on each side of the wall and hold securely in place. Before starting or resuming work, clean top surface of masonry in place of loose mortar and foreign material.

NOTE: This guide specification covers the requirements for glass unit masonry work.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1 GENERAL

The following information should be shown on the project drawings:

1. Head, jamb, sill, and intermediate support construction details.

2. Clearances required for deflection and expansion.

Refer to manufacturer’s data and TMS MSJC for glass unit panel size restrictions, limitations, and details. Refer to TMS MSJC for construction requirements for glass unit masonry.
1.1 SUMMARY

This section includes glass masonry units, hollow or solid, including mortar, joint reinforcement, and other accessories for constructing glass unit masonry panels.

1.2 REFERENCES

**************************************************************************

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

**************************************************************************

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

ASTM INTERNATIONAL (ASTM)

1.3 SUBMITTALS

**************************************************************************

NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.
Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

**SD-03 Product Data**
- Glass Masonry Units
- Water Repellent Additive or Admixture
- Joint Reinforcement
- Perimeter Anchorage
- Panel Anchors
- Expansion Strip

**SD-04 Samples**
- Glass Masonry Units
- Joint Reinforcement

- Panel Anchors
- Expansion Strip

**SD-07 Certificates**
- Glass Masonry Units
- Water Repellent Additive or Admixture
- Mortar

### 1.4 DELIVERY, STORAGE, AND HANDLING

Deliver cement, lime, and other cementitious materials to the site in unbroken containers, labeled with the manufacturers' names and brands. Store mortar materials in a manner to prevent the inclusion of foreign materials and damage by water or dampness. Avoid chipping, cracking and breakage of glass masonry units. Protect glass masonry units from contact with earth and exposure to the weather, and keep dry until used. Do not use materials containing frost or ice. Handle glass masonry units with care to avoid damage.

### 1.5 PROJECT/SITE CONDITIONS

Do not lay glass masonry units when the air temperature is 5 degrees C 40 degrees F and falling, or when it appears probable that temperatures below 5 degrees C 40 degrees F will be encountered before the mortar has set, unless protection is provided to prevent freezing. For protection, maintain the temperature of glass masonry units and mortar materials between 5 and 50 degrees C 40 and 160 degrees F. After erection, maintain air temperature above 5 degrees C 40 degrees F on both sides of glass masonry units for not less than 48 hours. Do not work with or on frozen materials. Cover the top of unfinished masonry work to protect it from the weather.
2.1 MANUFACTURED UNITS

NOTE: The desired physical characteristics (Light transmittance, reflectivity, pattern, size, etc.) should be described. The most commonly used glass masonry unit is nominally 200 mm 8 inch by 200 mm 8 inch by 100 mm 4 inch thick. Other square sizes, nominally 150 mm 6 inch by 150 mm 6 inch and 300 mm 12 inch by 300 mm 12 inch, are available, as well as rectangular sizes including 100 mm 4 inch by 200 mm 8 inch and 150 mm 6 inch by 200 mm 8 inch. The three most commonly specified patterns are listed by name, but other patterns are available.

Thin hollow units, which are common to residential construction, are not listed because published physical properties of glass units are based on testing of standard hollow units and thin solid units.

2.1.1 Glass Masonry Units

Provide glass masonry units of type[s], size, pattern and style specified. Do not change source of supply for material which will affect the appearance of the finished work after work has started. Keep on hand extra units amounting to [5] [%] percent of the number of units incorporated in the work. Use extra units to replace units found to be defective. Provide units in which the surfaces intended to be in contact with mortar are treated with polyvinyl butyral edge coating or latex-based paint.

2.1.1.1 Standard Hollow Glass Masonry Units

Provide hollow glass lock units that are partially evacuated and have a minimum average glass face thickness of 5 mm 3/16 inches. Provide [DECORA] [VUE] [ARGUS] [_____] pattern [with LX] [without] fibrous glass insert, [_____] sized [197 by 197] [_____] by 98 mm [7-3/4 by 7-3/4] [_____] by 3-7/8 inches. Where units are designated as "reflective glass masonry unit", provide a highly reflective oxide surface coating of a [gray] [_____] color. Provide units with [75] [%] percent light transmission.

2.1.1.2 Thin Solid Glass Masonry Units

Provide clear [VISTABRIK] [_____] or Stippled pattern, 194 by 194 by 76 mm 7-5/8 by 7-5/8 by 3 inches. Provide units with [75] [%] percent light transmission.

2.1.1.3 Fire Rated Glass Masonry Units

NOTE: Although walls are rated for fire resistance, windows (including glass unit masonry) are rated for fire protection. Although walls are tested for fire resistance, smoke resistance, and heat resistance, windows are only tested for fire and smoke resistance (not heat). Glass unit masonry can be rated for 45 minutes (up to 3 m by 3.7 m 10 ft by 12
feet); 60 minutes (up to 9.3 m² 100 sf or 3 m 10 ft maximum); and 90 minutes (up to 9.3 m² 100 sf or 3 m 10 ft maximum).

NFPA 80 requires that fire rated glass block units be listed by UL and tested per UL 9.

Where walls and partitions are indicated on the drawings to be fire rated and contain rated glass masonry unit window assemblies, use listed glass masonry units that have been fire tested in accordance with UL 9 to the indicated rating.

2.2 MORTAR

NOTE: A water-repellent additive (included in the manufacture of the cement) or a water-repellent admixture (added by the contractor during mortar mixing) should be required when the glass unit masonry panel will be exposed to the exterior.

2.2.1 Mortar

Comply with ASTM C270, Type S or N mortar, using white cementitious materials.

2.2.2 Water Repellent Additive or Admixture

Provide water repellent admixture, complying with ASTM C1384, in the mortar. Omit water repellent admixture if the cementitious materials include a water repellent additive.

2.2.3 Admixtures

Do not use admixtures unless approved by the Contracting Officer.

2.3 MORTAR MIXING

Mix cementitious materials and aggregate between 3 and 5 minutes in a mechanical batch mixer with a reduced amount of water to account for the lack of absorption of glass units. Hand mixing may be used only when specifically approved by the Contracting Officer.

2.4 ACCESSORIES

2.4.1 Joint Reinforcement

Comply with ASTM A951/A951M and, after fabrication, provide zinc coating by the hot-dip process conforming to ASTM A153/A153M, 458 g/m² 1.50 oz/ft², or fabricate from wire complying with ASTM A580/A580M. Provide reinforcement with two parallel longitudinal wires of size [MW11 W1.7] [3.4 mm 0.1483 inch] and butt-welded cross wires of size [MW11 W1.7] [3.4 mm 0.1483 inch] at not greater than 406 mm 16 inches on center. Provide longitudinal wires spaced 50 mm 2 inches apart when used with standard hollow glass units and 41 mm 1-5/8 inches apart when used with thin solid glass units. Provide joint reinforcement in flat sections, not less than 2.4 m 8 feet long, except that prefabricated corner reinforcements and other special shapes
may be shorter.

2.4.2  Perimeter Anchorage

**************************************************************************

NOTE: Glass unit masonry panels must be laterally supported at the top and sides by either panel anchors or channel restraints. The channel restraint may be designed as one piece or two pieces of angle stock. Channel-type restraints must be oversized to accommodate expansion material in the opening, and packing and sealant between the framing restraints and the glass unit masonry perimeter units. Lateral supports must be designed to resist applied loads or a minimum of **29919 N/m 200 lb/ft**, per TMS MSJC

**************************************************************************

2.4.2.1  Panel Anchors

Perforated steel strip not less than **0.9 mm 20 gauge**, minimum of **44 mm wide by 610 mm long 1-3/4 inches wide by 24 inches long**, punched with three staggered rows of elongated holes, and hot-dipped galvanized conforming to ASTM A153/A153M after fabrication; or perforated stainless steel strap not less than **0.8 mm 22 gauge**, minimum of **44 mm wide by 610 mm long 1-3/4 inches wide by 24 inches long**. Provide two fasteners per panel anchor, each capable of resisting a load of [_____] **N pounds**.

2.4.2.2  Channel-Type Anchorage

Clear anodized aluminum channels, **114 mm by 50 mm by 3 mm thick 4-1/2 inches by 2 inches by 1/8 inch thick** for use with standard hollow glass units and **102 mm by 50 mm by 3 mm thick 4 inches by 1-1/2 inches by 1/8 inch thick** or **95 mm by 50 mm by 3 mm thick 3-3/4 inches by 2 inches by 1/8 inch thick** for use with thin solid glass masonry units. Provide channels with bituminous coating on surfaces that will contact dissimilar metals.

2.4.3  Expansion Strip

Strip of closed cell polyethylene foam conforming to ASTM D4819, Type II, or strip of sponge rubber conforming to ASTM D1056; **9 mm 3/8 inches thick**.

2.4.4  Asphalt Emulsion

Asphalt emulsion conforming to ASTM D1187/D1187M, Type II for use on metal surfaces; and asphalt emulsion conforming to ASTM D1227, Type III, Class I for use on porous surfaces.

2.4.5  Sealant and Backer Rod

Comply with Section 07 92 00 JOINT SEALANTS.

PART 3  EXECUTION

3.1  PREPARATION

Before placing the mortar bed for the first course of glass masonry units, apply a heavy coat of asphalt emulsion to sill surfaces and allow to thoroughly dry.
3.2 INSTALLATION

3.2.1 Tolerances

Erect glass unit masonry within site tolerances of TMS MSJC, Article 3.3 F.

3.2.2 Mortar Preparation

Keep mortar boxes, pans, and mixer drums clean and free of debris and dried mortar. Do not retemper mortar after initial set. Discard mortar that has not been placed in final position within 1-5 hours after initial mixing.

3.2.3 Mortar Joints

Construct mortar joints 6 mm 1/4 inch wide when laying standard hollow glass masonry units, and 10 mm 3/8 inch wide when laying thin solid glass masonry units. Fill head and bed joints completely and evenly and do not furrow the mortar. Remove loose and excess mortar. The practice of buttering at the corners of the unit and then throwing mortar or scrapings into the empty joints will not be permitted. Maintain joint tolerances in accordance with TMS MSJC.

In joints to be reinforced, place half the thickness of mortar, press in the reinforcing, then apply the second half of mortar on top so that the reinforcing is in the middle of the mortar joint. Place full mortar bed for joints not requiring reinforcing.

3.2.4 Glass Masonry Unit Installation

Do not use steel tools to tap glass units into position. Place rubber crutch tips at the ends of trowels to tap glass masonry units.

Lay glass masonry units [in stacked bond] [____]. Do not realign, tap or otherwise move glass masonry units after initial placement.

3.2.5 Joint Reinforcement

Embed reinforcement in mortar bed joints at a maximum spacing of 400 mm centers 16 inch centers continuously from end to end of panel, except at expansion joints. Provide additional courses of joint reinforcement above and below openings within the glass masonry unit panel. Lap reinforcing not less than 150 mm 6 inches at splices where more than one length of reinforcement is used.

3.2.6 Lateral Support of Glass Masonry Unit Panels

3.2.6.1 General

Anchor walls and partitions to adjoining construction to provide lateral stability, but permit unrestricted deflection of construction above, using either channel type restraints or panel anchors.

3.2.6.2 Panel Anchors

Except where channel-type restraints are used, space panel anchors a maximum of 400 mm 16 inches apart at jambs (in same joint as panel reinforcing), and 400 mm 16 inches apart at heads. Embed panel anchors in the mortar joints a minimum of 300 mm 12 inches, except where panel
dimension is less than 600 Mm 2 feet. Provide a minimum embedment of 150 mm 6 inches when the panel dimension is less than 600 Mm 2 feet. Provide two fasteners per panel anchor.

3.2.7 Expansion Joints

Provide space indicated to permit expansion at heads and jambs of glass masonry unit panels. Maintain expansion joints at head, jambs and at intermediate supports free of mortar.

3.2.8 Mortar Joint Tooling

After initial set of mortar, tool exposed joints and compress with a rounded jointer. Provide finished surface of joint that is concave, smooth, and non-porous.

3.2.9 Sealing of Expansion Joints

After final set of mortar, remove mortar from expansion joints. Seal expansion joints at head, jamb and intermediate supports with sealant and backer rod specified in Section 07 92 00 JOINT SEALANTS, at least 24 hours after curing of the mortar.

3.3 ADJUSTING AND CLEANING

3.3.1 Repair of Defective Work

Upon completion of glass masonry unit erection, cut out defective mortar joints and tuck point joints solidly with mortar. Replace damaged glass masonry units by breaking out both faces of the unit and carefully removing the surrounding mortar and glass frames, making sure to avoid damage to adjacent units. Butter all edges of the replacement glass unit and place it in the opening. Using a tuckpointing trowel, push mortar through the joints from both sides of the panel, until joints are full, then tool when thumbprint hard.

3.3.2 Cleaning

Protect work that may be damaged, stained, or discolored by cleaning operations. Remove excess mortar from glass masonry units with damp cloth or sponge before set occurs. Clean exposed surfaces with clear water and stiff fiber brushes, and rinse with clear water. Where stains, mortar, or other soil remain, continue cleaning with warm water and soap. Do not use abrasive cleaners (steel wool, wire brush) or acids in conjunction with removing mortar or dirt from the glass masonry unit faces. Restore damaged, stained, or discolored work to original condition or provide new work.

-- End of Section Table of Contents --
NOTE: This specification covers the requirements for post-installed concrete and masonry anchors.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

NOTE: Show the following information on the project drawings:

Anchor type, diameter, effective embedment, spacing, critical edge distances used in the design. Proof load and/or capacity should be shown on the drawings or edited into this specification. Horizontal, inclined, or overhead anchors supporting sustained tension loads should be identified on the drawings for additional installer qualifications and QA/QC requirements.
PART 1  GENERAL

1.1  REFERENCES

**************************************************************************
NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.
**************************************************************************

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

AMERICAN CONCRETE INSTITUTE (ACI)

ACI 355.2  (2007) Qualification of Post-Installed Mechanical Anchors in Concrete and Commentary

ACI 355.4  (2011) Qualification of Post-Installed Adhesive Anchors in Concrete (ACI 355.4) and Commentary

ASTM INTERNATIONAL (ASTM)

ASTM A193/A193M  (2023) Standard Specification for Alloy-Steel and Stainless Steel Bolting Materials for High-Temperature Service and Other Special Purpose Applications

ASTM A615/A615M  (2022) Standard Specification for Deformed and Plain Carbon-Steel Bars for Concrete Reinforcement

1.2 APPLICABILITY

This guide specification covers the requirements for all anchors that are post-installed into hardened concrete, concrete masonry, or brick. This guide specification does not cover through bolts, powder or pneumatic actuated nails, or cast in anchors. Refer to Section 05 50 13 MISCELLANEOUS METAL FABRICATIONS for requirements of through bolts, powder or pneumatic actuated nails, or cast in anchors.

1.3 DEFINITIONS

1.3.1 Anchor

"Anchor" includes steel elements post-installed into hardened concrete, concrete masonry, or brick and used to transmit applied loads.

1.3.2 Periodic Special Inspections

"Periodic Special Inspection" as used herein means that, as a minimum, the Post-Installed Anchor Special Inspector must perform inspections in accordance with this specification.

1.3.3 Continuous Special Inspections

"Continuous Special Inspection" as used herein means that the Post-Installed Anchor Special Inspector observes the drilling and cleaning of holes, the injection of adhesive into the holes, and the insertion of anchors into the holes. When applicable for the type of installation, or as indicated in the project drawings, "Continuous Special Inspection" also includes observation of measures to secure the anchor during the adhesive curing period.

1.4 SUBMITTALS

**************************************************************************

NOTE: Review Submittal Description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item
if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.

**************************************************************************

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:
1.5 QUALITY ASSURANCE

Perform all work in accordance with EM 385-1-1 and all manufacturer's instructions and recommendations. To protect personnel from overexposure to toxic materials, conform to the applicable manufacturer's Material Safety Data Sheets (MSDS) or local regulation. Submit the MSDS for epoxies and other potentially hazardous materials.

1.5.1 Qualifications

The submittals must identify individuals who will be working on this contract and their relevant experience and training. Do not make changes in approved personnel without prior approval of the Contracting Officer.

1.5.1.1 Installer Qualifications

**************************************************************************
NOTE: Installation of post-installed anchors must be performed by personnel certified by an applicable certification program (such as ACI/CRSI Adhesive Anchor Installer), or equivalent instruction program through the manufacturer or manufacturer's representative. The acceptability of certification other than the ACI/CRSI Adhesive Anchor Installer Certification is the responsibility of the licensed design professional.
**************************************************************************

Each worker engaged in the installation of post-installed anchors must have satisfactorily completed an applicable certification program or equivalent instruction program through the manufacturer or manufacturer's representative for all anchoring products they will install. A manufacturer's representative must train all installers per the installation instructions as listed in the ICC-ES Evaluation Report for the anchor being installed. Training must consist of a review and performance test of the complete installation process, including but not limited to:

(1) Hole drilling procedure
(2) Hole preparation & cleaning technique
(3) Adhesive injection technique & dispenser training / maintenance
(4) Anchor/threaded rod preparation and installation
(5) Rebar dowel preparation and installation
(6) Proof loading/torquing
(7) Installation in horizontal and upward orientations

Submit certification for each worker showing that they have completed the
above training within three years prior to onsite work. Certification must include organization or manufacturer's name, instructor's name and qualifications, trainee's name, list of instruction received, date of instruction, and confirmation of successful performance tests.

1.5.1.2 Post-Installed Anchor Special Inspector Qualifications

**************************************************************************
NOTE: While inspector certification programs have been developed (such as ACI/CRSI Adhesive Anchor Installation Inspector), these programs are not readily available. At a minimum, the inspectors must have training as post-installed anchor installers and have sufficient relevant experience as an inspector.
**************************************************************************

The Contractor must retain the services of a third party Special Inspector independent of the installing contractor and manufacturer. The individual(s) who perform special inspections for post-installed anchors must meet all Installer Qualification requirements and have a minimum of [1][3][5] year[s] of experience as a Special Inspector on previous projects involving similar scope of work. Submit resumes, pertinent information, past experience, and training.

1.6 DELIVERY, STORAGE, AND HANDLING

1.6.1 Packing, Shipping, Handling, and Unloading

Deliver products to job site in manufacturer's or distributor's original packaging undamaged, complete with installation instructions. Inspect materials delivered to site for damage. Unload and store with minimal handling.

1.6.2 Storage

Protect, store, and handle materials in accordance with manufacturer's recommendations to prevent damage or deterioration. Do not allow chemical materials to freeze. Remove materials that have not be stored in accordance with the manufacturer's recommendations, including expired materials, from the job site.

PART 2 PRODUCTS

2.1 MATERIALS

2.1.1 Post-Installed Anchors

Provide anchors of the type, effective embedment, and diameter indicated on contract drawings. Minimum spacing and concrete edge distances must be as shown on contract drawings. Design values listed must be as tested according to ASTM E488/E488M for the substrate type, substrate moisture condition, concrete aggregate type (normal weight or lightweight concrete), and concrete/masonry strength. Minimum [allowable strength][ultimate strength] tension and shear values must be as indicated on contract drawings. If more than one type of anchor is to be used on a project, clearly indicate on the submittal where each type of anchor will be used.
2.1.1.1 Post-Installed Anchor Certification

Submit product information with recommended design values and physical characteristics for each type anchor shown on the drawings.

Provide certified test reports showing compliance with specified performance characteristics and physical properties. Anchors must have one of the following certifications:

(1) ICC-ES Evaluation Report indicating conformance with current applicable ICC ES Acceptance Criteria

(2) Third party Evaluation Report in conformance with ACI 355.2 or ACI 355.4, as applicable. Third party must be accredited under ISO/IEC 17025 by a recognized accreditation body conforming to the requirements of ISO/IEC 17011 in accordance with ACI 355.4."

2.1.1.2 Manufacturer's Printed Installation Instructions

Submit manufacturer's instructions for each anchor type shown on the drawings.

2.1.1.3 Mechanical Anchors in Concrete

Anchors must have been tested and qualified for performance in cracked and uncracked concrete in accordance with ACI 355.2.

Anchors must be galvanized in accordance with ASTM A153/A153M or stainless steel in accordance with ASTM A193/A193M unless otherwise indicated.

2.1.1.4 Adhesive Anchor System in Concrete

Use an adhesive to bond steel anchors to concrete. The adhesive must be a moisture insensitive, structural adhesive. Anchors must have been tested and qualified for performance in cracked and uncracked concrete, horizontal and overhead applications, and long term creep in accordance with ACI 355.4.

Threaded rod anchors must meet the requirements of [ASTM F1554 Grade [36][55][105]][ASTM A36/A36M][ASTM A193/A193M Grade B7][____]. Threaded rods must be galvanized in accordance with ASTM A153/A153M or stainless steel in accordance with ASTM A193/A193M unless otherwise indicated. Reinforcing bars must meet the requirements of ASTM A615/A615M Grade [60][75][100].

**************************************************************************
NOTE: The temperature ranges listed in the below sentence, and anchor sizes and bond strengths listed in the below table, should be modified for your specific project as stated in the ICC-ES Evaluation Report used in your calculations. It is recommended that you research the temperatures ranges and bond strength capacities listed in multiple manufacturer’s ICC-ES Evaluation Reports and include a range of acceptable values. This will allow flexibility based on product availability. Recommend deleting anchor sizes not used on your specific project.
**************************************************************************
Adhesive anchors must have the below characteristic bond strengths for uncracked and cracked concrete in [_____] MPa [_____] psi concrete with maximum short term temperatures of[_____] degrees C [_____] degrees F and maximum long term temperatures of[_____] degrees C [_____] degrees F:

<table>
<thead>
<tr>
<th>ANCHOR</th>
<th>Tau,uncr (characteristic bond strength, uncracked concrete)</th>
<th>Tau,cr (characteristic bond strength, cracked concrete)</th>
</tr>
</thead>
<tbody>
<tr>
<td>[&quot; diameter threaded rod]</td>
<td>[_____]</td>
<td>[_____]</td>
</tr>
<tr>
<td>[# reinforcing bar]</td>
<td>[_____]</td>
<td>[_____]</td>
</tr>
</tbody>
</table>

2.1.1.5  Mechanical and Adhesive Anchors in Masonry

Anchors must have been tested and qualified, by a third party, specifically for performance in [hollow concrete masonry][filled concrete masonry][brick] to match the project's actual base material.

Adhesives must be moisture insensitive, low creep, structural adhesive. Threaded rods must meet the requirements of [ASTM F1554 Grade [36][55][105]][ASTM A36/A36M][ASTM A193/A193M Grade B7][_____].

Anchors must be galvanized in accordance with ASTM A153/A153M or stainless steel in accordance with ASTM A193/A193M unless otherwise indicated.

2.2  EQUIPMENT

Assemble at the site of the work, sufficient equipment that is dependable, appropriate and adequate to accomplish the work specified. Maintain the equipment in good working condition.

PART 3  EXECUTION

3.1  ANCHORING AND REINFORCING

Install anchors in accordance with the spacing and edge clearances indicated on the drawings. Anchor capacity is also highly dependent on proper installation. Follow all manufacturer and Evaluation Report installation instructions.

3.1.1  Drilling and Installing Mechanical Anchors

Drill holes for anchors using drilling equipment and bits suitable for the intended purpose, in accordance with Manufacturer's published installation instructions. Diameter of holes must be as recommended by the anchor manufacturer. Unless otherwise shown on the Drawings, all holes must be drilled perpendicular to the concrete surface. Deviations more than 6 degrees from perpendicular are not acceptable. Unless otherwise specified, do not drill holes in concrete or masonry until concrete, mortar, or grout has achieved full design strength. Mechanical anchors must not be installed in concrete that is less than 7 days old.

Clean holes, install anchors and set anchors in place in accordance with the manufacturer's recommendations. Protect threads and anchor from damage during anchor installation. Ensure proper embedment and placement in accordance with contract documents and all other work. Aim wedges away...
from any concrete edges that are less than 9 inches from centerline of hole.

Tighten nuts against smooth washers to the manufacturer's recommended torque, using a calibrated torque wrench. Following attainment of 10 percent of the specified torque, 100 percent of the specified torque must be reached within 7 or less complete turns of the nut. If the specified torque is not achieved within the required number of turns, the anchor must be removed and replaced unless otherwise directed by the Engineer of Record.

3.1.2 Drilling and Installing Adhesive Anchors

Drill holes for anchors using drilling equipment and bits suitable for the intended purpose, in accordance with Manufacturer's Printed Installation Instructions and Evaluation Report installation instructions. Diameter of holes must be as recommended by the anchor manufacturer. Unless otherwise shown on the drawings, all holes must be drilled perpendicular to the concrete surface. Deviations more than 10 degrees from perpendicular are not acceptable. Unless otherwise specified, do not drill holes in concrete or masonry until concrete, mortar, or grout has achieved full design strength. Adhesive anchors must not be installed in concrete that is less than 21 days old.

Clean holes, place grout, and install anchors in accordance with anchor manufacturer's recommendations. Remove excess adhesive after the anchor has been set in place. Remove spills on adjacent surfaces. When installing resin cartridges or capsules in submerged conditions, place properly proportioned resin material in bottom of hole using a mixing tube prior to inserting the cartridge or capsule. Protect threads and anchor from damage during anchor installation. Ensure proper embedment and placement in accordance with contract documents and all other work. Do not disturb or load anchors before manufacturer specified cure time has elapsed.

Adhesives must be stored at temperatures prescribed by the manufacturer and must not be used beyond the expiration date.

3.1.3 Unused or Repairs to Drilled Holes

Any holes made for anchors that are not used must be filled with non-shrink, non metallic grout suitable for the orientation and size of hole and have a minimum compressive strength of 4000 psi. Repair must completely fill hole and be flush with existing concrete or masonry. Place in accordance with manufacturer's recommended instructions. Final anchor positions must not be within 25 mm inch of repair patches.

3.2 EMBEDDED ITEMS

Existing reinforcing bars or other embedded items in the structure may conflict with specified anchor locations. Existing reinforcing and embedded items must not be damaged during installation of post-installed anchors.

The contractor must review the [project][as-built] drawings [and must use Radar detection systems (such as Hilti Ferroscan), X-Ray, or other appropriate means ]to accurately locate the position of [existing ]reinforcing bars and embedded items at the locations of the anchors in the field. [ Scanning method must provide enough accuracy and precision to locate the space between rebar. Structural integrity of existing concrete or masonry must not be impaired by investigating method.]
Create a template at each anchor connection location prior to fabricating holes in connection plates. Template must be made by locating existing reinforcing with an approved reinforcement detection system.

3.3 TESTS AND INSPECTIONS

3.3.1 Mechanical Anchors

For mechanical anchors, periodic special inspections are required. Inspections must be in accordance with ICC IBC and the Evaluation Report.

Mechanical Anchors must be inspected during installation, to verify anchor type, anchor dimensions, base material type, drill bit, hole dimensions, hole cleaning procedures, anchor spacing, edge distances, base material thickness, base material age, effective embedment, tightening torque, adherence to the manufacturer's printed installation instructions, and any additional items recommended in the Evaluation Report.

For mechanical anchors whose strength is dependent on a minimum installation torque, the [installer under the supervision of the Special Inspector][Special Inspector] must torque test the anchors with a calibrated torque wrench. Perform torque testing immediately on the first three anchors of each type and size, for each installer, and a minimum of [5][10] percent of randomly selected anchors. Anchor selection will be determined by the [Post-Installed Anchor Special Inspector][Contracting Officer][Engineer of Record].

For mechanical anchors whose strength is not dependent on a minimum installation torque, the Special Inspector must perform proof loading on the first three anchors of each type and size, for each installer and a minimum of [5][10] percent of randomly selected anchors. Anchor selection will be determined by the [Post-Installed Anchor Special Inspector][Contracting Officer][Engineer of Record]. Perform confined tension proof load testing in accordance with ASTM E488/E488M. Use incremental loading for tensile test. Maintain proof load for a minimum of 10 seconds. Consider anchors to have failed if displacement exceeds 2.5 mm or 0.1 inch D/10, where D is the nominal anchor diameter, or if any of the failure modes listed in ASTM E488/E488M occur.

Proof loads must be the minimum of the value shown on the Drawings, the values shown in the table below, or 50 percent of the tension capacity of the anchor:

<table>
<thead>
<tr>
<th>ANCHOR</th>
<th>EFFECTIVE EMBEDMENT</th>
<th>CONFINED TENSION PROOF LOAD</th>
</tr>
</thead>
<tbody>
<tr>
<td>[Concrete Screw Anchor, _&quot; diameter]</td>
<td>[_&quot; to &quot;] in Concrete</td>
<td>[_____]</td>
</tr>
</tbody>
</table>

NOTE: The following table should be modified for your specific project and the capacities and anchors required.
3.3.2 Adhesive Anchors

For adhesive anchors, periodic special inspection are required as a minimum. Where adhesive anchors are used to resist sustained tension in horizontal or upwardly inclined orientations, or where the findings of the Evaluation Report for the adhesive anchor product require it, continuous special inspection is needed. Inspections must be in accordance with ICC IBC and the Evaluation Report.

Adhesive anchors must be inspected during installation, to verify anchor type, anchor dimensions, base material type, base material age, drill bit, hole dimensions, hole cleaning procedures, anchor spacing, edge distances, base material thickness, effective embedment, tightening torque, adhesive mixing, filling of the hole with adhesive, adherence to the manufacturer's printed installation instructions, and any additional items recommended in the Evaluation Report.

The Special Inspector must perform proof loading on the first three anchors of each type and size, for each installer, and a minimum of [5][10] percent of randomly selected anchors. Anchor selection will be determined by the [Post-Installed Anchor Special Inspector][Contracting Officer][Engineer of Record]. Perform confined tension proof load testing in accordance with ASTM E488/E488M. Use incremental loading for tensile test. Maintain proof load for a minimum of 10 seconds. Consider anchors to have failed if displacement exceeds $2.5 \text{ mm } 0.1 \text{ inch} \frac{D}{10}$, where $D$ is the nominal anchor diameter, or if any of the failure modes listed in ASTM E488/E488M occur.

Adhesive anchors and capsule anchors must not be torque tested.

Proof loads must be the minimum of the value shown on the Drawings, the values shown in the table below, or 50 percent of the tension capacity of the anchor:

<table>
<thead>
<tr>
<th>ANCHOR</th>
<th>EFFECTIVE EMBEDMENT</th>
<th>CONFINED TENSION PROOF LOAD</th>
</tr>
</thead>
<tbody>
<tr>
<td>[Masonry Screw Anchor, ___&quot; diameter]</td>
<td>[&quot; in Masonry]</td>
<td>[_____]</td>
</tr>
</tbody>
</table>

NOTE: The following table should be modified for your specific project and the capacities and anchors required. The proof load levels must not exceed the lesser of the required anchor strength, 50 percent of the expected peak load based on adhesive bond strength, or 80 percent of the anchor yield strength per ACI 355.4, section 13.3.4.
3.3.3 Action Required from Failed Tests/Inspections

Immediately report failed anchor locations and test results to the Contracting Officer. Anchors that fail to meet proof/torque load or installation requirements must be regarded as malfunctioning. Do not re-use holes unless specifically allowed by manufacturer's published instructions and approved by the Post-Installed Anchor Special Inspector.

If any of the tested anchors fail to achieve the specified torque or proof load within the limits of the contract documents, test a minimum of two adjacent anchors for each anchor that fails.

Continuously special inspect and proof load/torque test any replacement anchors.

Fill unused anchor holes and patch failed anchor locations in accordance with this specification. Prior to performing the repair, the Contractor must submit to the Contracting Officer for approval, the proposed fill and patch materials.

Additional tests, repairs, delays, or modification of work to accommodate failed tests will be at no cost to the Government.

3.3.4 Post-Installed Anchor Special Inspections Report

Report the results of all inspections [daily][weekly][biweekly]. Submit report as an electronic PDF file to the Contracting Officer for review by the Engineer of Record. The report must include the following:

1. Exact locations of the inspected and tested work
2. Inspector's name
3. Date of inspection
4. Summary of work completed during the inspection period
5. Test results
6. Statement by the Special Inspector that clearly identifies the tested anchors as being acceptable or rejected.
7. Statement by the Special Inspector confirming that the materials and installation procedures conform with the approved contract documents and the manufacturer's published installation instructions.
3.4 DUST CONTROL

Control dust resulting from demolition to prevent the spread of dust and avoid creation of a nuisance in the surrounding area. Do not use water when it will result in, or create, hazardous or objectionable conditions such as ice, flooding, or pollution.

  3.4.2 Inspection of Repairs

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for ultrasonic inspections of weldments; including qualifications and procedures.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1 GENERAL

1.1 REFERENCES

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature
to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

**AMERICAN SOCIETY FOR NONDESTRUCTIVE TESTING (ASNT)**

**ANSI/ASNT CP-189**
(2020) ASNT Standard for Qualification and Certification of Nondestructive Testing Personnel

**AMERICAN WELDING SOCIETY (AWS)**

**AWS D1.1/D1.1M**
(2020; Errata 1 2021) Structural Welding Code – Steel

1.2 DEFINITIONS

1.2.1 A Scan

Method of data presentation on a electronic screen using rectangular coordinates in which a horizontal base line indicates elapsed time when reading from left to right. A vertical deflection in the base line indicates reflect signal amplitude.

1.2.2 Acoustically Similar Material

Material the same as that to be inspected; or another material proven to have acoustical velocity within plus or minus 3 percent and an attenuation within plus or minus 0.009843 dB/mm 0.25 dB/inch of the inspected material for the inspection frequency and wave mode, using the same mode as that to be used for inspection.

1.2.3 Amplitude

When referring to an indication in A scan presentation, amplitude is the vertical height of the indication measured from peak-to-peak for radio frequency indications and trace-to-peak for video indications.

1.2.4 Attenuation

Dissipation or loss of energy as ultrasonic vibrations travel through the material. Attenuation is caused almost entirely by scattering of the ultrasonic vibrations generated by the search unit.

1.2.5 Back Reflection or End Reflection

Reflection from the opposite side, end, or boundary of the material into which the ultrasonic energy was introduced.
1.2.6 Calibration

Process of comparing an instrument or device with a standard to determine accuracy or produce a scale.

1.2.7 Couplant

Any material, usually a liquid or semiliquid, used between the search unit and the inspection surface to exclude air and to convey the ultrasonic vibrations between the search unit and the material being inspected.

1.2.8 Digital Display

Display capable of presenting multi-function a-scan, b-scan, c-scan or s-scan responses. This also includes instruments settings and parameters.

1.2.9 Decibel (dB)

Units for the logarithmic expression of the ratio of power levels. Power levels can be functions of voltage, current, or impedance, for example. Decibel units having no values of their own are only significant when a reference is stated, as 10 dB above one reference level or 6 dB below another reference level.

1.2.10 Discontinuity

Anything within a material that causes a detectable interruption in an ultrasonic beam.

1.2.11 Examination

Within the context of this specification, examination is equivalent to the word "inspection."

1.2.12 Hertz

One complete set of recurrent values of a periodic quantity comprises a cycle. In other words, any one set of periodic variations starting at one condition and returning once to the same condition is a cycle.

1.2.13 Immersion Techniques

Test methods in which the part to be tested and the search units are immersed in water or other suitable liquid couplant. A mechanical device is used to firmly hold and direct the wave angle of the search unit. The search unit does not contact the item being inspected.

1.2.14 Indication

Visual presentation on the digital display screen resulting from a sound beam reflection from a boundary surface or discontinuity.

1.2.15 Linearity

Property of an instrument revealed by a linear change in reflected signal or displacement. The vertical linearity is determined by plotting the change in ratios of signal amplitude from two adjacent reflections from an area of known size. The horizontal linearity is determined by plotting the distance the signal is displaced along the sweep against the change in
material thickness or by noting the spacing of multiple back reflections.

1.2.16 Longitudinal or Compressional Waves

Simple compression-rare-fraction waves in which particle motion within a material is linear and in the direction of wave propagation. Also called straight beams, or compressional or normal waves.

1.2.17 Longitudinal Wave Inspection

Ultrasonic technique, normally using straight beam methods, in which longitudinal waves are the dominant form.

1.2.18 Mid-Screen Reflection

Reflection whose amplitude is equal to one-half the useable screen height on the digital display.

1.2.19 Megahertz (MHz)

One million hertz per second frequency.

1.2.20 Pulse Repetition Rate

Number of spaced pulses of sound per second sent into the material being inspected.

1.2.21 Reflector

Boundary, consisting of an opposite side, crack, or separation, or a distinct change in material such as slag or porosity that reflects the ultrasonic energy the same as a mirror reflects light.

1.2.22 Refracted Waves

Waves that have undergone change of velocity and direction by passing from one material to another material with different acoustical properties. Refraction occurs wherever the angle of the incident wave to the interface is other than perpendicular.

1.2.23 Resolution

Ability to clearly distinguish signals obtained from two reflective surfaces with a minimum separation distance. Near-surface resolution is the ability to clearly distinguish a signal from a reflector at a minimum distance under the contact or near surface without interference from the initial pulse signal. Far-surface resolution is the ability to clearly distinguish signals from reflectors displaced at minimum distances from the far or back surface when the sound beam is normal to that back surface.

1.2.24 Search Unit

Device containing a piezoelectric material used for introducing vibrations into a material to be inspected or for receiving the vibrations reflected from the material. The active element of the search unit is defined as the effective transmitting area. Search units are also called transducers or probes. They may be single or dual and contain one or two piezoelectric elements, respectively, for transmission and reception. The single search unit is sometimes enclosed in a transducer wheel or search unit wheel. The
search unit may be manually handled and placed in direct contact with the material to be inspected or may be held in a fixture for immersion techniques.

1.2.25  Sensitivity

Measure of the ultrasonic equipment's ability to detect discontinuities. Quantitatively, it is the level of amplification of the receiver circuit in the ultrasonic instrument necessary to produce the required indication on the scope from the reference hole in the reference block. Also see "Standard Reference Level."

1.2.26  Shear Waves

Waves in which the particles within the material vibrate perpendicularly to the direction in which the wave travels or propagates. Also called transverse waves.

1.2.27  Standard Reference Level

Mid-screen height reflection when beaming at the 1.52 mm 0.06 inch hole in the primary reference block or the reference hole in the secondary standard.

1.3 SUBMITTALS

**************************************************************************
NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item
for Army projects.

Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-01 Preconstruction Submittals
Personnel Qualification; G[, [_____]]
Procedure description; G[, [_____]]

SD-03 Product Data
Equipment and accessories

SD-06 Test Reports
Equipment Qualifications
Inspection Test Reports

1.4 QUALITY ASSURANCE

1.4.1 Personnel Qualification

The three levels of responsibility associated with ultrasonic inspection are defined in ANSI/ASNT CP-189. Personnel performing NDT should be level II or Level I with direct supervision. For qualification to perform ultrasonic inspection, certify personnel in accordance with ANSI/ASNT CP-189 within a period of 1 year before the date of contract. Submit inspector qualifications per ANSI/ASNT CP-189. Other qualification or certification may be accepted at the Contracting Officer's discretion. Personnel with only an operator or inspector trainee certification will not be considered qualified to pass judgment on the acceptability of inspected items, but may work under the direct supervision of a qualified ultrasonic inspector. Qualified ultrasonic inspectors must be able to judge the acceptability of the item in accordance with paragraph ACCEPTANCE-REJECTION CRITERIA. Only serialized NIST traceable calibration standards are to be used. The procedures to be used for personnel and equipment qualification, equipment calibration, and inspection, at least 30 days prior to their intended use. Approval by the Government will in no way affect the obligation of the Contractor to employ qualified personnel, equipment, and procedures, and to perform the inspection as specified.

1.4.2 Examinations

If the Contracting Officer doubts an individual's ability as an operator, inspector, or supervisor, recertify the individual in accordance with ANSI/ASNT CP-189, using the practical exam. At the option of the Government, the Contracting Officer may witness the examination and in evaluating the results.
1.4.3 Reference Standards

Use reference standards to calibrate the inspection equipment, test its operating condition, and record the sensitivity or response of the equipment during the inspection in accordance with paragraph EQUIPMENT QUALIFICATIONS. The standards comprise a standard reference block and reference specimens as noted below.

a. Provide the standard reference block or primary standard consisting of the IIW block in AWS D1.1/D1.1M, Clause 6, Part F. Also use the standard reference block in any reinspection on the same basis as the original inspection, even though the reinspection is to be performed by other ultrasonic instruments and accessories.

b. As an option, use other recognized working standards detailed with the IIW block in AWS D1.1/D1.1M such as the Sensitivity Calibration (SC) block. However, reference such blocks to the IIW block as noted in paragraph EQUIPMENT CALIBRATION. Include details of their use in the submitted procedure description. These blocks are the secondary standards. They must be of acoustically similar material to the welds to be inspected. The secondary standards must be suited for the applicable tests specified in paragraph EQUIPMENT QUALIFICATIONS and are used as follows, except where the IIW block is specifically required:

1. To assure adequate penetration of the base material.
2. To provide a secondary field standard.
3. To calibrate the equipment and establish the standard reference level.

1.4.4 Resolution Test Block

Furnish a resolution test block in accordance with the details shown in AWS D1.1/D1.1M, Clause 6, Part F.

1.4.5 Equipment Qualifications

Calibrate and recalibrate all NDT equipment in accordance with AWS D1.1/D1.1M requirements.

PART 2 PRODUCTS

2.1 SYSTEM DESCRIPTION

**************************************************************************

NOTE: Welded joints to be inspected will be shown on the drawings, stated in other sections, or added to this paragraph. Because accessibility and geometry of the joint are factors in obtaining adequate ultrasonic penetration, consider these factors in the design of the joint. Drawings or listings in the specifications must clearly indicate which weld joints are to be inspected ultrasonically.

The use of advanced ultrasonic techniques in lieu of conventional UT will require the engineer to consider the establishment of an acceptance criteria in accordance with AWS D1.1. Prior to proposing the use of advanced UT (phased array, TOFD etc) or prior
to accepting the proposed use of advanced UT by the fabricator/contractor, the engineer will need to establish an acceptance criteria and require an additional procedure submittal for the use of advanced ultrasonic techniques.

2.1.1 Procedures and Methods

Use the pulse echo contact method with an A scan presentation for the ultrasonic inspection of welded joints, except that immersion techniques may be used for some applications when approved by the Contracting Officer. Use the procedures, methods, standards, and description of equipment specified herein for inspection of weldments. Include the following in the submitted procedure description:

a. Couplant.

b. Search unit characteristics including angle, size, shape, nominal frequency, type designation.

c. Method and type of wave.

d. Equipment and accessories including manufacturer, model number, date of manufacture, last date of calibration, and the manufacturer's electrical, physical, and performance specifications.

e. Decibel (dB) compensation system for distance-amplitude correction.

2.1.2 Wave Types

The types of waves and the conditions under which they are used are specified below. Unless conditions prohibit, use shear waves. A longitudinal wave procedure may be used instead, if approved by the Contracting Officer.

2.1.2.1 Shear Waves

Use refracted waves between 40 degrees and 70 degrees except where different angles are indicated in approved procedures, such as for materials less than 13 mm 1/2 inch thick, for materials with sound velocities greater than in steel, when the weldments are not readily accessible, or when existing backing rings or backing strips are not removed. For inspection of weldments containing backing rings or backing strips, adjust the instrument and select the refracted angles in a way to separate the weldment and the backing ring reflections. Establish the search unit angle and the resulting shear wave angle in the material to be inspected for each application and include this information in the procedure submitted for approval.

2.1.2.2 Longitudinal Waves

Specifically develop the procedure to suit the application and attain the prior approval of the Contracting Officer.

2.1.3 Changes in Procedure

Should application of an approved procedure not provide for good resolution or adequate ultrasonic penetration in the items to be inspected (see...
2.1.4 Ultrasonic Equipment

Provide ultrasonic equipment conforming to the requirements listed in AWS D1.1/D1.1M Clause 6, Part F, with the following exceptions:

a. The ultrasonic test instruments must be able to generate, receive, and to present pulses in the frequency range from 1 to 10 megahertz (MHz).

b. Measure the horizontal linearity of the ultrasonic instrument in accordance with paragraph EQUIPMENT QUALIFICATIONS.

c. In addition to the resolution test specified in AWS D1.1/D1.1M, Clause 6, Part F, conduct both near- and far-surface resolution tests in accordance with the tests specified for these characteristics in the paragraph EQUIPMENT QUALIFICATIONS.

PART 3 EXECUTION

3.1 PREPARATION OF MATERIALS FOR INSPECTION

Surfaces must be free of the following:

3.1.1 Weld Spatter

Remove spattering or any roughness that interferes with free movement of the search unit or impairs transmission of the ultrasonic vibrations.

3.1.2 Irregularities

Those which could mask or be confused with defect indications.

3.1.3 Weld Backing Strips

Remove strips that are not to remain in place and eliminate all sharp edges and valleys by grinding or other mechanical means.

3.1.4 Dirt

Remove all loose scale, rust, paint, and dirt from the coupling surface.

3.2 EQUIPMENT CALIBRATION

Calibrate equipment in accordance with AWS D1.1/D1.1M, Clause 6, Part F.

3.3 INSPECTION PROCEDURE

**************************************************************************

NOTE: When necessary, the designer should indicate on the drawing the area to be examined, the contact surface, and if welds are to be inspected from one
or both sides.

Inspect welds in accordance with AWS D1.1/D1.1M, Clause 6, Part F.

NOTE: Where welds are subjected to cyclic loading identify them on the construction documents and include Table 6.3 in the paragraph below.

3.4 ACCEPTANCE - REJECTION CRITERIA

In accordance with AWS D1.1/D1.1M, Table [6.2] [or 6.3].

3.4.1 Inspection Test Reports

Submit test reports containing the following information:

3.4.1.1 Identification and Location of Inspection

Connection identification and location of the inspected item, the person performing the inspection, and the date of inspection.

3.4.1.2 Detail of Inspections

Details of methods, types of waves used, search units, frequencies, inspection equipment identification, and calibration data with enough information to permit duplication of the inspection at a later date.

3.4.1.3 Identification of Unacceptable Areas

Locations, dimensions, types, and area of unacceptable defects and discontinuities giving reflections over 50 percent of the reject/repair line. Note on a sketch or marked-up drawing.

3.4.1.4 Record of Repair Areas

A record of repaired areas must be furnished as well as test results for the repaired areas.

3.4.2 Inspection of Repairs

All repairs undergo the same inspection procedure that originally revealed the discontinuities. Before acceptance, the welds must meet the standards required for the original weld.

-- End of Section Table of Contents --
NOTE: This guide specification covers the requirements for (1) qualifying welding procedures, welders and welding operators, and (2) the fabrication, welding and inspection of carbon steel, low alloy steel, extra-high-strength quenched and tempered low alloy steels, and austenitic stainless steel materials for structural steel for buildings, other structures and non-structural use.

Adhere to UFC 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

PART 1 GENERAL

NOTE: This specification can be used for other structures with similar types of live loads by implementing the requirements of AWS D1.1/D1.1M, as applicable, in the design of the weldments, and deleting the references to AISC Specification for the Design, Fabrication and Erection of Structural Steel for Buildings.
1.1 REFERENCES

**************************************************************************

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

**************************************************************************

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

AWS QC1 (2016) Specification for AWS Certification
1.2 SUBMITTALS

**************************************************************************
NOTE: Review submittal description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item, if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item for Army projects.

**************************************************************************
Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:
1.3 QUALITY ASSURANCE

Except for pre-qualified (in accordance with AWS D1.1/D1.1M) and previously qualified procedures, each Contractor performing welding must record in detail and qualify the welding procedure specification for any welding procedure followed in the fabrication of weldments. Conform welding procedure qualifications to AWS D1.1/D1.1M[, AWS D1.8/D1.8M] and to the specifications in this section. Submit for approval copies of the welding procedure specification and the procedure qualification records for each type of welding being performed. Submission of the welder, welding operator, or tacker qualification test records is also required. Approval of any procedure, however, does not relieve the Contractor of the sole responsibility for producing a finished structure meeting all the specified requirements. Submit this information on the forms in Annex M of AWS D1.1/D1.1M. Individually identify and clearly reference on the detail drawings and erection drawings all welding procedure specifications, or suitably key them to the contract drawings. In case of conflict between this specification and AWS D1.1/D1.1M, this specification governs.
1.3.1 General Requirements

**NOTE:** AISC has a certification program in effect that confirms that a certified structural steel fabricating facility has the personnel, organization, experience, procedures, knowledge, equipment, capability, and commitment to produce fabricated steel of the required quality for a given category of structural steel framing. Consider deleting this paragraph if there is a minimal amount of steel on the job.

Fabricate work in an AISC Certified Fabrication Plant, Category BU. Erect work by an AISC Certified Erector, Category CSE.

a. For Structural Projects, provide documentation of the following:

   (1) Component Thickness 3 mm 1/8 inch and greater: Qualification documents (WPS, PQR, and WPQ) in accordance with AWS D1.1/D1.1M [and AWS D1.8/D1.8M].

   (2) Component Thickness Less than 3 mm 1/8 inch: Qualification documents (WPS, PQR, and WPQ) in accordance with AWS D1.3/D1.3M.

   (3) Reinforcing Steel: Qualification documents (WPS, PQR, and WPQ) in accordance with AWS D1.4/D1.4M.

b. For other applications, provide documentation of the following:

   (1) Submit [two] [_____] copies of the Certified Welding Procedure Specifications (WPS), Certified Brazing Procedure Specifications (BPS) and Certified Procedure Qualification Records (PQR) to the Contracting Officer for [approval] [review].

   (2) Submit [two] [_____] copies of the Certified Welder Performance Qualifications (WPQ) and Certified Brazer Performance Qualifications (BPQ) to the Contracting Officer for [approval] [review] within [fifteen] [_____] calendar days prior to any employee welding on the project material.

   (3) Machinery: Qualification documents (WPS, PQR, and WPQ) in accordance with AWS D14.4/D14.4M.

1.3.2 Previous Qualifications

Welding procedures previously qualified by test in accordance with AWS D1.1/D1.1M, may be accepted for this contract without re-qualification, upon receipt of the test results, if the following conditions are met:

a. Testing was performed by an approved testing laboratory, technical consultant, or the Contractor's approved quality control organization.

b. The qualified welding procedure conforms to the requirements of this specification and is applicable to welding conditions encountered under this contract.

c. The welder, welding operator, and tacker qualification tests conform to
1.3.3 Pre-qualified Procedures

[Welding procedures which are considered pre-qualified as specified in AWS D1.1/D1.1M will be accepted without further qualification. Submit for approval a listing or an annotated drawing to indicate the joints not pre-qualified. Procedure qualification is mandatory for these joints.] [No pre-qualified welding procedures are allowed. Qualify the welding procedures and welders by tests prescribed in the applicable code or specification not withstanding the fact the code or specification may allow pre-qualified procedures.]

1.3.4 Welder, Welding Operator, and Tacker Qualification

**************************************************************************
NOTE: Insert additional requirements if necessary.
Determine and specify the methods of nondestructive testing required.
**************************************************************************

Each welder, welding operator, and tacker assigned to work on this contract must be qualified in accordance with the applicable requirements of AWS D1.1/D1.1M[, AWS D1.8/D1.8M] and as specified in this section. Welders, welding operators, and tackers who make acceptable procedure qualification test welds will be considered qualified for the welding procedure used within the applicable essential variables for welder qualification.

1.3.4.1 Previous Personnel Qualifications

At the discretion of the Contracting Officer, welders, welding operators, and tackers qualified by test within the previous 6 months may be accepted for this contract without re-qualification if all the following conditions are met:

a. Copies of the welding procedure specifications, the procedure qualification test records, and the welder, welding operator, and tacker qualification test records are submitted and approved in accordance with the specified requirements for detail drawings.

b. Testing was performed by an approved testing laboratory, technical consultant, or the Contractor’s approved quality control organization.

c. The welder, welding operator, and tacker qualification tests conform to the requirements of this specification and are applicable to welding conditions encountered under this contract.

1.3.4.2 Certificates

Before assigning any welder, welding operator, or tacker to work under this contract, submit the names and certification that each individual is qualified as specified. State in the certification the type of welding and positions for which the welder, welding operator, or tacker is qualified, the code and procedure under which the individual is qualified, the date qualified, and the name of the firm and person certifying the qualification tests. Keep the certification current, on file, and furnish 3 copies.
1.3.4.3 Renewal of Qualification

Re-qualification of a welder or welding operator is required under any of the following conditions:

a. It has been more than 6 months since the welder or welding operator has used the specific welding process for which he is qualified.

b. There is specific reason to question the welder or welding operator's ability to make welds that meet the requirements of these specifications.

c. The welder or welding operator was qualified by an employer other than those firms performing work under this contract, and a qualification test has not been taken within the past 12 months. Submit as evidence of conformance all records showing periods of employment, name of employer where welder, or welding operator, was last employed, and the process for which qualified.

d. A tacker who passes the qualification test is considered eligible to perform tack welding indefinitely in the positions and with the processes for which he/she is qualified, unless there is some specific reason to question the tacker's ability or there has been a gap greater than 6 months since he/she last used the process. In such a case, the tacker is required to pass the prescribed tack welding test.

1.3.5 Inspector Qualification

**************************************************************************
NOTE: Insert additional requirements if necessary.
Determine and specify the methods of nondestructive testing required. If quality control inspection is to be the responsibility of the Government, delete this paragraph.
**************************************************************************

Submit certificates indicating that certified welding inspectors meet the requirements of AWS QC1. Submit qualifications for nondestructive testing personnel in accordance with the requirements of ANSI/ASNT CP-189 for Levels I or II in the applicable nondestructive testing method. Level I inspectors must have direct supervision of a Level II inspector.

1.3.6 Symbols and Safety

Use symbols in accordance with AWS A2.4, unless otherwise indicated. Follow safe welding practices and safety precautions during welding in conformance with AWS Z49.1.

PART 2 PRODUCTS

2.1 SYSTEM DESCRIPTION

**************************************************************************
NOTE: Check the drawings to ensure that any supplementary information required by the paragraph has been shown and that there is no conflict between the drawings and the specifications. Clearly show on the drawings complete information about location, type, size, and extent of all welds and
nondestructive testing, where required. When welding is to be covered by more than one section in the contract specifications, this section covers all structural welding; the other sections cover the utilities or special equipment required inside the structure. Welding of utilities or special equipment to structural members must be done carefully so that the overall structure is not weakened. Clearly show on the drawings or cover by the contract specification the extent of the welding required. Revise this paragraph to clearly define the welding that is covered. Specify the strength of the base material on drawings or other section of the specifications.

Specify on the drawings or the text of the specifications the weld requirements: tensile strength, elongation, shear strength, size, length, type, and location.

Conform the design of welded connections to AISC 360, unless otherwise indicated or specified. Material with welds will not be accepted unless the welding is specified or indicated on the drawings or otherwise approved. Perform welding as specified in this section, except where additional requirements are shown on the drawings or are specified in other sections. Do not commence welding until welding procedures, inspectors, nondestructive testing personnel, welders, welding operators, and tackers have been qualified and the submittals approved by the Contracting Officer. Perform all testing at or near the work site. Maintain records of the test results obtained in welding procedure, welder, welding operator, and tacker performance qualifications.

2.1.1 Pre-erection Conference

NOTE: Use ASTM A992/A992M steel for all buildings which have groove welds in their lateral force resisting systems, and are either in Seismic Design Categories D, E, and F or in Category C and are Risk Category III; this and the following paragraph will be retained for this type of building.

Government personnel attending the pre-erection conference should include all field Quality Assurance (QA) inspectors, the building designer, the Engineer of Record (EOR) (if different from the designer) and the Project Manager (PM).

Hold a pre-erection conference prior to the start of the field welding, to bring all affected parties together and to gain a naturally clear understanding of the project and the Welding Procedure Specifications (WPS) (submitted for all welding, including welding done using pre-qualified procedures). Mandatory attendance is required by all Contractor’s welding production and inspection personnel and appropriate Government personnel. Include as items for discussion: responsibilities of various parties; welding procedures and processes to be followed; welding sequence (both
within a joint and joint sequence within the building); inspection requirements and procedures, both visual and nondestructive testing; welding schedule; and other items deemed necessary by the attendees.

2.2 WELDING EQUIPMENT AND MATERIALS

**************************************************************************
NOTE: Normally, the Contractor (fabricator) selects the specific electrode material for weldments based on the WPS for the project. If in special cases the selection of the proper electrode is critical to the design, the designer may specify the electrode to be used in this or other sections. In special cases, it may also be necessary to specify the welding process.
**************************************************************************

Provide all welding equipment, welding electrodes and rods, welding wire, and fluxes capable of producing satisfactory welds when used by a qualified welder or welding operator. [Use [_____] welding electrodes.] [Perform welding using the [_____] process.] Provide welding equipment and materials that comply with the applicable requirements of AWS D1.1/D1.1M and AWS D1.8/D1.8M. Submit product data on welding electrodes and rods.

PART 3 EXECUTION

3.1 WELDING OPERATIONS

3.1.1 Requirements

Conform workmanship and techniques for welded construction to the requirements of AWS D1.1/D1.1M, AWS D1.8/D1.8M and AISC 360. When AWS D1.1/D1.1M, AWS D1.8/D1.8M and the AISC 360 specification conflict, the requirements of AWS D1.1/D1.1M govern.

3.1.2 Identification

Identify all welds in one of the following ways:

a. Submit written records to indicate the location of welds made by each welder, welding operator, or tacker.

b. Identify all work performed by each welder, welding operator, or tacker with an assigned number, letter, or symbol to identify welds made by that individual. The Contracting Officer may require welders, welding operators, and tackers to apply their symbol next to the weld by means of rubber stamp, felt-tipped marker with waterproof ink, or other methods that do not cause an indentation in the metal. Place the identification mark for seam welds adjacent to the weld at 1 m 3 foot intervals. Identification with die stamps or electric etchers is not allowed.

3.2 QUALITY CONTROL

**************************************************************************
NOTE: AWS D1.1 requires 100% visual inspection of all welds. The requirement to utilize a Certified Welding Inspector to perform visual inspection is included in the specification as AWS does not
require this inspection be performed by a Certified Welding Inspector. AWS D1.1 does not require NDT for any welds. The engineer or specification writer must specify what welds require NDT in addition to visual. The methods of nondestructive testing required must be determined and specified by the designer. Determine the type of nondestructive testing (NDT) method to be used, considering joint design, material thickness, and accessibility to the joint. UT and RT are volumetric testing methods applicable to CJP groove welds. PT and MT are nonvolumetric testing methods applicable for PJP and Fillet welds. Determine joints critical to the structure which should be subjected to additional NDT. Clearly indicate in the specifications or on the drawings which welded joints require 100 percent NDT, which joints require random inspection, and which NDT method(s) are to be used for each joint.

The percentage of joints tested should be randomized throughout the structure unless specific locations require NDT as determined by the engineer of record. Joints not inspected by magnetic particle, liquid penetrant, or ultrasonic or radiographic methods are subject to visual inspections only. If quality control is to be primarily the Contractor's responsibility and the inspection and tests are adequately called out, then acceptance by the Government can rely on the Contractor's work and records -- with some spot checking to verify the results.

If the Contractor must perform nondestructive inspection other than visual, or inspection other than that covered by Section 6 of AWS D1.1/D1.1M, add these requirements to this paragraph. Clearly show the extent of inspection either on the drawings or by this or other sections of the specifications. Edit the bracketed portion of the paragraph to define the extent of nondestructive testing required.

All welded connections per AWS D1.1 will be tested to the static acceptance criteria by default. Connections that require testing to cyclic criteria must be specified by the engineer of record.

Perform testing using an approved inspection or testing laboratory or technical consultant; if approved, the Contractor's inspection and testing personnel may be used instead of the commercial inspection or testing laboratory or technical consultant. A Certified Welding Inspector must perform visual inspection on 100 percent of all welds. Document this inspection in the Visual Weld Inspection Log. Test [50%][_____] of CJP welds using ultrasonic testing per Table [6.2] [or 6.3] of AWS D1.1/D1.1M. Randomly test [50%][_____] of all PJP and fillet welds or as indicated by magnetic particle or dye penetrant testing. Verify the welds conform to paragraph STANDARDS OF ACCEPTANCE. Conform procedures and techniques for inspection with applicable requirements of AWS D1.1/D1.1M[, AWS D1.8/D1.8M ], ASTM E165/E165M, and ASTM E709. Submit a Welding Quality Assurance Plan.
and records of tests and inspections.

3.3 STANDARDS OF ACCEPTANCE

******************************************************************************
NOTE: Specify on the drawings or the text of the contract specifications must specify the weld requirements: tensile strength, elongation, shear strength, size, length, type, and location. Identify in the contract drawings complete penetration welds subject to primary tensile stress or cyclic loading for the purpose of selecting the correct NDT acceptance criteria.
******************************************************************************

Conform dimensional tolerances for welded construction, details of welds, and quality of welds with the applicable requirements of AWS D1.1/D1.1M[, AWS D1.8/D1.8M] and the contract drawings. Submit all records of nondestructive testing.

3.3.1 Nondestructive Testing

The welding is subject to inspection and tests in the mill, shop, and field. Inspection and tests in the mill or shop do not relieve the Contractor of the responsibility to furnish weldments of satisfactory quality. When materials or workmanship do not conform to the specification requirements, the Government reserves the right to reject material or workmanship or both at any time before final acceptance of the structure containing the weldment. Any indication of a defect is regarded as a defect, unless re-evaluation by nondestructive methods or by surface conditioning shows that no unacceptable defect is present. Submit all records of nondestructive testing in accordance with paragraph STANDARDS OF ACCEPTANCE.

3.3.2 Destructive Tests

Make all repairs when metallographic specimens are removed from any part of a structure. Employ only qualified welders or welding operators, and use the proper joints and welding procedures, including peening or heat treatment if required, to develop the full strength of the members and joints cut and to relieve residual stress.

3.4 GOVERNMENT INSPECTION AND TESTING

In addition to the inspection and tests performed by the Contractor for quality control, the Government will perform inspection and testing for acceptance to the extent determined by the Contracting Officer. The work may be performed by the Government's own forces or under a separate contract for inspection and testing. The Government reserves the right to perform supplemental nondestructive and destructive tests to determine compliance with paragraph STANDARDS OF ACCEPTANCE.

3.5 CORRECTIONS AND REPAIRS

If inspection or testing indicates defects in the weld joints, repair defective welds using a qualified welder or welding operator as applicable. Conduct corrections in accordance with the requirements of AWS D1.1/D1.1M[, AWS D1.8/D1.8M] and the specifications. Repair all defects in accordance with the approved procedures. Repair defects
discovered between passes before additional weld material is deposited. Wherever a defect is removed and repair by welding is not required, blend the affected area into the surrounding surface to eliminate sharp notches, crevices, or corners. After a defect is thought to have been removed, and before re-welding, examine the area by suitable methods to ensure that the defect has been eliminated. Repaired welds must meet the inspection requirements for the original welds.

-- End of Section Table of Contents --
NOTE: This guide specification covers requirements for structural steel used in building construction. Review the following publications for material selection and additional specification requirements before using this guide specification for the following types of construction:

This specification does not cover Highway Bridges or Railroad bridges due to the fracture critical requirements for bridges. For bridge design considerations see AASHTO or AREMA.

Adhere to UFCS 1-300-02 Unified Facilities Guide Specifications (UFGS) Format Standard when editing this guide specification or preparing new project specification sections. Edit this guide specification for project specific requirements by adding, deleting, or revising text. For bracketed items, choose applicable item(s) or insert appropriate information.

Remove information and requirements not required in respective project, whether or not brackets are present.

Comments, suggestions and recommended changes for this guide specification are welcome and should be submitted as a Criteria Change Request (CCR).

NOTE: Ensure the following information is shown on the project drawings:

1. The extent and location of structural steel;
2. Designations of steel members;
3. Type and yield strength of steel used in design;
4. Locations where galvanized steel will be used;
5. Types of connections (welded and bolted);
6. Locations where high-strength bolts and slip critical connections are required and the loads and stresses required if steel connection design is provided by Contractor; and
7. The location of welds requiring nondestructive testing, along with the type of testing required.
8. Type of steel coating and limits of coating application; and
9. Type of coating for hardware.

PART 1   GENERAL

1.1 REFERENCES

NOTE: This paragraph is used to list the publications cited in the text of the guide specification. The publications are referred to in the text by basic designation only and listed in this paragraph by organization, designation, date, and title.

Use the Reference Wizard's Check Reference feature when you add a Reference Identifier (RID) outside of the Section's Reference Article to automatically place the reference in the Reference Article. Also use the Reference Wizard's Check Reference feature to update the issue dates.

References not used in the text will automatically be deleted from this section of the project specification when you choose to reconcile references in the publish print process.

The publications listed below form a part of this specification to the extent referenced. The publications are referred to within the text by the basic designation only.

NOTE: Review Submittal Description (SD) definitions in Section 01 33 00 SUBMITTAL PROCEDURES and edit the following list, and corresponding submittal items in the text, to reflect only the submittals required for the project. The Guide Specification technical editors have classified those items that require Government approval, due to their complexity or criticality, with a "G." Generally, other submittal items can be reviewed by the Contractor's Quality Control System. Only add a "G" to an item if the submittal is sufficiently important or complex in context of the project.

For Army projects, fill in the empty brackets following the "G" classification, with a code of up to three characters to indicate the approving authority. Codes for Army projects using the Resident Management System (RMS) are: "AE" for Architect-Engineer; "DO" for District Office (Engineering Division or other organization in the District Office); "AO" for Area Office; "RO" for Resident Office; and "PO" for Project Office. Codes following the "G" typically are not used for Navy and Air Force projects.

The "S" classification indicates submittals required as proof of compliance for sustainability Guiding Principles Validation or Third Party Certification and as described in Section 01 33 00 SUBMITTAL PROCEDURES.

Choose the first bracketed item for Navy and Air Force projects, or choose the second bracketed item
Government approval is required for submittals with a "G" or "S" classification. Submittals not having a "G" or "S" classification are [for Contractor Quality Control approval.][for information only. When used, a code following the "G" classification identifies the office that will review the submittal for the Government.] Submit the following in accordance with Section 01 33 00 SUBMITTAL PROCEDURES:

SD-01 Preconstruction Submittals
   Erection and Erection Bracing Drawings; G[, [____]]

SD-02 Shop Drawings
   Fabrication Drawings Including Details of Connections; G[, [____]]

[1.3 AISC QUALITY CERTIFICATION

******************************************************************************
NOTE: AISC has a certification program in effect that confirms that a certified structural steel fabricating facility has the personnel, organization, experience, procedures, knowledge, equipment, capability, and commitment to produce fabricated steel of the required quality for a given category of structural steel framing. Consider deleting this paragraph if there is a minimal amount of steel on the job. MBMA has a certification program in effect that confirms that a certified metal building manufacturer’s fabrication facility has the quality management system ensuring continual compliance with requirements for Metal Building Systems.

******************************************************************************

Work must be fabricated by an AISC Certified Structural Steel Fabricator, in accordance with AISC 207, Category BU. Submit AISC Structural Steel Fabricator quality certification.

Work must be erected by an AISC Structural Steel Certified Erector, in accordance with AISC 207, Category CSE. Submit AISC Structural Steel erector quality certification.

[1.4 SEISMIC PROVISIONS

******************************************************************************
NOTE: Delete this paragraph when the steel seismic force resisting system is classified as a steel system not specifically detailed for seismic resistance in accordance with ASCE 7-16, Table 12.2-1.

******************************************************************************
Provide the structural steel system in accordance with AISC 341, Chapter J as amended by UFC 3-301-01.

1.5 QUALITY ASSURANCE

1.5.1 Preconstruction Submittals

1.5.1.1 Erection and Erection Bracing Drawings

**************************************************************************

NOTE: Include the last line when delegated design is performed by the contractor.
**************************************************************************

Submit for record purposes. Indicate the sequence of erection, temporary shoring and bracing. The erection drawings must conform to AISC 303.

**************************************************************************

Submit fabrication drawings for approval prior to fabrication. Prepare in accordance with AISC 303, AISC 326 and AISC 325. Fabrication drawings must not be reproductions of contract drawings. Sign and seal fabrication drawings by a registered professional engineer. Include complete information for the fabrication and erection of the structure's components, including the location, type, and size of bolts, welds, member sizes and lengths, connection details, blocks, copes, and cuts. Use AWS A2.4 standard welding symbols. Shoring and temporary bracing must be designed and sealed by a registered professional engineer and submitted for record purposes, with calculations, as part of the drawings. Clearly highlight any deviations from the details shown on the contract drawings highlighted on the fabrication drawings. Explain the reasons for any deviations from the contract drawings.

1.5.3 Delegated Connection Design

**************************************************************************

NOTE: Include this paragraph when delegated design is performed by the contractor.
**************************************************************************

Provide connection loads on the drawings and indicate whether the loads are LRFD, ASD, or Combined.

**************************************************************************

Design structural steel connection indicated in the contract documents per AISC 303, Option 3, using the connection loads indicated. Submit design calculations for steel connections signed and sealed by a registered professional engineer.
1.5.4 Certifications

1.5.4.1 Welding Procedures and Qualifications

Prior to welding, submit certification for each welder stating the type of welding and positions qualified for, the code and procedure qualified under, date qualified, and the firm and individual certifying the qualification tests.[ If the qualification date of the welder or welding operator is more than 6 months old, the welding operator's qualification certificate must be accompanied by a current certificate by the welder attesting to the fact that he has been engaged in welding since the date of certification, with no break in welding service greater than 6 months.]

Conform to all requirements specified in AWS D1.1/D1.1M[ and AWS D1.8/D1.8M ].

**************************************************************************
NOTE: Include the following paragraph when there is a top running bridge crane in the project.

NAVINST 11230.1F refers to CMAA for new equipment installation.
**************************************************************************

[1.5.4.2 Overhead, Top Running Crane Rail Beam

Submit written field survey results for overhead, top running crane rail beam verifying tolerance requirements per CMAA 70.

]PART 2 PRODUCTS

2.1 SYSTEM DESCRIPTION

**************************************************************************
NOTE: Check the design to ensure that adequate supports at appropriate spacings have been provided for the installation of piping, expansion tanks, unit heaters, suspended ceilings and similar items.

Consider provisions for using self-locking nuts where shock or vibration would be a problem.
**************************************************************************

Provide the structural steel system, including [shop primer] [galvanizing], complete and ready for use. Provide structural steel systems including design, materials, installation, workmanship, fabrication, assembly, erection, inspection, quality control, and testing in accordance with AISC 303, AISC 360, [AISC 341, ]and UFC 3-301-01 except as modified in this contract.

2.2 STEEL

**************************************************************************
NOTE: Select materials appropriate to the design and delete remaining materials.

Designer should require materials, products, and innovative construction methods and techniques which are environmentally sensitive, take advantage of
recycling and conserve natural resources.

NOTE: Designs requiring notch strength or installation and operation at low temperatures will require special material selections. Notch strength will be required based on design geometry or for dynamically loaded structures. When notch toughness is required, the supplementary requirements of the ASTM specification for the steel being considered should be reviewed and the appropriate supplementary requirements (ASTM A6/A6M) specified. In designs where the material will be exposed to temperatures below freezing, check the material type against the proposed ambient and working temperatures for resistance to brittle fracture.

2.2.1 Structural Steel

Use materials with recycled content where appropriate for use. Verify suitability, availability within the region, cost effectiveness and adequate competition (including verification of bracketed percentages included in this guide specification) before specifying product recycled content requirements.

Where minimums are stated, research shows the product is available among US national manufacturers above the minimum recycled content of the first bracket. Some manufacturers and regions have higher percentages. If desired, insert higher percentages into the second set of brackets and delete the first set of brackets. AISC 2017 white paper "More than Recycled Content: The Sustainable Characteristics of Structural Steel" indicates that the industry average recycled content is 93 percent.

Wide flange and WT shapes, ASTM A992/A992M. Angles, Channels and Plates, ASTM A36/A36M. Provide structural steel containing a minimum of \[80\][_____] percent recycled content. Submit data identifying percentage of recycled content for structural steel.

2.2.2 Structural Steel Tubing

NOTE: ASTM A500/A500M tubing is available in Grades A, B, C, and D with minimum yield strengths of 230, 290, 317, and 250 MPa 33, 42, 46, and 36 ksi for round structural tubing and 269, 317, 345, and 250
MPa 39, 46, 50, and 36 ksi for square or rectangular shaped structural tubing, respectively. ASTM A500/A500M tubing may not be suitable for dynamically loaded structures or applications requiring notch strength.

ASTM A1085 provides tighter shape tolerance over ASTM A500 and minimum yield strength of 345 MPa 50 ksi and a maximum yield strength of 485 MPa 70 ksi for all round, square and rectangular shapes. ASTM A1085/A1085M also provides standard requirements for charpy V-notch toughness.

Use materials with recycled content where appropriate for use. Verify suitability, availability within the region, cost effectiveness and adequate competition (including verification of bracketed percentages included in this guide specification) before specifying product recycled content requirements.

Where minimums are stated, research shows the product is available among US national manufacturers above the minimum recycled content of the first bracket. Some manufacturers and regions have higher percentages. If desired, insert higher percentages into the second set of brackets and delete the first set of bracket. AISC 2017 white paper "More than Recycled Content: The Sustainable Characteristics of Structural Steel" indicates that if the rolled coil used to form HSS shapes is from a basic oxygen furnace then the recycled content will be near 25 percent, but if the coil is from an electric arc furnace then the recycled content will be in 90 percent to 100 percent range.

******************************************************************************

ASTM A500/A500M, Grade [C][_____] [ ASTM A1085/A1085M.] Provide structural steel tubing containing a minimum of [25][90][_____] percent recycled content. Submit data identifying percentage of recycled content for structural steel tubing.

2.2.3 Steel Pipe

******************************************************************************

NOTE: ASTM A53/A53M pipe, Type E (Electric-resistance Welded) and Type S (Seamless), Grade B, has a minimum yield strength of 245 MPa 35 ksi and is available in the following weight classes: STD (Standard), XS (Extra Strong), and XXS (Double-extra Strong).

Use materials with recycled content where appropriate for use. Verify suitability, availability within the region, cost effectiveness and adequate competition (including verification of bracketed percentages included in this guide specification) before specifying product recycled content requirements.
Where minimums are stated, research shows the product is available among US national manufacturers above the minimum recycled content of the first bracket. Some manufacturers and regions have higher percentages. If desired, insert higher percentages into the second set of brackets and delete the first set of brackets.

**************************************************************************

**ASTM A53/A53M**, Type E or S, Grade B, weight class [STD (Standard) or as indicated][____]. Provide steel pipe containing a minimum of [50][____] percent recycled content. Submit data identifying percentage of recycled content for steel pipe.

2.3 **BOLTS, NUTS, AND WASHERS**

Submit the certified manufacturer's mill reports which clearly show the applicable ASTM mechanical and chemical requirements together with the actual test results for the supplied fasteners.

2.3.1 **Common Grade Bolts**

2.3.1.1 **Bolts**

**************************************************************************

**NOTE: When galvanizing ASTM A307 bolts specify either hot-dip process in ASTM F2329/F2329M or zinc-coated by the mechanical-deposition process in accordance with ASTM B695, Class 55.**

**************************************************************************

**ASTM A307**, Grade A, plain finish [hot dipped zinc coating][mechanically deposited zinc coating]. The bolt heads and the nuts of the supplied fasteners must be marked with the manufacturer's identification mark, the strength grade and type specified by ASTM specifications.

2.3.1.2 **Nuts**

**ASTM A563ASTM A563M**, Grade A, heavy hex style.

[2.3.1.3 **Self-Locking Nuts**

**************************************************************************

**NOTE: Drawings or specifications should identify where these items are used.**

**************************************************************************

Provide nuts with a locking pin set in the nut. The locking pin must slide along the bolt threads, and by reversing the direction of the locking pin, the nut can be removed without damaging the nut or bolt. Provide stainless steel locking pins.

]2.3.1.4 **Washers**

**ASTM F844.**
2.3.2 High-Strength Bolts

High strength bolts and nuts must be shipped together in the same shipping container. Fasteners indicated to be galvanized shall be tested by the supplier to show that the galvanized nut with the supplied lubricant provided may be rotated from the snug tight condition well in excess of the rotation required for pretentioned installation without stripping. The supplier shall supply nuts that have been lubricated and tested with the supplied bolts.

2.3.2.1 Bolts

******************************************************************************
NOTE: Do not galvanize Grade F2280 bolts.
******************************************************************************

******************************************************************************
NOTE: Do not mix bolt Grade A325M A325 and Grade A490M A490 on the same diameter bolts in high strength connections. The Grade A325M A325 and Grade A490M A490 bolts specified are for a maximum diameter of M36 1.5 inch. If larger bolts are required, include the following ASTM publications in reference article:

ASTM A354 – Quenched and Tempered Alloy Steel Bolts, Studs, and Other Externally Threaded Fasteners

ASTM A449 – Quenched and Tempered Steel Bolts and Studs.

Type 1 bolts are carbon steel. Type 3 bolts are weathering steel.

******************************************************************************

ASTM F3125/F3125M, Grade A325M A325 [A490M A490], Type 1 [3] Heavy Hex Head Style, plain finish [hot dipped zinc coating][mechanically deposited zinc coating].

2.3.2.2 Nuts

ASTM A563M ASTM A563, Grade and Style as specified in the applicable ASTM bolt standard.

2.3.2.3 Direct Tension Indicator Washers

******************************************************************************
NOTE: If direct tension indicator washers are not used then tension control bolts are required per UFC 3-301-01. Use the Tension Control Bolts paragraph and delete the BOLTS, NUTS AND DIRECT TENSION INDICATOR WASHERS paragraph.

Include bracketed phrase if tension indicator washers are to be galvanized.

******************************************************************************

ASTM F959/F959M.[ Provide ASTM B695, Class 55, Type 1 galvanizing.]
Submit product data for direct tension indicator washers.
2.3.2.4 Washers

ASTM F436/F436M, plain carbon steel.

2.3.3 Tension Control Bolts

**************************************************************************
NOTE: Use Grade F1852 where high strength bolts (AISC Group A) with a minimum tension strength of 120 ksi are required. Use Grade F2280 where high strength bolts (AISC Group B) with a minimum tension strength of 150 ksi are required. Grade F2280 tension control bolts only have a plain assembly finish.
**************************************************************************

ASTM F3125/F3125M, Grade [F1852][F2280], Type 1, twistoff style assemblies consisting of steel structural bolts with splined ends, heavy-hex carbon steel nuts, and hardened carbon steel washers. Assembly finish must be [plain][mechanically deposited zinc coating]. Submit product data for tension control bolts.

2.3.4 Foundation Anchorage

**************************************************************************
NOTE: For most jobs, ASTM F1554 36 ksi anchor rods are used. If high tensile loads are anticipated, consider the use of 55 ksi or 105 ksi ASTM F1554 anchor rods. If stainless steel is considered, select from material in ASTM A193/A193M.
**************************************************************************

2.3.4.1 Anchor Rods

ASTM F1554 Gr 36 [55][105], Class 1A[2A]. [Stainless steel ASTM A193/A193M.]

2.3.4.2 Anchor Nuts

ASTM A563 ASTM A563M, Grade A, hex style. [Stainless steel ASTM A193/A193M.]

2.3.4.3 Anchor Washers

ASTM F844. [Stainless steel [Type 304][Type 316] conforming to ASTM A276/A276M.]

2.3.4.4 Anchor Plate Washers

ASTM A36/A36M [Stainless steel [Type 304][Type 316] conforming to ASTM A276/A276M].

2.4 STRUCTURAL STEEL ACCESSORIES

2.4.1 Welding Electrodes and Rods

**************************************************************************
NOTE: Include AWS D1.8/D1.8M when required for seismic resisting systems.
**************************************************************************
AWS D1.1/D1.1M[ and AWS D1.8/D1.8M]. Submit product data for welding electrodes and rods.

2.4.2 Non-Shrink Grout

**************************************************************************
NOTE: Some nonshrink grouts derive their nonshrink properties from an increase in volume of metal due to oxidation. Where oxidation is not desired for appearance sake, specify nonmetallic grout.
**************************************************************************

ASTM C1107/C1107M, with no ASTM C827/C827M shrinkage.[ Grout must be nonmetallic.] Submit product data for non-shrink grout.

2.4.3 Welded Shear Stud Connectors

ASTM A29/A29M, Grades 1010 through 1020. AWS D1.1/D1.1M, Table 7.1, Type B.

[2.4.4 Pins and Rollers

ASTM A668/A668M, Class C, D, F, or G; ASTM A108, Grades 1016 to 1030. Provide as specified in AASHTO LRFD, Section 6.4.2, except provide pins in lengths to extend a minimum of 6 mm 0.25 inch beyond the outside faces of the connected parts.

][2.5 GALVANIZING

**************************************************************************
NOTE: Most structural steel is painted. If galvanized items are required, they must be indicated or specified. The galvanizing specified is by the hot-dip process. This process requires large amounts of energy and unevenly heats steel sections that are either large or thick, occasionally warping the steel sections. Using zinc coating by thermal spraying (metallizing) as an alternative to hot-dip galvanizing should be considered for certain steel sections. Consult the following American Welding Society (AWS) publications for further information:

TS-85 - Thermal Spraying - Practice, Theories, and Application

C2.2-67 - Recommended Practices for Metallizing with Aluminum and Zinc for Protection of Iron and Steel.
**************************************************************************

ASTM F2329/F2329M, ASTM F1136/F1136M, ASTM F2833 or ASTM B695 for threaded parts or ASTM A123/A123M for structural steel members, as applicable, unless specified otherwise galvanize after fabrication where practicable.

][2.6 FABRICATION

Fabrication must be in accordance with the applicable provisions of AISC 325. Fabrication and assembly must be done in the shop to the greatest extent possible. Punch, subpunch and ream, or drill bolt [and pin] holes
perpendicular to the surface of the member.

Compression joints depending on contact bearing must have a surface roughness not in excess of 13 micrometer 500 micro inch as determined by ASME B46.1, and ends must be square within the tolerances for milled ends specified in ASTM A6/A6M.

Shop splices of members between field splices will be permitted only where indicated on the Contract Drawings. Splices not indicated require the approval of the Contracting Officer.

**************************************************************************

NOTE: Include the following paragraph where there are truss chord splices on the project.

**************************************************************************

[ Do not splice truss top and bottom chords except as approved by the Contracting Officer. Provide chord splices at panel joints at approximately the third point of the span. The center of gravity lines of truss members must intersect at panel points unless otherwise approved by the Contracting Officer. When the center of gravity lines do not intersect at a panel point, make provisions for the stresses due to eccentricity. Camber of trusses must be 3 mm 1/8 inch in 3.048 meters 10 feet unless otherwise indicated.

2.6.1 Markings

Prior to erection, identify members by a painted erection mark. Connecting parts assembled in the shop for reaming holes in field connections must be match marked with scratch and notch marks. Do not locate erection markings on areas to be welded. Do not locate match markings in areas that will decrease member strength or cause stress concentrations.[ Affix embossed tags to hot-dipped galvanized members.]

**************************************************************************

NOTE: SPE-P1 is for enclosed paint shop, SPE-P2 is for an outside but covered paint shop and SPE-P3 is for an outside paint shop. There are other paint shop qualification including NACE and SSPC which exceed AISC paint endorsements.

**************************************************************************

2.6.2 Shop Primer

**************************************************************************

NOTE: Generally, for interior use, standard structural steel with a minimum coating system of a shop primer is adequate. For exterior environments or areas open to the exterior, use coated galvanized steel or a zinc rich coating system described in UFC 3-190-06, Protective Coatings and Paints.

**************************************************************************

SSPC Paint 20 or SSPC Paint 29, (zinc rich primer). Shop prime structural steel, except as modified herein, in accordance with SSPC PA 1. Do not prime steel surfaces embedded in concrete, galvanized surfaces,[ surfaces to receive sprayed-on fireproofing,][ surfaces to receive epoxy coatings,][ surfaces designed as part of a composite steel concrete section,] or surfaces within 13 mm 0.5 inch of the toe of the welds prior to welding.
(except surfaces on which metal decking and shear studs are to be welded). If flash rusting occurs, re-clean the surface prior to application of primer. Apply primer [in accordance with endorsement "SPE-P1"/"SPE-P2"/"SPE-P3" of AISC 420 or approved equal NACE or SSPC certification] to a minimum dry film thickness of 0.05 mm 2.0 mil. Submit shop primer product data.

Prime slip critical surfaces with a Class B coating in accordance with AISC 325. Submit test report for Class B coating.

Prior to assembly, prime surfaces which will be concealed or inaccessible after assembly. Do not apply primer in foggy or rainy weather; when the ambient temperature is below 7 degrees C or over 35 degrees C or over 95 degrees F; or when the primer may be exposed to temperatures below 4 degrees C 40 degrees F within 48 hours after application, unless approved otherwise by the Contracting Officer. Repair damaged primed surfaces with an additional coat of primer.

2.6.2.1 Cleaning

SSPC SP 6/NACE No.3, except steel exposed in spaces above ceilings, attic spaces, furred spaces, and chases that will be hidden to view in finished construction may be cleaned to SSPC SP 3 when recommended by the shop primer manufacturer. Maintain steel surfaces free from rust, dirt, oil, grease, and other contaminants through final assembly.

[2.6.3] [Fireproofing] [and] [Epoxy] Coated Surfaces

Clean and prepare surfaces to receive [sprayed-on fireproofing] [epoxy] coatings in accordance with the manufacturer's recommendations, and as specified in Section 07 81 00 SPRAY-APPLIED FIREPROOFING.

[2.6.4] Surface Finishes

**************************************************************************
NOTE: AISC states "finished" surfaces, where identified, should have a maximum roughness of 500. For pins and bearing surfaces, a maximum roughness of 125, in lieu of 500, is recommended.
**************************************************************************

ASME B46.1 maximum surface roughness of 125 for pin, pinholes, and sliding bearings, unless indicated otherwise.

2.7 DRAINAGE HOLES

Drill adequate drainage holes to eliminate water traps. Hole diameter must be 13 mm 1/2 inch and location indicated on the detail drawings. Hole size and locations must not affect the structural integrity.

PART 3 EXECUTION

3.1 ERECTION

**************************************************************************
NOTE: For low-rise structural steel buildings, design the structure to be erected in accordance with AISC DESIGN GUIDE 10.
**************************************************************************
a. Erection of structural steel, except as indicated in item b. below, must be in accordance with the applicable provisions of AISC 325, AISC 303 and 29 CFR Part 1926, Subpart R.

b. For low-rise structural steel buildings (18 m 60 feet tall or less and a maximum of 2 stories), erect the structure in accordance with AISC DESIGN GUIDE 10.

After final positioning of steel members, provide full bearing under base plates and bearing plates using nonshrink grout. Place nonshrink grout in accordance with the manufacturer's instructions.

3.1.1 STORAGE

Store the material out of contact with the ground in such manner and location as to minimize deterioration.

3.2 CONNECTIONS

Except as modified in this section, design connections indicated in accordance with AISC 360. Build connections into existing work. Do not tighten anchor bolts set in concrete with impact torque wrenches. Holes must not be cut or enlarged by burning. Bolts, nuts, and washers must be clean of dirt and rust, and lubricated immediately prior to installation.

3.2.1 Common Grade Bolts

Tighten ASTM A307 bolts to a "snug tight" fit. "Snug tight" is the tightness that exists when plies in a joint are in firm contact. If firm contact of joint plies cannot be obtained with a few impacts of an impact wrench, or the full effort of a man using a spud wrench, contact the Contracting Officer for further instructions.

3.2.2 High-Strength Bolts

**************************************************************************
NOTE: If only tension control bolts are used, delete this paragraph.
**************************************************************************

Provide direct tension indicator washers in all ASTM F3125/F3125M, Grade A325M A325 and Grade A490M A490 bolted connections. Bolts must be installed in connection holes and initially brought to a snug tight fit. After the initial tightening procedure, fully tension bolts, progressing from the most rigid part of a connection to the free edges.

Fastener components shall be protected from dirt and moisture in closed containers at the site of the installation. Fastener components that are not incorporated into the work shall be returned to protected storage at the end of the work shift.

3.2.2.1 Installation of Direct Tension Indicator Washers (DTIW)

Where possible, install the DTIW under the bolt head and tighten the nut. If the DTIW is installed adjacent to the turned element, provide a flat washer between the DTIW and nut when the nut is turned for tightening, and between the DTIW and bolt head when the bolt head is turned for tightening. In addition to the LIW, provide flat washers under both the bolt head and nut when ASTM F3125/F3125M, Grade A490M A490 bolts are used.
3.2.3  TENSION CONTROL BOLTS

Bolts must be installed in connection holes and initially brought to a snug tight fit. After the initial tightening procedure, fully tension bolts, progressing from the most rigid part of a connection to the free edges.

3.3  GAS CUTTING

Use of gas-cutting torch in the field for correcting fabrication errors is not permitted on any major member in the structural framing. Use of a gas cutting torch will be permitted on minor members not under stress only after approval has been obtained from the Contracting Officer.

3.4  WELDING

******************************************************************************
NOTE: Include AWS D1.8/D1.8M when required for seismic resisting systems.
******************************************************************************

Welding must be in accordance with AWS D1.1/D1.1M and AWS D1.8/D1.8M. Grind exposed welds smooth as indicated. Provide AWS D1.1/D1.1M qualified welders, welding operators, and tackers.

Develop and submit the Welding Procedure Specifications (WPS) for all welding, including welding done using prequalified procedures. Submit for approval all WPS, whether prequalified or qualified by testing.

3.4.1  REMOVAL OF TEMPORARY WELDS, RUN-OFF PLATES, AND BACKING STRIPS

******************************************************************************
NOTE: Include last bracketed statement where required by prequalified connection requirements in AISC 358.
******************************************************************************

[Removal is not required][Remove only from finished areas][ Remove backing strips from bottom flange of moment connections, backgouge the root pass to sound weld metal and reinforce with a 8 mm 5/16 inch fillet weld minimum.]

3.5  SHOP PRIMER REPAIR

Repair shop primer in accordance with the paint manufacturer's recommendation for surfaces damaged by handling, transporting, cutting, welding, or bolting.

3.5.1  FIELD PRIMING

Field prime steel exposed to the weather, or located in building areas without HVAC for control of relative humidity. After erection, the field bolt heads and nuts, field welds, and any abrasions in the shop coat must be cleaned and primed with paint of the same quality as that used for the shop coat.

[3.6  GALVANIZING REPAIR

Repair damage to galvanized coatings using ASTM A780/A780M zinc rich paint

SECTION 05 12 00 Page 22
for galvanizing damaged by handling, transporting, cutting, welding, or bolting. Do not heat surfaces to which repair paint has been applied.

3.7 FIELD QUALITY CONTROL

Perform field tests, and provide labor, equipment, and incidentals required for testing[, except that electric power for field tests will be furnished as set forth in Division 1]. Notify the Contracting Officer in writing of defective welds, bolts, nuts, and washers within 7 working days of the date of the inspection.

3.7.1 Welds

3.7.1.1 Visual Inspection

AWS D1.1/D1.1M. Furnish the services of AWS-certified welding inspectors for fabrication and erection inspection and testing and verification inspections. A Certified Welding Inspector must perform visual inspection on 100 percent of all welds. Document this inspection in the Visual Weld Inspection Log. Submit certificates indicating that certified welding inspectors meet the requirements of AWS QC1.

[ Inspect proper preparation, size, gaging location, and acceptability of all welds; identification marking; operation and current characteristics of welding sets in use.]

3.7.1.2 Nondestructive Testing

**************************************************************************

NOTE: Indicate the location of test welds and types of testing desired. The following information is presented as guidance. Dye penetrant testing detects small surface defects by enhancing the visibility of the flaw. Magnetic particle testing detects surface cracks and near-surface cracks; this test provides more information than the dye penetrant testing, and for approximately the same cost. Ultrasonic testing detect surface and internal cracks, delaminations, lack of fusion, and density and thickness variations. Generally, fillet welds can only be dye penetrant or magnetic particle tested. All complete penetration welds should be ultrasonically tested. See AWS D1.1/D1.1M for other methods of NDT that can be used for testing welds.

Include AWS D1.8/D1.8M when required for seismic resisting systems.

AWS D1.1 does not require any NDT other than visual inspection unless specified by the Engineer. AWS D1.8 specifically required NDT for seismic connections. The engineer must specify which welds require inspection.

For statically loaded welds test per Table 6.2 of AWS D1.1. For cyclically loaded welds test per Table 6.3 of AWS D1.1. Where welds are subjected to cyclic loading identify them on the construction documents.
Nondestructive testing must be in accordance with AWS D1.1/D1.1M and AWS D1.8/D1.8M. Ultrasonic testing must be performed in accordance with Table [6.2] [or 6.3] of AWS D1.1/D1.1M. Test locations must be [as indicated][selected by the Contracting Officer]. All personnel performing NDT must be certified in accordance with ANSI/ASNT CP-189 in the method of testing being performed. Submit certificates showing compliance with ANSI/ASNT CP-189 for all NDT technicians. If more than [20] [_____] percent of welds made by a welder contain defects identified by testing, then all groove welds made by that welder must be tested by ultrasonic testing, and all fillet welds made by that welder must be inspected by magnetic particle testing (MT) or dye penetrant testing (PT) as approved by the Contracting Officer. When groove welds made by an individual welder are required to be tested, magnetic particle or dye penetrant testing may be used only in areas inaccessible to ultrasonic testing. Retest all repaired areas. Submit weld inspection reports.

Testing frequency: Provide the following types and number of tests:

<table>
<thead>
<tr>
<th>Test Type</th>
<th>Number of Tests</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ultrasonic</td>
<td>[_____] 50 percent of CJP Welds</td>
</tr>
<tr>
<td>Magnetic Particle</td>
<td>[_____] 50 percent of PJP and Fillet Welds</td>
</tr>
<tr>
<td>Dye Penetrant</td>
<td>[_____] 50 percent of PJP and Fillet Welds</td>
</tr>
<tr>
<td>[_____]</td>
<td>[_____]</td>
</tr>
</tbody>
</table>

**NOTE:** If only tension control bolts are used, delete this paragraph.

3.7.2 Direct Tension Indicator Washers

3.7.2.1 Direct Tension Indicator Washer Compression

Test direct tension indicator washers in place to verify that they have been compressed sufficiently to provide the 0.38 mm 0.015 inch gap, as required by ASTM F959/F959M. Submit direct tension indicator washer inspection reports.

3.7.2.2 Direct Tension Indicator Gaps

**NOTE:** Use this paragraph on large complex structural steel systems or on jobs where minimal on site inspection is expected.

In addition to the above testing, an independent testing agency as approved by the Contracting Officer, must test in place the direct tension indicator gaps on 20 percent of the installed direct tension indicator washers to verify that the ASTM F959/F959M direct tension indicator gaps have been achieved. If more than 10 percent of the direct tension indicators tested have not been compressed sufficiently to provide the average gaps required
by ASTM F959/F959M, test all in place direct tension indicator washers to verify that the ASTM F959/F959M direct tension indicator gaps have been achieved. Test locations must be selected by the Contracting Officer.

3.7.3 High-Strength Bolts

3.7.3.1 Testing Bolt, Nut, and Washer Assemblies

Test a minimum of [3] bolt, nut, and washer assemblies from each mill certificate batch in a tension measuring device at the job site prior to the beginning of bolting start-up. Demonstrate that the bolts and nuts, when used together, can develop tension not less than the provisions specified in AISC 360, depending on bolt size and grade. The bolt tension must be developed by tightening the nut. A representative of the manufacturer or supplier must be present to ensure that the fasteners are properly used, and to demonstrate that the fastener assemblies supplied satisfy the specified requirements. Submit bolt testing reports.

3.7.3.2 Inspection

Inspection procedures must be in accordance with AISC 360. Confirm and report to the Contracting Officer that the materials meet the project specification and that they are properly stored. Confirm that the faying surfaces have been properly prepared before the connections are assembled. Observe the specified job site testing and calibration, and confirm that the procedure to be used provides the required tension. Monitor the work to ensure the testing procedures are routinely followed on joints that are specified to be fully tensioned.

[ Inspect calibration of torque wrenches for high-strength bolts.]

3.7.3.3 Testing

The Government has the option to perform nondestructive tests on [5] percent of the installed bolts to verify compliance with pre-load bolt tension requirements. Provide the required access for the Government to perform the tests. The nondestructive testing will be done in-place using an ultrasonic measuring device or any other device capable of determining in-place pre-load bolt tension. The test locations must be selected by the Contracting Officer. If more than [10] percent of the bolts tested contain defects identified by testing, then all bolts used from the batch from which the tested bolts were taken, must be tested at the Contractor's expense. Retest new bolts after installation at the Contractor's expense.

3.7.4 Testing for Embrittlement

ASTM A143/A143M for steel products hot-dip galvanized after fabrication. Submit embrittlement test reports.

3.7.5 Inspection and Testing of Steel Stud Welding

Perform verification inspection and testing of steel stud welding conforming to the requirements of AWS D1.1/D1.1M, Stud Welding Clause. The Contracting Officer will serve as the verification inspector. Bend test
studs that do not show a full 360 degree weld flash or have been repaired by welding as required by AWS D1.1/D1.1M, Stud Welding Clause. Studs that crack under testing in the weld, base metal or shank will be rejected and replaced by the Contractor at no additional cost.

1.2 DEFINITIONS

Establish levels of fabrication using the following classifications:

1.2.1 Class A Fabrication

Class A fabrication includes complete penetration weld joints only, and applies to those welds in critical applications where failure would cause a
loss of the system and be hazardous to personnel. Classify welds as a Class A fabrication for highly stressed dynamic and cyclic loading. Characterize welds as a single point of failure with no redundancy for the redistribution of stress into another member.

1.2.2 Class B Fabrication
